Cluster investigations that estimate the risk of transmission from an infected person or the impact of type of gathering on the size and extent of the transmission event are important to help inform high or low risk situations (Table 3) (Kim et al., 2020; Liu et al., 2020; Pfefferle et al., 2020). These investigations report that a small number of cases may be responsible for the majority of transmission events and that risk of transmission is highly variable. The latter studies are based on retrospective contact tracing investigations, which are at a high risk of bias and may not represent the spectrum of transmission events at gatherings that have occurred. Underreporting of transmission events from gatherings, particularly random mixing events such as public transportation, is highly likely as these events would be difficult to investigate.

General observations across super spreading events (SSEs) that have occurred outside of the household include (Table 3):

- Often the index case was asymptomatic or mildly symptomatic at the time of the transmission event.

- Most SSEs occurred in indoor environments.
- Most are associated with crowded spaces and a prolonged period of time spent in that space or close and intense contact with the infected person (Leclerc, Fuller, Knight, Funk, & Knight, 2020; Swinkels, 2020).
    - Activities such as close range interactions at elderly care homes and events with significant singing, loud conversation or shouting have been associated with SSEs.
- High-risk settings are places where a large number of people congregate. These include large group accommodations, confined working environments, and mass gatherings. (Note household accounts for 50-60%, (Swinkels, 2020)).
    - Approximately 15% of SSEs are associated with entertainment/leisure; dining, sports and fitness, parties, bars and nightclubs.
    - Approximately 5% of SSEs are associated with indoor shopping malls and supermarkets (three SSEs have been associated with outdoor markets).
    - Approximately 3% of SSEs are associated with religious gatherings.
    - Approximately 2% of SSEs are associated with schools.
    - Work environment SSEs (~7%) mostly include office environments followed by food processing plants. Few clusters were associated with working outdoors.
        - Food processing plant outbreaks globally have largely occurred in refrigerated processing environments over other types of facilities. This may be due to the working environment being favourable to SARS-CoV-2 persistence (low temperature and humidity, solid metallic surfaces), work places being crowded and transportation/accommodation being shared, and the workforce being unlikely to not work despite being symptomatic (Chong, Ng, Hori, & et al., 2020; Durand-Moreau et al., 2020).
    - Approximately 7% of SSEs have occurred in shared accommodation such as worker dormitories, prisons, and long-term care facilities.
    - Transportation (~1%) has also been associated with a few clusters including buses, flights and trains.

Table 3: Studies and repositories that summarize the characteristics of gathering events associated with transmission.

Reference	Study Description	Relevant Outcomes
Repositories of COVID-19 Transmission events		
(Swinkels, 2020)	Super Spreading Events Around the World [Google Sheet]. Update version August 15, 2020	- Project includes over 1,400 SSE events. The spreadsheet is available for download and analysis. *The summary*

	- Transmission events with >5 secondary cases are included in this list. - Sources are both primary literature and grey literature. - Details include location, setting, description, indoor, # cases, index date, reference, other settings. - They tag SSEs associated with loud vocalization and those that occur in a refrigeration setting.	*proportions in the text came from this work.* • Currently 21 SSEs are listed from Canada.
(Institute for Investigative Journalism, Concordia, 2020)	Project pandemic A Canadian list of clusters reported across Canada, compiled as a joint initiative of Canadian journalists. *This site is not freely accessible, but is a data repository that is not available elsewhere.*	As of August 18: - 58 food processing plant clusters, the largest was >650 infected - 53 detention facilities have reported clusters.
(Leclerc et al., 2020)	This rapid review and database of SSE events compiled literature up to June 7 2020 and after that, the effort has not been comprehensive. Details include setting, indoor, country, details, reference, date, number of clusters, total cases and attack rates.	SSE Setting / COUNT N=265 / % Building site 4 1.5% Conference 5 1.9% Elderly care 21 7.9% Food processing plant 21 7.9% Funeral 2 0.8% Hospital 9 3.4% Hotel 3 1.1% Household 38 14.3% Shared accommodation 30 11.3% Meal 17 6.4% Party 14 5.3% Prison 6 2.3% Public 6 2.3% Religious 22 8.3% School 11 4.2% Ship 5 1.9% Shipyard 1 0.4% Shopping 8 3.0% Sport 22 8.3% Transport 1 0.4%
Characteristics of Transmission Events and their Association with Gathering		
(Kuebart & Stabler, 2020)	This paper studies SSEs in Germany and considers the socio-spatial spread of SARS-CoV-2 and the drivers associated with spread.	- This article highlights the importance of place, crowd, and activity as facilitators of transmission:

		• A regional outbreak in Western Germany centred on the Heinsberg district (February 2020). • Tourists returning to their home regions while carrying an infection. • Infection networks based on specific focus places or events.
(Kim & Jiang, 2020) *preprint*	This study investigated the properties of the network of cases occurring in Korea. (n=3,127 cases) - Longitudinal transmission network - 147 clusters were identified - 12 had 20 or more cases	- Women had a higher Ro than men. - Older adults (not in long-term care) had higher Ro than young/middle age adults. - Religious gatherings, gyms, long-term care facilities and customer call center caused the longest transmission events.
(On Kwok et al., 2020)	The analysed epidemiological data up to March 3, 2020 from Hong Kong, Japan and Singapore to evaluate the presence and likelihood of clusters or transmission events. The mean cluster sizes were 2.54 (HK), 1.92 (JP) and 3.32 (SG); while the maximum were 16 (HK), 28 (JP) and 31 (SG).	- The probability of observing secondary case clusters of size ≥4 ranged from 10.6% – 21.5% of clusters.
(Adam et al., 2020) *preprint*	This study analyses the super spreading events in Hong Kong across 135 clusters.	- The analysis inferred 20% of infections were responsible for 80% of the transmission events in Hong Kong. - One notable cluster of 106 cases traced to bars and bands accounted for 30.4% of the local transmission early in the epidemic.
(Hamner et al., 2020)	High SARS-CoV-2 Attack Rate Following Exposure at a Choir Practice - Skagit County, Washington, March 2020.	- Among 61 people that attended choir practice on March 10, 2020, the secondary attack rate was 53% among confirmed individuals and 87% among all potential cases. - Singing has been attributed as the cause of the high attack rate.
(Nishiura et al., 2020) *preprint*	This article looks at epidemiological data on 11 clusters of 110 cases total that occurred in Japan as of 26 February: 4 in Tokyo and 1 each in Aichi, Fukuoka, Hokkaido, Ishikawa, Kanagawa and Wakayama prefectures.	- All clusters were associated with indoor environments: gym, restaurant, hospital, and a festival where eating occurred in tents. - This study estimated the odds of transmitting in a closed environment vs. open-air environment was OR 18.7 (95%CI 6.0-57.9). There was no control for confounders or potential interaction with other predictors in this analysis.

(S. Zhao et al., 2020) *preprint*	The analysis of the outbreak on the Diamond Cruise ship, February 2020.	- The dispersion term (k) was estimated to be 44 (95%CI 6-88), which is significantly larger than 1 and implies a lower chance of super-spreading events. In comparison to SARS and other coronaviruses, COVID-19 has less super spreading potential and high potential to persist in a population.
Synthesis of Clusters		
(Leclerc et al., 2020)	Systematic review, search date March 31, 2020, that summarizes 201 transmission clusters.	- Characteristics of clusters: • Indoor or indoor/outdoor settings (21/22). • Large clusters, such as those linked to churches and ships fewer than 100 cases (181/201). • > than 100 cases have been recorded in hospitals, elderly care, worker dormitories, food processing plants (9 clusters), prisons, schools (8 clusters), shopping and ship settings. • Clusters of 50-100 cases: sports, bar, wedding, work, conference. • Household was the most common cluster venue and these were usually <10 people.
(Bouffanais & Lim, 2020)	Comment on super spreading hotspots for COVID-19.	- 95% of Singapore's cases have occurred in dormitories that house migrant workers (42,000 cases or 12.5% of the people living in the dormitories).
(Prakash, 2020) *preprint*	This synthesis is not conducted using standard systematic review methodology although a thorough search was conducted. They identified 20 situations that resulted in 418 infections across 32 instances from 44 individuals (8 had mild symptoms, 36 were asymptomatic).	- Situation (transmission rate): • Meals/ family events 15.7% to 66.7%. • Meetings (1 hour private meeting, 72.7% (43.6-98.0). • Open workspace with people movement (78.7% (CI. 70.3-85.3%)). • Singing (e.g., 2 hour practice 86.7% (CI.76.2- 93.2%), (Hamner et al., 2020)). • Prayer service (resulted in 1-7 secondary infections per infected individual). • Travelling in a car (closed environment) and talking had a high risk (100% (CI.20-100%)).

		• Public transportation, wearing a mask with no talking (~0%). • Hotels 53.3% (30.1-75.2%)/cruise ships 28.1% (27.3-29.0%) where space is shared for days . • Direct interaction with an infected sales agent 25.0% (10.2-49.5%). • Nightclub, attack rate among direct contacts >50%, among patrons of the nightclub 6.27% (5.15-7.61%) (Adam et al., 2020). • Restaurant overall attack rate (9.9% (CI: 5.3-17.7%) vs. those in the flow of the air conditioner 45.0% (25.8-65.8%). - Across all these super spreading events, number of infections caused depends on the number of close contacts and in most cases the index case was not detectable at the time of transmission.
(Y. Liu, Eggo, & Kucharski,)	This short communication summarizes 9 outbreaks resulting in 48 secondary infections among 137 people in late January.	- This makes for a secondary attack rate of 35% (95%: 27-44). • 3 outbreaks are meals in the home ARs (100%, 31%, 44%). • 1 restaurant meal (21%). • 4 unknown meals (100%, 87.5%, 11.7%, 21%). • 1 Chalet in France (45%).
Primary Research of Clusters		
(Walker et al., 2020)	Germany's first super spreading event.	- The Heinsberg outbreak associated with attending a carnival session on February 15, 2020. - Resulted in Germany's first large outbreak. More than 1,700 cases have been traced back to this event.
(Pfefferle et al., 2020)	This study uses viral genomics and variant calling to follow-up viral transmission during the initial outbreak in Hamburg Germany. They provide evidence of high viral dose transmission and low viral dose transmission.	- Patient 0 had contact with 132 people at his work place within the two days before developing symptoms. These transmission events are considered to be low dose transmission events. - One high risk contact co-worker and his spouse became positive for SARS-CoV-2. 1/33 high risk interactions and 0/98 low risk interactions were positive.

		- The spouse was asymptomatic, but virus was cultured from her oropharyngeal swab and both she and the index case viral load decreased quickly in the first 5 days of illness. - A familial cluster also demonstrates evidence of minority sequence variants, which is indicative of a high viral load exposure by droplets.
(Ghinai et al., 2020)	Chicago outbreaks associated with a family gathering and funeral.	- Index case had recently travelled and was mildly symptomatic at the time of transmission. Transmission events include sharing a meal and attending the funeral where there was a fair amount of contact (handshaking and hugging) - The birthday party was in a home with 9 family members (hugging, sharing food). - Church service transmission due to close conversation and sitting within one row for 90 minutes.
(A. James et al., 2020a)	Arkansas church outbreak in March 2020.	- Two pre-symptomatic people attended church gatherings and resulting attack rate was 35/92 and at least 26 additional cases in the community.
(Shen, Xu et al., 2020)	Jiaxing city outbreaks where gathering events included weddings, birthday parties and work.	- The secondary attack rate (SAR) was 0.6% (3/473). Cases that tested positive had contact with the index case; ate at the same table during the wedding, had close conversations, spent extended periods in the same room. The SAR among close contacts was 29% (2/7).
(Breton et al., 2020)	The first cluster of cases in France associated with a church week of prayer February 17-21, 2020, n=2000 Ro= 1.4 Serial interval = 4 days.	- The epidemic threshold was estimated as 4 cases per day. - The curve of incidence shows that the epidemic begun before a sanitary alert was given and that some of the attendees to the Christian week of prayer displayed symptoms before the event.
(Chaw et al., 2020; Wong, Jamaludin, Alikhan, & Chaw, 2020)	Cluster of cases in Malaysia related to Tablighi Jamaat's religious gathering. 19/75 attendees were infected at the event, they caused 52 secondary cases. - Negative binomial model was used to explore risk factors.	- The strongest attack rate (AR) was the gathering: (14.8% 95% CI: 7.1, 27.7]). - Household ARs of symptomatic cases were higher (14.4% 95% CI: 8.8, 19.9]) than asymptomatic or pre-symptomatic cases (5.4% 95% CI: 1.2, 9.6]).

		- Low ARs (< 1%) were observed for workplace and social settings.
(Chen et al., 2020)	A retrospective study of 141 COVID-19 cases in Chongquing January-February 2020. 90 were part of clusters and 51 were considered sporadic.	- 82% of clustered cases were associated with exposure at a family gathering.
(Adam et al., 2020) *preprint*	A notable cluster early in the epidemic in Hong Kong.	- 106 cases traced to bars and bands accounted for 30.4% of the local transmission in Hong Kong early in the epidemic. - This is thought to have been caused by a series of super spreading events among staff, bands, and patrons.
(Ye et al., 2020)	(in Chinese) An outbreak in Ningbo associated with a Buddhist rally in which the index case used shared transportation by bus.	- The overall attack rate was 37/1,283, 2.88% and infection rate 48/1,008, 4.76%. However, the bus attack rate 33.82% (23/68), and infection rate 38.24% (26/68) accounted for most of the transmission. - The presumed index case had started showing symptoms 1 day before participating in the event.
(Y. F. Liu et al., 2020 (in Chinese); Wu et al., 2020; Y. Zhang et al., 2020)	Cluster investigation in Tianjin up to February 22, 2020. N=115 cases in 33 clusters.	- 28 familial clusters. - 1 work place cluster (index case infected >6 people). - 3 transport clusters (2 airplanes, 1 train). - 1 department store cluster (1 infected sales associate infected 20 patrons and 3 co-workers).
(Correa-Martínez et al., 2020)	An outbreak associated with a ski resort town, Ishgl, Austria. Recognised by a local hospital, University Hospital Münster (UKM) in Germany. N-19 cases.	- 36/90 COVID cases had recently visited Ischgl (39.6%), a ski resort town. An apres-ski bar where a bar-keeper tested positive was also frequented by many of the positive cases. This bar is considered the potential source of the SSE.
(Park et al., 2020)	This report describes an outbreak of COVID-19 at a call center in Korea. Of 1,143 individuals tested for COVID, 97 (8.5%) were positive. The majority of these employees (94/97) were working on an 11th floor call center with 216 employees.	- The attack rate was 43.5% (95% CI: 36.9-50.4%). The household secondary attack rate among symptomatic cases was 16.2% (95% CI: 11.6-22%).
(Shen et al., 2020) *preprint*	The first outbreak investigation involved transportation to a worship event on buses. A second outbreak involving a 30-person workshop with shared transportation.	- Outbreak 1: Bus #2 had an attack rate of 34.3%, and no one on bus #1 was infected.

	Tracing from index case to secondary cases and relative time spent in proximity of index case are part of the investigation.	- In the second outbreak, the overall attack rate was 48.3%. - Fans and air conditioning units on recirculation mode are hypothesized to have helped circulate the virus within the room/bus. They suggest that airborne transmission must be partially responsible for the high attack rates.
(Qian et al., 2020) *preprint*	This study analyzed all outbreaks involving 3 or more cases reported to the municipal health commissions in China January 4-February 11, 2020. 318 indoor outbreaks are described across 120 cities. 80% of the outbreaks involved <5 people.	- 318 indoor outbreaks involving family (129), relatives (133), socially connected people (29) and socially disconnected people (24) are described across 120 cities. 80% of the outbreaks involved <5 people. 83 outbreaks had multiple venues so total >100% (n=318) - 79.9% occurred within a home, - 34.0% transportation, - 4.4% at restaurant, - 2.2% shopping venue and - 9.7% at other venues.

Methods:

A daily scan of the literature (published and pre-published) is conducted by the Emerging Science Group, PHAC. The scan has compiled COVID-19 literature since the beginning of the outbreak and is updated daily. Searches to retrieve relevant COVID-19 literature are conducted in Pubmed, Scopus, BioRxiv, MedRxiv, ArXiv, SSRN, Research Square and cross-referenced with the literature on the WHO COVID literature list, and COVID-19 information centers run by Lancet, BMJ, Elsevier and Wiley. The daily summary and full scan results are maintained in a Refworks database and an excel list that can be searched. Targeted keyword searching was conducted within these databases to identify relevant citations on COVID-19 and SARS-CoV-2. Search terms used included: social AND (network, gathering, cluster, outbreak), superspread* OR (super spread*). Approximately 278 citations were screened for relevance and additional outbreaks were drawn from the list of outbreak papers in previous reviews of super spreading events and workplace/indoor transmission events. This review contains research published up to August 18, 2020

Nouveaux éléments de preuve sur la COVID-19

Note d'information sur la taille des rassemblements et les caractéristiques des événements à risque élevé de transmission

Introduction

Quelles sont les preuves disponibles quant au nombre maximal de participants à des rassemblements ou à des événements ou quant à la taille permise pour de telles activités?

Y a-t-il caractéristiques propres aux rassemblements qui feraient en sorte que ceux-ci présentent un risque élevé de transmission du SRAS-CoV-2?

Cette revue portera sur l'état des données probantes en date du 18 août 2020 en ce qui concerne la taille des rassemblements communautaires ainsi que les caractéristiques des rassemblements qui sont associés à la transmission du SRAS-CoV-2. Elle n'inclut pas la transmission à domicile, dans les lieux de vie collectifs (par exemple, les établissements de soins de longue durée, les prisons, les dortoirs) ou les centres de soins de santé, mais les rassemblements sociaux où les gens se connaissent ou non y sont distingués.

Points clés

- Cinquante-cinq études ont été recensées, dont des études de modélisation, des évaluations des risques, des études écologiques et épidémiologiques et des rapports sur les éclosions.
- Les études ont montré une relation claire entre l'augmentation de la taille du rassemblement et le risque, mais il n'y a pas eu d'évaluation cohérente des différents seuils déterminant la taille maximale d'un rassemblement (tableau 1).
    - Une étude écologique a estimé une réduction de 36 % du R0 si la taille limite des rassemblements était de 10 personnes, contre 21 % si elle était de 100 personnes, et une réduction de 2 % du R0 si la taille limite des rassemblements était de 1000 personnes (Brauner et coll., 2020). Une autre étude a estimé à 10 % la réduction globale du nombre d'infections associées aux restrictions de la taille des rassemblements (Esra et coll., 2020).
    - Deux modèles ont exploré des seuils permettant de faire chuter l'épidémie, l'un a relevé une limite de 23 personnes dans un rassemblement (St-Onge, 2020) et l'autre a relevé une limitation des contacts à sept personnes par période de 5 jours (Zhao, 2020).
- Plusieurs modèles prédictifs utilisant une structure de réseau ont été élaborés pour explorer l'impact de différentes tailles et types de rassemblements et pour savoir s'ils incluent des personnes qui se connaissent ou non (tableau 1).
    - Les petits réseaux communautaires fermés (par exemple, lorsque des groupes de personnes n'interagissent qu'avec un groupe choisi d'autres personnes et qu'il y a une interaction limitée

en dehors de ce réseau) ont été identifiés comme présentant un faible risque d'introduction de virus. Le risque augmente avec la multiplication des passerelles vers d'autres réseaux (par exemple, se rendre au travail dans un autre lieu, assister à un événement sportif) (Scott et coll., 2020; Sneppen et coll., 2020).

- Les événements qui supposent le mélange aléatoire des personnes, comme les transports publics, les restaurants/bars et les événements sportifs étaient des événements à risque élevé parce que les personnes de nombreux petits réseaux se mélangeaient et, s'il y avait transmission, les personnes atteintes pouvaient ramener le virus dans leur réseau (Scott et coll., 2020).

- Un certain nombre d'études ont évalué le risque associé à certaines activités :
  - Une évaluation a estimé que le risque relatif associé à la fréquentation d'une boîte de nuit était 200 fois plus élevé que de manger au restaurant (Dalton et coll., 2020). Cette constatation concorde avec une autre étude qui a révélé un taux d'attaque >50 % lors de contacts directs dans des boîtes de nuit (Prakash et coll., 2020); avec une évaluation qualitative des risques qui a identifié les boîtes de nuit, le karaoké, les restaurants, les gymnases, les stations de ski et les bateaux de croisière comme des lieux de rassemblement à risque élevé (Dalton et coll., 2020); et avec une étude réalisée à Hong Kong ayant révélé que 30,4 % des cas étaient liés à une exposition dans des bars et à des spectacles de groupes de musique (Adam et coll., 2020).
  - Les grands rassemblements sont associés aux plus importantes éclosions. À titre d'exemple, un carnaval en Allemagne a été associé à 1 700 cas (Walker et coll., 2020). Les événements sportifs ont été associés à environ 50 à 100 cas (Leclerc et coll., 2020). Les petits rassemblements, tels que les interactions entre les membres d'un ménage, font partie de la majorité des cas de transmission documentés, mais n'ont généralement donné lieu qu'à un petit nombre de cas secondaires (<5).
  - Parmi les autres lieux de rassemblement courants où les événements de transmission ont été documentés figurent les réunions familiales (fêtes d'anniversaire, repas, etc.), les rassemblements religieux, les mariages, les milieux sociaux, les gymnases, les centres commerciaux, les logements partagés et divers lieux de travail, allant des bureaux aux usines (comme les usines de transformation des aliments).
- Les interventions non pharmaceutiques, telles que les pratiques individuelles d'hygiène des mains et le port du masque dans la communauté et la limitation du nombre de contacts individuels, peuvent réduire le risque qu'un événement de transmission se produise lors de rassemblements, en particulier lors de rassemblements aléatoires (Scott et coll., 2020).
- Les événements de superpropagation (ESP) ont été associés à de grands rassemblements et présentent les caractéristiques suivantes (tableau 3) :
  - Le cas index est souvent asymptomatique ou ne présente que de légers symptômes.
  - Plusieurs études ont estimé que 10 à 20 % des cas de COVID-19 provoquent environ 80 % des nouvelles infections (Adam et coll., 2020; Pozderac et coll., 2020, James et coll., 2020, Laxminara et coll., 2020).

  - Le risque de transmission dans les environnements fermés est plus élevé que dans les environnements en plein air (CR 18,7 [6,0 à 57,9] [Nishiura et coll., 2020].
  - La plupart des cas de transmission ont été attribués au nombre de contacts étroits et soutenus; les conversations, les cris et les chants forts ont tous été associés à des taux d'attaque élevés.

- Ces résultats doivent être considérés à la lumière d'autres facteurs individuels qui peuvent affecter la transmission, tels que la charge virale (Pfefferle et coll., 2020) et le fait que certaines personnes peuvent avoir un R0 plus élevé que d'autres; par exemple, les femmes ont un R) plus élevé que les hommes dans les groupes coréens (Kim & Jiang, 2020).

Vue d'ensemble des éléments de preuve

Le risque de transmission lors des rassemblements et la relation entre la taille de ces rassemblements et le risque de transmission ont été directement et indirectement explorés dans un certain nombre de modèles prédictifs. Bon nombre des modèles qui explorent plus directement cette question sont des prépublications et doivent encore être soumis au processus d'examen par les pairs. Ces modèles sont fondés sur des scénarios et sont paramétrés à partir des données d'observation sur les éclosions. La mesure dans laquelle les résultats peuvent être généralisés au contexte local est variable et doit être utilisée avec prudence.

Les études écologiques publiées estiment l'impact des rassemblements sur l'épidémie en se fondant sur l'étude des changements de trajectoire de l'épidémie après la mise en place et/ou la levée des politiques de limitation de la taille des rassemblements dans une région ou un pays. Par nature, ces études présentent un risque élevé de partialité et de sophisme écologique.

Les estimations des taux de transmission et les descriptions des ESP ou des éclosions sont obtenues à partir des données recueillies lors d'enquêtes rétrospectives sur les éclosions, qui présentent un risque de biais élevé. Ainsi, ces études sont considérées comme étant de faible qualité et il est fort probable que la conclusion changera à mesure que des preuves supplémentaires seront disponibles.

TABLE DES MATIÈRES

SEUILS À OBSERVER POUR LES RASSEMBLEMENTS

Onze modèles basés sur les agents et autres modèles de réseau explorent l'impact de différentes restrictions sur les rassemblements et la manière dont des groupes segmentés qui ont un minimum de contacts aléatoires peuvent assurer une certaine protection (Block et coll., 2020; Deforche et coll., 2020; Kain et coll., 2020; Leng et coll., 2020; Phillips et coll., 2020; Scott et coll., 2020; Sneppen et coll., 2020; St-Onge et coll., 2020; Szapudi, 2020; Weiner et coll., 2020; Zhao, 2020). Certains des modèles explorent et expliquent le concept de petits réseaux communautaires segmentés offrant une protection accrue contre l'introduction du virus et les activités qui dégradent la protection d'un réseau segmenté. Les activités classées comme des rassemblements aléatoires où se mêlent des inconnus, comme le transport, les déplacements vers un lieu de travail en dehors du réseau segmenté, les lieux sociaux tels que les bars et les restaurants, ou les événements sportifs, ont été considérées comme dégradant la protection offerte par le fait d'avoir une communauté segmentée. D'autres modèles examinent les activités de superpropagation et la façon dont le nombre de contacts dans un rassemblement peut entraîner un nombre plus élevé de cas de transmission. Peu d'études ont fourni des valeurs seuils pour les rassemblements ou même exploré les répercussions des différents seuils.

Selon une étude écologique, l'impact des restrictions sur la taille des rassemblements se traduit généralement par une réduction de 10 % du nombre infections (Esra et coll., 2020). Une autre étude a estimé une réduction de 2 % du R0 si le seuil pour les différents rassemblements était de 1000 personnes, par rapport à 21 % pour un seuil de 100 personnes et 36 % pour un seuil de 10 personnes (Brauner et coll., 2020). Deux modèles ont exploré des seuils permettant de faire chuter l'épidémie, l'un suggérant une limite de 23 personnes dans un scénario (St-Onge et coll., 2020) et l'autre suggérant une limitation des contacts à sept personnes par période de 5 jours (P. J. Zhao, 2020).

Deux évaluations des risques mesurent le risque associé à certaines activités et tentent de mettre en perspective le risque individuel. Les premières estimations du risque de transmission étaient d'environ 1 infection pour 3,836 (plage : 626 à 31 800) contacts non protégés au niveau communautaire aux États-Unis le 3 mai 2020 (Bhatia et Klausner, 2020). Une évaluation qualitative des risques réalisée en Australie décrit plusieurs lieux de rassemblement à risque élevé et estime à 200 fois la différence entre le risque relatif d'aller dîner au restaurant et celui d'aller en boîte de nuit (Dalton et coll., 2020). Parmi les autres lieux non pris en compte dans cette évaluation des risques figurent les clubs de karaoké, les gymnases, les stations de ski et les bateaux de croisière (Dalton et coll., 2020).

Étant donné que les preuves sont principalement des modèles prédictifs, des évaluations de risques et des études écologiques, on ne sait pas dans quelle mesure les estimations peuvent être généralisées au-delà des populations et des scénarios étudiés. Il convient également de noter que la plupart des études épidémiologiques sur l'impact des interventions non pharmaceutiques (INP) ne sont pas incluses dans cette revue, car elles n'isolent pas l'effet des restrictions de taille des rassemblements des autres INP qui ont été mises en œuvre presque simultanément.

Tableau 1 : Treize modèles prédictifs et évaluations des risques qui explorent l'impact des rassemblements et le risque de transmission.

Référence	Description de l'étude	Résultats pertinents
Modèles prédictifs		
(Phillips et coll., 2020) *prépublication*	Modèle basé sur les agents pour explorer le potentiel d'éclosion dans les garderies/écoles en Ontario. Ils ont étudié les différents ratios enfants-éducateurs. Les simulations ont pris en compte les ratios enseignant-enfant suivants : 2:8, 3:7, 2:15, 1:15 et 1:30.	Conclusion : Un rapport de 3:7 était le plus protecteur et le modèle 2:15 était bien moins performant. - Le fait de doubler la taille des classes de 8 élèves à 15, puis à 30 élèves a doublé la taille de l'éclosion. - Facteurs de risque accru/impact des grandes classes = • probabilité plus élevée que quelqu'un reçoive un diagnostic positif • plus d'élèves touchés lorsque la classe est mise en quarantaine • la taille de l'éclosion est plus importante en raison du nombre plus élevé de personnes exposées
(Weiner et coll., 2020) *prépublication*	Modèle fondé sur l'âge au moment de l'infection développé pour explorer l'impact des INP sur la deuxième vague potentielle en Illinois. Le modèle commence le 1er août 2020. À des fins de comparaison, l'Arizona et la Floride sont également modélisés. Les données sont empruntées à d'autres États qui connaissent déjà leur deuxième vague, par exemple le Texas.	- Dans les deux scénarios envisagés, les limites strictes imposées à l'égard des rassemblements, de la fermeture des bars et des repas en salle pour maîtriser la superpropagation (en supposant que 80 % des cas proviennent de 10 à 20 % des personnes infectées) permettent d'éviter une deuxième vague.
(Szapudi, 2020) *prépublication*	Modèle SIR avec modification utilisant un modèle de loi exponentielle qui permet l'inclusion des réseaux de connexion sociale.	- Ce modèle montre qu'en stoppant la superpropagation de cas au moyen des INP, la pandémie est considérablement ralentie.
(Kain et coll., 2020)	Modèle SEIR paramétré pour la dynamique de l'épidémie de COVID-19 en estimant un taux de transmission variable dans le temps qui intègre l'impact des INP qui changent avec le temps, dans cinq contextes épidémiologiques distincts : Los Angeles et les comtés de Santa Clara, Californie; Seattle (comté de King), Washington; Atlanta (comtés de Dekalb et Fulton), Géorgie; et Miami (comté de Miami-Dade), Floride.	- Le nombre de reproduction effectif (Re) est rapidement tombé en dessous de 1, à la suite des ordonnances de distanciation sociale à la mi-mars 2020 - Le Re a commencé à augmenter fin mai 2020 à Los Angeles, Miami et Atlanta et en juin 2020 à Santa Clara et Seattle. - Les auteurs montrent qu'il est efficace de réduire le risque de superpropagation des cas (espaces clos bondés).

(Deforche et coll., 2020)	Modèle SEIR : Données sur l'incidence et nombre de décès dans 35 pays (dont le Canada) jusqu'à la mi-mai 2020. Les auteurs étudient quels changements de mobilité pendant le confinement ont été associés de manière significative aux changements dans la transmission de la maladie.	- La réduction du nombre de personnes utilisant les transports en commun et se rendant au travail était fortement corrélée à une réduction de l'incidence de la COVID-19 dans le modèle à variables multiples. - Les changements dans le commerce de détail et les loisirs ont été les plus significatifs/fortement associés aux changements de Rt : Réduction moyenne de Rt de 0,50 (IC 95 % 0,18 à 0,81), soit une réduction moyenne de 22 % (IC 95 % 8 à 35) de la transmission. - Ainsi, d'un pays à l'autre, le paramètre commerce de détail/loisirs indique que les lieux tels que les bars, les restaurants, les centres commerciaux et les rassemblements de masse constituent des circonstances optimales pour la propagation du SRAS-CoV-2, par opposition aux facteurs individuels.
(Block et coll., 2020)	Modèle stochastique : En adoptant une approche de réseau social, les auteurs évaluent l'efficacité de trois stratégies de distanciation conçues pour maintenir la courbe plate et aider à la conformité dans un monde post-confinement. Ils démontrent qu'une réduction stratégique des contacts basée sur les réseaux sociaux renforce fortement l'efficacité des mesures de distanciation sociale tout en maintenant les risques à un niveau plus bas.	Trois approches de la définition d'un réseau de contacts fermé ont été évaluées comme étant protectrices, et toutes peuvent l'être si elles sont respectées à la lettre. - Les individus choisissent leurs interlocuteurs en fonction de la similarité d'une caractéristique individuelle prédéterminée. Cela facilite la formation de petits groupes, par exemple de quartiers ou de petites organisations. - Les individus considèrent avec qui leurs interlocuteurs interagissent et ne voient pas les gens en dehors d'un réseau de contacts défini. - Construire des bulles par des contacts répétés. Les individus décident avec qui ils veulent interagir. Cela peut également être utilisé avec les unités de travail. Il est difficile pour le virus de pénétrer dans ces microcommunautés.
(Leng et coll., 2020)	Modèle basé sur l'individu : En prenant le Royaume-Uni comme cas d'étude, un modèle mathématique a été utilisé pour évaluer l'efficacité de diverses stratégies de bulles	- En utilisant un cas de base où les magasins non essentiels et les écoles sont fermés, le taux d'attaque des ménages est de 20 %, et R0 = 0,8, un

prépublication	sociales dans le cadre d'une stratégie de sortie progressive.	certain nombre de stratégies de bulles sociales sont simulées. Les résultats montrent que dans ce scénario de base, les bulles sociales ont réduit les cas et les décès de 17 % par rapport à une augmentation non concentrée des contacts. - Le regroupement des contacts en dehors du foyer dans des bulles sociales exclusives est une stratégie efficace pour augmenter les contacts tout en limitant une partie de l'augmentation du risque d'épidémie qui y est associée (p. ex. interaction entre deux familles).
(Scott et coll., 2020)	Modèle open source australien « Covasim » basé sur les agents. Ce modèle permet des réseaux de contacts et des interactions aléatoires/classées, en particulier : les ménages, les écoles, les lieux de travail, les réseaux sociaux, les cafés et restaurants, les pubs et bars, les transports publics, les lieux de culte, le sport professionnel, le sport de proximité, les plages, les divertissements (cinémas, salles de spectacle, etc.), les parcs nationaux, les parcs publics, les grands événements (concerts, festivals, jeux sportifs, etc.), la garde d'enfants et les soins aux personnes âgées.	- Le modèle indiquait que le plus grand risque était la réouverture des bars et des restaurants, suivie des lieux de travail et des grands événements. - Les rassemblements sociaux de moins de 10 personnes étaient le type de rassemblement le moins risqué. - Le modèle suppose également qu'il pourrait falloir plus de deux mois pour détecter une augmentation des cas. - Le plus grand risque de résurgence était de permettre aux individus d'avoir de grands réseaux de contacts, en particulier lorsqu'il y a mélange d'individus qui ne se connaissent pas. - Le mélange aléatoire d'un grand nombre de personnes, lors d'événements sportifs par exemple, est risqué, car il expose le réseau plus petit et plus dense de l'individu (domicile/travail/contacts étroits) à l'introduction potentielle du virus.
(Sneppen & et coll., 2020) *prépublication*	Ce modèle basé sur les agents a exploré l'impact des événements de superpropagation. Dans le modèle de base, les événements de superpropagation ont eu peu d'effet sur l'épidémie, mais selon diverses stratégies d'intervention, le fait de limiter les contacts sociaux diffus – les événements de rassemblement aléatoire dans des lieux tels que les bars, les transports, les restaurants, les	- La limitation des événements à rassemblement aléatoire a eu un impact important sur le risque de superpropagation de cas dans ce modèle, dans le cadre de scénarios où diverses stratégies d'intervention sont mises en œuvre.

	fêtes, les concerts et les salles de conférence – est bien plus efficace que de limiter le même nombre d'événements de contact au domicile et au travail.	
(Zhao, 2020) *prépublication*	Modèle de réseau social : L'épidémie dépend de la connectivité du réseau et du temps de propagation. Ainsi, la transmission du virus est affectée par les interventions de santé publique telles que l'isolement, la quarantaine et la distanciation physique. Ce modèle de réseau social explore le niveau d'INP nécessaire pour contenir la pandémie de COVID-19. Définition du contact : un conjoint, deux enfants, un ami, un voisin, un collègue et un caissier pendant les courses.	- Sans distanciation sociale, si un seul individu est infecté par la COVID-19, la probabilité moyenne qu'une personne donnée soit infectée est de 1 sur 1,03 million. - Après la fermeture de toutes les entreprises non essentielles en Italie le 21 mars, le nombre moyen de contacts uniques par individu au cours de chaque période de génération virale devrait être de 6,6, ce qui donne un taux de reproduction prévu de 0,97. - L'épidémie aux États-Unis peut être contrôlée en limitant le nombre moyen de contacts par personne à 7 individus uniques sur chaque période de 5 jours.
(St-Onge et coll., 2020) *prépublication*	Des auteurs canadiens (de l'Université Laval) fournissent des modèles SIS/SIR utilisant un cadre scientifique de réseau pour examiner l'impact de structures telles que les rassemblements (groupes/classes/équipes sportives, etc.).	- Ils démontrent que les épidémies localisées peuvent s'effondrer si la taille du groupe ou du rassemblement reste en dessous d'un seuil. - Le seuil du régime de localisation mésoscopique, avec un taux de transmission $\beta = 0,07$ était de 23 personnes et moins.
Évaluations des risques		
(Dalton et coll., 2020)	Il s'agit d'une évaluation qualitative des risques liés à la réouverture, dans laquelle on examine les caractéristiques des situations de vente au détail et de loisirs pour déterminer si le risque de superpropagation est élevé. On suppose que jusqu'à 80 % des cas peuvent être causés par 10 à 20 % des personnes infectées et que certaines caractéristiques du milieu présentent un risque plus élevé que d'autres. Les études de cas portaient sur des salles de discothèque et de karaoké, des gymnases, des stations de ski, des bateaux de croisière, des églises et des rassemblements religieux.	- Les lieux à risque élevé ne devraient commencer à ouvrir qu'après que les lieux à faible risque aient été ouverts suffisamment longtemps pour savoir qu'il n'y a pas de pic dans les cas. - Le risque relatif associé à la fréquentation d'une boîte de nuit est 200 fois plus élevé que de manger au restaurant. - Caractéristiques de la mise en place des études de cas : Boîtes de nuit : Des centaines de personnes, la proximité, une mauvaise ventilation, des comportements sociaux. Salles de karaoké : 10 personnes, salle fermée.

		Gymnases : surfaces fréquemment touchées et risque accru de transmission de gouttelettes/aérosols >1,5 mètre. Les cours de danse/aérobie présentent un risque plus élevé lorsqu'une fréquence respiratoire et des mouvements plus importants peuvent être associés à une transmission plus poussée. Stations de ski : pas clair Bateaux de croisière : 19 navires de croisière ont eu des cas avant mars 2020. La conception et les contacts étroits contribuent à des taux d'attaque élevés. Il est peu probable que le dépistage chez les membres de l'équipage et les passagers permette d'éviter les cas de COVID-19, même dans les zones de faible transmission. Églises : Les activités comprennent des chants et le partage d'un repas. Plusieurs épidémies ont été liées à ces activités.
(Bhatia et coll., 2020)	Évaluation des risques : Quelle est la probabilité moyenne de contracter la COVID-19, d'être hospitalisé ou de mourir à la suite d'un contact non protégé au niveau communautaire aux États-Unis? Les estimations de la probabilité d'infection par la COVID-19 au niveau individuel peuvent nous éclairer sur des perceptions plus précises du risque et faciliter le réengagement dans l'activité sociale. Parmi les 100 comtés américains les plus peuplés, pour la semaine se terminant le 30 mai 2020, l'incidence quotidienne médiane des cas est de 5,92 pour 100 000 (plage de 0,65 à 35).	- La probabilité médiane de transmission de l'infection par la COVID-19 est de 1 infection pour 3836 (plage : 626 à 31 800) contacts communautaires sans protection (par exemple, sans distanciation sociale, sans port de masque, sans hygiène des mains, etc.) - Pour un individu âgé de 50 à 64 ans, la probabilité médiane d'hospitalisation est estimée à 1 hospitalisation pour 852 000 (plage : 139 000 à 7 080 000) contacts personnels au niveau communautaire et la probabilité médiane de décès est de 1 décès pour 19,1 millions (plage : 3,13 millions à 159 000 000 millions) de contacts personnels au niveau communautaire.
Études écologiques – impact des politiques de restriction des rassemblements sur l'épidémie		
(Esra et coll., 2020) *prépublication*	Étude écologique : Cadre de modèle bayésien pour estimer la transmission associée aux INP dans 26 pays et 34 États américains.	- La réduction globale estimée de l'infection associée aux différentes INP était : • 23 % (95 % IC : 18 à 27 %) associés au confinement à la maison

		• 10 % (95 % IC : 1 à 18 %) avec des limites sur le nombre de personnes dans les rassemblements • 12 % (95 % IC : 5 à 19 %) avec des fermetures d'écoles • 17 % (95 % IC : 6 à 28 %) avec des politiques sur le port du masque. - 12 % (95 % IC : 9 à 15 %) au total
(Brauner et coll., 2020) *prépublication*	Étude écologique : Modèle hiérarchique bayésien, par une liaison des dates de mise en œuvre des interventions non pharmaceutiques (INP) avec le nombre de cas et de décès au niveau national. Les données chronologiques sur les INP dans 41 pays entre janvier et mai 2020 ont été analysées. L'effet de chaque INP a une réduction multiplicative (en pourcentage) du nombre de reproduction R. Bon nombre de ces mesures ont été mises en œuvre en même temps, mais les auteurs affirment que leur modèle a permis d'estimer l'effet de l'intervention individuelle en raison de la grande quantité de données. Ils présentent une longue analyse de sensibilité. La moyenne des résultats est calculée sur l'ensemble des pays, certains pays ayant peut-être eu plus de succès que d'autres, ce qui n'est pas reflété dans cette analyse. (le Canada et les États-Unis ne sont pas étudiés)	Estimation de la réduction moyenne du R0 dans l'ensemble des pays pour huit INP : - Obligation de porter un masque dans (certains) espaces publics (2 %; 95 % IC : -14 % à 16 %) – cette INP avait été mise en œuvre après que la plupart des autres INP ont été pleinement mises en œuvre. - Limiter les rassemblements à : • 1 000 personnes ou moins (2 %; 20 % à 22 %), • 100 personnes ou moins (21 %; 1 % à 39 %), • 10 personnes ou moins (36 %; 16 % à 53 %), - Fermeture de certaines entreprises à risque élevé (31 %; - 13 % à 46 %), - Fermeture de la plupart des entreprises non essentielles (40 %; 22 % à 55 %), - Fermeture d'écoles et d'universités (39 %; 21 % à 55 %). Le modèle ne peut pas faire la distinction entre ces dernières et il peut y avoir des effets additifs tels que le fait que les parents restent à la maison, ce qui augmente l'impact de ces INP. - Émettre des ordonnances de maintien à domicile (18 %; 4 % à 31 %).

SIR = modèle « susceptible – infecté – récupéré », SEIR = « susceptible - exposé - infecté - récupéré », INP = interventions non pharmaceutiques. R0= nombre de reproduction de base, Rt= nombre de reproduction effectif.

CARACTÉRISTIQUES DES CAS DE TRANSMISSION DANS LES RASSEMBLEMENTS COMMUNAUTAIRES

Les événements de superpropagation (ESP) ou les éclosions comprennent plusieurs personnes qui contractent une infection. Les rassemblements présentent un risque d'ESP. En limitant certaines activités à risque élevé et en mettant en œuvre des mesures de santé publique, notamment en limitant la taille des rassemblements, le risque de transmission du SRAS-CoV-2 et la probabilité de superpropagation devraient être réduits.

Le tableau 2 souligne l'importance de contrôler les supertransmetteurs ou les ESP. Des analyses rétrospectives estiment qu'une grande partie des cas (80 %) sont dus à une petite proportion des personnes infectées (10 à 20 %) (Adam et coll., 2020; Pozderac et coll., 2020; James et coll., 2020b; Laxminarayan et coll., 2020). Une étude écologique du sport professionnel nord-américain a fait état d'une association entre les matchs professionnels pratiqués au début de l'épidémie et le nombre de cas et de décès par la COVID-19 dans cette ville, qui a été attribuée aux grands rassemblements associés à ce sport (Wing, Simon et Carlin, 2020).

Trois études quantifient l'impact des restrictions de taille des rassemblements et des contacts individuels (Jarvis et coll., 2020; Scire et coll., 2020; Zhang et coll., 2020). Ces études fournissent une estimation du changement de comportement et peuvent aider à paramétrer ou à estimer les changements progressifs des schémas de contact qui sont tolérables à différents moments de l'épidémie.

Tableau 2 : Estimations sur l'importance de contrôler les cas et les événements de superpropagation.

Référence	Description de l'étude	Résultats pertinents
Estimations de l'impact		
(Wing et coll., 2020) *prépublication*	Étude écologique visant à comparer le nombre de cas de COVID-19 et la mortalité entre les villes qui ont accueilli de nombreux matchs de la LNH, de la NBA et de la NCAA au cours du premier trimestre de 2020.	- Une association avec le nombre de parties a été observée : • Chaque match de la LNH ou de la NBA a entraîné 783 cas supplémentaires et 52 décès entre mars et la mi-mai 2020. - Les parties de la NCAA ont été associées à 31 cas et 2,4 décès.
(Pozderac et Skinner, 2020) *prépublication*	Modèle permettant d'estimer la variation de l'infectiosité en examinant la variation des taux de croissance précoce des nouveaux cas parmi différentes sous-populations aux États-Unis.	- Estime la dispersion de l'épidémie et signale que 88 % des cas sont probablement issus de 10 % des cas.
(A. James et coll., 2020b) *prépublication*	Analyse de l'épidémie en Nouvelle-Zélande. Cas de COVID-19 = 1 499 Les enfants de moins de 10 ans étaient sous-représentés. Les enfants infectent moins de personnes/taux d'attaque secondaire inférieur.	- La surpropagation contribue de manière significative à la dynamique de l'épidémie, avec 20 % des cas chez les adultes responsables de 65 à 85 % de la transmission.

	Les cas asymptomatiques sont transmis à moins de personnes que les cas cliniques. Intervalle de série ~5 jours	
(Laxminarayan et coll., 2020) *préublication*	Cette étude analyse les données épidémiologiques de deux États de l'Inde. Enquêtes d'identification des cas et de recherche des contacts.	- L'analyse indique que 5,4 % des cas sont responsable de 80 % des contacts infectés.
(Adam et coll., 2020) *préimpression*	Cette étude analyse les événements de superpropagation à Hong Kong dans 135 groupes.	- L'analyse a permis de déduire que 20 % des infections étaient responsables de 80 % des cas de transmission à Hong Kong. - Un groupe notable de 106 cas, attribués aux bars et aux spectacles de groupes de musique, représentait 30,4 % de la transmission locale au début de l'épidémie.
Impact des restrictions relatives aux rassemblements		
(Saidan et coll., 2020)	Cette étude calcule le R0 propre au contexte en se fondant sur des enquêtes faites sur des groupes. Ce modèle de transmission (SIR) a été développé pour ne modéliser que les groupes comparés et non la population entière.	- Estimation du R0 par type de rassemblement • Mariages/fêtes R0=5 • Rassemblements religieux R0=2,5 • Usines de transformation (viande) R0=2,0
(Scire et coll., 2020)	Suisse, du 27 février au 22 avril 2020 : Des règles strictes limitant les rassemblements à moins de 5 personnes dans les lieux publics ont été mises en place, et une quarantaine volontaire de 10 jours a été instaurée pour toute personne présentant des symptômes. À partir des données de surveillance pour le nombre de cas, le R0 a été calculé pour différentes périodes de l'épidémie. L'analyse de sensibilité indique que ce résultat n'est pas un artefact de l'intensité du test.	- Avant les restrictions relatives aux rassemblements, le R0 était compris entre 1,5 et 2. Après la mise en place des restrictions relatives aux rassemblements, le R0 est tombé entre 0,6 et 0,8 dans le premier tiers d'avril 2020.
(Jarvis et coll., 2020)	Enquête britannique sur les habitudes de contact avant et après le confinement. L'enquête a été réalisée le lendemain du confinement; elle ne peut donc pas vraiment mesurer l'adhésion à long terme.	- Réduction de 74 % du nombre de contacts quotidiens (de 10,8 contacts par jour à 2,8). - Cela devrait permettre de réduire le R0 de 2,6 à 0,62 (95 %, IC : 0,37 à 0,53) pour tous les types de contacts.
(J. Zhang et coll., 2020)	Les contacts à Wuhan et à Shanghai ont été évalués avant et après le confinement à l'aide d'une enquête menée du 1er au	- La moyenne pondérée selon l'âge des contacts quotidiens était de 14,0 à 18,8 au départ et a été réduite à 1,9 à 2,1

	10 février 2020. Le terme « contact » désigne une conversation de trois mots ou plus en présence d'une autre personne et/ou un contact direct.	pendant la période d'éclosion (p<0,001). Dans l'ensemble, les contacts qui ont eu lieu pendant l'éclosion se sont surtout produits à la maison avec des membres du ménage (94,1 % à Wuhan et 78,5 % à Shanghai). - Il était prévu que les interventions (confinement) bloquent la transmission pour un R0 avant les interventions de 6 à 7,8.

Le tableau 3 énumère les répertoires d'ESP et de foyer d'éclosion de COVID-19, les études qui examinent les caractéristiques de ces groupes, la littérature qui résume les ESP de COVID-19 associés aux rassemblements et les enquêtes épidémiologiques primaires qui impliquent des rassemblements. Cette liste n'est pas exhaustive, mais décrit un large éventail de situations dans lesquelles des événements de transmission ont été documentés. Les recherches et les ressources présentées dans cette section comportent des limites, notamment des biais qui peuvent rendre certaines ESP plus susceptibles d'être identifiées et documentées. Par exemple, les événements sociaux sont plus susceptibles d'être gardés en mémoire que les activités quotidiennes; les événements sont donc plus faciles à retracer. En outre, certains milieux peuvent être mieux représentés parce qu'ils disposent de l'infrastructure nécessaire pour surveiller et identifier les éclosions (par exemple, les prisons ou les établissements de soins de longue durée peuvent appliquer une routine de surveillance et de tests).

Des bases de données d'ESP compilées par des chercheurs et des journalistes ont été identifiées; la plus complète compte actuellement plus de 1 400 ESP documentés à partir de la littérature primaire et grise (tableau 3). Toutes comprennent des descriptions de la taille, du contexte et d'autres attributs, tels que l'activité associée à l'ESP.

Les enquêtes sur les groupes, qui permettent d'estimer le risque de transmission par une personne infectée ou l'impact du type de rassemblement sur la taille et l'étendue de l'événement de transmission, sont importantes pour aider à étayer les situations à risque élevé ou faible (tableau 3) (Kim et coll., 2020; Liu et coll., 2020; Pfefferle et coll., 2020). Ces enquêtes montrent qu'un petit nombre de cas peut être responsable de la majorité des événements de transmission et que le risque de transmission est très variable. Ces dernières études sont fondées sur des enquêtes rétrospectives de recherche de contacts, qui présentent un risque élevé de biais et peuvent ne pas représenter le spectre des événements de transmission lors de rassemblements qui ont eu lieu. La sous-déclaration des événements de transmission lors de rassemblements, en particulier les situations où les gens sont rassemblés aléatoirement comme dans les transports publics, est très probable, car ces événements seraient difficiles à étudier.

Les observations générales concernant les événements de superpropagation (ESP) qui se sont produits en dehors du ménage sont les suivantes (tableau 3) :

- Souvent, le cas index était asymptomatique ou ne présentait que de légers symptômes au moment de l'événement de transmission.
- La plupart des ESP se sont produits dans des environnements intérieurs.
- La plupart sont associés à des espaces bondés et à une période prolongée passée dans cet espace ou à un contact étroit et intense avec la personne infectée (Leclerc, Fuller, Knight, Funk et Knight, 2020; Swinkels, 2020).
    - Des activités telles que les interactions à distance rapprochée dans les maisons de soins pour personnes âgées et les événements comportant des chants, des conversations ou des cris importants ont été associées aux ESP.
- Les milieux à risque élevé sont des lieux où un grand nombre de personnes se rassemblent. Il s'agit notamment de l'hébergement de grands groupes, d'environnements de travail confinés et de rassemblements de masse. [Notez que les ménages représentent de 50 à 60 % (Swinkels, 2020)].
    - Environ 15 % des ESP sont associés aux divertissements/loisirs : restaurants, sports et conditionnement physique, fêtes, bars et boîtes de nuit.
    - Environ 5 % des ESP sont associés à des centres commerciaux intérieurs et à des supermarchés (trois ESP ont été associés à des marchés extérieurs).
    - Environ 3 % des ESP sont associés à des rassemblements religieux.
    - Environ 2 % des ESP sont associés aux écoles.
    - Les ESP dans un environnement de travail (~7 %) comprennent principalement les environnements de bureau, suivis des usines de transformation des aliments. Peu de groupes étaient associés au travail à l'extérieur.
        - Les éclosions dans les usines de transformation d'aliments se sont surtout produites dans des environnements de transformation réfrigérés plutôt que dans d'autres types d'installations. Cela peut être dû au fait que l'environnement de travail est favorable à la persistance du SRAS-CoV-2 (basse température et humidité, surfaces métalliques solides), que les lieux de travail sont achalandés, que le transport et les logements sont partagés, et que la main-d'œuvre est peu susceptible de ne pas travailler malgré les symptômes (Chong, Ng, Hori, & et coll., 2020; Durand-Moreau et coll., 2020).
    - Environ 7 % des ESP ont eu lieu dans des logements partagés tels que des dortoirs de travailleurs, des prisons et des établissements de soins de longue durée.
    - Le transport (~1 %) a également été associé à quelques groupes, notamment les bus, les vols et les trains.

Tableau 3 : Études et répertoires qui résument les caractéristiques des rassemblements associés à la transmission.

Répertoire d'événements de transmission de la COVID-19		
(Swinkels, 2020)	Les événements de surpropagation dans le monde entier [Feuille de calcul Google]. Version mise à jour le 15 août 2020 - Les événements de transmission comptant plus de 5 cas secondaires sont inclus dans cette liste. - Les sources englobent à la fois la littérature primaire et la littérature grise. - Les détails comprennent l'emplacement, le contexte, la description, l'intérieur, le nombre de cas, la date d'index, la référence, et d'autres paramètres. - Les ESP associées à une forte vocalisation et ceux qui se produisent dans un environnement réfrigéré sont marqués.	- Le projet comprend plus de 1 400 ESP. La feuille de calcul est disponible aux fins de téléchargement et d'analyse. *Les proportions sommaires dans le texte sont issues de ce travail.* • Actuellement, 21 ESP sont répertoriés à partir du Canada.
(Institute for Investigative Journalism, Concordia, 2020)	Projet pandémie Une liste canadienne de groupes de déclarés dans tout le Canada, compilée dans le cadre d'une initiative conjointe de journalistes canadiens. *Ce site n'est pas accessible librement, mais il s'agit d'un répertoire de données qui n'est pas disponible ailleurs.*	En date du 18 août : - 58 groupes d'usines de transformation des aliments, le plus grand comptait plus de 650 cas d'infection - 53 centres de détention ont signalé des groupes
(Leclerc et coll., 2020)	Cet examen rapide et cette base de données sur les ESP ont compilé la littérature jusqu'au 7 juin 2020; par la suite, les efforts déployés n'ont pas été exhaustifs. Les détails comprennent le contexte, l'intérieur, le pays, les détails, la référence, la date, le nombre de groupes, le nombre total de cas et les taux d'attaque.	Contexte de l'ESP / COMPTE N=265 / % Chantier de construction 4 1,5 % Conférence 5 1,9 % Soins aux personnes âgées 21 7,9 % Usine de transformation des aliments 21 7,9 % Funérailles 2 0,8 % Hôpital 9 3,4 % Hôtel 3 1,1 % Ménage 38 14,3 %

		Logement partagé	30	11,3 %

		Chantier naval	1	0,4 %
		Achats	8	3,0 %
		Sport	22	8,3 %
		Moyen de transport	1	0,4 %
Caractéristiques des événements de transmission et leur association avec les rassemblements				
(Kuebart et Stabler, 2020)	Cet article étudie les ESP en Allemagne et examine la propagation sociospatiale du SRAS-CoV-2 et les facteurs associés à cette propagation.	- Cet article souligne l'importance du lieu, de la foule et de l'activité en tant que facilitateurs de la transmission : • Une éclosion régionale en Allemagne de l'Ouest centrée dans le district de Heinsberg (février 2020). • Les touristes qui retournent dans leur région d'origine alors qu'ils sont porteurs d'une infection. • Réseaux d'infection basés sur des lieux ou des événements spécifiques.		
(Kim et Jiang, 2020) *prépublication*	Cette étude a examiné les propriétés du réseau de cas survenant en Corée. (n=3 127 cas) - Réseau de transmission longitudinale - 147 groupes ont été identifiés - 12 comptaient 20 cas ou plus	- Les femmes avaient un R0 plus élevé que les hommes. - Les adultes plus âgés (ne bénéficiant pas de soins de longue durée) avaient un R0 plus élevé que les jeunes adultes et les adultes d'âge moyen. - Les rassemblements religieux, les gymnases, les établissements de soins de longue durée et les centres d'appel pour le service à la clientèle sont à l'origine des plus longs événements de transmission.		
(On Kwok et coll., 2020)	Analyse des données épidémiologiques jusqu'au 3 mars 2020 de Hong Kong, du Japon et de Singapour pour évaluer la	- La probabilité d'observer des groupes de cas secondaires de taille ≥ 4 varie de 10,6 % à 21,5 % des groupes.		

	présence et la probabilité de groupes ou d'événements de transmission. La taille moyenne des groupes était de 2,54 (HK), 1,92 (JP) et 3,32 (SG); tandis que les tailles maximales étaient de 16 (HK), 28 (JP) et 31 (SG).	
(Adam et coll., 2020) *prépublication*	Cette étude analyse les événements de superpropagation à Hong Kong dans 135 groupes.	- L'analyse a permis de déduire que 20 % des infections étaient responsables de 80 % des cas de transmission à Hong Kong. - Un groupe notable de 106 cas, attribués aux bars et aux spectacles de groupes de musique, représentait 30,4 % de la transmission locale au début de l'épidémie.
(Hamner et coll., 2020)	Taux élevé d'attaques par le SRAS-CoV-2 suite à une exposition lors d'une répétition de chorale – Skagit County, Washington, mars 2020	- Parmi les 61 personnes qui ont assisté à la répétition de la chorale le 10 mars 2020, le taux d'attaque secondaire était de 53 % chez les cas confirmés et de 87 % chez tous les cas potentiels. - Le chant a été attribué à la cause du taux d'attaque élevé.
(Nishiura et coll., 2020) *prépublication*	Cet article examine les données épidémiologiques sur 11 groupes de 110 cas au total qui se sont produits au Japon en date du 26 février : 4 à Tokyo et 1 dans chacune des préfectures de Aichi, Fukuoka, Hokkaido, Ishikawa, Kanagawa et Wakayama.	- Tous les groupes étaient associés à des environnements intérieurs : gymnase, restaurant, hôpital et un festival où l'on mangeait sous des tentes. - Cette étude a estimé que la probabilité de transmission dans un environnement fermé par rapport à un environnement en plein air était de CR 18,7 (95 % IC 6,0 à 57,9). Cette analyse n'a pas permis de contrôler les facteurs de confusion ou l'interaction potentielle avec d'autres prédicteurs.
(S. Zhao et coll., 2020) *prépublication*	L'analyse de l'éclosion sur le navire Diamond Cruise, février 2020.	- Le terme de dispersion (k) a été estimé à 44 (95 % IC 6 à 88), ce qui est nettement supérieur à 1 et suppose une probabilité moindre d'événements de superpropagation. En comparaison avec le SRAS et d'autres coronavirus, la COVID-19 a un potentiel de superpropagation moins élevé et un fort potentiel de persistance dans une population.

Synthèse des groupes		
(Leclerc et coll., 2020)	Revue systématique, date de recherche 31 mars 2020, qui résume 201 groupes de transmission.	- Caractéristiques des groupes : • Milieux intérieurs ou milieux intérieurs/extérieurs (21/22). • Grands groupes, comme ceux liés aux églises et aux navires, moins de 100 cas (181/201). • Plus de 100 cas ont été enregistrés dans des hôpitaux, des centres de soins pour personnes âgées, des dortoirs de travailleurs, des usines de transformation des aliments (9 groupes), des prisons, des écoles (8 groupes), des magasins et des navires. • Groupes de 50 à 100 cas : sport, bar, mariage, travail, conférence. • C'est dans les ménages que l'on a observé le plus de groupes, lesquels comptaient généralement moins de 10 personnes.
(Bouffanais et Lim, 2020)	Commentaire sur les points chauds de transmission de la COVID-19.	- 95 % des cas de Singapour se sont produits dans des dortoirs qui hébergent des travailleurs migrants (42 000 cas, soit 12,5 % des personnes vivant dans ces dortoirs).
(Prakash, 2020) *prépublication*	Cette synthèse n'a pas été réalisée selon la méthodologie standard d'examen systématique, bien qu'une recherche approfondie ait été effectuée. Ils ont identifié 20 situations qui ont donné lieu à 418 infections dans 32 cas chez 44 personnes (8 présentaient des symptômes légers, 36 étaient asymptomatiques).	- Situation (taux de transmission) : • Repas/événements familiaux, de 15,7 % à 66,7 %. • Réunions (1 heure de réunion privée, 72,7 % [43,6 à 98,0]. • Espace de travail ouvert avec mouvement des personnes [78,7 % (IC 70,3 à 85,3 %)]. • Chant [par exemple, pratique de 2 heures 86,7 % (IC 76.2 à 93,2 %)], (Hamner et coll., 2020)]. • Service de prière (a entraîné de 1 à 7 infections secondaires par personne infectée). • Voyager en voiture (environnement fermé) et parler présentait un risque élevé [100 % (IC 20 à 100 %)]. • Transports publics, port d'un masque sans parler (~0 %).

		• Hôtels 53,3 % (30,1 à 75,2 %)/bateaux de croisière 28,1 % (27,3 à 29,0 %) où l'espace est partagé pendant plusieurs jours. • Interaction directe avec un agent de vente infecté 25,0 % (10,2 à 49,5 %). • Boîte de nuit, taux d'attaque parmi les contacts directs >50 %, parmi les clients de la discothèque 6,27 % (5,15 à 7,61 %) (Adam et coll., 2020). • Taux d'attaque global dans les restaurants [9,9 % (IC : 5.3 à 17,7 %)] par rapport à celui associé à la circulation de l'air climatisé 45,0 % (25,8 à 65,8 %). - Parmi tous ces événements de superpropagation, le nombre d'infections causées dépend du nombre de contacts étroits et dans la plupart des cas, le cas index n'était pas détectable au moment de la transmission.
(Y. Liu, Eggo et Kucharski)	Cette courte communication résume 9 foyers d'éclosion ayant entraîné 48 infections secondaires chez 137 personnes à la fin du mois de janvier.	- Cela donne un taux d'attaque secondaire de 35 % (95 % : 27 à 44). • 3 foyers d'éclosion sont liés à des repas à domicile (AR : 100 %, 31 %, 44 %). • 1 repas au restaurant (21 %). • 4 repas inconnus (100 %, 87,5 %, 11,7 %, 21 %). • 1 Chalet en France (45 %).
Recherche primaire sur les groupes		
(Walker et coll., 2020)	Le premier événement de superpropagation en Allemagne.	- L'éclosion de Heinsberg associée à la participation à une activité pendant le carnaval, le 15 février 2020. - Elle a donné lieu à la première éclosion à grande échelle en Allemagne. Plus de 1 700 cas ont été retracés jusqu'à cet événement.
(Pfefferle et coll., 2020)	Cette étude a utilisé la génomique virale et l'appel de variantes pour suivre la transmission virale lors de l'éclosion initiale à Hambourg, en Allemagne. Ils fournissent des preuves de la transmission de doses virales élevées et de faibles doses virales.	- Le patient 0 a été en contact avec 132 personnes sur son lieu de travail dans les deux jours précédant l'apparition des symptômes. Ces événements de transmission sont considérés comme des événements de transmission à faible dose.

		- Un collègue de travail exposé à un risque élevé et son épouse ont reçu un diagnostic positif pour le SRAS-CoV-2. 1/33 des interactions à risque élevé et 0/98 des interactions à faible risque ont donné lieu à des cas positifs. - L'épouse était asymptomatique, mais le virus a été cultivé à partir de son prélèvement oropharyngé et sa charge virale ainsi que celle du cas index ont rapidement diminué au cours des 5 premiers jours de la maladie. - Un groupe familial présente également des preuves de variantes de séquences minoritaires, ce qui indique une exposition à une charge virale élevée par les gouttelettes.
(Ghinai et coll., 2020)	Les éclosions survenues à Chicago sont associées à une réunion de famille et à des funérailles.	- Le cas index avait récemment voyagé et était légèrement symptomatique au moment de la transmission. Les événements de transmission comprennent le partage d'un repas et la participation à l'enterrement où il y a eu plusieurs contacts (poignée de main et étreinte) - La fête d'anniversaire a eu lieu dans une maison avec 9 membres de la famille (se serrant dans les bras, partageant la nourriture). - La transmission survenue lors du service religieux découle d'une conversation entre des personnes très près l'une de l'autre, assises dans une même rangée pendant 90 minutes.
(A. James et coll., 2020a)	Éclosion dans une église de l'Arkansas en mars 2020.	- Deux personnes pré-symptomatiques ont assisté à des rassemblements à l'église et le taux d'attaque qui en a résulté était de 35/92 et au moins 26 cas supplémentaires ont été observés dans la communauté.
(Shen, Xu et coll., 2020)	La ville de Jiaxing a connu des éclosions où les rassemblements comprenaient des mariages, des fêtes d'anniversaire et des activités professionnelles.	- Le taux d'attaque secondaire (SAR) était de 0,6 % (3/473). Les cas de tests positifs ont eu un contact avec le cas index; ils ont mangé à la même table pendant le mariage, ont eu des conversations

		étroites, ont passé de longues périodes dans la même pièce. Le taux de SAR parmi les contacts proches était de 29 % (2/7).
(Breton et coll., 2020)	Premier groupe de cas en France associé à une semaine de prière à l'église du 17 au 21 février 2020, n=2 000 R0= 1,4 Intervalle de série = 4 jours.	- Le seuil épidémique a été estimé à 4 cas par jour. - La courbe d'incidence montre que l'épidémie a commencé avant qu'une alerte sanitaire ne soit donnée et que certains des participants à la semaine de prière chrétienne présentaient des symptômes avant l'événement.
(Chaw et coll., 2020; Wong, Jamaludin, Alikhan et Chaw, 2020)	Groupe de cas en Malaisie liés au rassemblement religieux de Tablighi Jamaat. 19/75 participants ont été infectés lors de l'événement, ils ont causé 52 cas secondaires. - Un modèle binomial négatif a été utilisé pour explorer les facteurs de risque.	- Le plus fort taux d'attaque (AR) a été le rassemblement : [14,8 % IC 95 % : 7,1, 27,7)]. - Les AR des ménages de cas symptomatiques étaient plus élevés (14,4 % IC 95 % : 8.8, 19.9) que les cas asymptomatiques ou présymptomatiques (5,4 % IC 95 % : 1,2, 9,6). - De faibles AR (< 1 %) ont été observés sur le lieu de travail et dans les milieux sociaux.
(Chen et coll., 2020)	Une étude rétrospective de 141 cas de COVID-19 à Chongquing en janvier-février 2020. 90 faisaient partie de groupes et 51 étaient considérés comme sporadiques.	- 82 % des cas de groupes étaient associés à une exposition lors d'une réunion familiale.
(Adam et coll., 2020) *prépublication*	Un groupe notable au début de l'épidémie à Hong Kong.	- Au début de l'épidémie, 106 cas retracés à des bars et des spectacles de groupes de musique représentaient 30,4 % de la transmission locale à Hong Kong. - On pense que cela a été causé par une série d'événements de superpropagation parmi le personnel, les groupes de musique et les clients.
(Ye et coll., 2020)	(en chinois) Une éclosion à Ningbo, associée à un rassemblement bouddhiste, dans lequel le cas index a utilisé le transport en commun (autobus).	- Le taux d'attaque global était de 37/1,283, soit 2,88 % et le taux d'infection de 48/1,008, soit 4,76 %. Cependant, le taux d'attaque dans les autobus de 33,82 % (23/68) et le taux d'infection de 38,24 % (26/68) représentaient la majeure partie de la transmission.

		- Le cas index présumé avait commencé à présenter des symptômes un jour avant de participer à l'événement.
(Y. F. Liu et coll., 2020 [en chinois]; Wu et coll., 2020; Y. Zhang et coll., 2020)	Enquête sur les groupes à Tianjin jusqu'au 22 février 2020. N=115 cas dans 33 groupes.	- 28 groupes familiaux. - 1 groupe dans un lieu de travail (le cas index a infecté >6 personnes). - 3 groupes liés au transport (2 avions, 1 train). - 1 groupe dans un grand magasin (1 vendeur infecté, 20 clients et 3 collègues).
(Correa-Martínez et coll., 2020)	Une épidémie associée à une ville où se trouve une station de ski, Ishgl, en Autriche. Reconnu par un hôpital local, l'hôpital universitaire de Münster (UKM) en Allemagne. N-19 cas.	- 36/90 cas de COVID s'étaient récemment rendus à Ischgl (39,6 %), une ville où se trouve une station de ski. Un bar d'après-ski où un barman a été déclaré positif a également été fréquenté par de nombreux cas positifs. Ce bar est considéré comme la source potentielle de l'ESP.
(Park et coll., 2020)	Ce rapport décrit une épidémie de COVID-19 dans un centre d'appel en Corée. Sur 1 143 personnes testées pour la COVID, 97 (8,5 %) ont reçu un résultat positif. La majorité de ces employés (94/97) travaillaient dans un centre d'appel du 11e étage comptant 216 employés.	- Le taux d'attaque était de 43,5 % (95 % IC : 36,9 à 50,4 %). Le taux d'attaque secondaire des ménages parmi les cas symptomatiques était de 16,2 % (IC à 95 %) : 11,6 à 22 %).
(Shen et coll., 2020) *prépublication*	La première enquête sur l'éclosion a porté sur le transport en autobus de personnes se rendant à un événement religieux. Une deuxième éclosion impliquant un atelier de 30 personnes utilisant un transport commun. L'enquête comprend la recherche de cas index et des cas secondaires, et la vérification du temps relatif passé à proximité du cas index.	- Éclosion 1 : L'autobus 2 a eu un taux d'attaque de 34,3 %, et personne dans l'autobus 1 n'a été infecté. - Lors de la deuxième éclosion, le taux d'attaque global a été de 48,3 %. - On suppose que les ventilateurs et les climatiseurs en mode recirculation ont contribué à la circulation du virus dans la pièce/autobus. Ils suggèrent que la transmission aérienne est probablement partiellement responsable des taux d'attaque élevés.
(Qian et coll., 2020) *prépublication*	Cette étude a analysé tous les foyers d'éclosion impliquant 3 cas ou plus signalés aux commissions municipales de santé en Chine du 4 janvier au 11 février 2020. 318 foyers d'éclosion intérieurs dans 120 villes sont décrits. 80 % des foyers	- 318 foyers d'éclosion intérieurs dans 120 villes impliquant la famille (129), les proches (133), les personnes socialement connectées (29) et les personnes socialement déconnectées (24) sont décrits. 80 % des foyers d'éclosion ont touché moins de 5 personnes. 83 foyers

	d'éclosion ont touché moins de 5 personnes.	d'éclosion touchaient plusieurs sites, soit un total de plus de 100 % (n=318) • 79,9 % ont eu lieu à l'intérieur d'une maison, • 34,0 % dans le transport, • 4,4 % au restaurant, • 2,2 % dans des commerces de détail • 9,7 % dans d'autres lieux.

Méthodologies

Une recension quotidienne de la littérature (publiée et prépubliée) est effectuée par le Groupe des sciences émergentes de l'ASPC. Cette recension a permis de compiler la littérature sur la COVID-19 depuis le début de l'épidémie et est mise à jour quotidiennement. Les recherches pour trouver de la littérature pertinente sur la COVID-19 sont menées dans Pubmed, Scopus, BioRxiv, MedRxiv, ArXiv, SSRN, Research Square et sont mises en correspondance avec les publications figurant sur la liste de littérature de l'OMS au sujet de la COVID, et les centres d'information sur la COVID-19 gérés par Lancet, BMJ, Elsevier et Wiley. Le résumé quotidien et les résultats complets de la recension sont conservés dans une base de données Refworks et une liste Excel qui peut être consultée. Une recherche ciblée par mot-clé a été effectuée dans ces bases de données pour y relever des citations pertinentes sur la COVID-19 et le SRAS-CoV-2. Les termes de recherche utilisés sont les suivants : « social » ET (« network », « gathering », « cluster », « outbreak »), « superspread »* OU (« super spread »*). Environ 278 citations ont été examinées pour en déterminer la pertinence et d'autres foyers d'éclosion ont été tirés de la liste des documents relatifs aux foyers d'éclosion dans les précédents examens des événements de superpropagation et des événements de transmission sur le lieu de travail/à l'intérieur. Cette revue contient des recherches publiées avant le 18 août 2020.

Emerging Evidence on COVID-19

Evidence Brief of SARS-CoV-2 Risks in Arenas

Introduction

What evidence exists for the risk of SARS-CoV-2 transmission in arenas, on and off the ice surface?

COVID-19 outbreaks related to arenas and ice sports have highlighted the need to understand how transmission is occurring and what environmental and behavioural factors may be altered to lower the risk of transmission. Professional and recreational hockey, along with other indoor ice surface sports such as curling, ringette, skating and sledge hockey exposures were considered relevant for this evidence brief. Evidence on transmission risks in ice arenas and literature specific to COVID-19 for sport or recreational participants, coaches, spectators, and arena staff was collected. Activities in different sub-environments (e.g., use of the lobby, dressing rooms and hallways before and after on-ice activities, the spectator areas and the on-ice activities) were considered when reviewing the evidence. Reviews on the effect of temperature and humidity on transmission of SARS-CoV-2 were also included in this brief as indirect evidence of SARS-CoV-2 survival under cold conditions. The use of combustion engine ice resurfacing equipment has lead to indoor ice facility air quality concerns in the past, but no connection of this research to COVID-19 risks has been documented, so it not considered. This brief summarizes review and primary literature available up to February 12, 2021.

Key Points

- This review included 13 publications: two outbreak investigations related to ice hockey (1, 2), and two related to curling bonspiels (3, 4). Two cross-sectional studies included observational data from August to October 2020 looking at risk factors for COVID-19 associated with other recreational sports in the USA (5, 6). Three reviews summarize the literature on SARS-Cov-2 under cold or low humidity environments such as those found in the arena.

Arena/Ice Sports:

- Hockey provides favourable conditions for SARS-CoV-2 transmission due to:
  - Heavy breathing on ice and on the bench due to high intensity physical activity;
  - Close proximity of players, coaches;
  - Indoor gathering;
  - Dry, cold air of the arena; and
  - Segregated air mass due to ~10 foot barriers around the ice leading to poor air circulation. (1, 2, 7).

- An investigation of a June 2020 outbreak among recreational men's hockey teams theorized that one presymptomatic individual lead to 14 symptomatic adults (12 confirmed, 2 not tested), 13 players across both teams and 1 arena employee (2). No PHMs were reported to have been in place.

- An outbreak within the Finnish U-20 hockey league was investigated and speculated to have likely been caused by one asymptomatic player, resulting in transmission to two opposing teams and tertiary transmission to senior league teams for a total of 49 confirmed COVID-19 infections (1). After the outbreak, the league implemented measures to minimize the risk COVID-19 transmission, including associating with only one team.

- Two bonspiel outbreak investigations noted social gatherings with few precautions for a prolonged period of time (3, 4). Thus, transmission risk cannot be attributed to the sport or the venue.

- When resuming both recreational and professional hockey and other indoor ice activities, strategies for reducing transmission risk include: limiting the number of individuals in the arena, lessening time in the arena, screening of individuals and increasing sanitation, cohorting players, minimizing exposure time and sharing of equipment, using masks and maintaining physical distancing (5-9).

Other Sports:

- Evidence from two cross-sectional studies describes lower risk of COVID-19 among outdoor sports compared to indoor sports, non-contact sports compared to contact sports and that for some indoor sports, wearing a mask had a significant protective association (5, 6).

Indirect Evidence:

- Evidence of the survival and transmission potential of SARS-CoV-2 in cold and low humidity level environments has not been studied well in the literature. However recent reviews that looked at experimental evidence consistently indicate lower temperatures and humidity are favorable for SARS-CoV-2 survival. Similarly, studies of weather and environment consistently indicate higher SARS-CoV-2 transmission in areas with low temperatures (0-17°C) and a significant interaction between temperature and humidity, but not humidity on its own (10-16).

Overview of the Evidence

Thirteen articles were included in this brief, six primary literature articles that provide descriptions of outbreaks related to sports, four guidance documents for resumption of hockey (two for professional hockey leagues, one for Canadian hockey and one for youth sports) and three reviews that cover transmission of SARS-CoV-2 or survival in cold temperatures. Four outbreaks, two non-professional hockey and two curling bonspiels and two cross-sectional analyses of non-arena based sports at high school and youth soccer were included. No evidence was found related to other indoor ice activities, such as skating, sledge hockey or ringette.

Outbreak investigations are retrospective collections of evidence and findings are at risk of several biases; and all identified uncertainty about where transmission occurred. Some cross-sectional studies were included, which provide a point in time dataset of a population, however they can only establish associations and not causation between an exposure and an outcome. A range of review types were included, and systematic reviews were rated by the AMSTAR-2 tool. Narrative literature reviews were considered low quality due to a high risk of bias. The limitations of the evidence include a very small number of articles in the literature related to arenas, despite many jurisdictions reporting cases or outbreaks traced to hockey teams or curling (e.g., CBC news January 16, 2021). The nature of sports makes it difficult to establish with certainty where transmission occurred, as teammates often spend time together for practice, training, game travel, meals and recreational activities. Tournaments can add more mixing opportunities and exposures between teams, as well. Lastly, all of the outbreaks currently in the literature occurred early in the pandemic, when mask use and other public health measures were not widely used.

CONTENTS

INDOOR ICE SPORT OUTBREAKS

Table 1: Transmission Linked to Indoor Ice Sports and Other Sports (n=6)

STUDY	OUTBREAK DESCRIPTION	KEY OUTCOMES
Hockey (n=2)		
Atrubin (2020) (2) Outbreak investigation United States Jun 2020	2 Teams (A & B) played a recreational hockey game June 16, 2020 (day 0) in Tampa Bay, Florida. Each team had 11 male members, aged 19-53 years. By June 21 (day 5), 15 individuals were symptomatic with suspected COVID-19. • Index patient – Team A player, who was symptomatic 1 day after the game; and tested positive on day 3. • Secondary cases – 14 symptomatic adults (12 confirmed, 2 not tested); 13 of the game players and 1 employee at the arena. • Asymptomatic contacts of the game were not tested.	Subsequent cases: • 8 of 10 teammates of the index case became symptomatic; • 5 of 11 players of opposing team became symptomatic; • 1 arena employee symptomatic; and • Asymptomatic contacts not tested: players (8 of 21), 2 referees and 1 spectator. • PHMs were not reported including wearing masks. • Game play was 60 minutes. • Locker rooms used, one for each team, 20 minutes before and after game.

		• Transmission opportunity existed only at the arena, no other contact the week prior. Authors note that hockey provides favourable conditions for SARS-CoV-2 transmission: • Heavy breathing on ice and on the bench due to high intensity physical activity; • Close proximity of players; • Indoor gathering; and • Segregated air mass due to ~10 foot barriers around the ice.
Kuituen (2021) (1) Outbreak investigation Finland Sep 2020	This descriptive report covers transmission of SARS-CoV-2 in a Finnish U-20 hockey league. Team A played team B Sept 4, 2020 (day 0) and team C Sept 5, 2020 (day 1). Some players on all 3 teams also train with senior teams. An asymptomatic player was the index case, and 49 secondary and tertiary cases were detected in 5 teams and 6 teams were quarantined (U-20 A, B and C and Senior A, B and C). • Index case – assumed to be a Team A player who was asymptomatic but infective on day 0. (Given there was a high number of asymptomatic positive test results on day 3 post the first game, the index case was not identified.) • Secondary cases (U-20 league): TEAM A - 3 players symptomatic on day 2 and tested positive. Team A all tested day 3 (28 players + staff) with 22 positive players. Team A spent 10h on a bus together travelling to and from their games.	An asymptomatic hockey player is hypothesized to have been the source of the outbreak that resulted in 49 confirmed COVID-19 infections during a 16-day follow-up. Precautions employed in league: - No guidance on face coverings (masks were not worn by players); - Teams did not shake hands in games; and - Spectators were limited so social distancing could be maintained. Transmission within a team may have occurred through travel on the team bus, the locker room or other common team gathering, transmission to team B and C players was determined to have most likely occurred during game play. Multiple close contacts and heavy breathing from high intensity activity during the game are identified as risks for on-ice transmission. As well, the dry, cold air of the arena is suggested to increase the risk of aerosolization of expelled SARS-CoV-2 droplets.

	TEAM B - 3 players tested positive on day 5; 11 more cases subsequently detected. TEAM C – 6 players test positive day 6 (exposure to team A on day 1); 10 more cases subsequently detected. • Tertiary cases (senior league): TEAM A – no detected cases. TEAM B – 2 players tested positive. TEAM C – 1 player tested positive.	This outbreak resulted in a change in the Finnish leagues, disallowing U-20 players to train or play with more than 1 team. Bubbles and continuous testing used in professional level sports are not feasible for amateur and youth hockey. A limitation of this investigation is that it is based on publically available data and authors did not interview the players or have access to their health records. This means that the index case was not identified, but assumed to be an asymptomatic player and the likely sequence of transmission is unknown (i.e., how many people were likely infected during the game vs. by their infected teammates at a later date).
Curling (n=2)		
Burak (2021) (3) Outbreak investigation Alberta, Canada Mar 2020	A curling bonspiel in Edmonton Mar 11-14, 2020 was attended by 73 individuals. This descriptive study is based on interviews of the attendees between Apr 17 and May 5. In addition to the self-reported symptoms and test results, samples were collected for serology testing from 62 of 73 participants. 58 of the 73 participants in the bonspiel were physicians, all were healthcare workers. 40 curlers tested positive for SARS-CoV-2, and 30 of these individuals had a positive serology result within 222 days after the bonspiel. 16 others who reported symptoms tested negative or were not tested (14 of these are reported as probable cases) and 7 of the probable cases had positive serology results. Asymptomatic attendees were not tested. Serology testing was negative for 12 and positive in 1 of the 17 asymptomatic curlers. 35 suspected cases of secondary	The curling event and related social activities led to a 74% attack rate for COVID-19 in participants. No index case was identified, but 10 individuals reported minor nonspecific symptoms at the time of the bonspiel. The study does not determine the activities that resulted in transmission, but does hypothesize shared meals as the source due to surveys of participants' activities.

	transmission were reported by participants due to symptoms or positive tests of household contacts after the event.	
Luethy (2020) (4) Preprint Outbreak investigation United States Mar 2020	The 2020 USA Curling Club Nationals was held Mar 7-14, 2020 in Laurel, Maryland. 88 athletes/coaches from across the US travelled to participate in the tournament, with a total attendance of 187 individuals. Traditional banquets were replaced with single use, disposable container packaged meals and increased cleaning was implemented during the tournament to mitigate SARS-CoV-2 transmission. Despite efforts, this descriptive study documents 55.6% of participants reported COVID-19 symptoms after their attendance at the tournament. Participants, volunteers and spectators were informed on Mar 18 that a person in attendance had tested positive for COVID-19. A second announcement on Mar 27 reported multiple participants had tested positive for COVID-19. A survey of players, coaches, officials, volunteers and spectators (n=187) was undertaken Sept 1-13, 2020 with an 85% (159/187) response rate and results presented in this descriptive study.	55.6% (104/187) of attendees reported symptoms consistent with COVID-19. A large difference was found between coaches/players and volunteers, of whom 77.3% (68/88) and 33.0% (29/88), respectively, reported symptoms. Testing for SARS-CoV-2 was reported by 44 individuals; 19.8% (37/187) of attendees reported positive tests for SARS-CoV-2, and 3.7% (7/187) reported negative. Serology testing of 73 individuals is reported, with 66 testing positive. Due to the large amount of mixing and length of the tournament, as well as the lack of testing available at the time of the tournament, the time and place of the transmissions cannot be determined. Similarly, no index case(s) are identified.
Non-arena based sports (n=2)		
Watson (2021) (5) Preprint Cross-sectional study United States Aug-Oct 2020	A nationwide survey of USA high school athletes that participated in fall sports included 991 schools, 152484 athletes on 5844 teams. Analyses are adjusted by state COVID-19 incidence, and school instruction type.	2565 athletes reported COVID-19 of which 69 were directly attributed to sport contact. The total rate was 24.6 per 100 000 player-days. COVID-19 incidence was lower: • Outdoor versus indoor sports (incidence rate ratio [IRR]=0.54, 95% CI=0.49-0.60, p<0.001). • Non-contact versus contact sports (IRR=0.78 [0.70-0.87], p<0.001).

		• No difference between team versus individual sports (IRR=0.96 [0.84-1.1], p=0.49). Face mask use (reported by 28% of schools) was associated with a decreased incidence in some sports: • Girls' volleyball (IRR=0.53 [0.37-0.73], p<0.001). • Boys' basketball (IRR=0.53 [0.33-0.83], p=0.008). • Girls' basketball (IRR=0.36 [0.19-0.63], p<0.001). • Football (IRR=0.79 [0.59-1.04], p=0.10). • Cheer/dance (IRR=0.75 [0.53-1.03], p=0.081). • No association was found for other sports.
Watson (2020) (6) Preprint Cross-sectional study United States Aug 2020	A survey of soccer clubs in the USA and the incidence of COVID-19 within the club in the preceding 10 weeks. 129 clubs responded to the survey, 124 had reinitiated soccer and included 91007 players for a median duration of 73 days. 119 clubs had progressed to group activities.	Among these 218 COVID-19 cases were reported among 85861 players. Youth soccer players had a lower case rate and incidence rate than the national rate for children in the US (254 v. 477 cases per 100,000; IRR = 0.511, 95% CI = [0.40-0.57], p<0.001). After adjusting for local COVID-19 incidence, there was no relationship between club COVID-19 incidence and phase of return (non-contact).

GUIDANCE FOR HOCKEY DURING COVID-19

Table 2: Guidance for hockey and youth sports (n=4)

STUDY	METHOD	KEY OUTCOMES
Scientific Literature		
DiFiori (2020) (7) Protocol United States Sep 2020	This protocol was written by physicians associated with professional sports associations in North America (NBA, MLB, NHL, MLS, NFL) and discusses resumption of professional sports during the COVID-19 epidemic.	The paper does not address hockey or arena specific issues, but the following recommendations for all professional sports are of note:

	The focus is 'phased-in-play' so resumption of spectators is not considered within the paper.	• Plan to switch the protocol rapidly if the level of disease transmission in the community changes; • Provide hand sanitizer and masks; • Consider heightened hygiene practices and preventative measure such as mask wearing for all involved in the sport at all times; • Ensure thorough and regular disinfection of the sport facility; • Increase ventilation and airflow in the sport facility; • Reduce the number of people in the facility significantly; • Conduct pre-event screening; and • Limit shared materials.
Parker (2020) (17) Guidance Document United States Oct 2020	This paper details the considerations of reopening large stadiums and arenas, specifically in the US, in the COVID-19 era.	No specific attention is given to arenas and the unique challenges the cold indoor air may present. The main focus of the paper is public health initiatives and guidance for mass gatherings and the risk points involved in the facility use.
National & Regional Guidance		
Hockey Canada (2020) (8) Online Resource Centre Canada Jun 2020	As the Canadian governing body for the sport of hockey in Canada, Hockey Canada provides a central resource for return to hockey information and updates within the country. Information regarding safety, seasonal structure, coaching, officiating, regulations and up-to-date provincial and territorial guidelines. Safety guidelines from Hockey Canada provide an overview of how to organize or participate in hockey during the COVID-19 pandemic. The common theme is checklists of what information to gather from local health authorities and facilities; and dissemination of that information to participants, families, etc.	In addition to guidance to follow local public health protocols, Hockey Canada lists common hygiene and COVID-19 prevention recommendations, such as: • Hand washing; • Hand sanitizer use; • Containing droplets when coughing or sneezing; • Physical distancing; • Individual water bottles; and • Avoid group transportation (i.e. bus) to games. Upon a positive test for COVID-19, Hockey Canada advises: • Immediate removal of household members from hockey setting; • Further action based on advice of local public health; and

	Links are provided for hockey associations within provinces and territories to provide local updates and information:

	  • Hockey Nova Scotia
	• Prince Edward Island
	  • Hockey P.E.I.
	• Newfoundland & Labrador
	  • Hockey Newfoundland & Labrador
	• Northwest Territories & Nunavut
	  • Hockey North
		• Return to hockey only upon written medical authority.

CDC (2020) (9) Guidance Document United States Dec 2020	CDC provides national guidance for youth sport administrators during the COVID-19 pandemic, and advises them to consult and follow their local public health officials. Guidance on assessing the level of risk, reducing transmission, maintaining healthy environments and operations and how to prepare strategies for when a participant becomes sick are provided.	Level of risk for a sport should be assessed by considering: • Community levels of COVID-19; • Proximity of individuals during game play, practice, etc, the number of individuals exposed to one another and the duration of close proximity; • Physical intensity of activities; • Indoor vs. outdoor gathering; • Shared equipment; and • Player age and risk of severe illness. With respect to hockey, the following recommendations apply:

		• Indoor settings are higher risk than outdoor, and proper ventilation systems are needed to circulate air; • Physical distancing and mask wearing reduce risk for all participants; • High intensity activity increases risk due to increased breathing rates; • Larger teams increase potential for transmission to others; • Nonessential spectators should not be present; • Communal space (i.e. locker rooms) should have increased time between use by different groups if being utilized, and cleaning and disinfecting is required; and • Cohorting of small groups of individuals.

EFFECTS OF TEMPERATURE AND HUMIDITY

Given the lack of published research considering SARS-CoV-2 transmission dynamics and viability within indoor ice rinks/arenas, indirect evidence was also considered. Weather related associations (temperature and humidity) summarized in a recent review with evidence up to October 1, 2020 concluded the highest incidence of COVID-19 was between the temperatures of 0-17°C, humidity had mixed results and a significant interaction was reported between temperature and humidity. Few basic research studies have described experiments on SARS-CoV-2 survival in cold temperature environments. A small experiment reported survival at 4°C for 14 days.

Table 3: Reviews of the Effect of Temperature and Humidity on SARS-CoV-2 (n=3)

STUDY	METHOD	KEY OUTCOMES
McClymont (2020) (10) Review Australia 2019-Oct 2020	This review considers the effect of weather, temperature and relative humidity, on the number of COVID-19 cases. The search was limited to publications up to Oct 1, 2020; and 23 articles were included in the review after full inclusion criteria were met and a quality assessment performed.	Ecological studies found correlations with higher transmission in areas with lower temperatures and humidity early in the epidemic. Temperature was a significant climatic factor in the 20 of the 23 studies, with a negative correlation to COVID-19 cases for 13 of the studies. Humidity was reported as significant in 12 of the 16 studies considering humidity, but with mixed results of positive (n=4) or

		negative (n=6) correlations or an optimal range (n=2). It is noted that winter conditions can contribute to increased COVID-19 transmission.
Aboubakr, 2020 (11) Review United States Jul 2020	This review includes studies presenting data for the stability of coronaviruses, including SARS-CoV-2. The persistence of coronaviruses in aerosols, on surfaces, in human fluids and in water is considered within the review, as well as the influence of temperature and humidity, pH and climatic and meteorological factors.	No studies on virus survival directly for arena temperatures/humidity were presented in this review. One study extensively tested the effects of temperature on stability of SARS-CoV-2 and found it to be highly stable at 4°C (the lowest temperature within the presented experiments) (13).
Abd El-Wahab (2020) (12) Review Egypt Dec 2019 – Jul 2020	Articles concerning SARS-CoV-2 transmission from Dec 28, 2019 – July 31, 2020 were included in this review. 302 articles are included in the review, considering three main themes of transmission: 1) SARS-CoV-2 survival; 2) transmission period and transmissibility; and 3) routes of SARS-CoV-2 spread.	This review captures the same experiment as (11) of SARS-CoV-2 stability at various temperatures (13). Empirical data that 90% of COVID-19 cases before March 22, 2020 were recorded in non-tropical countries (14) and investigations of temperature and humidity found that high temperatures were associated with lower R_e of SARS-CoV-2 (15, 16).

Methods:

A daily scan of the literature (published and pre-published) is conducted by the Emerging Science Group, PHAC. The scan has compiled COVID-19 literature since the beginning of the outbreak and is updated daily. Searches to retrieve relevant COVID-19 literature are conducted in Pubmed, Scopus, BioRxiv, MedRxiv, ArXiv, SSRN, Research Square and cross-referenced with the COVID-19 information centers run by Lancet, BMJ, Elsevier, Nature and Wiley. The daily summary and full scan results are maintained in a refworks database and an excel list that can be searched. Targeted keyword searching was conducted within these databases to identify relevant citations on COVID-19 and SARS-COV-2. Search terms used included: hockey OR ((arena OR curling OR skating OR ringette OR (sports AND outbreak)) [TITLE]). Information on how air conditions can affect SARS-CoV-2 transmission were also sought from the daily scan database with a search of: temperature AND humidity AND review [TITLE]. This review contains research published up to February 12, 2021. Each potentially relevant reference was examined to confirm it had relevant data and relevant data was extracted

into the review. Grey literature was included, specifically guidance on hockey, or sports in general, from national health agencies or hockey associations within North America.

Prepared by: Ainsley Otten and Lisa Waddell. Emerging Science Group, PHAC.

Nouveaux éléments de preuve sur la COVID-19

Synthèse en bref sur les risques associés au SRAS-CoV-2 dans les arénas

Introduction

Quelles preuves existe-t-il à propos du risque de transmission du SRAS-CoV-2 dans les arénas, sur la glace et à l'extérieur de celle-ci?

Les éclosions de COVID-19 associées aux arénas et aux sports sur glace ont fait ressortir la nécessité de comprendre comment se produit la transmission et quels facteurs environnementaux et comportementaux peuvent être modifiés pour réduire le risque de transmission. Le hockey professionnel et amateur, ainsi que d'autres sports intérieurs sur glace comme le curling, la ringuette, le patinage et le hockey sur luge, ont été jugés pertinents pour la présente revue. On a recueilli des données probantes sur les risques de transmission dans les patinoires et de la documentation propre à la COVID-19 en ce qui concerne les participants aux activités sportives ou récréatives, les entraîneurs, les spectateurs et le personnel de l'aréna. Les activités dans différents sous-environnements (p. ex., l'utilisation du hall d'entrée, les vestiaires et les couloirs avant et après les activités sur glace, les aires réservées aux spectateurs et les activités sur glace) ont été prises en compte lors de l'examen des preuves. Nous avons également inclus dans la revue des études sur l'effet de la température et de l'humidité sur la transmission du SRAS-CoV-2 comme preuve indirecte de la survie du SRAS-CoV-2 dans des conditions froides. L'utilisation des moteurs à combustion dans l'équipement de resurfaçage de la glace a déjà suscité des préoccupations relatives à la qualité de l'air dans les installations avec glace intérieure, mais aucun lien entre cette recherche et les risques liés à la COVID-19 n'a été documenté. Elle n'a donc pas été prise en compte. Le présent document résume tous les examens et la littérature primaire disponibles jusqu'au 12 février 2021.

Points clés

- Cette revue a porté sur 13 publications, soit deux enquêtes sur des éclosions liées au hockey sur glace (1, 2) et deux autres liés à des tournois de curling (3, 4). Deux études transversales comprenaient des données d'observation recueillies entre août et octobre 2020 et portant sur les facteurs de risque pour la COVID-19 associés à d'autres sports amateurs aux États-Unis (5, 6). Trois revues résument la documentation sur le SRAS-CoV-2 dans des environnements froids ou avec un faible niveau d'humidité comme ce que l'on trouve dans les arénas.

Aréna/sports de glace :

- Le hockey offre des conditions favorables à la transmission du SRAS-CoV-2 pour les raisons suivantes :
    - Respiration forte, tant sur la glace que sur le banc, en raison d'une activité physique intense;

  - Proximité des joueurs et des entraîneurs;
  - Rassemblement à l'intérieur;
  - Air sec et froid de l'aréna;
  - Masse d'air séparée en raison des barrières d'environ 3 mètres (10 pieds) de hauteur tout autour de la glace, ce qui cause une mauvaise circulation de l'air. (1, 2, 7).

- Une enquête sur une éclosion qui s'est produite en juin 2020 dans des équipes de hockey masculin amateur a permis de théoriser qu'une personne présymptomatique avait contaminé 14 adultes symptomatiques (12 confirmés, 2 non testés), 13 joueurs des deux équipes et 1 employé de l'aréna (2). Aucune mesure de santé publique n'a été mise en place.

- Une éclosion dans la ligue de hockey U-20 de Finlande a fait l'objet d'une enquête. On a présumé qu'elle avait probablement été causée par un joueur asymptomatique, ce qui a permis de transmettre le virus à deux équipes opposées et donné lieu à une transmission tertiaire aux équipes de la ligue senior, pour un total de 49 infections à la COVID-19 confirmées (1). Après l'éclosion, la ligue a instauré des mesures pour réduire au minimum le risque de transmission de COVID-19, y compris en ne s'associant qu'avec une seule équipe.

- Deux enquêtes sur les éclosions qui se sont produites lors d'un bonspiel ont révélé que peu de précautions avaient été prises lors de rencontres sociales ayant duré longtemps (3, 4). Le risque de transmission ne peut donc pas être attribué au sport ou au site.

- Lors de la reprise du hockey amateur et professionnel et d'autres activités sur glace, à l'intérieur, les stratégies mises en œuvre afin de réduire le risque de transmission ont inclus le fait de limiter le nombre de personnes pouvant se trouver dans l'aréna, de réduire le temps passé dans l'aréna, d'effectuer le dépistage des personnes et d'améliorer l'hygiène, de regrouper les joueurs, de minimiser le temps d'exposition et le partage du matériel, de favoriser le port de masques et d'assurer le maintien de la distanciation physique (5 à 9).

Autres sports :

- Les données probantes tirées de deux études transversales décrivent un risque plus faible d'attraper la COVID-19 lorsque l'on fait des activités sportives en plein air comparativement aux activités sportives pratiquées à l'intérieur, lorsque les sports sans contact sont pratiqués comparativement aux sports de contact et que, en ce qui concerne certains sports de plein air, le port d'un masque avait eu un effet protecteur important (5, 6).

Preuve indirecte :

- Les données probantes sur la survie et le potentiel de transmission du SRAS-CoV-2 dans des environnements froids et à faible taux d'humidité n'ont pas été étudiées de façon appropriée dans la littérature. Cependant, des études récentes qui ont examiné les preuves expérimentales indiquent

chaque fois que la baisse des températures et de l'humidité est favorable à la survie du SRAS-CoV-2. De même, les études sur les conditions météorologiques et l'environnement indiquent toujours une transmission plus élevée du SRAS-CoV-2 dans les régions où les températures sont basses (0 à 17 °C) et une interaction importante entre la température et l'humidité, mais pas l'humidité en elle-même (10 à 16).

Vue d'ensemble des éléments de preuve

Treize articles ont été inclus dans cette revue, six articles provenant de la littérature primaire qui décrivent des éclosions liées aux sports, quatre documents d'orientation en ce qui concerne la reprise du hockey (deux pour les ligues de hockey professionnel, un pour le hockey canadien et un pour les sports chez les jeunes) et trois revues qui portent sur la transmission du SRAS-CoV-2 ou la survie de ce virus par temps froid. Quatre éclosions, deux matchs de hockey et deux tournois de curling amateurs ainsi que deux analyses transversales sur des sports pratiqués hors des arénas dans des écoles secondaires et sur le soccer pour les jeunes ont été incluses. On n'a trouvé aucune preuve à propos d'autres activités sur glace à l'intérieur, comme le patinage, le hockey sur luge ou la ringuette.

Puisque les enquêtes sur les éclosions sont des collectes rétrospectives de données probantes, les constatations risquent de comporter plusieurs biais, ainsi que toutes les incertitudes en ce qui concerne l'endroit où la transmission s'est produite. Certaines des études transversales qui ont été incluses fournissent un ensemble de données chronologiques d'une population, mais ne peuvent qu'établir des associations (sans cause) entre une exposition et un résultat. Un éventail de types d'examen ont été inclus, et les examens systématiques ont été évalués avec l'outil AMSTAR-2. Les revues de la littérature narrative ont été jugées être comme de faible qualité en raison d'un risque élevé de biais. Les limites de la preuve comprennent un très petit nombre d'articles dans la littérature sur les arénas, malgré le fait que bon nombre d'administrations aient signalé des cas ou des éclosions liés à des équipes de hockey ou de curling (p. ex., CBC News, 16 janvier 2021). En raison de la nature des sports, il est difficile d'établir avec certitude l'endroit où la transmission s'est produite, puisque les coéquipiers passent souvent du temps ensemble lorsqu'ils s'exercent, s'entraînent, se déplacent pour se rendre aux différentes parties, mangent et participent à des activités récréatives. Les tournois peuvent également augmenter le nombre possible de rencontres et d'exposition entre les équipes. Enfin, toutes les éclosions actuellement mentionnées dans la revue ont eu lieu au début de la pandémie, lorsque les couvre-visages et d'autres mesures de santé publique n'étaient pas utilisés à grande échelle.

TABLE DES MATIÈRES

ÉPIDÉMIES DANS LES SPORTS SUR GLACE À L'INTÉRIEUR

Tableau 1 : Transmission liée aux sports sur place à l'intérieur et à d'autres sports (n = 6)

ANNÉE	DESCRIPTION DE L'ÉCLOSION	PRINCIPAUX RÉSULTATS
Hockey (n = 2)		
Atrubine (2020) (2) Enquête sur l'épidémie États-Unis Juin 2020	Deux équipes (A et B) ont joué un match de hockey amateur le 16 juin 2020 (jour 0) à Tampa Bay, en Floride. Chaque équipe comprenait 11 hommes âgés de 19 à 53 ans. Le 21 juin (jour 5), 15 personnes présentaient des symptômes soupçonnés de COVID-19. • Patient index – Joueur de l'équipe A, qui était symptomatique un jour après la partie et a obtenu un résultat positif le jour 3. • Cas secondaires – 14 adultes symptomatiques (12 confirmés, 2 non testés); 13 joueurs et 1 employé de l'aréna. • Les cas asymptomatiques liés à la partie n'ont pas subi de test.	Cas suivants : • 8 des 10 coéquipiers du cas index sont devenus symptomatiques; • 5 des 11 joueurs de l'équipe adverse sont devenus symptomatiques; • 1 employé de l'aréna est devenu symptomatique; • cas asymptomatiques non testés : joueurs (8 sur 21), 2 arbitres et 1 spectateur. • Aucune mesure de sécurité publique n'a été mise en œuvre, y compris le fait de porter un couvre-visage. • La partie a duré 60 minutes. • Les vestiaires ont été utilisés, un par équipe, 20 minutes avant et après la partie. • La possibilité de transmission n'existait qu'à l'aréna, aucun autre contact n'avait eu lieu la semaine précédente. Les auteurs font remarquer que le hockey offre des conditions favorables pour la transmission du SRAS-CoV-2 : • Respiration forte, tant sur la glace que sur le banc, en raison d'une activité physique intense; • Proximité des joueurs; • Rassemblement à l'intérieur; • Masse d'air séparée en raison des barrières d'environ 3 mètres (10 pieds) de hauteur tout autour de la glace.
Kuituen (2021) (1) Enquête sur l'épidémie	Ce rapport descriptif porte sur la transmission du SRAS-CoV-2 dans une ligue de hockey finlandaise, U-20.	On suppose qu'un joueur de hockey asymptomatique a été la source de l'éclosion qui a entraîné 49 infections

Finlande Septembre 2020	L'équipe A a joué contre l'équipe B le 4 septembre 2020 (jour 0) et l'équipe C le 5 septembre 2020 (jour 1). Certains joueurs des trois équipes s'entraînent également avec des équipes de niveau senior. Un joueur asymptomatique était le cas index, et 49 cas secondaires et tertiaires ont été détectés dans 5 équipes. Six équipes ont alors été mises en quarantaine (équipes A, B et C du U-20 et équipes senior A, B et C). • Cas index - on suppose qu'il s'agit d'un joueur de l'équipe A qui était asymptomatique, mais infectieux le jour 0. (Étant donné qu'il y avait un nombre élevé de résultats positifs asymptomatiques le jour 3 après la première partie, le cas index n'a pas été déterminé.) • Cas secondaires (ligue U-20) : ÉQUIPE A - 3 joueurs symptomatiques le jour 2 avec résultat positif au test. Tous les membres de l'équipe A ont passé le test le jour 3 (28 joueurs + membres du personnel) et 22 joueurs ont obtenu des résultats positifs. L'équipe A a passé 10 heures dans un autobus pour aller aux parties et en revenir. ÉQUIPE B - 3 joueurs ont obtenu un résultat positif le jour 5; 11 autres cas ont ensuite été détectés. ÉQUIPE C – 6 joueurs ont obtenu un résultat positif le jour 6 (exposition à l'équipe A le jour 1); 10 autres cas ont été détectés par la suite. • Cas tertiaires (ligue senior) : ÉQUIPE A – aucun cas détecté. ÉQUIPE B – 2 joueurs ont obtenu un résultat positif. ÉQUIPE C – un joueur a obtenu un résultat positif.	confirmées par la COVID-19 au cours d'un suivi ayant duré 16 jours. Précautions prises par la ligue : - Aucune directive en ce qui concerne le port du couvre-visage (les joueurs n'en portaient pas) - les équipes ne se sont pas serré la main pendant les parties; - Le nombre de spectateurs était limité pour assurer le maintien de distanciation sociale. La transmission au sein d'une équipe peut s'être produite lors d'un déplacement effectué dans l'autobus de l'équipe, dans le vestiaire ou lors d'un autre rassemblement d'équipe, et la transmission aux joueurs des équipes B et C a été déterminée comme ayant fort probablement eu lieu pendant la partie. Les multiples contacts rapprochés et la respiration forte résultant d'une activité intense pendant le jeu sont vus comme des risques de transmission sur glace. De plus, l'on suggère que l'air sec et froid de l'aréna augmente le risque d'aérosolisation des gouttelettes de SARS-CoV-2 expulsées. Cette éclosion a entraîné la mise en place de modifications pour les ligues finlandaises qui empêchent désormais les joueurs de la ligue U-20 de s'entraîner ou de jouer avec plus d'une équipe. L'utilisation des bulles et des tests continus dans les sports de niveau professionnel n'est pas possible pour le hockey amateur et les jeunes. Une des limites de cette enquête est le fait qu'elle est fondée sur des données accessibles au public et que les auteurs

		n'ont pas interviewé les joueurs ou n'ont pas eu accès à leur dossier de santé. Cela signifie que le cas index n'a pas été déterminé, mais l'on présume qu'il s'agit d'un joueur asymptomatique et que la séquence probable de transmission est inconnue (c.-à-d. combien de personnes ont probablement été infectées pendant la partie par rapport à leurs coéquipiers qui ont été infectés à une date ultérieure).
Curling (n = 2)		
Burak (2021) (3) Enquête sur l'épidémie Alberta, Canada Mars 2020	Du 11 au 14 mars 2020, 73 personnes ont participé à un bonspiel de curling à Edmonton. Cette étude descriptive est fondée sur des entrevues réalisées avec des participants effectuées entre le 17 avril et le 5 mai. En plus des symptômes autodéclarés et des résultats des tests, des échantillons ont été prélevés pour des tests sérologiques auprès de 62 participants sur 73. 58 des 73 participants au bonspiel étaient des médecins alors que tous étaient des travailleurs de la santé. 40 joueurs de curling ont eu un résultat positif au test de dépistage du SRAS-CoV-2, et 30 d'entre eux ont obtenu un résultat sérologique positif dans les 222 jours qui ont suivi le bonspiel. 16 autres personnes qui ont déclaré que les symptômes ont reçu un résultat négatif ou n'ont pas été testées (14 de ces cas ont été déclarés comme étant des cas probables) et 7 des cas probables ont obtenu un résultat positif à la sérologie. Les participants asymptomatiques n'ont pas été testés. Les tests sérologiques ont été négatifs pour 12 personnes et positifs pour 1 des 17 joueurs asymptomatiques. Les participants ont également signalé 35 cas soupçonnés de transmission secondaire associés à des symptômes ou	L'événement de curling et les activités sociales connexes ont donné un taux d'attaque de 74 % de la COVID-19 chez les participants. Aucun cas index n'a été déterminé, mais 10 personnes ont signalé des symptômes non spécifiques mineurs au moment du bonspiel. Même si l'étude ne permet pas de déterminer quelles activités ont entraîné la transmission, elle se fonde plutôt sur les émet plutôt l'hypothèse que les repas partagés en sont la source en raison des enquêtes sur les activités des participants.

	à des tests positifs reçus par des contacts des ménages, après l'événement.	
Luethy (2020) (4) Prépublication Enquête sur l'épidémie États-Unis Mars 2020	Les championnats nationaux de curling des États-Unis ont eu lieu du 7 au 14 mars 2020 à Laurel, au Maryland. 88 athlètes et entraîneurs de partout aux États-Unis ont participé au tournoi, auquel ont assisté 187 participants. Les banquets traditionnels ont été remplacés par des repas emballés dans des contenants jetables à usage unique et un nettoyage accru a été effectué pendant le tournoi afin d'atténuer la transmission du SRAS-CoV-2. Malgré les efforts déployés, l'étude descriptive indique que 55,6 % des participants ont signalé des symptômes de la COVID-19 après avoir pris part au tournoi. Les participants, les bénévoles et les spectateurs ont été informés le 18 mars qu'une des personnes présentes avait obtenu un résultat positif au test de dépistage de la COVID-19. Une deuxième annonce faite le 27 mars a indiqué que plusieurs participants avaient obtenu un résultat positif au test de COVID-19. Un sondage effectué auprès des joueurs, des entraîneurs, des officiels, des bénévoles et des spectateurs (n = 187) du 1er au 13 septembre 2020 a obtenu un taux de réponse de 85 % (159/187) et les résultats sont présentés dans cette étude descriptive.	55,6 % (104/187) des participants ont signalé avoir eu des symptômes correspondant à la COVID-19. On a constaté une grande différence entre les entraîneurs/joueurs et les bénévoles, dont 77,3 % (68/88) et 33,0 % (29/88), respectivement, ont déclaré des symptômes. 44 personnes ont dit avoir subi des tests de dépistage du SRAS-CoV-2. 19,8 % (37 sur 187) des participants ont déclaré avoir reçu un résultat positif au SRAS-CoV-2 alors que 3,7 % (7 sur 187) ont dit avoir reçu un résultat négatif. Des tests sérologiques ont été effectués sur 73 personnes et ont entraîné 66 résultats positifs. En raison du grand nombre de rassemblements et de la longueur du tournoi, ainsi que du manque de tests disponibles au moment du tournoi, il est impossible de déterminer l'heure et le lieu des transmissions. Aucun cas index n'a pu être déterminé.
Sports à l'extérieur des arénas (n = 2)		
Watson (2021) (5) Prépublication Étude transversale États-Unis Août à octobre 2020	Un sondage effectué à l'échelle nationale auprès d'athlètes des écoles secondaires américaines ayant participé à des sports d'automne a inclus 991 écoles et 152 484 athlètes de 5 844 équipes.	Parmi les 2 655 athlètes qui ont dit avoir eu la COVID-19, 69 cas étaient directement attribuables à des contacts dans le cadre du sport, pour un taux total de 24,6 par 100 000 jours-joueurs. L'incidence de la COVID-19 était plus faible dans les cas suivants :

	Les analyses sont ajustées selon l'incidence de la COVID-19 et selon le type d'enseignement.	• Sports pratiqués à l'extérieur c. à l'intérieur (ratio du taux d'incidence [TRI] = 0,54, IC à 95 % = 0,49 à 0,60, p < 0,001). • Sports sans contact c. sports avec contact (TRI = 0,78 [0,70 à 0,87], p < 0,001). • Aucune différence entre les sports d'équipe et les sports individuels (TRI = 0,96 [0,84 à 1,1], p = 0,49). Le port du couvre-visage (indiqué par 28 % des écoles) était associé à une diminution de l'incidence dans certains sports : • Volley-ball féminin (TRI = 0,53 [0,37 à 0,73], p < 0,001). • Basket-ball des garçons (TRI = 0,53 [0,33 à 0,83], p = 0,008). • Basket-ball féminin (TRI = 0,36 [0,19 à 0,63], p < 0,001). • Football (TRI = 0,79 [0,59 à 1,04], p = 0,10). • Cheerleading/danse (TRI = 0,75 [0,53 à 1,03], p = 0,081). • Aucune association n'a été trouvée pour les autres sports.
Watson (2020) (6) Prépublication Étude transversale États-Unis Août 2020	Une enquête sur les clubs de soccer aux États-Unis et l'incidence de la COVID-19 dans les clubs au cours des 10 semaines précédentes. 129 clubs ont répondu au sondage. De ces clubs, 124 avaient recommencé à jouer au soccer et comptaient 91 007 joueurs pour une durée médiane de 73 jours. 119 clubs sont passés à des activités de groupe.	Parmi les 85 861 joueurs, 218 cas de COVID-19 ont été signalés. Les jeunes joueurs de soccer affichaient un taux de cas et un taux d'incidence plus faibles que le taux national pour les enfants aux États-Unis (254 c. 477 cas par 100 000; TRI = 0,511, IC à 95 % = [0,40 à 0,57], p < 0,001). Après correction de l'incidence locale de la COVID-19, il n'y avait aucun lien entre l'incidence de COVID-19 du club et la phase de retour (sans contact).

ORIENTATION EN CE QUI CONCERNE LE HOCKEY EN PÉRIODE DE COVID-19

Tableau 2 : Orientation pour le hockey et les sports pratiqués par les jeunes (n = 4)

ANNÉE	MÉTHODE	PRINCIPAUX RÉSULTATS
Littérature scientifique		
DiFiori (2020) (7) Protocole États-Unis Septembre 2020	Ce protocole a été rédigé par des médecins qui collaborent avec des associations sportives professionnelles en Amérique du Nord (NBA, MLB, NHL, MLS, NFL) et traite de la reprise des sports professionnels pendant l'épidémie de COVID-19. Puisque l'accent est mis sur la « mise en œuvre progressive », le retour des spectateurs n'a pas été pris en compte dans le document.	Le document ne traite pas de questions propres au hockey ou à l'aréna, mais les recommandations suivantes portant sur l'ensemble des sports professionnels sont dignes de mention : • Prévoir de changer rapidement le protocole si le niveau de transmission de la maladie dans la collectivité change; • Fournir du désinfectant pour les mains et des couvre-visage; • Penser à mettre en place des pratiques d'hygiène plus strictes et des mesures préventives comme obliger le port en tout temps d'un couvre-visage pour ceux qui ne pratiquent pas le sport; • Assurer la désinfection complète et régulière des installations sportives; • Augmenter la ventilation et la circulation d'air dans les installations sportives; • Réduire considérablement le nombre de personnes qui se trouvent dans les installations; • Effectuer un contrôle avant l'événement; • Limiter le partage de l'équipement ou du matériel.
Parker (2020) (17) Ligne directrice États-Unis Octobre 2020	Ce document décrit en détail les éléments dont il faut tenir compte avant de rouvrir les grands stades et arénas, en particulier aux États-Unis, à cette ère de COVID-19.	Aucune attention particulière n'est accordée aux arénas ni aux défis uniques associés à l'air froid à l'intérieur des installations. Le document met principalement l'accent sur les initiatives de santé publique et l'orientation pour les rassemblements de masse et les points de risque liés à l'utilisation des installations.
Orientation nationale et régionale		
Hockey Canada (2020) (8)	En tant qu'organisme dirigeant du hockey au Canada, Hockey Canada est une ressource centrale pour le retour de	En plus des directives sur le respect des protocoles locaux de santé publique, Hockey Canada présente différentes

CDC (2020) (9) Ligne directrice États-Unis Décembre 2020	Le CDC fournit des lignes directrices destinées aux administrateurs des sports pour les jeunes pendant la pandémie de COVID-19 et leur conseille de consulter les responsables locaux de la santé publique et de suivre leurs orientations. Conseils sur l'évaluation du niveau de risque, la réduction de la transmission, le maintien d'environnements et d'opérations sains et la façon de préparer des stratégies lorsqu'un joueur est malade.	Le niveau de risque associé à un sport doit être évalué en tenant compte de ce qui suit : • Niveaux communautaires de COVID-19; • Proximité des personnes pendant la partie, la pratique, etc., le nombre d'individus exposés les uns aux autres et la durée de la proximité; • Intensité physique des activités; • Rassemblement à l'intérieur ou à l'extérieur; • Équipement partagé; et • Âge du joueur et risque de maladie grave. En ce qui concerne le hockey, les recommandations suivantes s'appliquent : • Les installations intérieures présentent un risque plus élevé que les installations extérieures, et des systèmes de ventilation appropriés sont nécessaires pour faire circuler l'air; • La distanciation physique et le port d'un couvre-visage réduisent le risque pour tous les participants; • L'activité intense augmente le risque en raison de l'augmentation de la fréquence respiratoire; • Les équipes plus grandes augmentent le potentiel de transmission aux autres; • Les spectateurs non essentiels ne doivent pas être présents; • Le temps entre l'utilisation des espaces communautaires (c.-à-d. les vestiaires) par différents groupes devrait être augmenté, et si différents groupes les utilisent, ils doivent être nettoyés et désinfectés entre chaque groupe;

		• Les personnes doivent être regroupées en petites cohortes.

EFFETS DE LA TEMPÉRATURE ET DE L'HUMIDITÉ

En raison du manque de recherches publiées sur la dynamique de transmission du SRAS-CoV-2 et sa viabilité dans les patinoires et les arénas intérieurs, des preuves indirectes ont également été prises en compte. Des liens établis avec les conditions météorologiques (température et humidité) ont été présentés dans une revue récente comprenant des preuves recueillies jusqu'au 1er octobre 2020. Ils concluaient notamment que l'incidence de COVID-19 était plus forte dans les températures entre 0 et 17 °C. Le taux d'humidité n'a donné que des résultats mitigés, mais un lien significatif a été établi entre la température et l'humidité. Peu d'études de recherche fondamentale ont décrit des expériences sur la survie du SARS-CoV-2 dans des environnements froids. Une petite expérience a cependant montré que le virus survivait à une température de 4 °C pendant 14 jours.

Tableau 3 : Examens de l'effet de la température et de l'humidité sur le SRAS-CoV-2 (n = 3)

ANNÉE	MÉTHODE	PRINCIPAUX RÉSULTATS
McClymont (2020) (10) Revue Australie 2019 à octobre 2020	Cette revue a examiné l'effet des conditions météorologiques, de la température et de l'humidité relative sur le nombre de cas de COVID-19. La recherche s'est limitée aux publications diffusées jusqu'au 1er octobre 2020, et 23 articles ont été inclus dans l'examen après que les critères d'inclusion complets ont été remplis et qu'une évaluation de la qualité a été effectuée.	Au début de l'épidémie, des études écologiques ont révélé des corrélations avec un niveau de transmission plus élevé dans les régions où les températures et l'humidité étaient plus basses. La température a été un facteur climatique important dans 20 des 23 études, avec une corrélation négative avec les cas de COVID-19 dans 13 des études. L'humidité a été signalée comme étant significative dans 12 des 16 études tenant compte de l'humidité, mais avec des résultats mixtes de corrélations positives (n = 4) ou négatives (n = 6) ou une plage optimale (n = 2). Il est à noter que les conditions hivernales peuvent contribuer à accroître la transmission de la COVID-19.

Aboubakr, 2020 (11) Revue États-Unis Juillet 2020	Cet examen comprend des études qui présentent des données sur la stabilité des coronavirus, y compris le SRAS-CoV-2. Il tient compte de la persistance des coronavirus dans les aérosols, sur les surfaces, dans les fluides humains et dans l'eau, ainsi que de l'influence de la température et de l'humidité, du pH et des facteurs climatiques et météorologiques.	Aucune étude sur la survie du virus ne portant précisément sur les températures et l'humidité dans les arénas n'a été présentée dans cette revue. Une étude a abondamment testé les effets de la température sur la stabilité du SRAS-CoV-2 et a révélé qu'il était très stable à 4 °C (la température la plus basse dans les expériences présentées) (13).
Abd El-Wahab (2020) (12) Revue Égypte Décembre 2019 à juillet 2020	Les articles portant sur la transmission du SRAS-CoV-2 du 28 décembre 2019 au 31 juillet 2020 ont été inclus dans cet examen. La revue a porté sur 302 articles et a tenu compte de trois principaux thèmes de transmission : 1) la survie du SRAS-CoV-2; 2) la période de transmission et la transmissibilité; et 3) les voies de propagation du SRAS-CoV-2.	Cette revue reprend la même expérience que (11) de stabilité du SRAS-CoV-2 à diverses températures (13). Les données empiriques selon lesquelles 90 % des cas de COVID-19 avant le 22 mars 2020 ont été enregistrés dans des pays non tropicaux (14) et les enquêtes sur la température et l'humidité ont révélé que les températures élevées étaient associées à des taux R_e plus faibles de SARS-CoV-2 (15, 16).

Méthodologie :

Une analyse documentaire quotidienne (ouvrages publiés et en prépublication) est effectuée par le Groupe des sciences émergentes de l'ASPC. L'analyse a compilé les ouvrages sur la COVID-19 depuis le début de l'éclosion et est mise à jour quotidiennement. Les recherches visant à extraire les ouvrages pertinents sur la COVID-19 sont menées dans Pubmed, Scopus, BioRxiv, MedRxiv, ArXiv, SSRN et Research Square, et les résultats sont recoupés avec les ouvrages figurant sur la liste de la documentation sur la COVID de l'Organisation mondiale de la Santé et des centres d'information sur la COVID-19 gérés par Lancet, BMJ, Elsevier, Nature et Wiley. Le résumé quotidien et les résultats complets de l'analyse sont conservés dans une base de données RefWorks et dans une liste Excel consultable. Une recherche ciblée par mot-clé a été effectuée dans ces bases de données pour recenser les citations pertinentes sur la COVID-19 et le SRAS-CoV-2. Les termes de recherche utilisés comprenaient : hockey OU ((arena OU curling OU skating OU ringette OU (sports ET outbreak)) [TITRE]). Des renseignements sur la manière dont les conditions atmosphériques peuvent affecter la transmission du SRAS-CoV-2 ont également fait l'objet de recherches dans la base de données de l'analyse quotidienne avec les termes temperature ET humidity ET review [TITRE]. La présente revue contient des recherches publiées jusqu'au 12 février 2021. Chaque référence potentiellement pertinente a été examinée pour confirmer qu'elle comportait des données pertinentes, qui ont été extraites dans la

revue. De la littérature grise a été incluse, plus particulièrement des conseils sur le hockey, ou le sport en général, fournie par des agences nationales de santé ou des associations de hockey en Amérique du Nord.

Préparée par : Ainsley Otten et Lisa Waddell. Groupe des sciences émergentes, ASPC.

Emerging Evidence on COVID-19

Rapid Review of COVID-19 hospitalizations and length of stay

Introduction

This rapid review identifies and summarizes published and pre-published data on the proportion of COVID-19 cases hospitalized, admitted to intensive care unit (ICU) and requiring invasive mechanical ventilation as well as their average or median length of stay in hospital, ICU and duration of ventilation up to August 20, 2020. Both the scarcity of hospitalization data in the Canadian context and variability in these data across studies has lead to the on-going collection and synthesis of global results to improve and/or validate parameters in predictive models that aimed to measure the capacity of the Canadian health systems to manage the pandemic.

What's New?

- Six new studies from United States (3), United Kingdom (1), Italy (1) and China (1). The following tables were updated Proportion of patients in ICU, Proportion of ventilated patients, Length of stay in hospital, LOS in ICU, Duration of ventilation
- One study conducted in United States involved exclusively patients under 18 years of age. LOS by age-group were provided.
- Changes are highlighted.

Key Points

- The average percentage of hospitalization of COVID-19 cases varied 11%-77% over the study population. Older age groups had increasing proportion hospitalized.
- The percentage of admission to Intensive Care Unit (ICU) of COVID-19 cases varied from:
  - 1% to 32% among infected patients
  - 12% to 40% among hospitalized patients
- The percentage of patients requiring ventilation varied from:
  - 1% to 13% among infected patients
  - 5% to 19% among hospitalized (including ICU) patients
  - 28% to 94% among patients in ICU; the two recent studies were 92% and 94%
- The length of stay (LOS) for hospitalization (including ICU) of COVID-19 cases median days across studies was 4-19 days with an interquartile range (IQR) of 3 to 27 days:
  - Among survivors median LOS for hospitalization varied from 5 to 9 days with a IQR of 3 to 13

    - Among non-survivors median LOS for hospitalization varied from 4 to10 with a IQR of 3 to 16
- The median length of stay in ICU varied from 4 to 23 days with a IQR of 2 to 32 days among all patients in ICU
    - Among survivors, median LOS in ICU varied from 8 to 26 days with a IQR of 5 to 46 days
    - Among non-survivors, median LOS in ICU varied from 6 to 12 days with a range of 2 to 26 days
- Median duration of ventilation for patients who required mechanical ventilation was 6 to 13 days with a range of 5 to 22 days.
- In August 2020, MMWR published an analysis of pediatric COVID-19 hospitalization data from 14 states (L. Kim et al., 2020a). It found that although the cumulative rate of COVID-19–associated hospitalization among children (8.0 per 100,000 population) was low compared with that in adults (164.5), the hospitalization rates among Hispanic was eight times higher, and among black children was five times higher, than the rate in white children. An underlying medical condition was present in 42% of the children; obesity was the most prevalent underlying medical condition.
    - Hospitalization rate was highest for those under 2 years of age (24.8 per 100,000 population).
    - One third of hospitalized patients were admitted to the ICU (33.2%)
    - The proportion of hospitalized patients requiring invasive mechanical ventilation was 5.8%
    - The median LOS in hospital overall was 2.5 days with a range of 1 to 5 days
    - The median LOS in ICU was 2 days with a range of 1 to 5 days

Overview of the Evidence

The review identified and summarized 64 published and pre-published studies. Most of the studies were retrospective observational studies conducted at the hospital level, and do not necessarily represent the nationwide statistics. Results of studies with low sample size should be interpreted with caution.

CONTENTS

PROPORTION OF HOSPITALIZATION (OVERALL)

Table 1 presents the percentage of hospitalized COVID-19 patients overall, including patients admitted to the ICU, among COVID-19 cases.

Methods:

A weekly scan of the literature (published and pre-published) related to hospitalization and length of stay of COVID-19 patients is conducted by the Emerging Science Group, PHAC. Searches to retrieve relevant literature are conducted in the Refworks database and an Excel Spreadsheet maintained by the Emerging Science team. The Refworks database and the Excel file gather literature related to COVID-19 since the beginning of the outbreak. The literature is retrieved from Pubmed, Scopus, BioRxiv, MedRxiv, ArXiv, SSRN, Research Square and cross-referenced, the WHO COVID literature list, and COVID-19 information centers run by Lancet, BMJ, Elsevier and Wiley.

This review contains research related to hospitalization and length of stay of COVID-19 patients published up to August 20, 2020

Each potentially relevant reference was examined to confirm it had relevant data and relevant data is extracted into the review. Research studies with large sample size are preferred. Studies with less than 100 hospitalized patients, less than 25 patients admitted in ICU, or less than 10 patients under ventilation are excluded. However, this selection criteria was not applied to systematic reviews.

Appendix

(Guan et al., 2020)	Definition of 'severe':
	Validated definition includes either 1 major or 3 or more minor criteria
	• Minor criteria
	  ○ Respiratory rate > 30 breaths/min
	  ○ PaO2/FIO2 ratio < 250
	  ○ Multilobar infiltrates
	  ○ Confusion/disorientation
	  ○ Uremia (blood urea nitrogen level >20 mg/dl)
	  ○ Leukopenia* (white blood cell count, 4,000 cells/ml)
	  ○ Thrombocytopenia (platelet count, 100,000/ml)
	  ○ Hypothermia (core temperature , 368C)
	  ○ Hypotension requiring aggressive fluid resuscitation
	• Major criteria
	  ○ Septic shock with need for
	  ○ vasopressors
	  ○ Respiratory failure requiring mechanical

(L. Kim et al., 2020b)	-States included in the study: California, Colorado, Connecticut, Georgia, Iowa, Maryland, Michigan, Minnesota, New Mexico, New-York, Ohio, Oregon, Tennessee, and Utah.
(Garibaldi et al., 2020)	-Definition are based on WHO classification (WHO. WHO R&D Blueprint: Novel Coronavirus. COVID-19 Therapeutic Trial Synopsis2020.) -Hospitalized, mild disease: Hospitalized, no oxygen therapy OR oxygen by mask or nasal prongs. -Hospitalized, severe disease: Non-invasive ventilation or high flow oxygen, Intubation od mechanical ventilation, ventilation + additional organ support – pressor, RRT, ECMO.
(Nabavi et al., 2020)	-Mild/Moderate: no or mild pneumonia; -Severe: with dyspnea (respiratory rate >30) or hypoxia (O2 saturation <93); Critical: with respiratory failure, shock, or multi-organ dysfunction
(Yu et al., 2020)	-Severe COVID-19 was defined if they meet one of following criteria: (1) Respiratory distress with respiratory frequency ≥30 breaths per min with shortness of breath or difficulty breathing; (2) Oxygen saturation ≤93% at rest; (3) Artery partial pressure of oxygen (PaO2)/inspired oxygen fraction (FiO2) ≤300 mmHg (1 mmHg = 0.133 kPa).

Preuve émergente sur la COVID-19

Examen rapide des hospitalisations liées à la COVID-19 et de la durée du séjour

Introduction

Cette revue rapide a permis de cerner et de résumer les données publiées et pas encore publiées jusqu'au 20 août 2020 sur la proportion de cas de COVID-19 ayant donné lieu à des hospitalisations, à des admissions aux services de soins intensifs (SSI) et à l'utilisation d'un ventilateur mécanique invasif. Elle présente également des données sur la durée moyenne ou médiane du séjour à l'hôpital ou aux soins intensifs, ainsi que la période pendant laquelle le patient a été sous ventilateur. La rareté des données sur les hospitalisations dans le contexte canadien et la variabilité de ces données entre les études ont mené à la collecte et à la synthèse de résultats provenant de partout dans le monde afin d'améliorer ou de valider les paramètres des modèles prédictifs visant à mesurer la capacité des systèmes de santé canadiens à gérer la pandémie.

Quoi de neuf?

- Six nouvelles études ont été menées aux États-Unis (3), au Royaume-Uni (1), en Italie (1) et en Chine (1). Les tableaux suivants ont été mis à jour Proportion de patients au SERVICE **des soins intensifs**, Proportion de patients ayant **exigé un ventilateur**, Durée du séjour **à l'hôpital**, Durée du séjour **aux soins intensif**, Durée de la **ventilation**
- Une étude menée aux États-Unis a porté exclusivement sur des patients âgés de moins de 18 ans. La durée du séjour par groupe d'âge a été fournie.
- Les modifications sont mises en évidence.

Points clés

- Le pourcentage moyen d'hospitalisation de patients atteints de COVID-19 variait de 11 % à 77 % dans la population incluse dans l'étude. La proportion d'hospitalisations était cependant plus grande chez les personnes âgées.
- Les variations étaient les suivantes en ce qui concerne le pourcentage d'admissions de patients atteints de COVID-19 au service de soins intensifs :
    - Entre 1 et 32% de patients infectés;
    - Entre 12 et 40 % de patients hospitalisés.
- Le pourcentage de patients qui se sont retrouvés sous ventilateur variait ainsi :
    - Entre 1 et 13 % de patients infectés;

  - Entre 5 % et 19 % de patients hospitalisés (y compris ceux qui se sont retrouvés aux soins intensifs);
  - De 28 % à 94 % de patients aux soins intensifs, alors que deux études récentes indiquaient des pourcentages de 92 % et de 94 %.
- La durée médiane d'hospitalisation (y compris le séjour aux soins intensifs) des patients atteints de COVID-19 entre les études variait de 4 à 19 jours avec un écart interquartile (EI) de 3 à 27 jours :
  - Chez les survivants, la durée médiane de l'hospitalisation variait de 5 à 9 jours avec un EI de 3 à 13.
  - Chez les patients décédés, la durée médiane de l'hospitalisation variait de 4 à 10 jours avec un EI de 3 à 16.
- La durée médiane du séjour aux soins intensifs variait de 4 à 23 jours avec un EI de 2 à 32 jours pour tous les patients qui s'y sont retrouvés.
  - Chez les survivants, la durée médiane du séjour aux soins intensifs variait de 8 à 26 jours avec un EI de 5 à 46 jours.
  - Chez les patients décédés, la durée médiane du séjour aux soins intensifs variait de 6 à 12 jours, avec un intervalle de 2 à 26 jours.
- La durée médiane d'utilisation du ventilateur mécanique pour les patients qui en ont eu besoin était de 6 à 13 jours, avec un intervalle de 5 à 22 jours.
- En août 2020, MMWR a publié une analyse des données sur l'hospitalisation pour COVID-19 des enfants provenant de 14 États (L. Kim et al., 2020a). Cette analyse a révélé que même si le taux cumulatif d'hospitalisations associées à la COVID-19 chez les enfants (8,0 pour 100 000 habitants) était faible comparativement à celui des adultes (164,5), le taux d'hospitalisation chez les Hispaniques était huit fois plus élevé et qu'il était cinq fois plus élevé chez les enfants noirs que celui qui a été observé chez les enfants blancs. Une condition médicale sous-jacente était également présente chez 42 % des enfants, l'obésité était la plus prévalente.
  - Le taux d'hospitalisation était le plus élevé chez les enfants de moins de deux ans (24,8 pour 100 000 habitants).
  - Un tiers des patients hospitalisés ont été admis aux soins intensifs (33,2 %).
  - La proportion de patients hospitalisés qui ont exigé le recours à un ventilateur mécanique invasif était de 5,8 %.
  - La durée médiane de l'hospitalisation globale était de 2,5 jours, avec un intervalle de 1 à 5 jours.
  - La durée médiane du séjour aux soins intensifs était de 2 jours, avec un intervalle de 1 à 5 jours.

Vue d'ensemble des éléments de preuve

La revue a permis de cerner et de résumer 64 études publiées et pas encore publiées. Bon nombre des études étaient des études d'observation rétrospectives effectuées au niveau de l'hôpital. Elles ne représentent donc pas nécessairement les statistiques nationales. Il faut faire preuve de prudence au moment d'interpréter les résultats lorsque les études ne comportent qu'un échantillon de petite taille.

CONTENU

PROPORTION DES HOSPITALISATIONS (DANS L'ENSEMBLE)

Le tableau 1 présente le pourcentage de patients hospitalisés en raison de la COVID-19 dans l'ensemble, ce qui inclut les patients admis aux services de soins intensifs (SSI).

TABLEAU 1: Proportion d'hospitalisations déclarées dans 14 études

Méthodes :

Une analyse hebdomadaire de la littérature (publiée et prépubliée) en ce qui concerne l'hospitalisation et la durée du séjour pour les patients atteints de COVID-19 est effectuée par le groupe des sciences émergentes de l'ASPC. Les recherches pour trouver de la documentation pertinente sont effectuées dans la base de données Refworks et dans une feuille de calcul Excel gérée par le groupe des sciences émergentes. La base de données Refworks et le fichier Excel rassemblent la documentation relative à la COVID-19 depuis le début de l'épidémie. La littérature est extraite de Pubmed, de Scopus, de BioRxiv, de MedRxiv, d'ArXiv, de SSRN, de Research Square et croisée avec la liste de littérature sur la COVID de l'OMS et des centres d'information sur la COVID-19 gérés par Lancet, BMJ, Elsevier et Wiley.

Cette revue contient les recherches relatives à l'hospitalisation et à la durée de séjour des patients atteints de la COVID-19 publiées jusqu'au 20 août 2020.

Chaque référence potentiellement pertinente a été examinée pour confirmer qu'elle comportait des données pertinentes et les données pertinentes sont extraites dans l'examen. Il est préférable d'utiliser des études de recherche avec un grand échantillon. Les études qui portent sur moins de 100 patients hospitalisés, moins de 25 patients admis aux soins intensifs ou moins de 10 patients sous ventilation sont exclues. Toutefois, ces critères de sélection n'ont pas été appliqués aux revues systématiques.

Annexe

(Guan et al., 2020)	Définition de « grave » :
	La définition validée comprend soit un critère majeur, soit trois critères mineurs ou plus
	
	• Critères mineurs
	  ○ Fréquence respiratoire > 30 respirations/min
	  ○ Rapport PaO2/FiO2 < 250
	  ○ Infiltrations multilobées
	  ○ Confusion/désorientation
	  ○ Urémie (niveau d'azote uréique dans le sang >20 mg/dl)
	  ○ Leucopénie* (nombre de globules blancs, 4 000 cellules/ml)
	  ○ Thrombocytopénie (numération des plaquettes, 100 000/ml)
	  ○ Hypothermie (température centrale de 36,8 °C)
	  ○ Hypotension nécessitant une réanimation liquidienne énergique
	• Critères majeurs
	  ○ Choc septique nécessitant des vasopresseurs
	  ○
	  ○ Insuffisance respiratoire nécessitant un traitement mécanique

(L. Kim et al., 2020b)	– États inclus dans l'étude : Californie, Colorado, Connecticut, Géorgie, Iowa, Maryland, Michigan, Minnesota, Nouveau-Mexique, New York, Ohio, Oregon, Tennessee et Utah.
(Garibaldi et al., 2020)	– Les définitions sont basées sur la classification de l'OMS (OMS R&D Blueprint: Novel Coronavirus. COVID-19 Therapeutic Trial Synopsis 2020.) – Hospitalisation, maladie peu sévère : Hospitalisation, pas d'oxygénothérapie OU oxygène par masque ou pince nasale. – Hospitalisation, atteinte grave : ventilation non invasive ou oxygène à haut débit, intubation ou ventilateur mécanique, ventilation + soutien supplémentaire pour les organes - hypertenseur, transplantation rénale, OCEC.
(Nabavi et al., 2020)	– Peu sévère/modérée : aucune pneumonie ou pneumonie légère; – Sévère : avec dyspnée (fréquence respiratoire > 30) ou hypoxie (saturation en O_2 < 93); Critique : en cas d'insuffisance respiratoire, de choc ou de dysfonctionnement de plusieurs organes
(Yu et al., 2020)	– La COVID-19 sévère doit satisfaire l'un des critères suivants : (1) détresse respiratoire avec fréquence respiratoire ≥ 30 respirations par minute avec essoufflement ou difficulté à respirer; (2) saturation en oxygène ≤ 93 % au repos; (3) pression partielle artérielle de l'oxygène (PaO_2)/fraction d'oxygène inspirée (FiO_2) ≤ 300 mmHg (1 mmHg = 0,133 kPa).

Emerging Evidence on COVID-19

Evidence Brief of COVID-19 Infectious Period in Immunosuppressed/Immunocompromised Individuals

Introduction

What is the length of the infectious period of SARS-CoV-2 in immunosuppressed and immunocompromised individuals?

The infectious period (also known as the communicability period) is defined as the time during which an infected person can transmit an infectious agent to another person. The infectious period is an important clinical and epidemiologic parameter to understand for the control of any infectious disease. Estimates of the average infectious period of SARS-CoV-2 for mild/moderately symptomatic immunocompetent cases is considered to start on average 2.5 days before developing symptoms, peak around day 4 of symptoms and decrease to low levels within 8-10 days after the start of symptoms for a total of 10-13 days (see Rapid Review on Infectious Period, Sep 2020).

In this brief, immunosuppressed and immunocompromised populations are considered. Immunosuppression may result from certain immune-mediated diseases and/or therapies (e.g. anti-cancer therapy, anti-rejection medication, etc.). Immunocompromised individuals may have an immune deficiency from infectious or genetic causes. Early case reports have documented longer periods (>14 days) during which replication-competent (i.e., culture positive) SARS-CoV-2 can be recovered in these populations and in severe cases of COVID-19. Further, immunosuppression has been shown to be associated with higher odds of persistent viral RNA shedding (>21 days) in two studies (1, 2), while another study found no significant association (3). Potential prolonged and recurrent infections in this population identified the need for further research on infectiousness and unique strategies for safe de-isolation to prevent further transmission.

This brief focuses on research conducted to document infectious period in immunosuppressed/immunocompromised cases of COVID-19 published up to February 5, 2021. They have been organized by underlying disease condition and type of study. Because of their preliminary nature, case reports were not included in this review. Infectious period estimates were determined by a combination of epidemiological and clinical investigations that together informed when an infected person could, or was likely to, no longer transmit the virus. Most studies used RT-PCR to diagnose cases of COVID-19 and to monitor viral RNA shedding over time. However, detection of viral RNA by RT-PCR does not provide proof of infectivity as this test also gives positive results when non-infectious virus particles are present. These particles are commonly shed from

infected tissue for a period of time after an infection has been cleared by the host immune system (4). Recovery of replication-competent virus has been used as an *in vitro* proxy for human-to-human infectiousness. To establish if viable virus has been isolated in a sample, replication of virus is established most reliably by cell culture. Unfortunately, few studies employed culture methods because they can be slow and expensive. Detection of subgenomic RNA has been recommended as a proxy for shedding of infectious virus (5), however there is not yet consensus on this application (6).

Key Points

- The review identified 19 studies including 1 bidirectional cohort, 1 prospective cohort, 10 retrospective cohort studies, and 7 longitudinal case series. Immunosuppressed populations included cancer (n=11) and transplant patients (n=6). Immunocompromised patients included those with HIV (n=2). Only two studies provided evidence of viable virus via cell culture while the others described the length of viral RNA shedding via RT-PCR or qRT-PCR.

Culture studies (n=2)

- Recovery of replication-competent SARS-CoV-2 has been reported in patients immunosuppressed due to hematologic cancers for at least 2 months. This is much longer than the infectious period estimated in the average immunocompetent populations (10-13 days, see Rapid Review on Infectious Period).

RT-PCR studies (n=17)

- RT-PCR conducted on respiratory samples from mildly symptomatic immunocompentent typically become negative within 14-20 days. As shown in the points below, time to viral RNA clearance was much longer in immunosuppressed/immunocomptent individuals. How long there was viral RNA shedding depended to some degree on the cause of the immunosuppression/immunocompromise.
    - In cancer patients, median time to viral RNA clearance ranged from 12-50 days with an overall range of 9-78 days. Systemic anticancer therapy (i.e., chemotherapy, hormonal therapy, targeted drugs, and immunotherapy), before or during COVID-19 positivity, was not significantly associated with viral clearance time.
    - In solid organ transplant patients undergoing immunosuppressive therapy, time to viral clearance ranged from 9-66 days. Mean viral RNA shedding was significantly

longer in kidney transplant patients than immunocompetent individuals (28.4 days vs. 12.2 days, $p<0.01$). Further, evidence from one study reported high viral loads at day 30 of infection in a group of transplant patients indicating high likelihood of SARS-CoV-2 transmission 30 days after symptom onset.

- In patients with HIV, RNA viral clearance occurred over a median of 18 days (IQR 7-28) but remained detectable in some patients >40 days post symptom onset. Severe HIV cases had a longer duration of viral RNA shedding compared to mild/moderate cases.

Overview of the Evidence

A total of 19 studies were included in this review, including cohort studies and longitudinal case series. Many of these are pre-prints and have not undergone a peer-review process. Prospective cohorts are of lower risk of bias and are considered higher quality research, but there are few of this study design contributing to this question. Case series suffer from low sample size, selection bias and recall bias (e.g., self-report symptom onset). In addition, many of the immunosuppressed/immunocompromised cases described in this review also had additional underlying chronic health conditions and it is difficult to determine if and how this affected the results. Overall, due to the risks of bias, these studies should be interpreted with caution, as results are likely to change with additional research.

Several knowledge gaps exist for the infectious period of SARS-CoV-2 in special populations. Few studies utilize cell culture and instead depend on detection of viral RNA as a proxy for potential infectious period. Such methods cannot distinguish between infectious and non-infectious viral particles, however, the relationship between viral load and probability of culture positivity has been covered in the literature. Additional research on immunity and how infectious period is impacted by immunosuppressive therapies for other immune-mediated diseases (e.g., rheumatoid arthritis, Crohn's disease, etc.) is needed. As well, further exploration into strategies for safely de-isolating these cases to prevent further transmission is warranted.

CONTENTS

INFECTIOUS PERIOD OF IMMUNO-SUPPRESSED/COMPROMISED INDIVIDUALS

Cancer/hematological disease patients (n=11):

- Only two studies provided evidence of replication-competent virus via cell culture:
    - Patients with immunosuppression due to hematologic cancers, that underwent allogenic or autologous hematopoietic cell transplantation or received cellular therapies, shed replication-competent SARS-CoV-2 for at least 2 months (7, 8). This was much longer than in immunocompetent patients (<7 days) (8).
- Many cases had additional underlying chronic health conditions (9, 10).
- Majority of cases required >14 days to achieve consecutive negative PCR results, with a median time ranging from 12-50 days and an overall range of 9-78 days (7-17).
- Anticancer therapy (i.e., chemotherapy, hormonal therapy, targeted drugs, and immunotherapy), before or during COVID-19 positivity, was not significantly associated with viral RNA clearance time (11, 12, 16).
- Severe cases had a longer duration of viral RNA shedding compared to mild/moderate cases, but this finding was not significant (13).

Solid organ transplant patients (n=6):

- The majority of patients were taking immunosuppressive therapy (18-21).
- No studies provided evidence of viable virus via cell culture.
- The majority of cases required >14 days to achieve consecutive negative PCR results, with an overall range of approximately 9-66 days (18-23).
- The mean time of SARS-CoV-2 viral RNA shedding in a group of kidney transplant patients was 28.4 ± 9.3 days, which was significantly longer than that of immunocompetent individuals (12.2 ± 4.6 days, $p<0.01$) (23).
- A study of kidney transplant recipients reported 43% of patients still had positive RT-PCR results at day 30 of follow-up with viral loads above 3 $\log^{10}$ copies per reaction, the threshold for which there is a risk of SARS-CoV-2 transmission (22).

- Severe cases had a longer duration of viral RNA shedding compared to mild/moderate cases, but this association was not statistically investigated (21).

Human immunodeficiency virus (HIV) patients (n=2):

- All patients were on antiretroviral therapy (24, 25).
- No studies provided evidence of viable virus via cell culture.
- RNA viral clearance occurred over a median of 18 days (IQR 7-28) post symptom onset (24).
- SARS-CoV-2 viral RNA may remain detectable in some HIV patients for >40 days post symptom onset (24, 25).
- Patients with longer times to viral RNA clearance had more severe disease, higher ICU admission, lower nadir CD4 cell counts, and a higher proportion of comorbidities than individuals with shorter times to viral clearance ($p<0.05$) (24).

Table 1: Studies reporting infectious period estimates in immunosuppressed and immunocompromised COVID-19 patients (n=19)

STUDY	METHOD	KEY OUTCOMES
IMMUNOSUPPRESSED PATIENTS		
Cancer patients (n=11)		
Roedl 2020 (8) *LTE* Retrospective cohort study Germany Nov 2020*	Studied patients with malignancies being treated with allogenic hematopoietic stem cell transplant (HSCT) recipients or chimeric antigen receptor T-cell (CAR-T) therapy who also required ICU treatment for COVID-19 (n=6). Outcomes were compared with COVID-19 patients without a history of malignant disease (n=18). SARS-CoV-2 was detected by RT-PCR and viral isolation was performed using cell culture. After 48–72 hours of incubation, infected Vero cells (CCL81; American Type Culture Collection) were monitored for cytopathic effect.	Bronchoalveolar and plasma samples -In patients with history of HSCT or CAR-T, viral loads remained high until end of follow-up, day 28 (in both respiratory and plasma samples). In contrast, SARS-CoV-2 RNA was below the limit of detection after 21 and 11 days in respiratory and plasma samples, respectively, in immunocompetent patients. -Infectious virus was isolated from five samples from four patients with a history of HSCT or CAR-T therapy, obtained 4-28 days post ICU admission. In immunocompetent patients, infectious virus could not be detected after Day 7.

Aydillo 2020 (7) *LTE* Longitudinal case series USA Mar-Apr 2020	Analyzed longitudinal samples collected from immunocompromised cancer patients with COVID-19 (n=20). Cell culture was used to detect viable virus and whole-genome sequencing was used to detect genetic variants. Inoculated Vero E6 cell monolayers were incubated for a week and monitored daily for cytopathic effect. Time from symptom onset to negative RT-PCR was also measured.	Nasopharyngeal and sputum swabs -There were 18 recipients of allogenic (n=6) or autologous (n=10) hematopoietic stem-cell transplants or chimeric antigen receptor (CAR) T-cell therapy (n=2). Fifteen were receiving active treatment or chemotherapy. -Viral RNA was detected up to 78 days after the onset of symptoms (IQR: 24-64 days). -Viable virus was isolated from follow-up samples from five patients for 8, 17, 25, 26, and 61 days after the onset of symptoms. -The patients with viable virus for more than 20 days had received allogeneic hematopoietic stem-cell transplants or CAR T-cell therapy within the previous 6 months and remained seronegative for antibodies to viral nucleoprotein. Two of these patients had severe COVID-19. -Whole-genome sequencing showed no major changes in the consensus sequences of the original serial specimens or cultured isolates, consistent with persistent infection.
Wong 2020 (15) Bidirectional cohort study USA Dec 2020*	Cancer patients positive for SARS-CoV-2 that had undergone cancer-directed therapy (n=26) were tested every two weeks by PCR (targeting N2 and ORF1a) until two successive negative PCR results were obtained.	Nasopharyngeal swabs -Various cancer cases were included, 15 of which (58%) had advanced stage IV disease. -Mean time to consecutive negative PCR results was 32 days. -Twenty (77%) patients required >14 days to achieve consecutive negative PCR results.
Nakamura 2020 (10) *Preprint* Retrospective cohort study Japan Jan-May 2020	Analyzed data from COVID-19 patients with a history of cancer (n=32). Measured the time between illness onset and the first of two consecutive negative SARS-CoV-2 RT-PCR results.	Nasopharyngeal swab -Twenty-five patients (78%) had solid tumors, while 7 (22%) had hematologic malignancies. Nineteen (59%) also had at least one comorbidity (e.g. hypertension, 41%). Thirteen patients (41%) received cancer treatment within the last 30 days. -The median period between illness onset and the first of two consecutive negative SARS-CoV-2 RT-PCR results was 22 days (IQR: 18–25) in survivors (n=224).
Fox 2020 (11)	Analyzed data from COVID-19 patients with a hematological disorder, mostly cancers (n=55). The duration of viral RNA	Nose and throat swabs -94% (52/55) of patients were currently on or had previously received systemic anti-cancer therapy (chemotherapy or immunotherapy).

Retrospective cohort study UK Mar-May 2020	shedding was analyzed using Kaplan-Meier methods from date of illness onset to first of consecutive negative SARS-CoV-2 RT-PCR results (targeting the N gene).	-The median duration of SARS-CoV-2 viral RNA shedding was 34 days in survivors (n=27, 95% CI, 27–47). The longest duration of shedding (still positive at the end of follow-up) was 49 days. -The duration of viral RNA shedding was not prolonged in patients treated with chemo- or immuno-therapy in the last 14 or 28 days.
Ramaswamy 2020 (16) Retrospective cohort study India Apr-Jun 2020	Cancer patients undergoing systemic therapy with laboratory confirmed COVID-19 (n=230) were tested every 3-4 days until RT-PCR negativity. Logistic regression analysis was conducted to evaluate factors affecting delayed conversion to RT-PCR negativity.	Oropharyngeal or nasopharyngeal swab -Patients had various cancer diagnoses, the most prevalent malignancies were acute leukemia (20%) and gastrointestinal malignancies (17%). -53% of patients had evidence of remission or controlled cancer status, while 14% had uncontrolled cancer status or were on active symptom control. -The median time to SARS-CoV-2 seroconversion was 17 days (IQR: 17-28). -Duration of viral RNA shedding was ≤14 days for 52 patients (30%; n=182), 52 patients (30%) tested negative between 15 and 21 days, and 50 patients (29%) were still positive >21 days of follow-up. -None of the factors evaluated, including age, gender, diabetes mellitus, hematolymphoid malignancies, uncontrolled cancer status, and nonmyelosuppressive systemic therapy were found be significantly associated with prolonged viral RNA shedding.
Infante 2020 (9) *LTE* Retrospective cohort study Spain Mar-Apr 2020	Analyzed data from COVID-19 patients with hematological malignancies (n=41). Time to viral clearance was measured by RT-PCR but start/end points were not defined.	Nasal swab -Twenty-nine (70%) of patients had a lymphoid malignancy. Twenty-one (51%) were under active treatment at the time of COVID-19. -The majority of patients (93%) had additional chronic medical conditions. -The median duration of viral RNA shedding was 32.7 days (range 10-70) in surviving patients (n=26). A patient with acute myeloid leukemia under induction therapy at the time of infection was still positive by RT-PCR after 70 days of follow-up.
Xu 2020 (12) *Preprint* Retrospective cohort study USA	Analyzed all patients at a tertiary care hospital with confirmed COVID-19, who had a cancer-related clinical visit within 3 years, and at least one follow-up SARS-CoV-2 assay (n=32). Time to viral clearance was analyzed using Kaplan-Meier methods, for which	Nasopharyngeal swab -Sixteen patients had metastatic disease, 17 were on active treatment at the time of COVID-19 diagnosis, with 8 receiving cytotoxic chemotherapy. -The median time to viral clearance was estimated at 50 days (95% CI, 33-58 days). -Using the UK-NICE guidelines, median time to clearance was 31 days (95% CI, 26-42 days).

Mar-June 2020	data was censored at the time of the last known RT-PCR assay. This method was compared with other guidelines for viral clearance: • UK-NICE guidelines: measured as time to one negative RT-PCR test. • CDC criteria: Symptom/time based strategy measured as 10 days after first positive RT-PCR and 3 days after last symptoms.	-Using a symptom/time-based strategy per CDC criteria, median time to clearance was 13 days (95% CI, 10-17 days). -Cox proportional hazards models showed symptomatic patients had longer viral RNA shedding than asymptomatic patients (HR 0.25 for negative PCR, 95% CI 0.08-0.76, p=0.01). -Anticancer therapy (chemo-, immuno-, targeted- or hormonal therapy), before or during COVID-19 positivity, was not significantly associated with viral clearance time.
Berghoff 2020 (17) Retrospective cohort study Austria Mar-May 2020	Patients with cancer (n=1,016) were routinely tested for SARS-CoV-2 RNA by RT-PCR. Measured time from first positive test to first negative RT-PCR test.	Nasal or pharyngeal swab -SARS-CoV-2 infection was confirmed in 4 of 1,016 (0.4%) patients. Cancers included stomach (n=1), sarcoma (n=1) and head and neck cancer (n=2). Two of the patients were under active anticancer therapy. -Viral clearance was achieved in three patients 14-56 days after testing positive. One patient had still not achieved viral clearance 28 days after first positive at time of this report.
Sanchez-Pina 2020 (13) Retrospective matched cohort study Spain Mar-Apr 2020	Analyzed patients with COVID-19 and haematological malignancies (n=39). Outcomes were compared to a matched control group of 53 non-cancer patients with COVID-19. Follow-up COVID-19 PCR testing was performed in a subset of the cancer patients (n=20) to measure time to viral clearance.	Nasopharyngeal swab -The most frequent haematological diseases were lymphoma (n=12), multiple myeloma (n=12), and chronic lymphocytic leukaemia (n = 6). -In the 20 follow-up cases, median time to achieve PCR negativity was 14 days. -Five patients experienced prolonged viral RNA shedding with a median duration of 23 days (range 16-31 days). -Severe cases had a longer duration of viral RNA shedding compared to mild/moderate cases (22 vs. 14 days), but this finding was not significant (p=0.441).
O'Nions 2020 (14) *Preprint* Longitudinal case series UK Apr-May 2020	Analyzed longitudinal samples from hospitalized COVID-19 patients with aggressive hematological malignancy on systemic anti-cancer treatment (n=10). Measured days from symptom onset to negative PCR result.	Nose and throat swabs -Hematological malignancies included acute myeloid leukaemia, B-lymphoblastic leukaemia, T lymphoblastic leukaemia, and diffuse large B cell lymphoma. -All patients received systemic anti-cancer treatment within 28 days of developing COVID-19. - Eight patients seroconverted and developed antibodies to the major SARS-CoV-2 antigens (S1 and N) with six producing neutralising antibody responses.

		-The median duration of PCR positivity was 12 days (IQR 24). -Days from symptom onset to negative PCR ranged from 9-62 days.
Solid organ transplant patients (n=6)		
Benotmane 2020 (18) Retrospective cohort study France Mar-Apr 2020	Studied kidney transplant recipients with COVID-19 (n=40). qRT-PCR was used to detected SARS-CoV-2 nucleic acid (targeting two regions on the RNA dependent RNA polymerase gene). Patients were followed up weekly until discharge then tested at 30, 45, and 60 days after symptom onset. Viral clearance was defined as at least 1 negative RT-PCR test.	Nasopharyngeal swabs and plasma samples -The median time after kidney transplantation was 6.6 years (IQR: 2.8-14.6 years). At the time of COVID-19 diagnosis, 35 (87.5%) patients were taking immunosuppressive therapy. -The viral load of most patients (74.4%) peaked at the time of diagnosis. -No patient showed a viral clearance before day 21. Ten patients (24.4%) showed persistent viral RNA shedding after 31 days. -Patients receiving immunosuppressive therapy tended to have more positive RNAemia, but this finding was not significant (p=0.29).
Zhu 2020 (23) Retrospective cohort study China Jan-Mar 2020	Analyzed data from renal transplant recipients with laboratory-confirmed COVID-19 pneumonia (n=10). Also collected and compared clinical data from immunocompetent family members with COVID-19 pneumonia (n=10). Time of virus shedding, defined as illness onset to negative RT-PCR test, was monitored.	Throat swabs -The mean time of virus shedding in the transplant patients was 28.4 ± 9.3 days. This was significantly longer than that of the immunocompetent family members (12.2 ± 4.6 days , p<0.01).
Caillard 2020 (22) *LTE* Longitudinal case series France Oct 2020*	Prospectively monitored kidney transplant recipients with COVID-19 (n=42). RT-PCR was used to detect SARS-CoV-2 nucleic acid (targeting two regions on the RNA dependent RNA polymerase gene).	Nasopharyngeal swab, saliva, and respiratory specimens -At day 30, 15/35 (43%) patients tested still had positive RT-PCR results, with viral loads above the threshold for which there is a risk of SARS-CoV-2 transmission (>3 log10 copies per reaction). -At day 45, 12 patients (34%) still had positive RT-PCR results. -At 60 days, 6 patients (17%) had low but still detectable SARS-CoV-2 loads.
Gaston 2020 (19) Longitudinal case series	Analyzed data from solid organ transplant recipients on maintenance immunosuppression with symptomatic COVID-19 infection (n=25). Viral positivity	Nasopharyngeal and oropharyngeal swabs -Only 5 patients had serial testing. -4/5 patients had RT-PCR results longer than 21 days post symptom onset.

USA Mar-May 2020	was assessed by RT-PCR (targeting N1 and N2 SARS-CoV-2 gene).	-Two patients were still positive ≥27 days post symptom onset. -One patients was still positive at day 38.
Christensen 2020 (20) Longitudinal case series USA Mar-May 2020	Analyzed data from symptomatic kidney/liver transplant recipients with COVID-19 (n=6). Viral positivity was assessed by qRT-PCR.	Nasopharyngeal swabs -The median time from transplant was 1.9 years (range: 0.21-9.3). All six patients had hypertension (100%) and 5 had diabetes (83%). -All patients had been on immunosuppressant medication prior to COVID-19 diagnosis. Five had their immunosuppressant medication stopped at time of hospital admission while the other patient who was managed as an outpatient had their medication reduced by 50%. -Four of 5 patients (80%) were positive for SARS-CoV-2 viral RNA, while 1 patients only had a positive SARS-CoV-2 neutralizing antibody test. -One patient had a positive RT-PCR result for 28 days of follow-up, despite presence of SARS-Cov-2 IgG.
Silvano 2021 (21) Longitudinal case series Portugal Mar-Jun 2020	Analyzed data from kidney transplant patients with COVID-19 (n=6). Duration of viral RNA shedding measured and defined as the time between the first and the last positive RT-PCR SARS-CoV-2 test.	Nasopharyngeal and oropharyngeal swabs -The median time from transplant to COVID-19 diagnosis was 161 months (range: 8-235). Only one patients had undergone transplantation in the past year. All patients were on immunosuppression therapy. -Duration of viral RNA shedding was measured for five of the patients. -For the two patients with moderate severity, the duration of viral RNA shedding was <9 days. -For the three patients with severe disease, the duration of viral RNA shedding was >40 days, persisting despite symptom resolution. Two still had positive RT-PCR swabs at the end of follow-up (>44 and >66 days).
IMMUNOCOMPROMISED PATIENTS		
People with HIV (n=2)		
Vizcarra 2020 (24) Prospective cohort study Spain	Studied consecutive HIV-infected adults who had suspected or confirmed COVID-19 as of April 30, 2020 (n=51). SARS-CoV-2 was detected by qRT-PCR.	Nasopharyngeal swabs, sputum, or lower respiratory tract aspirates -54% (19/35) of individuals with laboratory-confirmed SARS-CoV-2 infection had follow-up qRT-PCR assays conducted. -All patients were on antiretroviral therapy. -Viral clearance occurred over a median of 18 days (IQR 7-28) post symptom onset for 68% (13/19) of

May 2020*		individuals. For the other six individuals, SARS-CoV-2 remained detectable for a median of 40 days (IQR 13–45) post symptom onset. These patients had more severe disease, higher ICU admission, lower nadir CD4 cell counts are a higher proportion of comorbidities than individuals with shorter times to viral clearance ($p<0.05$).
Mondi 2020 (25) Longitudinal case series Italy Mar-May 2020	Analyzed data from HIV-positive patients hospitalized with COVID-19 (n=5). Viral clearance was defined as two consecutive negative RT-PCR tests for SARS-CoV-2 (targeting the E and RNA-dependent RNA polymerase genes).	Nasopharyngeal swab -All five patients were virologically suppressed on antiretroviral therapy. -Serial testing results were only available for two patients. For these two patients, viral clearance occurred on day 29 and 43, from symptom onset.

LTE=Letter to the editor

Methods:

A daily scan of the literature (published and pre-published) is conducted by the Emerging Science Group, PHAC. The scan has compiled COVID-19 literature since the beginning of the outbreak and is updated daily. Searches to retrieve relevant COVID-19 literature are conducted in Pubmed, Scopus, BioRxiv, MedRxiv, ArXiv, SSRN, Research Square and cross-referenced with the COVID-19 information centers run by Lancet, BMJ, Elsevier, Nature and Wiley. The daily summary and full scan results are maintained in a refworks database and an excel list that can be searched. Targeted keyword searching was conducted within the excel database to identify relevant citations on COVID-19 and SARS-COV-2. Search terms used included: (immunosup* OR immunocomp* OR transplant OR cancer) AND (persist* OR prolonged OR viable OR shed* OR culture OR dynamics OR clearance). This review contains research published up to February 5, 2021. Each potentially relevant reference was examined to confirm it had relevant data and relevant data is extracted into the review.

Nouveaux éléments de preuve sur la COVID-19

Synthèse en bref sur la période infectieuse de la COVID-19 chez les personnes immunodéprimées ou immunodéficientes

Introduction

Quelle est la durée de la période infectieuse du SRAS-CoV-2 chez les personnes immunodéprimées et immunodéficientes?

La période infectieuse (aussi appelée période de contagiosité) est définie comme la durée pendant laquelle une personne infectée peut transmettre un agent infectieux à une autre personne. Il s'agit d'un paramètre clinique et épidémiologique important à comprendre pour pouvoir contrôler quelque maladie infectieuse que ce soit. On estime que la période infectieuse moyenne du SRAS-CoV-2 pour les immunodépressifs légers/moyennement symptomatiques commence en moyenne 2,5 jours avant l'apparition des symptômes, atteint un sommet vers le jour 4 puis redescend dans un délai de 8 à 10 jours après le début des symptômes, ce qui donne environ 10 à 13 jours de contagiosité (se reporter à la Revue rapide de la période infectieuse, septembre 2020).

La présente synthèse porte sur les populations immunodéprimées et immunodéficientes. L'immunosuppression peut découler de certaines maladies ou de certains traitements d'origine immunologique (p. ex., traitement anticancéreux, médicament antirejet, etc.) alors que l'immunodéficience peut être liée à des causes infectieuses ou génétiques. Les premiers exposés de cas ont mentionné de plus longues périodes (> 14 jours) pendant lesquelles on pouvait obtenir un SRAS-CoV-2 réplicatif (c.-à-d. positif à la coproculture) dans ces populations et chez les personnes gravement atteintes de la COVID-19. Deux études (1, 2) ont aussi démontré que l'immunosuppression est associée à une probabilité plus élevée d'excrétion d'ARN viral persistant (> 21 jours) alors qu'une autre n'a révélé aucun lien significatif (3). La possibilité d'infections prolongées et récurrentes dans cette population a fait ressortir la nécessité d'effectuer d'autres recherches sur l'infectiosité et de mettre en place des stratégies uniques pour sortir ces personnes de l'isolement de façon sécuritaire tout en prévenant la transmission de la maladie.

La présente synthèse en bref porte sur la recherche effectuée et publiée jusqu'au 5 février 2021 et vise à documenter la période infectieuse chez les personnes immunodéficientes ou immunodéprimées atteintes de COVID-19. Les études présentées ont été organisées par maladie sous-jacente et type d'étude. En raison de leur nature préliminaire, les exposés de cas n'ont pas été inclus dans cette synthèse. Les estimations en ce qui concerne la période infectieuse ont été établies

en combinant des études épidémiologiques et cliniques qui ont permis de préciser le moment où une personne infectée ne pouvait plus transmettre le virus ou n'était plus susceptible de pouvoir le transmettre. La plupart des études ont utilisé le RT-PCR pour diagnostiquer les cas de COVID-19 et surveiller l'excrétion de l'ARN viral avec le temps. Même si le test RT-PCR peut être utilisé pour détecter l'ARN viral, il ne fournit aucune preuve d'infectivité puisqu'il donne également des résultats positifs lorsque des particules virales non infectieuses sont présentes. Les tissus infectés continuent généralement d'excréter ces particules pendant un certain temps après que l'infection a été éliminée par le système immunitaire hôte (4). La récupération d'un virus réplicatif a été utilisée comme substitut *in vitro* de l'infectiosité entre humains. Pour déterminer si un virus viable a été isolé dans un échantillon, la culture cellulaire est la façon la plus fiable d'en établir la réplication. Peu d'études ont malheureusement utilisé des méthodes de culture parce qu'elles peuvent être lentes et coûteuses. La détection de l'ARN subgénomique a été recommandée comme substitut pour l'excrétion du virus infectieux (5), mais il n'y a pas encore de consensus à cet effet (6).

Points clés

- Dix-neuf études ont été examinées dans cette synthèse, dont une cohorte bidirectionnelle, une cohorte prospective, dix études de cohorte rétrospectives et sept séries de cas longitudinales. Les populations immunodéprimées incluaient des personnes atteintes d'un cancer (n = 11) et des patients qui ont subi une greffe (n = 6). Des personnes atteintes du VIH figuraient parmi les personnes immunodéprimées (n = 2). Seules deux études ont fourni des preuves de la présence d'un virus viable dans la culture cellulaire, alors que les autres ont décrit la durée de l'excrétion d'ARN viral à l'aide du test RT-PCR ou qRT-PCR.

Études portant sur les cultures (n = 2)

- Deux mois après l'infection, le virus SRAS-CoV-2 réplicatif était encore présent chez des patients immunodéprimés en raison de cancers hématologiques, une période beaucoup plus longue que la période infectieuse estimée dans les populations immunocompétentes moyennes (entre 10 et 13 jours, comme indiqué dans la Revue rapide de la période infectieuse).

Études portant sur le test RT-PCR (n = 17)

- Tests RT-PCR effectués sur des échantillons respiratoires provenant d'une personne immunocompétente légèrement symptomatique deviennent généralement négatifs dans les 14 à 20 jours. Comme le montrent les points ci-dessous, la clairance de l'ARN viral était

beaucoup plus longue chez les personnes immunodéprimées ou immunocompétentes. La durée de l'excrétion de l'ARN viral dépendait dans une certaine mesure de la cause de l'immunosuppression ou de l'immunodéficience.

- Chez les patients atteints de cancer, le délai médian avant la clairance de l'ARN viral variait de 12 à 50 jours, avec une plage globale allant de 9 à 78 jours. La thérapie anticancéreuse systémique (c.-à-d. chimiothérapie, hormonothérapie, médicaments à cible définie et immunothérapie), avant ou pendant la positivité à la COVID-19, n'était pas associée de façon significative à la durée de la clairance virale.

- Chez les patients qui ont subi une greffe d'organe entier et suivent une thérapie immunosuppressive, le temps qui s'est écoulé avant la clairance virale variait entre 9 et 66 jours. L'excrétion moyenne d'ARN viral était beaucoup plus longue chez les patients ayant subi une greffe de rein que chez les personnes immunocompétentes (28,4 jours comparativement à 12,2 jours, $p < 0,01$). Les données d'une étude ont, en outre, révélé une charge virale élevée au jour 30 de l'infection chez un groupe de patients ayant subi une greffe, ce qui indique une probabilité élevée de transmission du SRAS-CoV-2 30 jours après l'apparition des symptômes.

- Chez les patients atteints de VIH, la clairance virale de l'ARN a atteint 18 jours en moyenne (EI 7 à 28), mais elle est demeurée détectable chez certains patients plus de 40 jours après l'apparition des symptômes. On a cependant vu une plus longue excrétion d'ARN viral chez les cas graves de VIH que chez les cas légers/modérés.

Vue d'ensemble des éléments de preuve

Au total, 19 études ont été incluses dans la présente synthèse, ce qui inclut des études de cohorte et des séries de cas longitudinales. Bon nombre d'entre elles sont des prépublications qui n'ont donc pas fait l'objet d'un examen par les pairs. Les cohortes prospectives présentent un risque de biais plus faible et sont vues comme des recherches de meilleure qualité, mais peu d'études portent sur cette question. Les séries de cas comprennent un petit échantillon, en plus de présenter un biais de sélection et un biais de rappel (p. ex., apparition de symptômes autodéclarés). En outre, bon nombre des cas de personnes immunodéprimées ou immunodéficientes décrits dans la présente revue présentaient également d'autres problèmes de santé chroniques sous-jacents, et il est difficile de déterminer si ces problèmes ont influé sur les résultats et si oui, de quelle façon ils ont influé sur

ceux-ci. Dans l'ensemble, en raison des risques de biais, il faut faire preuve de prudence au moment d'interpréter ces études, puisque les résultats sont susceptibles de changer si des recherches supplémentaires sont effectuées.

Il existe également plusieurs lacunes dans les connaissances sur la période infectieuse du SRAS-CoV-2 dans des clientèles ayant des besoins particuliers. Peu d'études ont utilisé la culture cellulaire et se sont plutôt tournées vers la détection de l'ARN viral comme indicateur pour la période infectieuse potentielle. De telles méthodes ne permettent pas de faire la distinction entre les particules virales infectieuses et non infectieuses, mais la relation entre la charge virale et la probabilité de positivité de la culture a été abordée dans la littérature. Il faut effectuer d'autres recherches sur l'immunité et sur l'incidence des thérapies immunosuppressive sur la période infectieuse d'autres maladies d'origine immunitaire (p. ex., arthrite rhumatoïde, maladie de Crohn, etc.). Il sera également justifié d'explorer plus à fond des stratégies pour pouvoir sortir ces personnes de l'isolement de façon sécuritaire et empêcher une transmission du virus.

TABLE DES MATIÈRES

PÉRIODE INFECTIEUSE DES PERSONNES IMMUNODÉPRIMÉES OU IMMUNODÉFICIENTES

Patients atteints d'un cancer ou d'une maladie hématologique (n = 11) :

- Seules deux études ont fourni des preuves de la capacité de réplication du virus par culture cellulaire :
    - Les patients dont l'immunosuppression est due à des cancers hématologiques, qui ont subi une greffe de cellules hématopoïétiques allogéniques ou autologues ou qui ont reçu des thérapies cellulaires, ont excrété des virus SARS-CoV-2 réplicatifs pendant au moins deux mois (7, 8), ce qui est beaucoup plus long que ce qui a été noté chez les patients immunocompétents (< 7 jours) (8).
- De nombreux patients souffraient d'autres maladies chroniques sous-jacentes (9, 10).
- Dans la majorité des cas, il a fallu plus de 14 jours pour obtenir des résultats négatifs après le test PCR avec un délai médian variant entre 12 et 50 jours et une plage globale de 9 à 78 jours (7 à 17).

- La thérapie anticancéreuse (c.-à-d. chimiothérapie, hormonothérapie, médicaments à cible définie et immunothérapie), avant ou pendant la positivité à la COVID-19, n'était pas associée de façon significative à la durée de la clairance de l'ARN viral.

- Les cas graves présentaient une durée d'élimination de l'ARN viral plus longue que les cas légers/modérés, mais cette constatation n'était cependant pas significative (13).

Patients ayant subi une greffe d'organe entier (n = 6) :

- La majorité des patients suivaient un traitement immunosuppresseur (18 à 21).

- Aucune étude n'a démontré la présence d'un virus viable obtenu par culture cellulaire.

- Dans la majorité des cas, il a fallu plus de 14 jours pour obtenir des résultats négatifs après le test PCR avec une plage globale variant entre 9 et 66 jours (18 à 23).

- Le temps moyen d'excrétion de l'ARN viral du SRAS-CoV-2 dans un groupe de patients ayant subi une greffe de rein était de 28,4 ± 9,3 jours, ce qui était considérablement plus long que pour les personnes immunocompétentes (12,2 ± 4,6 jours, $p < 0,01$) (23).

- Une étude menée auprès de receveurs de greffes du rein a révélé que 43 % des patients présentaient toujours des résultats positifs au test RT-PCR au 30^{e} jour avec une charge virale supérieure à 3 copies log^{10} par réaction, soit le seuil pour lequel il existe un risque de transmission du SRAS-CoV-2 (22).

- Les cas graves ont cependant eu une durée d'élimination de l'ARN viral plus longue que les cas légers/modérés, mais cette association n'a pas l'objet d'une enquête statistique (21).

Patients atteints du virus de l'immunodéficience humaine (VIH) (n = 2) :

- Tous les patients suivaient un traitement antirétroviral (24, 25).

- Aucune étude n'a démontré la présence d'un virus viable obtenu par culture cellulaire.

- La clairance virale de l'ARN s'est produite sur une médiane de 18 jours (EI 7 à 28) après l'apparition des symptômes (24).

- L'ARN viral du SRAS-CoV-2 a pu continuer d'être détecté chez certains patients atteints du VIH pendant plus de 40 jours après l'apparition des symptômes (24, 25).

- Les patients pour qui le temps de clairance de l'ARN viral était plus long étaient atteints d'une forme plus grave de la maladie, avaient été admis plus souvent aux soins intensifs, avaient un nadir de

compte de cellules CD4 moins élevé et une plus forte proportion de comorbidités que les personnes dont le temps de clairance virale était plus court ($p < 0,05$) (24).

Tableau 1 : Études faisant état d'estimations de la période infectieuse chez les patients immunodéprimés et immunodéficients ayant la COVID-19 (n = 19)

ANNÉE	MÉTHODE	PRINCIPAUX RÉSULTATS
PATIENTS IMMUNODÉPRIMÉS		
Patients atteints de cancer (n = 11)		
Roedl 2020 (8) *Lettre à la rédaction* Étude de cohorte rétrospective Allemagne Novembre 2020*	Étude portant sur des patients dont la tumeur maligne a été traitée par une greffe allogénique de cellules souches hématopoïétiques (GCSH) ou par un traitement avec lymphocytes T à récepteur antigénique chimérique (CAR-T) et qui ont dû être hospitalisés aux soins intensifs en raison de la COVID-19 (n = 6). Les résultats ont été comparés à ceux des patients atteints de la COVID-19 qui n'avaient aucun antécédent d'affection maligne (n = 18). Le SRAS-CoV-2 a été détecté par RT-PCR et l'isolement de virus a été effectué par culture cellulaire. Puis, après 48 à 72 heures d'incubation, l'effet cytopathique dans les cellules Vero infectées (CCL81; American Type Culture Collection) a été évalué.	Échantillons broncho-alvéolaires et de plasma -Chez les patients qui ont des antécédents de GCSH ou de CAR-T, les charges virales sont demeurées élevées jusqu'à la fin du suivi, soit jusqu'au jour 28 (tant dans les échantillons respiratoires que de plasma). En revanche, l'ARN du SRAS-CoV-2 était inférieur à la limite de détection après 21 et 11 jours dans les échantillons respiratoires et les échantillons de plasma, respectivement, chez des patients immunocompétents. -Le virus infectieux a été isolé dans cinq échantillons provenant de quatre patients ayant des antécédents de GCSH ou de thérapie CAR-T, obtenus entre 4 et 28 jours après l'admission aux soins intensifs. Chez les patients immunocompétents, le virus infectieux n'a pas pu être détecté après le jour 7.
Aydillo 2020 (7) *Lettre à la rédaction* Séries de cas longitudinales ÉTATS-UNIS Mars et avril 2020	Analyse d'échantillons longitudinaux prélevés chez des patients immunodéprimés et atteints de cancer ayant eu la COVID-19 (n = 20). La culture cellulaire a été utilisée pour détecter des virus viables et le séquençage du génome entier a été utilisé pour détecter des variantes génétiques. Les monocouches de cellules Vero E6 inoculées ont été incubées	Sécrétions rhinopharyngées prélevées par écouvillonnage et expectorations -Dix-huit personnes ont reçu une greffe allogénique (n = 6) ou autologue (n = 10) de cellules souches ou un traitement avec lymphocytes T à récepteur antigénique chimérique (CAR-T) (n = 2). Quinze recevaient un traitement ou une chimiothérapie actif. -L'ARN viral a été détecté jusqu'à 78 jours après l'apparition des symptômes (EI : 24 à 64 jours). -Un virus viable a été isolé dans les échantillons de suivi de cinq patients 8, 17, 25, 26 et 61 jours après l'apparition des symptômes.

	pendant une semaine et surveillées quotidiennement afin d'en voir l'effet cytopathique. Le temps qui s'est écoulé entre l'apparition des symptômes et le résultat négatif au test RT-PCR a également été mesuré.	-Les patients chez qui l'on a retrouvé un virus viable depuis plus de 20 jours avaient reçu des greffes allogéniques de cellules souches hématopoïétiques ou un traitement avec lymphocytes T à récepteur antigénique chimérique dans les six derniers mois et étaient demeurés séronégatifs pour les anticorps à la nucléoprotéine virale. Deux de ces patients ont eu une forme grave de la COVID-19. -Le séquençage du génome entier n'a révélé aucun changement important dans les séquences consensus des spécimens en série originaux ou des isolats en culture, ce qui correspond à une infection persistante.
Wong 2020 (15) Étude de cohorte bidirectionnelle ÉTATS-UNIS Décembre 2020*	Étude qui évalue des patients cancéreux ayant eu un résultat positif au SRAS-CoV-2 qui avaient subi un traitement anticancéreux (n = 26) et ont subi un test PCR (ciblant les gènes N2 et ORF1a) toutes les deux semaines jusqu'à ce qu'ils aient obtenu deux résultats négatifs successifs à ce test.	Sécrétions rhinopharyngées prélevées par écouvillonnage -Différents cas de cancer ont été inclus, dont 15 (58 %) présentaient une maladie au stade avancé (stade IV). -Le temps moyen avant d'obtenir des résultats négatifs au test PCR était de 32 jours. -Il a fallu plus de 14 jours à vingt (77 %) patients avant d'obtenir des résultats négatifs à des tests PCR consécutifs.
Nakamura 2020 (10) *Prépublication* Étude de cohorte rétrospective Japon Janvier à mai 2020	Analyse des données provenant de patients atteints de la COVID-19 et ayant des antécédents de cancer (n = 32). Mesure le temps qui s'est écoulé entre l'apparition de la maladie et le premier de deux résultats négatifs consécutifs au test de dépistage RT-PCR pour le SARS-CoV-2.	Sécrétions rhinopharyngées prélevées par écouvillonnage -Vingt-cinq patients (78 %) avaient des tumeurs solides, tandis que sept (22 %) avaient une hémopathie maligne. Dix-neuf (59 %) avaient aussi au moins une comorbidité (p. ex., hypertension, 41 %). Treize patients (41 %) avaient reçu un traitement contre le cancer au cours des 30 derniers jours. -La période médiane entre l'apparition de la maladie et le premier de deux résultats négatifs consécutifs au test de dépistage RT-PCR pour le SARS-CoV-2 était de 22 jours (EI : 18 à 25) chez les survivants (n = 224).
Fox 2020 (11) Étude de cohorte rétrospective Royaume-Uni	Analyse des données provenant de patients atteints de la COVID-19 et ayant des troubles hématologiques, majoritairement des cancers (n = 55). La durée de l'excrétion d'ARN viral a été analysée avec les méthodes Kaplan-Meier, de la date de l'apparition de la maladie au	Échantillon prélevé dans la gorge et dans le nez -94 % (52/55) des patients suivaient ou avaient déjà suivi un traitement anticancer systémique (chimiothérapie ou immunothérapie). -Le délai médian d'excrétion de l'ARN viral du SARS-CoV-2 était de 34 jours chez les survivants (n = 27, IC à 95 %, 27 à 47). La plus longue période d'excrétion a été de 49 jours (même si le résultat était toujours positif à la fin de la période de suivi).

Mars à mai 2020	premier de deux résultats négatifs consécutifs au test de dépistage RT-PCR pour le SARS-CoV-2 (ciblant le gène N).	-La durée de l'excrétion de l'ARN viral n'a pas été prolongée chez les patients qui ont reçu un traitement par chimiothérapie ou immunothérapie au cours des 14 ou des 28 derniers jours.
Ramaswamy 2020 (16) Étude de cohorte rétrospective Inde D'avril à juin 2020	Étude dans laquelle les patients atteints de cancer qui suivent une thérapie générale et dont la COVID-19 a été confirmée en laboratoire (n = 230) ont subi des tests de dépistage tous les 3 ou 4 jours jusqu'à ce que le résultat du test RT-PCR soit négatif. Une analyse de régression logistique a été effectuée pour évaluer les facteurs qui retardaient la conversion en RT-PCR négatif.	Écouvillonnage du rhinopharynx ou du nasopharynx -Les patients étudiés avaient reçu divers diagnostics de cancer, dont les plus malins étaient la leucémie aiguë (20 %) et les tumeurs gastro-intestinales malignes (17 %). -53 % des patients présentaient des signes de rémission ou de cancer contrôlé, alors que 14 % avaient un cancer non contrôlé ou étaient en contrôle actif de leurs symptômes. -Le délai médian avant la séroconversion du SRAS-CoV-2 était de 17 jours (EI : 17 à 28). -La durée de l'excrétion de l'ARN viral était de 14 jours pour 52 patients (30 %; n = 182), 52 patients (30 %) ont obtenu un résultat négatif après 15 à 21 jours alors que pour 50 patients (29 %), le résultat était toujours positif après plus de 21 jours de suivi. -Aucun des facteurs évalués, incluant compris l'âge, le sexe, le diabète sucré, les cancers hématolymphoïdes, le cancer non contrôlé et la thérapie systémique non myélosuppressive, n'a été associé de façon significative à l'excrétion prolongée d'ARN viral.
Infante 2020 (9) *Lettre à la rédaction* Étude de cohorte rétrospective Espagne Mars et avril 2020	Analyse des données provenant de patients atteints de la COVID-19 et ayant une hémopathie maligne (n = 41). Le temps nécessaire à la clairance virale a été mesuré avec le test RT-PCR, mais les dates de début et de fin n'ont pas été précisées.	Écouvillonnage du nez -Vingt-neuf (70 %) des patients avaient une lymphopathie maligne. Vingt et un (51 %) étaient sous traitement actif au moment où ils ont attrapé la COVID-19. -La majorité des patients (93 %) avaient d'autres problèmes de santé chroniques. -Le délai médian de l'excrétion d'ARN viral était de 32,7 jours (plage de 10 à 70 jours) chez les patients survivants (n = 26). Un patient atteint de leucémie myéloïde aiguë qui recevait un traitement d'induction au moment de l'infection a obtenu un résultat positif au test RT-PCR après 70 jours.
Xu 2020 (12) *Prépublication*	Analyse de tous les patients d'un hôpital de soins tertiaires dont la COVID-19 a été confirmée, qui ont dû consulter un médecin en raison	Sécrétions rhinopharyngées prélevées par écouvillonnage -Seize patients avaient une maladie métastatique, 17 suivaient un traitement actif au moment du

Étude de cohorte rétrospective ÉTATS-UNIS Mars à juin 2020	d'un cancer dans les trois dernières années et au moins un essai de suivi sur le SRAS-CoV-2 (n = 32). Le temps avant la clairance virale a été analysé à l'aide des méthodes Kaplan-Meier, pour lesquelles les données ont été censurées au moment du dernier essai RT-PCR connu. Cette méthode a été comparée à d'autres lignes directrices sur la clairance virale : • Lignes directrices UK-NICE : délai mesuré avant d'obtenir un résultat négatif au test RT-PCR. • Critères du CDC : Stratégie basée sur les symptômes/délai mesurés 10 jours après le premier résultat positif au test RT-PCR et 3 jours après les derniers symptômes.	diagnostic de COVID-19 et huit recevaient un traitement cytotoxique. -Le délai médian avant la clairance virale a été estimé à 50 jours (IC à 95 %, 33 à 58 jours). -Selon les lignes directrices UK-NICE, le délai médian avant la clairance était de 31 jours (IC à 95 %, 26 à 42 jours). -En fonction d'une stratégie basée sur les symptômes/délai et fondée sur les critères du CDC, le temps moyen avant la clairance était de 13 jours (IC à 95 %, 10 à 17 jours). -Les modèles des risques proportionnels de Cox ont montré que les patients symptomatiques présentaient une excrétion d'ARN viral plus longue que les patients asymptomatiques (HR 0,25 pour un résultat négatif au test PCR, IC à 95 % 0,08 à 0,76, p = 0,01). -La thérapie anticancéreuse (chimiothérapie, immunothérapie, thérapie ciblée ou hormonale), avant ou pendant la positivité à la COVID-19, n'a pas été associée de façon significative à la durée de la clairance virale.
Berghoff 2020 (17) Étude de cohorte rétrospective Autriche Mars à mai 2020	Les patients atteints de cancer (n = 1 016) étaient régulièrement soumis à des tests de dépistage RT-PCR pour l'ARN du SRAS-CoV-2. Temps entre le premier résultat positif et le premier résultat négatif.	Écouvillonnage du nez ou pharyngé -L'infection par le SRAS-CoV-2 a été confirmée chez 4 des 1 016 patients (0,4 %). Les patients touchés étaient atteints d'un cancer de l'estomac (n = 1), d'un sarcome (n = 1) et d'un cancer de la tête et du cou (n = 2). Deux des patients suivaient une thérapie anticancéreuse active. -La clairance virale a été atteinte chez trois patients entre 14 et 56 jours après avoir obtenu un résultat positif au test. Au moment de la rédaction du rapport, un patient n'avait pas encore atteint la clairance virale 28 jours après le premier résultat positif.
Sanchez-Pina 2020 (13) Étude rétrospective de cohorte appariée Espagne	Étude ayant analysé les résultats des patients atteints de COVID-19 et de cancers hématologiques (n = 39). Les résultats ont été comparés à un groupe témoin apparié comprenant 53 patients non atteints de cancer, mais ayant la COVID-19. Un test PCR de suivi pour la COVID-19 a été effectué	Sécrétions rhinopharyngées prélevées par écouvillonnage -Les cancers hématologiques les plus fréquents étaient un lymphome (n = 12), un myélome multiple (n = 12) et la leucémie lymphocytaire chronique (n = 6). -Dans les 20 cas de suivi, il a fallu un délai médian de 14 jours avant d'obtenir un résultat négatif au test de PCR.

Mars et avril 2020	chez un sous-ensemble de patients cancéreux (n = 20) pour mesurer le temps nécessaire à la clairance virale.	-Cinq patients ont subi une excrétion prolongée d'ARN viral avec un délai médian de 23 jours (plage variant entre 16 et 31 jours). -Les cas graves présentaient une durée d'excrétion de l'ARN viral plus longue que les cas légers/modérés (22 jours plutôt que 14), mais cette constatation n'était cependant pas significative (p = 0,441).
O'Nions 2020 (14) *Prépublication* Séries de cas longitudinales Royaume-Uni Avril et mai 2020	Analyse d'échantillons longitudinaux provenant de patients hospitalisés pour la COVID-19 et atteints d'une tumeur hématologique agressive suivant un traitement anticancer systémique (n = 10). Nombre de jours mesuré entre l'apparition des symptômes et le résultat négatif au test de PCR.	Échantillon prélevé dans la gorge et dans le nez -Les hémopathie maligne incluaient la leucémie myéloïde aiguë, la leucémie lymphoblastique B, la leucémie lymphoblastique T et le lymphome diffus à grandes cellules B. -Tous les patients ont reçu un traitement anticancer systémique dans les 28 jours suivant l'apparition de la COVID-19. - Huit patients ont eu une séroconversion et développé des anticorps contre les principaux antigènes du SARS-CoV-2 (S1 et N) avec six réponses d'anticorps neutralisants. -Le délai médian de la positivité évaluée par test PCR était de 12 jours (EI : 24). -Le nombre de jours entre l'apparition des symptômes et un résultat négatif au test PCR variait de 9 à 62 jours.
Patients ayant subi une greffe d'organe entier (n = 6)		
Benotmane 2020 (18) Étude de cohorte rétrospective France Mars et avril 2020	Étude ayant évalué des personnes ayant reçu une greffe de rein alors qu'elles avaient la COVID-19 (n = 40). Le procédé qRT-PCR a été utilisé pour détecter l'acide nucléique du SARS-CoV-2 (ciblant deux régions du gène polymérase de l'ARN dépendant de l'ARN). Les patients faisaient l'objet d'un suivi hebdomadaire jusqu'à leur congé, après quoi ils ont subi de nouveaux tests 30, 45 et 60 jours après l'apparition des symptômes. La clairance virale a été définie comme exigeant au moins 1 résultat négatif au test RT-PCR.	Sécrétions rhinopharyngées prélevées par écouvillonnage et échantillons de plasma -Le délai médian après une greffe de rein était de 6,6 ans (EI : entre 2,8 et 14,6 ans). Au moment du diagnostic de COVID-19, 35 (87,5 %) patients suivaient un traitement immunosuppresseur. -La charge virale de la plupart des patients (74,4 %) a atteint un sommet au moment du diagnostic. -Aucun patient n'a montré de clairance virale avant le 21e jour. Dix patients (24,4 %) montraient encore une excrétion persistante d'ARN viral après 31 jours. -Les patients qui recevaient un traitement immunosuppresseur avaient tendance à avoir une RNAémie plus positive, mais ce résultat n'était pas significatif (p = 0,29).
Zhu 2020 (23)	Données analysées provenant de personnes ayant reçu une	Prélèvements de gorge

Étude de cohorte rétrospective Chine Janvier à mars 2020	transplantation rénale et atteinte d'une pneumonie due à la COVID-19 confirmée en laboratoire (n = 10). Des données cliniques des membres immunocompétents de la famille, qui étaient aussi atteints de pneumonie due à la COVID-19 (n = 10), ont également été recueillies et comparées. Le temps avant l'excrétion du virus, défini comme l'obtention d'un résultat négatif au test RT-PCR, a été surveillé.	-La durée moyenne d'excrétion du virus chez les patients qui ont subi une greffe était de 28,4 ± 9,3 jours. Ce délai était beaucoup plus long que celui obtenu pour les membres immunocompétents de la famille (12,2 ± 4,6 jours, p < 0,01).
Caillard 2020 (22) *Lettre à la rédaction* Séries de cas longitudinales France Octobre 2020*	Étude prospective ayant évalué des personnes ayant reçu une greffe de rein et atteintes de la COVID-19 (n = 42). Le test RT-PCR a été utilisé pour détecter l'acide nucléique du SARS-CoV-2 (ciblant deux régions du gène polymérase de l'ARN dépendant de l'ARN).	Sécrétions rhinopharyngées prélevées par écouvillonnage, prélèvements de salive et respiratoires -Au jour 30, 15 patients sur les 35 (43 %) ayant été testés présentaient toujours des résultats positifs au test RT-PCR, avec des charges virales supérieures au seuil pour lesquelles il y a un risque de transmission du SRAS-CoV-2 (> 3 copies log10 par réaction). -Au jour 45, 12 patients (34 %) obtenaient encore des résultats positifs au test RT-PCR. -Au jour 60, 6 patients (17 %) présentaient des charges de SRAS-CoV-2 faibles, mais néanmoins détectables.
Gaston 2020 (19) Séries de cas longitudinales ÉTATS-UNIS Mars à mai 2020	Analyse des données de personnes ayant subi une greffe d'organes entiers qui reçoivent une immunosuppression d'entretien et ont une infection symptomatique à la COVID-19 (n = 25). La positivité virale a été évaluée à l'aide du test RT-PCR (ciblant les gènes N1 et N2 du SARS-CoV-2).	Sécrétions rhinopharyngées et oropharyngées prélevées par écouvillonnage -Seulement 5 patients ont subi des tests en série. -4 patients sur 5 ont obtenu des résultats positifs au test RT-PCR plus de 21 jours après l'apparition des symptômes. -Deux patients ont reçu des résultats positifs 27 jours après l'apparition des symptômes. -Un patient a obtenu un autre résultat positif au jour 38.
Christensen 2020 (20) Séries de cas longitudinales	Analyse des données sur des personnes ayant reçu une greffe de rein ou de foie symptomatiques pour la COVID-19 (n = 6). La positivité virale a été	Sécrétions rhinopharyngées prélevées par écouvillonnage -Le délai médian de la greffe était de 1,9 an (plage : 0,21 à 9,3). Les six patients souffraient tous de l'hypertension (100 %) et cinq étaient diabétiques (83 %).

ÉTATS-UNIS Mars à mai 2020	évaluée à l'aide du procédé qRT-PCR.	-Tous les patients avaient pris des immunosuppresseurs avant le diagnostic de COVID-19. Cinq patients ont cessé de prendre leurs immunosuppresseurs au moment de leur admission à l'hôpital, alors que l'autre patient qui a été vu en consultation externe a vu ses médicaments réduits de 50 %. -Quatre des cinq patients (80 %) ont obtenu un résultat positif pour l'ARN viral du SRAS-CoV-2, tandis qu'un seul patient a obtenu un résultat positif au test d'anticorps neutralisant du SRAS-CoV-2. -Un patient a obtenu un résultat positif au test RT-PCR pendant les 28 jours de suivi, malgré la présence d'IgG de SARS-Cov-2.
Silvano 2021 (21) Séries de cas longitudinales Portugal Mars à juin 2020	Analyse de données provenant de patients ayant subi une greffe de rein et atteints de la COVID-19 (n = 6). La durée de l'excrétion de l'ARN viral a été mesurée et définie comme le temps écoulé entre le premier et le dernier résultat positif au test RT-PCR pour le SARS-CoV-2.	Sécrétions rhinopharyngées et oropharyngées prélevées par écouvillonnage -Le délai médian entre la greffe et le diagnostic de COVID-19 était de 161 mois (plage : entre 8 et 235). Un seul patient avait subi une transplantation au cours de la dernière année. Tous les patients prenaient un traitement d'immunosuppression. -La durée de l'excrétion d'ARN viral a été mesurée pour cinq des patients. -Pour les deux patients atteints d'une forme modérée de la maladie, la durée de l'excrétion d'ARN viral était inférieure à 9 jours. -Pour les trois patients atteints d'une forme grave de la maladie, la durée de l'excrétion d'ARN viral était supérieure à 40 jours et a persisté malgré la disparition des symptômes. Deux avaient ont obtenu des écouvillons positifs au test RT-PCR à la fin du suivi (> 44 et > 66 jours).
PATIENTS IMMUNODÉPRIMÉS		
Personnes atteintes du VIH (n = 2)		
Vizcarra 2020 (24) Étude de cohorte prospective Espagne Mai 2020*	Étude portant sur des adultes infectés par le VIH et dont l'infection à la COVID-19 était soupçonnée ou confirmée au 30 avril 2020 (n = 51). Le SRAS-CoV-2 a été détecté par le procédé qRT-PCR.	Sécrétions rhinopharyngées prélevées par écouvillonnage, expectorations ou prélèvement par aspiration dans les voies respiratoires inférieures -54 % (19 sur 35) des personnes atteintes d'une infection au SRAS-CoV-2 confirmée en laboratoire ont fait l'objet de tests qrt-PCR de suivi. -Tous les patients suivaient un traitement antirétroviral. -La clairance virale s'est produite pendant une médiane de 18 jours (EI : entre 7 et 28) après

		l'apparition des symptômes chez 68 % (13/19) des personnes. Chez les six autres personnes, le SRAS-CoV-2 est demeuré détectable pendant une période médiane de 40 jours (EI : entre 13 et 45) après l'apparition des symptômes. Ces patients étaient atteints d'une forme plus grave de la maladie, avaient été admis plus souvent aux soins intensifs, avaient un nadir de compte de cellules CD4 moins élevé et une plus forte proportion de comorbidités que les personnes dont le temps de clairance virale était plus court ($p < 0,05$).
Mondi 2020 (25) Séries de cas longitudinales Italie Mars à mai 2020	Analyse des données sur des patients séropositifs hospitalisés et atteints de la COVID-19 (n = 5). La clairance virale a été définie comme deux résultats négatifs aux tests RT-PCR consécutifs pour le SRAS-CoV-2 (ciblant les gènes de la polymérase de l'ARN dépendant de l'E et de l'ARN).	Sécrétions rhinopharyngées prélevées par écouvillonnage -Les cinq patients faisaient tous l'objet d'une suppression virologique par traitement antirétroviral. -Les résultats des tests en série n'étaient disponibles que pour deux patients. Pour ces deux patients, la clairance virale a eu lieu les 29e et 43e jours après l'apparition des symptômes.

Méthodologie :

Une analyse documentaire quotidienne (ouvrages publiés et en prépublication) est effectuée par le Groupe des sciences émergentes de l'ASPC. L'analyse a compilé les ouvrages sur la COVID-19 depuis le début de l'éclosion et est mise à jour quotidiennement. Les recherches visant à extraire les ouvrages pertinents sur la COVID-19 sont menées dans Pubmed, Scopus, BioRxiv, MedRxiv, ArXiv, SSRN et Research Square, et les résultats sont recoupés avec les ouvrages figurant sur la liste de la documentation sur la COVID de l'Organisation mondiale de la Santé et des centres d'information sur la COVID-19 gérés par Lancet, BMJ, Elsevier, Nature et Wiley. Le résumé quotidien et les résultats complets de l'analyse sont conservés dans une base de données RefWorks et dans une liste Excel consultable. Une recherche ciblée par mot-clé a été effectuée dans ces bases de données pour recenser les citations pertinentes sur la COVID-19 et le SRAS-CoV-2. Les termes de recherche utilisés comprenaient : (immunosup* OU immunocomp* OU transplant OU cancer) ET (persist* OU prolonged OU viable OU shed* OU culture OU dynamics OU clearance). La présente revue contient des recherches publiées jusqu'au 5 février 2021. Chaque référence potentiellement pertinente a été examinée pour confirmer qu'elle comportait des données pertinentes, qui ont été extraites dans la revue.

Emerging Evidence on COVID-19

Evidence Brief of Ivermectin

Introduction

Is there evidence that Ivermectin is an efficacious treatment for COVID-19?

Ivermectin is a broad-spectrum anti-parasitic agent approved in Canada to treat intestinal strongyloidiasis and onchocerciasis, tropical parasitic infections, and is considered safe at dosages <200 ug/kg (1, 2). Ivermectin has not been authorized for use in the treatment of COVID-19 by Health Canada, Food and Drug Administration of the USA, and the European Medicines Authority, and has not been recommended by the Pan American Health Organization (PAHO) or the World Health Organization (WHO) except in clinical trials (1-5). However, it has been explored for use in COVID-19 due to its antiviral activity *in vitro* against a range of viruses including SARS-CoV-2 (6, 7). The suggested mechanism of action is that ivermectin inhibits and disrupts binding of the SARS-CoV-2 S protein at the ACE-2 receptor (8). Ivermectin was not included in the WHO SOLIDARITY trial for repurposing drugs for COVID-19, some authors suggest this is because the anti-viral effects seen *in vitro* would require nine times the recommended dosage of ivermectin (6). Dosages evaluated across studies were generally <200 ug/kg with some dosing 2 – 3 times 200 ug/kg and ranged from a single dose to treatment over several days up to 14 days. This review summarises systematic reviews and new randomized controlled trials (RCTs) on the efficacy and safety of ivermectin compared to a standard of care or placebo for the prevention of infection with SARS-CoV-2 (post-exposure prophylaxis) and for use as a treatment of COVID-19 cases receiving either inpatient or outpatient care published up to July 5, 2021.

Key Points

- The WHO updated its living guidelines March 31, 2021 to include ivermectin (1) and currently does not recommend the use of ivermectin for the treatment of COVID-19 due to low certainty in the evidence and the availability of other more efficacious treatments.
- Eight systematic or rapid reviews on ivermectin as a therapeutic including two guidelines documents from WHO and PAHO that were underpinned by synthesis research are summarized below. Three systematic reviews summarized the literature on prophylactic use of ivermectin to prevent COVID-19.
- There was variability in the meta-analyses between reviews due to variability in studies included. Across meta-analyses some syntheses included randomized controlled trials (RCTs) only, others restricted to RCTs with low risk of bias, while others included observational studies of both prospective and retrospective design.
    - Moderate/high risk of bias RCTs frequently had inadequate randomization and/or allocation concealment.
    - Many of the RCTs on ivermectin have been small and thus lack power and precision in the estimates.
- There is low or very low certainty in the results for all COVID-19 outcomes, which are summarized below.

Mortality:

- Meta-analyses on the prevention of mortality with ivermectin treatment are inconsistent and had very low to moderate certainty depending on the analysis. The meta-analyses with the most restrictive inclusion criteria (e.g., RCTs of low risk of bias) did not report an association with mortality, whereas those that included RCTs of moderate/high risk of bias or non-RCTs reported an association as shown in the PAHO rapid review (2).

  No association with mortality:

  - 28-day mortality RR 0.33 (95% 0.01-8.14) from 3 RCTs/ 60 day mortality RR 2.00 (0.18-21.91) from 1 RCT (9).
  - RR 0.94 (95%CI 0.51-1.73) from 4 RCTs at low risk of bias / RR 0.32 (95%CI 0.16-0.64) from 6 RCTs at moderate/high risk of bias (2).
  - RR 0.37 (95%CI 0.12 to 1.13) from 5 RCTs, very low certainty of evidence and the subgroup analysis showed a reduction in mortality across 3 RCTs at high risk of bias (RR 0.18, 95%CI 0.07-0.49) (10).

  Reduced mortality

  - OR 0.19 (95%CI 0.09-0.36) from 7 RCTs very low certainty (1).
  - RR 0.38 (95%CI 0.19 -0.73) from 15 studies (RCT and observational studies) moderate certainty evidence, this persisted only for mild/moderate cases (RR 0.24, 95%CI 0.06-0.94) in subgroup analysis (11).
  - RR 0.31 (95%CI 0.15–0.62) from 8 RCTs that persisted only for mild/moderate COVID-19 (RR 0.15, 95%CI 0.03-0.67) in a sub-group analysis (12).
  - OR 0.39 (95%CI 0.22-0.70) from 22 studies (RCT, observational, descriptive) and very low certainty in the evidence. Clinical trials only (OR 0.32, 95%CI 0.15-0.65) had similar results and the authors note that the benefit of ivermectin treatment was only seen in mild/moderate cases (13).

Severe disease:

- Ivermectin was not shown to reduce the risk of symptomatic disease, hospitalization or mechanical ventilation, or length of stay (1, 2, 9-11, 13-15)
  - One meta-analysis reported reduced severity of COVID-19 (RR 0.43 [95% CI 0.23–0.81], I2=65%, p = 0.008, 8 RCTs, n=1638), in the subgroup analysis reduced severity was only associated with mild/moderate cases (RR 0.44, 95%CI 0.22–0.85) (12).

Time to symptom resolution:

- Conflicting results for symptom resolution or improvement were reported across analyses with many reporting no difference (1).
  - RR 1 (95%CI 0.9-1.11, I^2=30%) 2 RCTs low risk of bias and moderate certainty of evidence vs. RR 1.35 (95%CI 1.16-1.57) 6 RCTS of moderate/high risk of bias (2).

Time to PCR negative:

- Time to viral clearance was similar between ivermectin and controls in several analyses (1, 10, 15)
  - Faster time to PCR negative (HR 2.70, 95%CI 1.21- 6.04, 1 RCT) in mild cases, an outcome reported in only 1 of 18 included RCTs, very low certainty (9).
  - Higher PCR negative rate (RR 1.23, 95% CI 1.01–1.51) from 9 RCTs, low certainty and shorter time to PCR negative (mean difference [MD] −3.29, 95%CI −5.69, −0.89) from 6 studies (12).
  - Compared to Lopinavir-Ritonavir, the ivermectin treatment group had a faster time to PCR negative (HR 2.02, 95%CI 1.28-3.18) among hospitalized cases in 1 RCT (9).

Severe adverse events:

- There is no evidence that there was an association between ivermectin treatment and severe adverse events (1, 2, 9-11, 13-15).

Prophylactic use to prevent COVID-19:

- Three systematic reviews report on the RCTs and/or clinical trials on prophylaxis have shown some protective effect of ivermectin supplementation however, the certainty in this evidence is very low to low:
  - Ivermectin prophylaxis reduced COVID-19 infection by 86% (95%CI 79-91%, 3 studies, 738 participants) – low certainty of evidence (11).
  - Ivermectin alone on suspected, probable, or laboratory confirmed COVID-19 infection (159 fewer per 1000, 165 fewer to 144 fewer) remain very uncertain (16)
  - A protective effect of ivermectin supplementation to prevent symptomatic COVID-19 (RR 0.13, 95%CI 0.08-0.21, 1 RCT) or confirmed COVID-19 (RR 0.20, 95%CI 0.04-0.89, 1 RCT) very low certainty of evidence (9).

On-going ivermectin and COVID-19 research:

- On clinicaltrials.gov there are 24 trials involving ivermectin that have been completed and 48 that are registered an in various stages of execution as of July 7, 2021. Some of the registered trials are large, placebo-controlled RCTs on ivermectin that should have enough power to address some of the concerns about the existing evidence (17).

Overview of the Evidence

Systematic reviews of RCTs and RCTs published since the last SR search date were included in this evidence brief. Systematic reviews were evaluated using the AMSTAR 2 tool for systematic reviews (18).

CONTENTS

THERAPEUTIC USE

Therapeutic use of ivermectin in the treatment of COVID-19 has been studied in several clinical trials and a wide range of severities and outcomes have been reported. Several reviews report moderate/high risk of bias in many of the RCTs examining ivermectin treatment. To minimize the bias in the analyses some authors analysed low risk of bias RCTs separate from moderate/high risk of bias RCTs (2, 10) and in some analyses authors have limited analysis to RCTs (1, 12, 13), while others have included multiple study designs in one meta-analysis (11, 13, 14). There are also websites that collect and meta-analyse the literature on ivermectin without conducting a systematic review process. These were excluded from this evidence brief, but are listed in the appendix for reference.

Most RCTs on ivermectin as a therapeutic were small, which impact power and precision of the results and many were at risk of bias due to inappropriate randomization or inadequate allocation concealment. Thus, the studies included in each meta-analysis differed from one systematic review to the next and for a few outcomes (e.g., mortality) the analyses were conflicting.

Table 1: Treatment of COVID-19 with ivermectin (n=8 systematic/rapid reviews and 1 new RCT)

STUDY	METHOD	KEY OUTCOMES
Evidence-Based Guidelines		
WHO Living guideline on Therapeutics for COVID-19 (1) Mar 2021	The living guideline is underpinned by a systematic review process with GRADE certainty of evidence. 16 RCTs (2407 participants) were included and all other study designs were excluded. Many RCTs did not report on patient-important outcomes. Meta-analysis and sub-group analysis was conducted by grouping different ivermectin dosages. There are few RCTs available on ivermectin and RCTs are small with few events. Relative to alternative treatment options, there is a high degree of uncertainty in the evidence. *See figure in appendix*.	Recommendation: WHO recommends not to use ivermectin in patents with COVID-19 except in the context of a clinical trial. This recommendation applies to patients with any disease severity and any duration of symptoms. WHO recommendation: "*A recommendation to only use a drug in the setting of clinical trials is appropriate when there is very low certainty evidence and future research has a large potential for reducing uncertainty about the effects of the intervention and for doing so at reasonable cost.*" For most key outcomes, including mortality, mechanical ventilation, hospital admission, duration of hospitalization and viral clearance, the panel considered the evidence of very low certainty *(Summary of Findings table in Appendix*). Note the meta-analytic findings for mortality were significant (OR 0.19, 95%CI

		0.09-0.36, from 7 RCTs n=1419 observations), however the certainty in the evidence was rated as very low. Evidence was rated as very low certainty primarily because of very serious imprecision for most outcomes: the aggregate data had wide confidence intervals and/or very few events. There were also serious concerns related to risk of bias for some outcomes, specifically lack of blinding, lack of trial pre-registration, and lack of outcome reporting for one trial that did not report mechanical ventilation despite pre-specifying it in their protocol (publication bias). Ivermectin used to treat COVID-19, more than 66 RCTs planning to enrol more than 12 000 participants (range 24 - 2724) are registered or on-going.
Pan American Health Organization (PAHO) Living Update of COVID-19 Therapeutic Options (2) Rapid Review May 2021	The rapid review follows systematic review methodology and uses the Living OVerview of Evidence (L·OVE; https://iloveevidence.com) platform to identify studies for inclusion in this review. Studies included up to May 6, 2021. RCTs of therapeutic interventions for COVID-19 were included. The outcomes focused on were comparative effectiveness studies that provide evidence on outcomes of crucial importance to patients (mortality, invasive mechanical ventilation, symptom resolution or improvement, infection [prophylaxis studies] and severe adverse events) Meta-analysis: Random effects meta-analysis was performed. Where significant heterogeneity existed, subgroup analysis by risk of bias was performed considering: 1) Risk of bias (high/moderate vs low risk of bias), 2) Disease severity (mild, moderate, severe	28 RCTs (4837 cases, mild to severe) and most were very small RCTs with a small number of events (low power and high imprecision). • 17 did not report any clinically important outcomes. • 11 of those studies reported on clinically important outcomes. • Methodological limitations in studies that reported clinically important outcomes included inappropriate randomization or allocation concealment. Results: • Ivermectin may not significantly reduce mortality, RR 0.94 (95%CI 0.51 to 1.73 I^2 =1%); RD - 0.96% (95%CI -7.8% to 11.7%); low certainty based on 4 low risk of bias studies. High risk of bias RCTs (n=6) showed significant protection from mortality (RR 0.32, 95%CI 0.16-0.64, I^2 = 39%), 2/6 found an association within study. • It is uncertain if ivermectin affects mechanical ventilation requirements, RR 0.89 (95%CI 0.38 to 2.07); RD -1.9% (95%CI -10.7% to 18.5%); very low certainty based on 4 low risk of bias RCTs.

	or critical); and 3) Intervention's characteristics A risk of bias assessment was applied to RCTs focusing on randomization, allocation concealment, blinding, attrition, or other biases relevant to the estimates of effect. The GRADE approach was used to assess the certainty on the body of evidence for every comparison on an outcome basis.	• Ivermectin probably does not improve symptom resolution or improvement, RR 1 (95%CI 0.9-1.11, I^2=30%); RD 0% (95%CI -6%-6.6%); moderate certainty based on 2 RCTS with low risk of bias. 2/6 high risk of bias RCTs found an association symptom improvement (RR 1.35, 95%CI 1.16-1.57, I^2=60%). • It is uncertain if ivermectin affects symptomatic infection, RR 0.22 (95%CI 0.09 to 0.53); RD -13.6% (95%CI -15.8% to -8.2%); very low certainty based on 4 low risk of bias studies. • It is uncertain if ivermectin affects hospitalizations in non-severe patients, RR 0.66 (95%CI 0.69 to 2.30); RD 2.5% (95%CI -6% to 9.6%); very low certainty from 1 RCT at low risk of bias. • It is uncertain if there are severe adverse events (RR 1.04, 95%CI 0.32 – 3.38); very low certainty from 4 low risk of bias RCTs.
Synthesis Research		
COVID nma (2021) (9) Living Systematic Review June 2021* NA*	Current up to June 24, 2021. This is a living summary of RCTs on pharmacological interventions updated weekly. The outcomes considered were clinical improvement, mortality, viral negative conversion, serious adverse events, as well as time to these events. Meta-analysis is conducted for each outcome. The Cochrane Risk of Bias 2.0 tool is used assess risk of bias and GRADE is used to assess the certainty of the evidence. Results are updated weekly.	26 RCTs have investigated ivermectin. 8 high risk of bias and 18 with some concerns. Trial size was 32-476 people. No significant outcomes of treatment were reported in studies varying the dosage of ivermectin, for 4 RCTs on ivermectin vs. hydroxychloroquine or 1 RCT on Ivermectin+Doxycycline vs Hydroxychloroquine+Azithromycin Outcomes with at least one significant result: MILD CASES • 1/18 RCTs on ivermectin vs. placebo reported faster time to PCR negative (HR 2.70, 95%CI 1.21- 6.04, 1 RCT) in mild cases. No other outcomes were significant. • 1/4 RCTs on ivermectin+Doxycyclin vs.placebo showed better clinical improvement in the placebo group (RR 0.63, 95%CI 0.45-0.87) and faster time

		to clinical improvement (HR 0.51, 95%CI 0.32-0.81) in the placebo group. HOSPITALIZED CASES • 1 RCT on ivermectin+Doxycycline vs. ivermectin reported more adverse events in the ivermectin+Doxycycline group (RR 1.69, 95%CI 1.15- 2.49). • 1 RCT on ivermectin vs. Lopinavir-Ritonavir reported faster time to PCR negative (HR= 2.02, 95%CI 1.28-3.18) among hospitalized patients in the ivermectin group. GRADE for the ivermectin outcomes ranged from very low to moderate certainty.
Bryant (2021) (11) Systematic Review Jun 2021* (AMSTAR rating high)	Search date April 26, 2021. RCTs and quasi-RCTs were included. Objective was to assess the efficacy of ivermectin treatment in reducing mortality, and in chemoprophylaxis, among people with, or at high risk of, COVID-19 infection. Secondary outcomes included hospital stay, admission to hospital/ICU and adverse outcomes. Cochrane Risk of Bias 2.0 was used. GRADE was used to assess the certainty of the evidence.	24 RCTs (n=3406 participants) met the inclusion criteria- 22 studies on treatment. • Across 15 RCTs ivermectin reduced risk of death to 2.3% vs. 7.8% among hospitalized cases (RR 0.38, 95%CI 0.19 - 0.73, I^2=49%, 15 studies) – moderate certainty evidence. This was robust in a sensitivity analysis. • For moderate/mild COVID the reduced risk of mortality RR 0.24 (95%CI 0.06 -0.94) and no association for severe COVID-19 RR 0.51 (95%CI 0.22 – 1.14). • Deterioration of disease status RR 0.35 (0.19-0.65, 7 studies). • No benefit from ivermectin was identified in prevention of ICU admission or mechanical ventilation- very low /low certainty of evidence. • No association with adverse events – low certainty.
Roman (2021) (10) Systematic Review May 2021* (AMSTAR rating high)	Search conducted March 22, 2021 for Published and preprint randomized controlled trials (RCTs) assessing ivermectin treatment effects on COVID-19 adult patients. Primary outcomes were all-cause mortality, length of stay (LOS), and adverse events (AE). Secondary outcomes included viral clearance and severe AEs.	Ten RCTs (n=1173) were included. RCTs sample size ranged from 24 to 398 patients, and severity of COVID-19 disease was mild in 8 RCTs, moderate in one RCT, and mild and moderate in one RCT. • Ivermectin did not reduce all-cause mortality vs. controls (RR 0.37, 95%CI 0.12 to 1.13, I^2=16%, 5 RCTs, very low QoE-Quality of Evidence).

	Risk of bias (RoB) conducted with the Cochrane RoB 2·0 tool. Meta-analysis was conducted. Subgroup analyses by severity of disease and RoB, and sensitivity analyses by time of follow-up were conducted.	○ A significant reduction in mortality was seen across 3 RCTs at high risk of bias (RR 0.18, 95%CI 0.07-0.49; RoB p for interaction=0.1) ○ Sensitivity analyses excluding RCTs with follow up <21 days showed no difference in all-cause mortality. • Ivermectin did not reduce LOS vs. controls (MD 0.72 days, 95%CI -0.86 to 2.29, I^2=0%, 3 RCTs, very low QoE). • Severe adverse effects were similar between ivermectin and controls (RR 0.95, 95%CI 0.85 to 1.07, I^2=0%, 3 RCTs, low QoE) • Viral clearance was similar between ivermectin and controls (RR 0.96, 95%CI 0.79 to 1.16, I2 =0%, 4 RCTs low QoE)
Hariyanto (2021) (12) Systematic Review (AMSTAR rating moderate)	Search date May 10, 2021. Published RCTs on COVID-19 and ivermectin as a treatment for COVID-19 cases were included. Outcomes: severe COVID-19, mortality, negative RT-PCR test results rate, time to negative RT-PCR test results, symptoms alleviations rate, time to symptoms alleviations and time to hospital discharge. The quality of the study was assessed using Jadad scale assessment tool for clinical trial studies. Overall meta-analysis included all studies regardless of the COVID-19 severity included in the study. Sub-group analysis separating mild/moderate and severe COVID was conducted and is noted in key observations where heterogeneity was explained or only one subgroup remained significant. Several outcomes had high heterogeneity >60% that was not explained by sub-group analysis. This variability in the outcome reduces our confidence that the meta-analytic summary represents the true value, thus	19 RCTs with 2768 COVID-19 patients were included (10 open-label and 9 double blinded). Ivermectin was associated with: • Reduction in severity of COVID-19 (RR 0.43 [95% CI 0.23–0.81], I^2=65%, p = 0.008, 8 studies, n=1638). ○ Sub-group analysis was only significant for mild/moderate COVID-19: RR 0.44 [95%CI 0.22–0.85], p= 0.01, I^2= 47%, n = 1294. • Reduction of mortality (RR 0.31 [95% CI 0.15–0.62], p = 0.001, I^2=40%, 8 studies, n-1726.) ○ Sub-group analysis of mild/moderate COVID-19 only: RR 0.15 [95%CI 0.03–0.67], p = 0.01, I^2 = 0%, n = 1169 ○ Sub group analysis of severe COVID-19: RR 0.41 [95%CI 0.16–1.04], p = 0.06, I^2 = 58%, n = 377. • Higher negative RT-PCR test results rate (RR 1.23 [95% CI 1.01–1.51], p = 0.04, I^2=91%, 9 studies, n=1205). • Shorter time to negative RT-PCR test results (mean difference [MD] −3.29 [95% CI −5.69, −0.89], p = 0.007, I^2=96%, 6 studies, n=782). • Higher symptoms alleviations rate (RR 1.23 [95% CI 1.03−1.46], p = 0.02, I^2=85%, 8 studies, n=1535).

	the value would be expected to change with additional research.	• Shorter time to symptoms alleviations (MD −0.68 [95% CI −1.07,-0.29], p = 0.0007, I^2=68%, 6 studies, n=950).
		  ○ Sub-group analysis of mild/moderate COVID-19 only: MD −0.65 (95% CI −1.12, −0.18), p = 0.007, I^2 = 0%, 4 studies, n = 701.
		  ○ Sub group analysis of severe COVID-19: MD −1.00 [95% CI −1.14, −0.86), p < 0.00001, I2 = 0%, 1 study, n = 69.
		• Shorter time to hospital discharge (MD −2.66 [95%CI −4.49, -0.82], p = 0.004, I^2=98%, 7 studies, n=1032).
		Ivermectin administered to mild/moderate cases had a greater benefit of reducing severity and morality.

Karale (2021) *preprint* (13) Systematic Review May 2021* (AMSTAR rating moderate)	Search date Feb 2020 to Mar 27, 2021 Primary outcomes were overall mortality, need for intensive care unit (ICU) admission; secondary outcomes were - adverse effects, need for mechanical ventilation. Random-effects meta-analysis was conducted. Cochrane ROB and and NIH quality assessment tools were used and evidence was GRADED for certainty. 38 studies were included (n=15002) 19 RCTs, 14 observational, 6 case series; 30 included in the meta-analysis.	Mortality is reported in 22 studies: • Mortality overall: The odds of mortality in the ivermectin group were significantly lower compared to control group (OR 0.39, 95%CI 0.22-0.70, p=0.002; I^2=81%) but evidence was graded very low. • Mortality clinical trials: Subgroup analysis of 15 clinical trials (RCTs N=12, Non-RCTs N=3) and observed similar mortality benefit (OR 0.32, 95%CI 0.15-0.65, p=0.002; I^2 =65%). • Mortality benefit was not observed in severe/critical cases, thus ivermectin was only indicated as possibly beneficial to mild/moderate cases. Severity outcomes ICU admission (n=5 studies) and Mechanical ventilation (n=9) were not associated with ivermectin. Adverse events are reported in 10 studies; • Adverse events in the ivermectin treatment arms were not associated with treatment in 17 studies (245/973) vs control group (234/945). We did not find an association between ivermectin and rate of adverse events as compared to controls (OR 0.92, 95%CI 0.64- 1.33, p=0.67; I^2 =14%).
Murchu (2021) (14)	Search date January 6, 2021. Clinical trials (RCT or nRCT) were included and risk of bias assessment	One study on a combination intervention of oral ivermectin plus doxycycline, conducted in Iraq (n=96). Treatment: 200 µg/kg ivermectin

Systematic review Jun 2021* (AMSTAR rating moderate)	was conducted using the Cochrane RoB 2.0 and the certainty of evidence was assessed with GRADE. The review assessed ambulatory treatments for COVID-19. 8 RCTs were included, only one was on an ivermectin plus Doxycycline treatment.	orally daily for 2 to 3 days and 100 mg oral doxycycline twice daily for 5 to 10 days plus standard therapy. • Mean time to recovery in patients with mild/moderate disease was 6.34 days (SD = 2.4) in the intervention group compared with 13.66 days (SD = 6.4) in the control group ($P < 0.01$). • Progression to severe disease or mortality and adverse reactions did not occur in this study.
New RCTs		
Vallejos (2021) (15) RCT Aug 2020 – Feb 2021 Argentina	RCT double-blind, placebo-controlled study (n=501) "IVERCORCOVID19" ivermectin treatment to prevent hospitalization in individuals with early COVID-19 cases. Dose was according to weight: mean dose 192.37 µg/kg/day (SD ± 24.56) up to 80kg received 12mg/d for 2 days. >80kg received 18mg/d for 2 days. >110kg received 24mg/d for 2 days. Mean age was 42 years (SD ± 15.5) and the median time since symptom onset to the inclusion was 4 days [interquartile range 3-6]. ClinicalTrials.gov (NCT04529525)	• Hospitalizations: 14/250 (5.6%) ivermectin group vs. 21/251 (8.4%) placebo group (OR 0.65; 95%CI 0.32-1.31; p = 0.227). • Time to hospitalization was not statistically different between groups. • The mean time from study enrollment to invasive mechanical ventilation was 5.25 days (SD ± 1.71) in ivermectin group vs. 10 days (SD ± 2) in placebo group, (p = 0.019). • No statistically significant differences in the other secondary outcomes including polymerase chain reaction test negativity and safety outcomes.

LTE= letter to editor, * the date or location is based on citation information. QoE= quality of evidence

PROPHYLAXIS

Three systematic reviews report on the RCTs and/or clinical trials on prophylaxis have shown some protective effect of ivermectin supplementation however the certainty in this evidence is very low to low

Table 2: Prophylaxis (n=3)

Systematic review		
Bartoszko (2021) (16) Living Systematic Review	Search date Feb 2020 to Mar 27, 2021 Included randomised trials of people at risk of covid-19 who were assigned to receive prophylaxis or no prophylaxis (standard care or placebo).	There was serious risk of bias and very serious imprecision for each outcome, thus there is very low certainty in this evidence. • The effects of ivermectin combined with iota-carrageenan on laboratory confirmed

May 2021* (AMSTAR quality high)	Random effects Bayesian network meta-analysis was performed. Risk of bias was assessed by a modification of the Cochrane risk of bias 2.0 tool and GRADE was applied for the certainty of evidence.	COVID-19 (52 fewer per 1000, 58 fewer to 37 fewer). • Ivermectin alone on laboratory confirmed COVID-19 infection (50 fewer per 1000, 59 fewer to 16 fewer). • Ivermectin alone on suspected, probable, or laboratory confirmed COVID-19 infection (159 fewer per 1000, 165 fewer to 144 fewer), remains very uncertain.
Bryant (2021) (11) Systematic Review Jun 2021* (AMSTAR rating high)	Search date April 26, 2021. RCTs and quasi-RCTs were included. Objective was to assess the efficacy of ivermectin treatment in reducing mortality, and in chemoprophylaxis, among people with, or at high risk of, COVID-19 infection. Secondary outcomes included hospital stay, admission to hospital/ICU and adverse outcomes. Cochrane Risk of Bias 2.0 was used. GRADE was used to assess the certainty of the evidence.	24 RCTs (n=3406 participants) met the inclusion criteria – 3 studies on prophylaxis. • Ivermectin prophylaxis reduced COVID-19 infection by 86% (95%CI 79-91%, 3 studies, 738 participants); low certainty of evidence. .
COVID nma (2021) (9) Living Systematic Review June 2021* NA*	Current up to June 2021. This is a living summary of RCTs on pharmacological interventions. The outcomes considered were clinical improvement, mortality, viral negative conversion, serious adverse events, as well as time to these events. Meta-analysis is conducted for each outcome. The Cochrane Risk of Bias 2.0 tool is used assess risk of bias and GRADE is used to assess the certainty of the evidence. Results are updated weekly. 4 RCTs investigated ivermectin as a preventative treatment.	Ivermectin vs. placebo: 2 RCTS • A protective effect of ivermectin supplementation to prevent symptomatic COVID-19 (RR 0.13, 95%CI 0.08-0.21, 1 RCT) or confirmed COVID-19 (RR 0.20, 95%CI 0.04-0.89, 1 RCT); very low certainty of evidence. Ivermectin vs. Vitamin C: 1 RCT • No difference in incidence of symptomatic or confirmed COVID-19, adverse events, hospitalization, ICU admission or mortality. Ivermectin+Iota-Carrageenan vs. Placebo: 1 RCT • Ivermectin +Iota-Carrageenan reduced the risk of confirmed COVID-19 (RR 0.13, 95%CI 0.04-0.47), risk of symptomatic COVID-19 (RR 0.04, 95%CI 0.01-0.30), and there was no mortality in either group.

Methods:

A daily scan of the literature (published and pre-published) is conducted by the Emerging Science Group, PHAC. The scan has compiled COVID-19 literature since the beginning of the outbreak and is updated daily. Searches to retrieve relevant COVID-19 literature are conducted in Pubmed, Scopus, BioRxiv, MedRxiv, ArXiv, SSRN, Research Square and cross-referenced with the COVID-19 information centers run by Lancet, BMJ, Elsevier, Nature and Wiley. The daily summary and full scan results are maintained in a refworks database and an excel list that can be searched. Targeted keyword searching is conducted within these databases to identify relevant citations on COVID-19 and SARS-COV-2. Search term used included: ivermectin.
This review contains research published up to July 5, 2021.
Each potentially relevant reference was examined to confirm it had relevant data and relevant data is extracted into the review.

Peer-review

APPENDIX

Figure: WHO Living Guidelines on Therapeutics: Network meta-analysis figure indicates that the data and studies supporting the data for Ivermectin is weak.

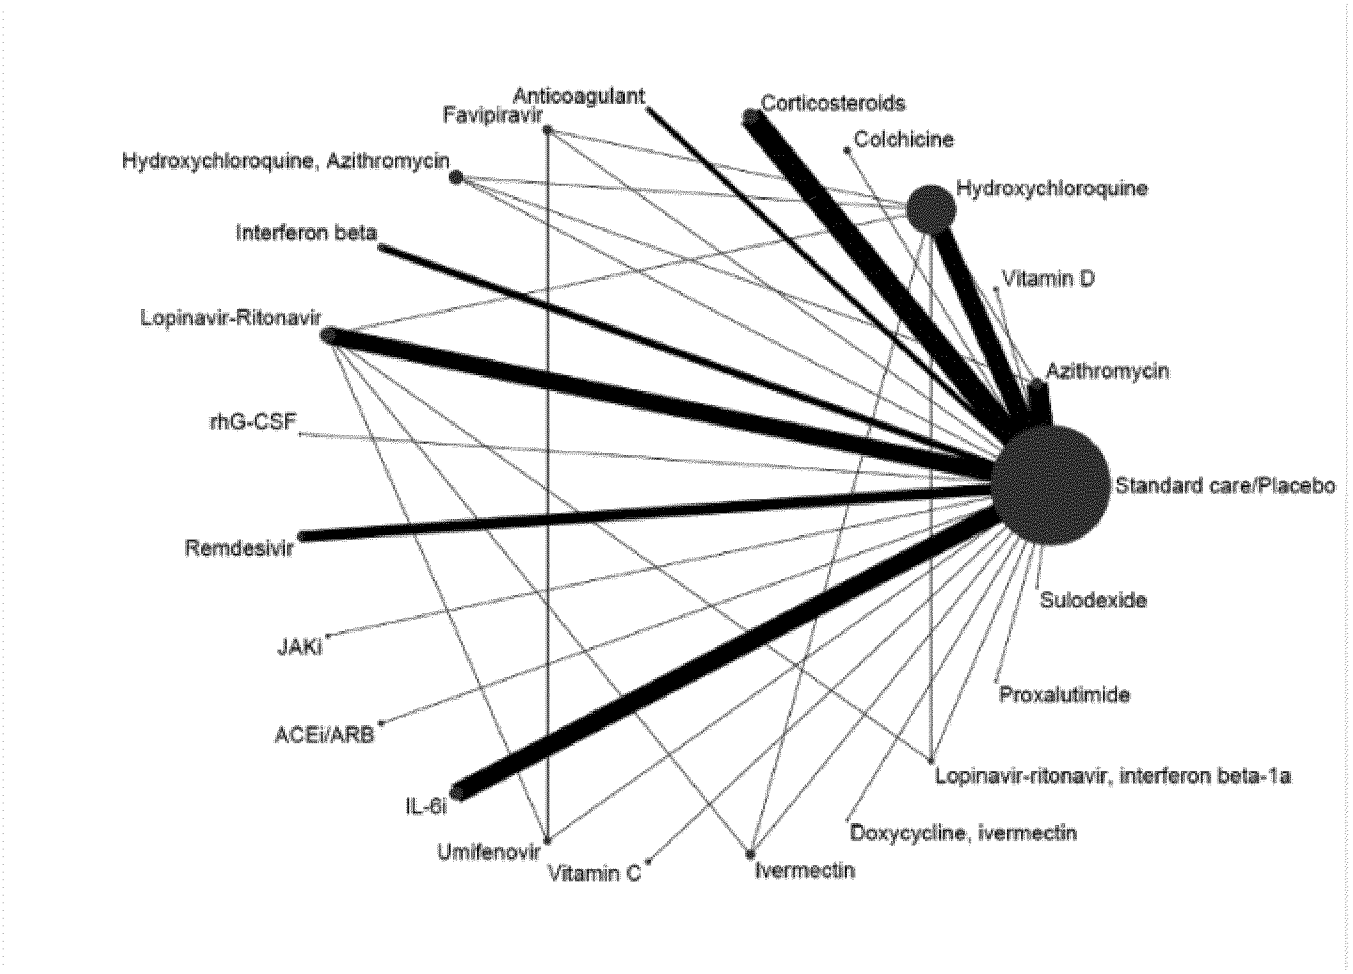

Table: WHO Living Guidelines on Therapeutics: The summary of findings analysis conducted on RCT trial on Ivermectin.

Clinical question/ PICO

Population: Patients with COVID-19 infection (all disease severities)
Intervention: Ivermectin
Comparator: Usual care

Summary

Outcome Timeframe	Study results and measurements	Absolute effect estimates Standard care	 Ivermectin	Certainty of the evidence (Quality of evidence)	Plain text summary
Mortality	Odds ratio 0.19 (CI 95% 0.09 - 0.36) Based on data from 1,419 patients in 7 studies. [1] (Randomized controlled)	70 per 1000	14 per 1000 Difference: **56 fewer** per 1000 (CI 95% 63 fewer - 44 fewer)	Very Low Due to serious risk of bias and very serious imprecision [2]	The effect of ivermectin on mortality is uncertain.
Mechanical ventilation	Odds ratio 0.51 (CI 95% 0.12 - 1.77) Based on data from 687 patients in 5 studies. (Randomized controlled)	20 per 1000	10 per 1000 Difference: **10 fewer** per 1000 (CI 95% 18 fewer - 15 more)	Very Low Due to very serious imprecision and publication bias [3]	The effect of ivermectin on mechanical ventilation is uncertain.
Viral clearance 7 days	Odds ratio 1.62 (CI 95% 0.95 - 2.86) Based on data from 625 patients in 6 studies. (Randomized controlled)	500 per 1000	618 per 1000 Difference: **118 more** per 1000 (CI 95% 13 fewer - 241 more)	Low Due to serious inconsistency and imprecision [4]	Ivermectin may increase or have no effect on viral clearance.
Hospital admission (outpatients only)	Odds ratio 0.36 (CI 95% 0.08 - 1.48) Based on data from 398 patients in 1 studies. (Randomized controlled)	50 per 1000	18 per 1000 Difference: **32 fewer** per 1000 (CI 95% 47 fewer - 23 more)	Very Low Due to extreme imprecision [5]	The effect of ivermectin on hospital admission is uncertain.
Serious adverse events	Odds ratio 3.07 (CI 95% 0.77 - 12.09) Based on data from 584 patients in 3 studies. (Randomized controlled)	9 per 1000	27 per 1000 Difference: **18 more** per 1000 (CI 95% 2 fewer - 89 more)	Low Due to very serious imprecision [6]	Ivermectin may increase the risk of serious adverse events leading to drug discontinuation.

Outcome Timeframe	Study results and measurements	Absolute effect estimates Standard care	 Ivermectin	Certainty of the evidence (Quality of evidence)	Plain text summary
Time to clinical improvement	Measured by: days Lower better Based on data from: 633 patients in 2 studies. (Randomized controlled)	11 days (Mean)	10.5 days (Mean) Difference: MD 0.5 fewer (CI 95% 1.7 fewer - 1.1 more)	Low Due to very serious imprecision [7]	Ivermectin may have little or no difference on time to clinical improvement
Duration of hospitalization	Measured by: days Lower better Based on data from: 252 patients in 3 studies. (Randomized controlled)	12.8 days (Mean)	11.7 days (Mean) Difference: MD 1.1 fewer (CI 95% 2.3 fewer - 0.1 more)	Very Low Due to serious imprecision, inconsistency and serious risk of bias [8]	The effect of ivermectin on hospital length of stay is uncertain.
Time to viral clearance	Measured by: days Lower better Based on data from: 559 patients in 4 studies. (Randomized controlled)	7.3 days (Mean)	5.7 days (Mean) Difference: MD 1.6 fewer (CI 95% 4.1 fewer - 3 more)	Very Low Due to very serious imprecision and serious risk of bias. [9]	We are uncertain whether ivermectin improves or worsen time to viral clearance

1. Systematic review (3). **Baseline/comparator:** Control arm of reference used for intervention. We elected to use the control arm of the WHO solidarity trial, reflecting usual care across countries participating in the trial.
2. **Risk of bias: Serious.** The large trial contributing most of the effect estimate was driven by studies that were not blinded.. **Inconsistency: No serious. Indirectness: No serious. Imprecision: Very Serious.** The number of total events was very small.. **Publication bias: No serious.**
3. **Inconsistency: No serious. Indirectness: No serious. Imprecision: Very Serious.** Very few events and credible intervals that include both important benefit and harm.. **Publication bias: Serious.**
4. **Inconsistency: Serious.** The point estimates varied widely and credible intervals do not substantially overlap.. **Indirectness: No serious. Imprecision: Serious.** Credible interval includes no effect.. **Publication bias: No serious.**
5. **Inconsistency: No serious. Indirectness: No serious. Imprecision: Very Serious.** Credible interval includes important benefit and harm.. **Publication bias: No serious.**
6. **Inconsistency: No serious. Indirectness: No serious. Imprecision: Serious.** Credible interval includes little to no difference.. **Publication bias: No serious.**
7. **Inconsistency: No serious. Indirectness: No serious. Imprecision: Very Serious. Publication bias: No serious.**
8. **Risk of bias: Serious.** Result driven by one study that was not blinded.. **Inconsistency: Serious.** Despite overlapping confidence intervals, point estimates discrepant.. **Indirectness: No serious. Imprecision: Serious.** Credible intervals include no difference.. **Publication bias: No serious.**
9. **Risk of bias: Serious.** Concerns around risk of bias.. **Inconsistency: No serious. Indirectness: No serious. Imprecision: Very Serious.** Credible interval includes important benefit and important harm.. **Publication bias: No serious.**

Search strategy not specified, references taken from a website: Primary Outcome: death Study design: RCT and observational studies included. Risk of Bias: ROBINS-I for non-randomized studies of interventions and the Cochrane handbook for randomized trials. Meta-analysis methods: Random effects meta-analysis and heterogeneity was evaluated by I^2 and was assessed by visual inspection of forest plots. Study designs were pooled together (not appropriate), and no analysis by risk of bias was conducted. Studies examined were those included by Kory 2021.	15 studies (2 reported two studies), 10 randomized controlled trials and 7 controlled observational studies (6 considered low, 9 moderate and 2 high risk of bias.) Outcome RR CERTAINTY (# studies): • Mortality: RR 0.17 (95% 0.08 to 0.35) MODERATE (5 studies) • Condition improvement (mild to moderate COVID19) RR 1.34 (1.22 to 1.48) MODERATE (5 studies) • Condition improvement (severe COVID-19) RR 1.88 (1.54 to 2.30) LOW (1 study) • Condition deterioration RR 0.47 (0.29 to 0.77) MODERATE (4 studies) • Admission to ICU RR 0.11 (0.01 to 0.80) LOW (1 study) • Prophylaxis to prevent COVID-19 infection RR 0.12 (0.08 to 0.18) MODERATE (4 studies) NOTE: Lawrie excluded 12 of the 27 studies considered by Kory.

Kory (2021) Review of the Emerging Evidence Demonstrating the Efficacy of Ivermectin in the Prophylaxis and Treatment of COVID-19. American Journal of Therapeutics Review May 2021 (Journal not indexed, identified in grey literature search) Previous preprint version posted on this site: https://covid19criticalcare.com/	This is a review with meta-analysis and there are no methods. Primary Outcome: time to clinical recovery and mortality. Included study: RCT and observational studies. Published peer-reviewed studies, preprints, expert meta-analyses, and numerous epidemiological analyses of regions with Ivermectin distribution campaigns. Meta-analyses are not underpinned by a systematic review. There is no protocol, no inclusion criteria, no information on search or risk of bias assessment.	27 studies included, meta-analyses based on 18 randomized controlled treatment trials of Ivermectin in COVID-19 have found large, statistically significant reductions in mortality, time to clinical recovery, and time to viral clearance. Furthermore, results from numerous controlled prophylaxis trials report significantly reduced risks of contracting COVID-19 with the regular use of Ivermectin.

Nouveaux éléments de preuve sur la COVID-19

Synthèse en bref sur l'ivermectine

Introduction

Existe-t-il des preuves que l'ivermectine est un traitement efficace contre la COVID-19?

L'ivermectine est un agent antiparasitaire à large spectre approuvé au Canada pour traiter la strongyloïdose intestinale et l'onchocercose, des infections parasitaires tropicales, et est considérée comme sûre à des doses < 200 ug/kg (1, 2). L'utilisation de l'ivermectine dans le traitement de la COVID-19 n'a pas été autorisée par Santé Canada, la Food and Drug Administration des États-Unis et l'Autorité européenne des médicaments, et n'a pas été recommandée par l'Organisation panaméricaine de la santé (OPS) ou l'Organisation mondiale de la santé (OMS), sauf dans le cadre d'essais cliniques (1 à 5). Cependant, son utilisation dans le traitement de la COVID-19 a été étudiée en raison de son activité antivirale *in vitro* contre une série de virus, dont le SRAS-CoV-2 (6, 7). Le mécanisme d'action suggéré est que l'ivermectine inhibe et perturbe la liaison de la protéine S du SRAS-CoV-2 au récepteur ACE-2 (8). L'ivermectine n'a pas été incluse dans l'essai SOLIDARITY de l'OMS pour la réorientation des médicaments vers la COVID-19, certains auteurs suggèrent que c'est parce que les effets antiviraux observés *in vitro* nécessiteraient neuf fois la dose recommandée d'ivermectine (6). Les doses évaluées dans l'ensemble des études étaient généralement < 200 ug/kg, certaines doses étant 2 à 3 fois supérieures à 200 ug/kg et allant d'une dose unique à un traitement sur plusieurs jours, voire 14 jours. Cette revue résume les revues systématiques et les nouveaux essais contrôlés randomisés (ECR) sur l'efficacité et la sécurité de l'ivermectine par rapport à une norme de soins ou un placebo pour la prévention de l'infection par le SRAS-CoV-2 (prophylaxie post-exposition) et pour l'utilisation comme traitement des cas de COVID-19 recevant des soins hospitaliers ou ambulatoires publiés jusqu'au 5 juillet 2021.

Points clés

- L'OMS a mis à jour ses lignes directrices évolutives le 31 mars 2021 pour inclure l'ivermectine (1) et ne recommande actuellement pas l'utilisation de l'ivermectine pour le traitement de la COVID-19 en raison du faible degré de certitude des preuves et de la disponibilité d'autres traitements plus efficaces.
- Huit revues systématiques ou rapides sur l'ivermectine en tant que thérapeutique, y compris deux documents de directives de l'OMS et de l'OPS, qui ont été étayés par une recherche de synthèse, sont résumés ci-dessous. Trois revues systématiques ont résumé la littérature sur l'utilisation prophylactique de l'ivermectine pour prévenir la COVID-19.
- Les méta-analyses varient d'une revue à l'autre en raison de la variabilité des études incluses. Parmi les méta-analyses, certaines ne comprenaient que des essais contrôlés randomisés (ECR), d'autres se limitaient aux ECR présentant un faible risque de biais, tandis que d'autres encore incluaient des études observationnelles de conception prospective et rétrospective.
    - Les ECR à risque modéré/élevé de biais présentaient fréquemment une randomisation et/ou une assignation secrète inadéquate.

    - Bon nombre des ECR sur l'ivermectine sont de petite taille et ne permettent donc que des estimations manquant de puissance et de précision.
- La certitude des résultats pour tous les extrants de la COVID-19 est basse, voire très basse, ce qui est résumé ci-dessous.

Mortalité :

- Les méta-analyses sur la prévention de la mortalité par le traitement à l'ivermectine sont incohérentes et présentent un degré de certitude très faible à modéré selon l'analyse. Les méta-analyses dont les critères d'inclusion étaient les plus restrictifs (par exemple, les ECR à faible risque de biais) n'ont pas fait état d'une association avec la mortalité, tandis que celles qui incluaient des ECR à risque modéré/élevé de biais ou des ECNR ont fait état d'une association, comme le montre la revue rapide de l'OPS (2).

  Aucune association avec la mortalité :

  - Mortalité à 28 jours RR 0,33 (95 % de 0,01 à 8,14) de 3 ECR/ Mortalité à 60 jours RR 2,00 (de 0,18 à 21,91) de 1 ECR (9).
  - RR 0,94 (IC à 95 % de 0,51 à 1,73) de 4 ECR à faible risque de biais / RR 0,32 (IC à 95 % de 0,16 à 0,64) de 6 ECR à risque de biais modéré/élevé (2).
  - RR 0,37 (IC à 95 % de 0,12 à 1,13) de 5 ECR, très faible certitude de preuve et l'analyse de sous-groupe a montré une réduction de la mortalité dans 3 ECR à haut risque de biais (RR 0,18, IC à 95 % de 0,07 à 0,49) (10).

  Réduction de la mortalité

  - RC 0,19 (IC à 95 % de 0,09 à 0,36) de 7 ECR à très faible certitude (1).
  - RR 0,38 (IC à 95 % de 0,19 à 0,73) à partir de 15 études (ECR et études observationnelles) preuve de certitude modérée, ceci a persisté seulement pour les cas légers/modérés (RR 0,24, IC à 95 % de 0,06 à 0,94) dans l'analyse de sous-groupe (11).
  - RR 0,31 (IC à 95 % de 0,15 à 0,62) de 8 ECR qui n'a persisté que pour la COVID-19 légère/modérée (RR 0,15, IC à 95 % de 0,03 à 0,67) dans une analyse de sous-groupe (12).
  - RC 0,39 (IC à 95 % de 0,22 à 0,70) à partir de 22 études (ECR, observationnelles, descriptives) et très faible certitude dans les preuves. Les essais cliniques uniquement (RC 0,32, IC à 95 % de 0,15 à 0,65) ont donné des résultats similaires et les auteurs notent que le bénéfice du traitement à l'ivermectine n'a été constaté que dans les cas légers/modérés (13).

Maladie sévère :

- Il n'a pas été démontré que l'ivermectine réduisait le risque de maladie symptomatique, d'hospitalisation ou de ventilation mécanique, ou la durée du séjour (1, 2, 9 à 11, 13 à 15)
  - Une méta-analyse a rapporté une réduction de la sévérité de la COVID-19 (RR 0,43 [IC à 95 % de 0,23 à 0,81], I2=65 %, p = 0,008, 8 ECR, n=1638), dans l'analyse de sous-groupe, la réduction de la sévérité n'était associée qu'aux cas légers/modérés (RR 0,44, IC à 95 % de 0,22 à 0,85) (12).

Temps pour la résolution des symptômes :

- Des résultats contradictoires concernant la résolution ou l'amélioration des symptômes ont été rapportés dans toutes les analyses, beaucoup d'entre elles ne faisant état d'aucune différence (1).
    - RR 1 (0,9 à 1,11, I^2=30 %) 2 ECR à faible risque de biais et certitude modérée des preuves comparés à RR 1,35 (IC à 95 % de 1,16 à 1,57) 6 ECR à risque modéré/élevé de biais (2).

Temps jusqu'à une PCR négative :

- Le délai de clairance virale était similaire entre l'ivermectine et les témoins dans plusieurs analyses (1, 10, 15)
    - Temps plus court pour obtenir un résultat négatif à la PCR (TR 2,70, IC à 95 % de 1,21 à 6,04, 1 ECR) dans les cas légers, un résultat rapporté dans seulement 1 des 18 ECR inclus, très faible certitude (9).
    - Taux de PCR négative plus élevé(RR 1,23, IC à 95 % de 1,01 à 1,51) selon 9 ECR, faible certitude et délai plus court pour obtenir une PCR négative (différence moyenne [DM] -3,29, IC à 95 % de -5,69 à -0,89) selon 6 études (12).
    - Comparativement au groupe Lopinavir-Ritonavir, le groupe traité à l'ivermectine a eu une PCR négative après un temps plus rapide (TR 2,02, IC à 95 % de 1,28 à 3,18) parmi les cas hospitalisés dans 1 ECR (9).

Événements indésirables graves :

- Rien ne prouve qu'il y ait eu une association entre le traitement par l'ivermectine et les événements indésirables graves (1, 2, 9 à 11, 13 à 15).

Utilisation prophylactique pour prévenir la COVID-19 :

- Trois revues systématiques rapportent que les ECR et/ou les essais cliniques sur la prophylaxie ont montré un certain effet protecteur de l'apport complémentaire en ivermectine; cependant, le degré de certitude de ces preuves est très faible à faible :
    - La prophylaxie à l'ivermectine a réduit l'infection à la COVID-19 de 86 % (IC à 95 % de 79 à 91 %, 3 études, 738 participants) – faible degré de certitude des preuves (11).
    - L'efficacité de l'ivermectine seule en cas d'infection suspectée, probable ou confirmée en laboratoire à la COVID-19 (159 de moins pour 1000, 165 de moins à 144 de moins) reste très incertaine (16)
    - Un effet protecteur de l'apport complémentaire en ivermectine pour prévenir les COVID-19 symptomatiques (RR 0,13, IC à 95 % de 0,08 à 0,21, 1 ECR) ou confirmés (RR 0,20, IC à 95 % de 0,04 à 0,89, 1 ECR) : très faible certitude de preuve (9).

Recherche en cours sur l'ivermectine et la COVID-19 :

- Sur le site clinicaltrials.gov, il y a 24 essais impliquant l'ivermectine qui sont terminés et 48 qui sont enregistrés et à différents stades d'exécution au 7 juillet 2021. Certains des essais enregistrés sont de grands ECR contrôlés par placebo sur l'ivermectine qui devraient avoir une puissance suffisante pour répondre à certaines des préoccupations concernant les preuves existantes (17).

Vue d'ensemble des éléments de preuves

Les revues systématiques d'ECR et les ECR publiés depuis la dernière date de recherche de SR ont été inclus dans cette synthèse en bref. Les revues systématiques ont été évaluées à l'aide de l'outil AMSTAR 2 pour les examens systématiques (18).

TABLE DES MATIÈRES

UTILISATION THÉRAPEUTIQUE

L'utilisation thérapeutique de l'ivermectine dans le traitement de la COVID-19 a été étudiée dans plusieurs essais cliniques et un large éventail de sévérités et de résultats a été rapporté. Plusieurs revues font état d'un risque de biais modéré/élevé dans bon nombre des ECR portant sur le traitement à l'ivermectine. Pour minimiser le biais dans les analyses, certains auteurs ont analysé les ECR à faible risque de biais séparément des ECR à risque modéré/élevé de biais (2, 10) et dans certaines analyses, les auteurs ont limité l'analyse aux ECR (1, 12, 13), tandis que d'autres ont inclus plusieurs modèles d'étude dans une méta-analyse (11, 13, 14). Il existe également des sites Web qui rassemblent et méta-analysent la littérature sur l'ivermectine sans procéder à une revue systématique. Ils ont été exclus de cette synthèse en bref, mais sont listés dans l'appendice pour référence.

La plupart des ECR sur l'ivermectine en tant que traitement sont de petite taille, ce qui a un impact sur la puissance et la précision des résultats, et beaucoup présentent un risque de biais en raison d'une randomisation inappropriée ou d'une dissimulation inadéquate de l'allocation. Ainsi, les études incluses dans chaque méta-analyse différaient d'une revue systématique à l'autre et pour quelques résultats (par exemple, la mortalité), les analyses étaient contradictoires.

Tableau 1 : Traitement de la COVID-19 avec l'ivermectine (n=8, revues systématiques/rapides et 1 nouvel ECR)

ÉTUDES	MÉTHODE	RÉSULTATS PERTINENTS
Lignes directrices fondées sur des données probantes		
QUI Ligne directrice évolutive sur la thérapeutique	La ligne directrice évolutive est étayée par un processus de revue systématique avec une certitude de preuves évaluée à l'aide de GRADE.	Recommandation : L'OMS recommande de ne pas utiliser l'ivermectine pour traiter la COVID-19 sauf dans le cadre d'un essai clinique. Cette recommandation s'applique aux patients,

pour la COVID-19 (1) Mars 2021	16 ECR (2407 participants) ont été retenus et tous les autres modèles d'étude ont été exclus. De nombreux ECR n'ont pas fait état de résultats importants pour le patient. Une méta-analyse et une analyse de sous-groupes ont été réalisées en regroupant les différents dosages d'ivermectine. Il y a peu d'ECR disponibles sur l'ivermectine et les ECR sont de petite taille avec peu d'événements. Par rapport aux autres options thérapeutiques, les données probantes présentent un degré élevé d'incertitude. *Voir la figure en annexe*.	quelles que soient la gravité de la maladie et la durée des symptômes. Recommandation de l'OMS : « *Une recommandation d'utiliser un médicament uniquement dans le cadre d'essais cliniques est appropriée lorsqu'il y a des preuves de très faible certitude, que les recherches futures ont un grand potentiel pour réduire l'incertitude sur les effets de l'intervention et que cela puisse être fait à un coût raisonnable*. » Pour la plupart des résultats clés, y compris la mortalité, la ventilation mécanique, l'admission à l'hôpital, la durée de l'hospitalisation et la clairance virale, le panel a considéré que les preuves avaient un degré de certitude très faible *(tableau de résumé des résultats dans l'appendice*). Il convient de noter que les résultats de la méta-analyse concernant la mortalité étaient significatifs (RC 0,19, IC à 95 % de 0,09 à 0,36, à partir de 7 ECR n=1419 observations), mais que le degré de certitude des preuves a été jugé très faible. La certitude des preuves a été évaluée comme étant très faible principalement en raison de l'imprécision très sérieuse de la plupart des résultats : les données agrégées ayant de larges intervalles de confiance et/ou très peu d'événements. Il y avait également de sérieuses préoccupations liées au risque de biais pour certains résultats, en particulier l'absence d'insu, l'absence de préinscription à l'essai et l'absence de rapport sur les résultats pour un essai qui n'a pas fait état de la ventilation mécanique bien qu'elle ait été spécifiée dans son protocole (biais de publication). L'ivermectine a été utilisée pour traiter la COVID-19, plus de 66 ECR prévoyant d'enrôler plus de 12 000 participants (entre 24 et 2724) sont enregistrés ou en cours.
Organisation panaméricaine de la santé (OPS) Mise à jour régulière des	La revue rapide suit une méthodologie d'examen systématique et utilise la plateforme Living OVerview of Evidence (L-OVE; https://iloveevidence.com) pour	28 ECR (4837 cas, légers à graves) et la plupart étaient de très petits ECR avec un petit nombre d'événements (faible puissance et forte imprécision).

options thérapeutiques pour la COVID-19 (2) Revue rapide Mai 2021	identifier les études à inclure dans cette revue. Études incluses jusqu'au 6 mai 2021. Les ECR d'interventions thérapeutiques pour la COVID-19 ont été inclus. Les résultats visés sont les études d'efficacité comparative qui fournissent des preuves sur des résultats d'une importance cruciale pour les patients (mortalité, ventilation mécanique invasive, résolution ou amélioration des symptômes, infections [études de prophylaxie] et événements indésirables graves) Méta-analyse : une méta-analyse à effets aléatoires a été réalisée. En cas d'hétérogénéité significative, une analyse de sous-groupe en fonction du risque de biais a été réalisée en considérant : 1) le risque de partialité (élevé/modéré comparé à faible), 2) la gravité de la maladie (légère, modérée, sévère ou critique); et 3) les caractéristiques de l'intervention Une évaluation du risque de biais a été appliquée aux ECR en se concentrant sur la randomisation, la dissimulation de l'allocation, l'insu, l'attrition ou d'autres biais pertinents pour les estimations de l'effet. L'approche GRADE a été utilisée pour évaluer la certitude de l'ensemble des preuves pour chaque comparaison sur la base des résultats.	• 17 n'ont pas rapporté de résultats cliniquement importants. • 11 de ces études ont fait état de résultats cliniquement importants. • Les limites méthodologiques des études qui ont rapporté des résultats cliniquement importants comprenaient une randomisation ou une assignation secrète inappropriée. Résultats : • L'ivermectine pourrait ne pas réduire significativement la mortalité, RR 0,94 (IC à 95 % de 0,51 à 1,73 I2 =1 %); RD – 0,96 % (IC à 95 % de -7,8 % à 11,7 %); faible certitude basée sur 4 études à faible risque de biais. Les ECR à risque élevé de biais (n=6) ont montré une protection significative contre la mortalité (RR 0,32, IC à 95 % de 0,16 à 0,64, I2 = 39 %), 2 sur 6 ont trouvé une association au sein de l'étude. • Il n'est pas certain que l'ivermectine affecte les besoins en ventilation mécanique, RR 0,89 (IC à 95 % de 0,38 à 2,07); RD -1,9 % (IC à 95 % de -10,7 % à 18,5 %); très faible certitude basée sur 4 ECR à faible risque de biais. • L'ivermectine n'améliore probablement pas la résolution ou l'amélioration des symptômes, RR 1 (IC à 95 % de 0,9 à 1,11, I2=30 %); RD 0 % (IC à 95 % de -6 % à -6,6 %); certitude modérée basée sur 2 ECT avec un faible risque de biais. 2 ECR sur 6 à haut risque de biais ont trouvé une amélioration des symptômes d'association (RR 1,35, IC à 95 % de 1,16 à 1,57, I2=60 %). • Il est incertain que l'ivermectine affecte l'infection symptomatique, RR 0,22 (IC à 95 % de 0,09 à 0,53); RD -13,6 % (IC à 95 % de -15,8 % à -8,2 %); très faible certitude basée sur 4 études à faible risque de biais. • Il n'est pas certain que l'ivermectine affecte les hospitalisations chez les patients non sévères, RR 0,66 (IC à 95 % de 0,69 à 2,30);

		RD 2,5 % (IC à 95 % de -6 % à 9,6 %); très faible certitude à partir d'un ECR à faible risque de biais. • Il n'est pas certain qu'il y ait des effets indésirables graves (RR 1,04, IC à 95 % de 0,32 à 3,38); très faible certitude à partir de 4 ECR à faible risque de biais.
Recherche de synthèse		
COVID-nma (2021) (9) Revue systématique évolutive Juin 2021* S.O.*	En vigueur jusqu'au 24 juin 2021. Il s'agit d'un résumé évolutif portant sur les ECR d'interventions pharmacologiques, mis à jour chaque semaine. Les résultats pris en compte étaient l'amélioration clinique, la mortalité, la conversion virale négative, les événements indésirables graves, ainsi que le délai d'apparition de ces événements. Une méta-analyse est effectuée pour chaque résultat. L'outil Cochrane Risk of Bias 2.0 est utilisé pour évaluer le risque de biais et l'approche GRADE est utilisée pour évaluer la certitude des preuves. Les résultats sont mis à jour chaque semaine.	26 ECR ont étudié l'ivermectine. 8 avec un risque élevé de biais et 18 avec quelques préoccupations. La taille des essais était de 32 à 476 personnes. Aucun résultat significatif du traitement n'a été rapporté dans les études faisant varier le dosage de l'ivermectine, pour 4 ECR sur l'ivermectine comparée à l'hydroxychloroquine ou 1 ECR sur l'ivermectine + la doxycycline comparées à l'hydroxychloroquine + l'azithromycine Résultats avec au moins un résultat significatif : CAS LÉGERS • 1 ECR sur 18 sur l'ivermectine par rapport au placebo a rapporté un temps plus rapide pour obtenir une PCR négative (TR 2,70, IC à 95 % de 1,21- 6,04, 1 ECR) dans des cas légers. Aucun autre résultat n'était significatif. • 1 ECR sur 4 sur l'ivermectine + la doxycyclinepar rapport au placebo ont montré une meilleure amélioration clinique dans le groupe placebo (RR 0,63, IC à 95 % de 0,45 à 0,87) et un délai plus rapide d'amélioration clinique (TR 0,51, IC à 95 % de 0,32 à 0,81) dans le groupe placebo. CAS HOSPITALISÉS • Un ECR sur l'ivermectine + la doxycycline par rapport à l'ivermectine a rapporté plus d'événements indésirables dans le groupe ivermectine + doxycycline (RR 1,69, IC à 95 % de 1,15 à 2,49).

		• Un ECR sur l'ivermectine par rapport au lopinavir-ritonavir a rapporté un temps plus rapide pour obtenir une PCR négative (TR = 2,02, IC à 95 % de 1,28 à 3,18) chez les patients hospitalisés dans le groupe ivermectine. L'évaluation GRADE des résultats obtenus avec l'ivermectine allait d'une certitude très faible à modérée.
Bryant (2021) (11) Revue systématique Juin 2021* (Cote AMSTAR élevée)	Date de recherche : 26 avril 2021. Les ECR et les quasi ECR ont été inclus. L'objectif était d'évaluer l'efficacité du traitement à l'ivermectine dans la réduction de la mortalité, et dans la chimioprophylaxie, chez les personnes atteintes ou à haut risque d'infection par la COVID-19. Les résultats secondaires comprenaient le séjour à l'hôpital, l'admission à l'hôpital ou à l'USI et les résultats indésirables. La version Cochrane Risk of Bias 2.0 a été utilisée. L'approche GRADE a été utilisée pour évaluer le degré de certitude des preuves.	24 ECR (n=3406 participants) ont répondu aux critères d'inclusion – 22 études sur le traitement. • Sur l'ensemble des 15 ECR, l'ivermectine a réduit le risque de décès à 2,3 % contre 7,8 % chez les cas hospitalisés (RR 0,38, IC à 95 % de 0,19 -0,73, I2=49 %, 15 études) - preuve de certitude modérée. L'analyse de la sensibilité a été robuste. • Pour les cas de COVID modérée/douce, la réduction du risque de mortalité est de 0,24 (IC à 95 % de 0,06 -0,94) et aucune association pour les cas de COVID-19 sévère RR 0,51 (IC à 95 % de 0,22 - 1,14). • Détérioration de l'état de la maladie RR 0,35 (0,19 à 0,65, 7 études). • Aucun avantage de l'ivermectine n'a été identifié dans la prévention de l'admission en soins intensifs ou de la ventilation mécanique - certitude très faible / faible des preuves. • Aucune association avec des événements indésirables - faible certitude.
Roman (2021) (10) Revue systématique Mai 2021* (Cote AMSTAR élevée)	Recherche effectuée le 22 mars 2021 pour les essais contrôlés randomisés (ECR) publiés et prépubliés évaluant les effets du traitement à l'ivermectine sur les patients adultes atteints de la COVID-19. Les principaux résultats étaient la mortalité toutes causes confondues, la durée du séjour (DS) et les événements indésirables (EI). Les résultats secondaires comprenaient la clairance virale et les effets indésirables graves.	Dix ECR (n=1173) ont été inclus. La taille de l'échantillon des ECR varie de 24 à 398 patients, et la gravité de la maladie COVID-19 était légère dans 8 ECR, modérée dans un ECR, et légère et modérée dans un ECR. • L'ivermectine n'a pas réduit la mortalité toutes causes confondues par rapport aux groupes témoins (RR 0,37, IC à 95 % de 0,12 à 1,13, I2=16 %, 5 ECR, qualité des preuves (QP) très faible). ○ Une réduction significative de la mortalité a été observée dans 3 ECR à

	Le risque de biais a été évalué avec l'outil Cochrane RoB 2.0. Une méta-analyse a été réalisée. Des analyses de sous-groupes en fonction de la gravité de la maladie et du risque de biais, ainsi que des analyses de sensibilité en fonction de la durée du suivi ont été réalisées.	haut risque de biais (RR 0,18, IC à 95 % de 0,07 à 0,49; risque de biais pour interaction=0,1) ○ Les analyses de sensibilité excluant les ECR avec un suivi < 21 jours n'ont montré aucune différence dans la mortalité toutes causes confondues. • L'ivermectine n'a pas réduit la durée de séjour par rapport aux groupes témoins (DM 0,72 jours, IC à 95 % de -0,86 à 2,29, I2=0 %, 3 ECR, QP très faible). • Les effets indésirables graves étaient similaires entre les patients traités à l'ivermectine et les groupes témoins (RR 0,95, IC à 95 % de 0,85 à 1,07, I2=0 %, 3 ECR, QP faible) • La clairance virale était similaire entre les patients traités à l'ivermectine et les groupes témoins (RR 0,96, IC à 95 % de 0,79 à 1,16, I2 =0 %, 4 ECR à QP faible)
Hariyanto (2021) (12) Revue systématique (cote AMSTAR modérée)	Date de recherche : 10 mai 2021. Les ECR publiés sur la COVID-19 et l'ivermectine comme traitement des cas de COVID-19 ont été inclus. Résultats : COVID-19 sévère, mortalité, taux de résultats négatifs au test RT-PCR, temps jusqu'à l'obtention de résultats négatifs au test RT-PCR, taux de soulagement des symptômes, temps jusqu'au soulagement des symptômes et temps jusqu'à la sortie de l'hôpital. La qualité de l'étude a été évaluée à l'aide de l'outil d'évaluation d'échelle Jadad pour les études d'essais cliniques. La méta-analyse globale a inclus toutes les études, quelle que soit la sévérité de la COVID-19 incluse dans l'étude. Une analyse de sous-groupe séparant la COVID léger/modéré et sévère a été menée et est notée dans les observations clés où l'hétérogénéité a été expliquée ou un seul sous-groupe est resté significatif. Plusieurs résultats présentaient une hétérogénéité élevée	19 ECR avec 2768 patients atteints de la COVID-19 ont été inclus (10 ouverts et 9 à double insu). L'ivermectine a été associée aux faits suivants : • Réduction de la sévérité de la COVID-19 (RR 0,43 [IC à 95 % de 0,23 à 0,81], I2=65 %, p = 0,008, 8 études, n=1638). ○ L'analyse des sous-groupes n'était significative que pour les cas de COVID-19 légers/modérés : RR 0,44 [IC à 95 % de 0,22 à 0,85], p= 0,01, I2= 47 %, n = 1294. • Réduction de la mortalité (RR 0,31 [IC à 95 % de 0,15 à 0,62], p = 0,001, I2=40 %, 8 études, n-1726) ○ Analyse du sous-groupe des cas de COVID-19 légers/modérés uniquement : RR 0,15 [IC à 95 % de 0,03 à 0,67], p = 0,01, I2 = 0 %, n = 1169 ○ Analyse des sous-groupes des cas de COVID-19 sévères : RR 0,41 [IC à 95 % de 0,16 à 1,04], p = 0,06, I2 = 58 %, n = 377.

	>60 % qui n'était pas expliquée par l'analyse des sous-groupes. Cette variabilité des résultats réduit notre confiance dans le fait que le résumé méta-analytique représente la valeur réelle, et on peut donc s'attendre à ce que la valeur change avec des recherches supplémentaires.	• Taux plus élevé de résultats négatifs au test RT-PCR (RR 1,23 [IC à 95 % de 1,01 à 1,51], *p* = 0,04, I2=91 %, 9 études, n=1205).
		• Temps plus court pour obtenir des résultats négatifs au test RT-PCR (différence moyenne [DM] -3,29 [IC à 95 % de -5,69 à -0,89], *p* = 0,007, I2=96 %, 6 études, n=782).
		• Taux plus élevé de soulagement des symptômes (RR 1,23 [IC à 95 % de 1,03 à 1,46], *p* = 0,02, I2=85 %, 8 études, n=1535).
		• Temps plus court jusqu'au soulagement des symptômes (DM -0,68 [IC à 95 % de -1,07 à -0,29], *p* = 0,0007, I2=68 %, 6 études, n=950).
		  ○ Analyse du sous-groupe des cas de COVID-19 légers/modérés uniquement : DM -0,65 (IC à 95 % de -1,12 à -0,18), *p* = 0,007, I2 = 0 %, 4 études, *n* = 701.
		  ○ Analyse des sous-groupes des cas de COVID-19 sévères : DM -1,00 [IC à 95 % de -1,14 à -0,86], p < 0,00001, I2 = 0 %, 1 étude, n = 69.
		• Temps plus court jusqu'à la sortie de l'hôpital (DM -2,66 [IC à 95 % de -4,49 à -0,82], *p* = 0,004, I2=98 %, 7 études, n=1032).
		L'ivermectine administrée aux cas légers/modérés a permis de réduire davantage la gravité et la moralité.

Karale (2021) *prépublication* (13) Revue systématique Mai 2021* (Cote AMSTAR modérée)	Date de recherche : de février 2020 au 27 mars 2021 Les résultats primaires étaient la mortalité globale, la nécessité d'une admission en unité de soins intensifs (USI); les résultats secondaires étaient les effets indésirables, la nécessité d'une ventilation mécanique. Une méta-analyse à effets aléatoires a été réalisée. Les outils d'évaluation de la qualité Cochrane ROB et du NIH ont été utilisés et les preuves ont été notées en fonction de leur degré de certitude.	La mortalité est rapportée dans 22 études : • Mortalité globale : Les chances de mortalité dans le groupe traité à l'ivermectine étaient significativement plus faibles que dans le groupe témoin (RC 0,39, IC à 95 % de 0,22 à 0,70, p=0,002; I2=81 %), mais les preuves ont été catégorisées comme très faibles. • Essais cliniques sur la mortalité : Analyse en sous-groupe de 15 essais cliniques (ECR N=12, ECNR N=3) et observation d'un bénéfice similaire en termes de mortalité (RC 0,32, IC à 95 % de 0,15 à 0,65, p=0,002; I2 =65 %). • Aucun avantage en termes de mortalité n'a été observé dans les cas graves/critiques, et

	38 études ont été incluses (n=15002) 19 ECR, 14 études d'observation, 6 séries de cas; 30 ont été incluses dans la méta-analyse.	l'ivermectine n'a donc été indiquée que comme pouvant être bénéfique pour les cas légers/modérés. Les résultats de la sévérité de l'admission en USI (n=5 études) et de la ventilation mécanique (n=9) n'étaient pas associés à l'ivermectine. Des événements indésirables sont rapportés dans 10 études. • Les événements indésirables dans les bras utilisés pour administrer le traitement à l'ivermectine n'étaient pas associés au traitement dans 17 études (245 sur 973) par rapport au groupe témoin (234 sur 945). Nous n'avons pas trouvé d'association entre l'ivermectine et le taux d'événements indésirables par rapport aux groupes témoins (RC 0,92, IC à 95 % de 0,64 à 1,33, p=0,67; I2 =14 %).
Murchu (2021) (14) Revue systématique Juin 2021* (Cote AMSTAR modérée)	Date de recherche : 6 janvier 2021. Les essais cliniques (ECR ou ECNR) ont été inclus et l'évaluation du risque de biais a été réalisée à l'aide du Cochrane RoB 2.0 et la certitude des preuves a été évaluée avec GRADE. La revue a évalué les traitements ambulatoires pour la COVID-19. 8 ECR ont été inclus, un seul portait sur un traitement à base d'ivermectine et de doxycycline.	Une étude sur une intervention combinant l'ivermectine orale et la doxycycline, menée en Irak (n=96). Traitement : 200 µg/kg d'ivermectine par voie orale par jour pendant 2 à 3 jours et 100 mg de doxycycline par voie orale deux fois par jour pendant 5 à 10 jours en plus du traitement standard. • Le temps moyen de récupération chez les patients atteints d'une maladie légère/modérée était de 6,34 jours (ET = 2,4) dans le groupe d'intervention, contre 13,66 jours (ET = 6,4) dans le groupe témoin *(P* < 0,01). • Il n'y a pas eu de progression vers une maladie grave, ni de mortalité, ni d'effets indésirables dans cette étude.
Nouveaux ECR		
Vallejos (2021) (15) ECR D'août 2020 à février 2021 Argentine	ECR étude à double insu, contrôlée par placebo (n=501) « IVERCORCOVID19 » Traitement à l'ivermectine pour prévenir l'hospitalisation chez les personnes présentant des cas précoces de COVID-19. La dose était fonction du poids : dose moyenne de 192,37 µg/kg/jour (ET ± 24,56)	• Hospitalisations : 14 sur 250 (5,6 %) dans le groupe traité à l'ivermectine contre 21 sur 251 (8,4 %) dans le groupe placebo (RC 0,65; IC à 95 % de 0,32 à 1,31; p = 0.227). • Le délai d'hospitalisation n'était pas statistiquement différent entre les groupes. • Le délai moyen entre l'inscription à l'étude et la ventilation mécanique invasive était de 5,25 jours (ET ± 1,71) dans le groupe traité à

	Jusqu'à 80 kg : 12 mg/j administrés pendant 2 jours. > 80 kg : 18 mg/j administrés pendant 2 jours. > 110 kg : 24 mg/j administrés pendant 2 jours. L'âge moyen était de 42 ans (ET ± 15.5) et le temps médian depuis l'apparition des symptômes jusqu'à l'inclusion était de 4 jours [intervalle interquartile 3-6]. ClinicalTrials.gov (NCT04529525)	l'ivermectine contre 10 jours (ET ± 2) dans le groupe placebo (p = 0,019). • Aucune différence statistiquement significative dans les autres résultats secondaires, y compris la négativité du test de réaction en chaîne par polymérase et les résultats de sécurité.

PROPHYLAXIE

Trois revues systématiques font état d'ECR et/ou d'essais cliniques sur la prophylaxie qui ont montré un certain effet protecteur de l'apport complémentaire en ivermectine, mais le degré de certitude de ces preuves est très faible à faible

Tableau 2 : Prophylaxie (n=3)

Revue systématique		
Bartoszko (2021) (16) Revue systématique évolutive Mai 2021* (qualité AMSTAR élevée)	Date de recherche : de février 2020 au 27 mars 2021 Comprend des essais randomisés portant sur des personnes à risque de Covid-19 qui ont été assignées à recevoir une prophylaxie ou aucune prophylaxie (soins standard ou placebo). Une méta-analyse en réseau bayésienne à effets aléatoires a été réalisée. Le risque de biais a été évalué à l'aide d'une modification de l'outil Cochrane Risk of bias 2.0 et l'approche GRADE a été appliquée pour évaluer la certitude des preuves.	Vu le risque sérieux de biais et l'imprécision très sérieuse de chaque résultat, cette preuve présentait une très faible certitude. • Les effets de l'ivermectine associée à l'iota-carraghénane sur les cas de COVID-19 confirmés en laboratoire (52 en moins pour 1000, 58 en moins à 37 en moins). • L'ivermectine seule contre les infections à la COVID-19 confirmée en laboratoire (50 en moins pour 1000, 59 en moins à 16 en moins). • L'efficacité de l'ivermectine seule contre une infection suspectée, probable ou confirmée en laboratoire à la COVID-19 (159 en moins pour 1000, 165 en moins à 144 en moins) reste très incertaine.
Bryant (2021) (11) Revue systématique Juin 2021*	Date de recherche : 26 avril 2021. Les ECR et les quasi ECR ont été inclus. L'objectif était d'évaluer l'efficacité du traitement à l'ivermectine dans la réduction de la mortalité, et dans la chimioprophylaxie, chez les personnes atteintes ou à haut risque d'infection par	24 ECR (n=3406 participants) répondaient aux critères d'inclusion – 3 études sur la prophylaxie. • La prophylaxie à l'ivermectine a réduit l'infection à la COVID-19 de 86 % (IC à 95 % de 79 à 91 %, 3 études, 738

(Cote AMSTAR élevée)	la COVID-19. Les résultats secondaires comprenaient le séjour à l'hôpital, l'admission à l'hôpital ou à l'USI et les résultats indésirables. La version Cochrane Risk of Bias 2.0 a été utilisée. L'approche GRADE a été utilisée pour évaluer le degré de certitude des preuves.	participants); faible certitude des preuves. .
COVID-nma (2021) (9) Revue systématique évolutive Juin 2021* S.O.*	En cours jusqu'en juin 2021. Il s'agit d'un résumé vivant des ECR d'interventions pharmacologiques. Les résultats pris en compte étaient l'amélioration clinique, la mortalité, la conversion virale négative, les événements indésirables graves, ainsi que le délai d'apparition de ces événements. Une méta-analyse est effectuée pour chaque résultat. L'outil Cochrane Risk of Bias 2.0 est utilisé pour évaluer le risque de biais et l'approche GRADE est utilisée pour évaluer la certitude des preuves. Les résultats sont mis à jour chaque semaine. 4 ECR ont étudié l'ivermectine comme traitement préventif.	ivermectine contre placebo : 2 ECR • Un effet protecteur de la supplémentation en ivermectine pour prévenir les COVID-19 symptomatiques (RR 0,13, IC à 95 % de 0,08 à 0,21, 1 ECR) ou confirmés (RR 0,20, IC à 95 % de 0,04 à 0,89, 1 ECR) : très faible certitude de preuve. ivermectine contre vitamine C : 1 ECR • Pas de différence dans l'incidence de COVID-19 symptomatique ou confirmé, d'événements indésirables, d'hospitalisation, d'admission en soins intensifs ou de mortalité. ivermectine+iota-carraghénane c. placebo : 1 ECR • L'ivermectine + iota-carraghénane a réduit le risque de COVID-19 confirmé (RR 0,13, IC à 95 % de 0,04 à 0,47), le risque de COVID-19 symptomatique (RR 0,04, IC à 95 % de 0,01 à 0,30), et il n'y a pas eu de mortalité dans les deux groupes.

Méthodes :

Une analyse quotidienne de la littérature (publiée et prépubliée) est effectuée par le groupe des sciences émergentes de l'ASPC. L'analyse a permis de compiler la littérature sur la COVID-19 depuis le début de l'épidémie et est mise à jour quotidiennement. Les recherches visant à extraire les ouvrages pertinents sur la COVID-19 sont menées dans Pubmed, Scopus, BioRxiv, MedRxiv, ArXiv, SSRN et Research Square, et les résultats sont recoupés avec les ouvrages figurant sur la liste de la documentation sur la COVID de l'Organisation mondiale de la Santé et des centres d'information sur la COVID-19 gérés par Lancet, BMJ, Elsevier, Nature et Wiley. Le résumé quotidien et les résultats complets des analyses sont conservés dans une base de données RefWorks et dans une liste Excel qui peut être consultée. Une recherche ciblée par mot clé

est effectuée dans ces bases de données pour identifier les citations pertinentes sur la COVID-19 et le SRAS-COV-2. Les termes de recherche utilisés comprennent : ivermectine.
Cette revue contient des recherches publiées jusqu'au 5 juillet 2021.
Chaque référence potentiellement pertinente a été examinée pour confirmer qu'elle comportait des données pertinentes et les données pertinentes sont extraites pour être incluses dans la revue.

Examen par les pairs

Ce document a fait l'objet d'un examen par les pairs dirigé par un expert en la matière et d'un examen en ce qui concerne la rédaction et la science par le Bureau de la Conseillère scientifique en chef.

Préparé par : Lisa Waddell, LNM, Groupe des sciences émergentes, ASPC.

Connaissances mobilisées par le Bureau de la Conseillère scientifique en chef : phac.ocsoevidence-bcscdonneesprobantes.aspc@canada.ca

Clinical question/ PICO

Population: Patients with COVID-19 infection (all disease severities)
Intervention: Ivermectin
Comparator: Usual care

Summary

Outcome Timeframe	Study results and measurements	Absolute effect estimates Standard care	 Ivermectin	Certainty of the evidence (Quality of evidence)	Plain text summary
Mortality	Odds ratio 0.19 (CI 95% 0.09 - 0.36) Based on data from 1,419 patients in 7 studies. [1] (Randomized controlled)	70 per 1000	14 per 1000 Difference: **56 fewer** per 1000 (CI 95% 63 fewer - 44 fewer)	Very Low Due to serious risk of bias and very serious imprecision [2]	The effect of ivermectin on mortality is uncertain.
Mechanical ventilation	Odds ratio 0.51 (CI 95% 0.12 - 1.77) Based on data from 687 patients in 5 studies. (Randomized controlled)	20 per 1000	10 per 1000 Difference: **10 fewer** per 1000 (CI 95% 18 fewer - 15 more)	Very Low Due to very serious imprecision and publication bias [3]	The effect of ivermectin on mechanical ventilation is uncertain.
Viral clearance 7 days	Odds ratio 1.62 (CI 95% 0.95 - 2.86) Based on data from 625 patients in 6 studies. (Randomized controlled)	500 per 1000	618 per 1000 Difference: **118 more** per 1000 (CI 95% 13 fewer - 241 more)	Low Due to serious inconsistency and imprecision [4]	Ivermectin may increase or have no effect on viral clearance.
Hospital admission (outpatients only)	Odds ratio 0.36 (CI 95% 0.08 - 1.48) Based on data from 398 patients in 1 studies. (Randomized controlled)	50 per 1000	18 per 1000 Difference: **32 fewer** per 1000 (CI 95% 47 fewer - 23 more)	Very Low Due to extreme imprecision [5]	The effect of ivermectin on hospital admission is uncertain.
Serious adverse events	Odds ratio 3.07 (CI 95% 0.77 - 12.09) Based on data from 584 patients in 3 studies. (Randomized controlled)	9 per 1000	27 per 1000 Difference: **18 more** per 1000 (CI 95% 2 fewer - 89 more)	Low Due to very serious imprecision [6]	Ivermectin may increase the risk of serious adverse events leading to drug discontinuation.

Outcome Timeframe	Study results and measurements	Absolute effect estimates Standard care	 Ivermectin	Certainty of the evidence (Quality of evidence)	Plain text summary
Time to clinical improvement	Measured by: days Lower better Based on data from: 633 patients in 2 studies. (Randomized controlled)	11 days (Mean)	10.5 days (Mean) Difference: MD 0.5 fewer (CI 95% 1.7 fewer - 1.1 more)	Low Due to very serious imprecision [7]	Ivermectin may have little or no difference on time to clinical improvement
Duration of hospitalization	Measured by: days Lower better Based on data from: 252 patients in 3 studies. (Randomized controlled)	12.8 days (Mean)	11.7 days (Mean) Difference: MD 1.1 fewer (CI 95% 2.3 fewer - 0.1 more)	Very Low Due to serious imprecision, inconsistency and serious risk of bias [8]	The effect of ivermectin on hospital length of stay is uncertain.
Time to viral clearance	Measured by: days Lower better Based on data from: 559 patients in 4 studies. (Randomized controlled)	7.3 days (Mean)	5.7 days (Mean) Difference: MD 1.6 fewer (CI 95% 4.1 fewer - 3 more)	Very Low Due to very serious imprecision and serious risk of bias. [9]	We are uncertain whether ivermectin improves or worsen time to viral clearance

1. Systematic review (3). **Baseline/comparator:** Control arm of reference used for intervention. We elected to use the control arm of the WHO solidarity trial, reflecting usual care across countries participating in the trial.
2. **Risk of bias: Serious.** The large trial contributing most of the effect estimate was driven by studies that were not blinded.. **Inconsistency: No serious. Indirectness: No serious. Imprecision: Very Serious.** The number of total events was very small.. **Publication bias: No serious.**
3. **Inconsistency: No serious. Indirectness: No serious. Imprecision: Very Serious.** Very few events and credible intervals that include both important benefit and harm.. **Publication bias: Serious.**
4. **Inconsistency: Serious.** The point estimates varied widely and credible intervals do not substantially overlap.. **Indirectness: No serious. Imprecision: Serious.** Credible interval includes no effect.. **Publication bias: No serious.**
5. **Inconsistency: No serious. Indirectness: No serious. Imprecision: Very Serious.** Credible interval includes important benefit and harm.. **Publication bias: No serious.**
6. **Inconsistency: No serious. Indirectness: No serious. Imprecision: Serious.** Credible interval includes little to no difference.. **Publication bias: No serious.**
7. **Inconsistency: No serious. Indirectness: No serious. Imprecision: Very Serious. Publication bias: No serious.**
8. **Risk of bias: Serious.** Result driven by one study that was not blinded.. **Inconsistency: Serious.** Despite overlapping confidence intervals, point estimates discrepant.. **Indirectness: No serious. Imprecision: Serious.** Credible intervals include no difference.. **Publication bias: No serious.**
9. **Risk of bias: Serious.** Concerns around risk of bias.. **Inconsistency: No serious. Indirectness: No serious. Imprecision: Very Serious.** Credible interval includes important benefit and important harm.. **Publication bias: No serious.**

Evidence Snapshot:

Therapeutic or Prophylactic Use of Ivermectin for COVID-19

Context

Ivermectin is a broad-spectrum anti-parasitic agent approved in Canada to treat intestinal strongyloidiasis and onchocerciases infections. Ivermectin is not authorized for use in the treatment of COVID-19 by Health Canada, Food and Drug Administration or the European Medicines Authority. It is also not recommended by the World Health Organization (WHO) or Pan American Health Organization who are maintaining living guidelines on COVID-19 therapeutics. Due to antiviral activity seen in *in vitro* studies, several clinical trials have been conducted to evaluate the therapeutic or prophylactic use of ivermectin for COVID-19.

Key Findings

This evidence brief summarizes systematic reviews and new randomized controlled trials (RCTs) on ivermectin treatment (n=9) or prophylactic use (n=3) in COVID-19 up to July 5, 2021.
The key findings were:

- The WHO living guideline does not recommend the use of ivermectin for treatment of COVID-19 due to low certainty in the evidence and availability of more efficacious treatments.
- Ivermectin trials have been small with very few events reported per trial, thus precision from individual trials was very low. Risk of bias in the majority of trials was moderate or high due to inappropriate randomization or allocation concealment. Taken together the overall certainty in the evidence is low to very low for each outcome.
- Several meta-analyses reported a protective association with ivermectin treatment and mortality, however this was only seen when RCTs of moderate or high-risk bias or non-RCTs were included in the analysis. There was very low certainty in this outcome.
- Only a couple meta-analyses reported an association with reduced severity in the ivermectin treatment group, others reported no association with hospitalization, mechanical ventilation or length of stay.
- There were conflicting results on whether ivermectin decreased the time to viral clearance or symptom resolution.
- There was no evidence for an association with severe adverse effects of ivermectin treatments which ranged from <200ug/kg (safe dosage) to 2-3 times higher across trials.
- Across meta-analyses a protective effect of prophylactic was observed, however the certainty of this evidence was very low to low.

Considerations

There are over 48 registered on-going trials and over 24 completed, some of which are not yet published. Among the on-going trials are larger, placebo-controlled RCTs on ivermectin that may have enough power to address some of the concerns about the existing evidence.

Aperçu des éléments de preuve : **Utilisation thérapeutique ou prophylactique de l'ivermectine pour traiter la COVID-19**

Contexte

L'ivermectine est un agent antiparasitaire à large spectre approuvé au Canada pour traiter les infections intestinales de strongyloïdose et d'onchocercose. L'ivermectine n'est pas autorisée pour le traitement de la COVID-19 par Santé Canada, la Food and Drug Administration ou l'Autorité européenne des médicaments. Elle n'est pas non plus recommandée par l'Organisation mondiale de la santé (OMS) ou l'Organisation panaméricaine de la santé qui maintiennent des lignes directrices évolutives sur la thérapeutique de la COVID-19. En raison de l'activité antivirale observée dans les études *in vitro*, plusieurs essais cliniques ont été menés afin d'évaluer l'utilisation thérapeutique ou prophylactique de l'ivermectine pour traiter la COVID-19.

Principales constatations

Cette note de synthèse résume les revues systématiques et les nouveaux essais contrôlés randomisés (ECR) sur le traitement à l'ivermectine (n=9) ou l'utilisation prophylactique (n=3) contre la COVID-19 jusqu'au 5 juillet 2021.

Les principales conclusions sont les suivantes :

- La ligne directrice évolutive de l'OMS ne recommande pas l'utilisation de l'ivermectine pour le traitement de la COVID-19 en raison de la faible certitude des preuves et de la disponibilité de traitements plus efficaces.
- Les essais sur l'ivermectine ont été de petite taille avec très peu d'événements rapportés par essai, la précision des essais individuels était donc très faible. Le risque de biais dans la majorité des essais était modéré ou élevé en raison d'une randomisation ou d'une assignation secrète inappropriée. Dans l'ensemble, la certitude globale des preuves est faible à très faible pour chaque résultat.
- Plusieurs méta-analyses ont fait état d'une association protectrice entre le traitement à l'ivermectine et la mortalité, mais cette association n'a été observée que lorsque des ECR présentant un risque de biais modéré ou élevé ou des ECNR ont été inclus dans l'analyse. La certitude de ce résultat était très faible.
- Seules quelques méta-analyses ont rapporté une association avec une réduction de la gravité dans le groupe traité à l'ivermectine, d'autres n'ont rapporté aucune association avec l'hospitalisation, la ventilation mécanique ou la durée du séjour.
- Les résultats étaient contradictoires quant à savoir si l'ivermectine diminuait le délai de clairance virale ou de résolution des symptômes.
- Rien ne prouve l'existence d'une association avec les effets indésirables graves des traitements à l'ivermectine, qui varient de < 200 ug/kg (dose sûre) à 2 à 3 fois plus selon les essais.

- Dans toutes les méta-analyses, un effet protecteur de la prophylaxie a été observé, mais le degré de certitude de cette preuve était très faible à faible.

Facteurs dont il faut tenir compte

Il existe plus de 48 essais enregistrés en cours et plus de 24 essais terminés, dont certains ne sont pas encore publiés. Parmi les essais en cours, il y a des ECR de plus grande envergure, avec des placebos comme témoin, sur l'ivermectine qui pourraient avoir une puissance suffisante pour répondre à certaines des préoccupations concernant les preuves existantes.

Emerging Evidence on COVID-19

Rapid Review on the Characteristics of Effective Non-Medical Face Masks in Reducing the Risk of SARS-CoV-2 Transmission

Introduction

What is the evidence on the characteristics (e.g., design, material, fit) and efficacy of non-medical face masks in reducing SARS-CoV-2 transmission? (i.e., prevention of the spread of SARS-CoV-2 if worn by an infectious person or protection afforded to the wearer from inhaling SARS-CoV-2.)

Many public health organizations globally such as the World Health Organization recommend the use of face masks in public spaces to protect against COVID-19. Non-medical face masks (i.e. homemade or manufactured) are not regulated as personal protective equipment as they are not tested according to a set of standardized test methods (e.g., NIOSH, ASTM F2100 or EN 14683) like medical masks are (e.g., N95 respirators and surgical masks). Thus, they are not recommended for use by healthcare professionals and those with an increased risk of infection in situations where physical distancing is not possible (1).

The focus of this review was on the efficacy of non-medical masks for use in the general population during the COVID-19 pandemic. As such, articles that only evaluated respirators or surgical masks were not included in this review. Articles that compare the performance of respirators or surgical masks to non-medical masks are included and benchmarking outcomes were of interest to understand how the performance of different non-medical masks contrasts to the performance of medical masks. This rapid review summarizes literature until December 2, 2020 on evidence of the characteristics of non-medical face masks including the material, design and fit that make masks effective at filtering SARS-CoV-2 while maintaining an appropriate level of breathability. In the context of the COVID-19 pandemic and this review, studies examined masks both as a form of source control (i.e. preventing the spread of SARS-CoV-2 if worn by an infectious person) as well as protection they afford to the wearer from inhaling SARS-CoV-2. There is a synergistic effect when both the virus receiver and spreader wear masks (2).

Key Points

- Fifty-four primary research articles were identified, which included 22 studies investigating the prevention of the spread of SARS-CoV-2 by non-medical masks if worn by an infectious person (source control) and 37 studies investigating the protection provided by non-medical masks to a non-infected individual from inhaling SARS-CoV-2. Studies were conducted utilizing human volunteers (n=15), manikins (n=15), filter-holders (n=34) and animal models (n=1).

- Experimental simulation studies have found that non-medical masks are more effective for source control (Table 1) than protection of uninfected individuals (Table 2). There is a synergistic effect when both the uninfected person and the infected person wear masks (2).
- A face mask can significantly limit the distance respiratory droplets travel during indoor talking, coughing and sneezing, however, the efficacy of non-medical masks depends on three characteristics: 1) filtration efficiency 2) breathability and 3) fit.
- Filtration efficiency depends on the type, size, and velocity of the respiratory droplets and is dependent on the fabric quality (tightness of the weave, fibre or thread diameter) and inherent characteristics of the fabric (e.g., electrostatic charge and hydrophobicity).
- When made of high quality fabrics with multiple layers that fit snuggly around the mouth and nose, non-medical face masks can reduce the risk of spreading or being exposed to SARS-CoV-2, although to a lesser extent than medical masks.
    - Tight-fitting, double-layered masks comprising different material types (e.g., combed cotton and polyester) or masks made from one type of material but with greater than 2 layers exhibited similar outward blocking efficiencies as medical masks (>90%) while still maintaining comparable breathability.
    - Masks that do not fit tightly against the skin were shown to significantly reduce the mask effectiveness and in some studies the reduction was more than 50% in filtration effectiveness.
- A diverse range of non-medical face masks and materials were evaluated for filtration efficiency in 42 studies and a wide range of filtration efficiency results were reported (<10% to >95%).
    - Multiple layers for cloth masks improve filtration efficiency, however breathability decreases with additional layers. Research shows that greater than three layers significantly reduces breathability. Some samples fabricated with three layers were able to reach filtration efficiencies >90%.
    - Filtration efficiencies of most household materials were higher for larger droplets and droplets expelled at lower velocity.
- Studies show the type of fabric and use of mixed fabrics improve the filterability, breathability and longevity (i.e. reusability).
    - Materials used for masks should be a fine or tightly woven fabric. Some fabrics are hydrophobic (e.g., polyester, spunbound polypropylene, or polyaramid) or can capture charged particles via a form of static electricity (e.g., polyester or silk), while others may have hydrophilic properties to enhance comfort and longevity (e.g., cotton).
    - Multiple studies found a triple-layered mask made of a hydrophobic exterior, blended non-woven fabric middle, and hydrophilic interior was found to be an ideal combination to

maximize both the transmission-reducing potential and protection capacity of non-medical masks.

- Some fabrics are not recommended for use in non-medical face masks.
    - Vacuum cleaner bags have been shown to have filtration efficiencies comparable to medical masks, however they are not certified clinical products and may contain unhealthy ingredients and harmful fibers.
    - Loosely folded face masks, bandana-style face masks, and single-layered neck gaiters do a poor job at blocking respiratory droplets and offer little protection. The evidence is highly variable for neck gaiters, several studies showed no protection by neck gaiters, one showed enhanced production of aerosols, while another study reported blocking efficiencies similar to a cotton face mask.
    - Respirators with an exhalation valve can protect the wearer from SARS-CoV-2 but do not prevent virus dispersion by the wearer, and thus are not effective for source control.

Overview of the Evidence

There were 54 primary research articles pertaining to the characteristics and effectiveness of non-medical face masks in reducing the risk of SARS-CoV-2 transmission identified and included in this review. The focus of the review was on the efficacy of non-medical masks for use in the general population. As such, articles that only evaluated respirators or surgical masks were not included in this review. Articles that compare the performance of respirators or surgical masks to non-medical masks are included and benchmarking outcomes were of interest to understand how the performance of different non-medical masks contrasts to the performance of medical masks that are regulated. A rapid review on the use of face masks to prevent COVID-19 in community settings has been conducted and is available through the Emerging Science Secretariat.

The majority of studies included in this review were quasi- and simulation experiments that investigated the blocking/filtration efficiency, breathability and fit (i.e. a measure of how well the mask conforms to the face leaving minimal space or gaps between the mask and the skin) of various non-medical mask materials and styles utilizing human volunteers, manikins, animal models, and/or fabric filter holders. These experiments are an approximation of a real situation and are subject to the limitations of the models used. Manikins do not perfectly mimic human face shapes, movement (i.e. impacting fit) or respiratory activities, so extrapolation of these results to humans should be done with caution. Similarly, experiments using filter holders overestimate mask efficacy as they only evaluate the filterability of the fabric and not the fit of a mask on a person, thus the efficiency of a mask on volunteers or manikins would be expected to be lower due to leakage around the mask. None of the studies identified evaluate how effective specific types of non-medical masks are in real world settings, thus the results of this review only represent the efficacy of different masks evaluated under controlled experimental conditions. Further, while it was possible to compare and rank different

designs/materials/fit within studies, differing methodologies and material combinations made comparisons across studies difficult.

A SARS-CoV-2 virion is 0.1 µm in diameter, but is usually transported within other particles such as respiratory particles that come in a continuum of sizes ranging in size from <1 µm to >5 µm. Please request the review on aerosol transmission for further information. Particle sizes and velocities were not consistent between studies and filtration of different particle sizes varied across fabrics, thus filtration efficiencies are difficult to compare/synthesize. Many studies did not use real respiratory droplets or virus laden particles and instead utilized aerosol dispersion of alternative particles (e.g., NaCl, starch, bacteria, latex, silicon dioxide). The existing research on how effective non-medical masks are is of low quality and results will likely change with additional research.

CONTENTS

NON-MEDICAL MASKS FOR SOURCE CONTROL

Human and manikin studies (n=15):

The effectiveness of non-pharmaceutical interventions, such as social distancing, can be increased by reducing the level of infectious droplets/aerosols in the air of shared spaces (3). In light of the fact that people infected with COVID-19 can be asymptomatic or pre-symptomatic, universal masking in public areas is recommended as a means of source control to reduce exhalation particle dispersion, velocity and potential transmission.

Studies on human volunteers (n=10) and manikins (n=7) have been conducted. Manikins do not perfectly mimic human skin and movement (i.e. impacting fit) or respiratory activities as the air typically travels in only one direction (4).

Non-medical masks are better at source control (blocking viral droplets/aerosols (i.e. limiting transmission from an infected individual) (Table 1) than providing protection to uninfected people (Table 2) (2, 4, 5).

- Fabric masks, such as those made from cotton, are not as effective as medical masks at reducing outward droplet/aerosol dispersal (6, 7). This is likely due to the fabric used in the mask as well as increased air leakage resulting from a looser fit (6, 8).

- Compared to no mask, having a mask reduced the outward droplet/aerosol dispersal, however the magnitude of the reduction varied by the composition of the mask and specific attributes of the experiment (Table 1):
    - A cloth mask (fabric/composition not reported) was effective in reducing the respiratory jet distance while breathing and coughing from beyond the experimental field of view at 562mm (no face mask) to 150mm (similar to a surgical mask) (6).
    - A mask made from quilting cotton reduced the respiratory jet distance from 8ft to 2.5in (8).
    - A person standing 2m from someone coughing without a mask was exposed to over 1000 times more respiratory droplets than from someone standing 5 cm away wearing a basic single layer mask (9).
- Tightly-fitted surgical style masks made with multiple layers that included 100% cotton fabric and middle layers of non-woven polypropylene is very effective in reducing droplet dispersal (3, 10). Duckbill mask designs also demonstrated satisfactory fit and blocking efficiency (11). Breathability was not assessed in these studies. Examples of these styles are provided in the Appendix.
- Double-layered masks perform better at blocking droplets/aerosols during speaking, coughing, and sneezing than a single layer cloth face mask (12).
- A triple-layered cotton mask was found to be just as effective as a surgical mask at supressing respiratory droplet dispersion (86.4% and 99.9%, $p>0.05$, respectively) (13).
- Adding a filter layer such as a kitchen paper towel could significantly reduce the transmission potential (14).
- Loosely folded face masks and bandana-style coverings do a poor job at blocking respiratory droplets (8). When used as a single-layered face covering, polyester neck gaiters are not effective in preventing droplet/aerosol dispersion (14, 15), however, when double-layered, they provide blocking efficiencies similar to that of cloth face masks (16).
- Respirators with a valve do not prevent virus dispersion by the wearer (6, 15).

Filter holder studies (n=7):

Filter holder studies use fabric samples mounted in place by a filter holder and do not take fit of a human face into account, and thus may over-estimate the efficacy of face masks.

- Double-layered masks exhibited better blocking efficiencies than single-layered masks (17-19). Further, double-layered masks comprising different material types (e.g., combed cotton and polyester) or masks made from one type of tightly woven material (e.g., cotton), but with more than 2 layers

exhibited similar blocking efficiencies as medical masks (>90%) while still maintaining comparable breathability to surgical masks (20-23).

- Blocking efficiency is much higher for low-velocity droplets (e.g., generated by speaking) than high velocity droplets (e.g., generating by sneezing) (21).
- Fabric compositions that performed best included hydrophilic materials such as terry cloth, quilting cotton or flannel in combination with a hydrophobic barrier layer comprising nonwoven polypropylene, polyester or polyaramid which prevents more aerosols from getting through the mask (20).
- N95 standards are set using a particle size range of 0.1-0.3 µm. The majority of studies on non-medical masks have also used a similar size range in their experiments. Filtration efficiency for medical masks and many household fabrics was shown to be lower for smaller particles compared to larger droplets. One experiment on ultrafine particles (<0.1 µm) reported N95 respirators and surgical masks had 52.5% and 47.5% filtration efficiencies, respectively (19). In comparison, felted wool (35.87%), quilting cotton (34.54%) and cotton flannel (28.50%) had lower filtration efficiencies for these very small particles (19).
- Layered silk had a 94% filtration efficiency against small aerosol-sized particles (0.75 µm), likely because of its electrostatic charge (18). Silk did not perform as well for larger particles.
- Layered materials, including a hydrophobic outer layer (e.g., polyester, spunbound polypropylene, or polyaramid), an inner layer of high quality cotton fabric, and a middle layer of non-woven or electrostatically charged materials (e.g., natural silk, chiffon, or polyester) would be an ideal combination to maximize both the protection capacity and transmission-reducing potential of non-medical masks.
- A wide range of materials were investigated across studies, some of which may not be safe to use as a mask. Vacuum bags for example were shown to be effective at filtering in more than one study, however, they may have component materials that are unsafe to inhale or come into close contact with the face (19).

Table 1: Studies that investigate source control characteristics of non-medical masks (n=22)

STUDY*	METHOD	KEY OUTCOMES
Experiments conducted with human volunteer(s) and manikins (n=15)		
Ho 2020 (13) Quasi-experiment China	Assessment of the filtration efficiency of a 3-layer cotton mask and a surgical mask worn by adult patients (n=211) with confirmed influenza (n=208) and suspected cases of COVID-19 (n=6) compared with no mask and the background particles in the unoccupied	- The filtration efficiency of the triple-layered cotton mask was 86.4% and the surgical mask was 99.9%. - In both the bedroom and an air-conditioned car, the mean particle concentration for volunteers wearing no mask was significantly higher than in those wearing a surgical mask

Sep 2020	space, in two settings: a bedroom and a car with air conditioning. Four repeat measurements of 1-hr were taken with a particle counter located within 1m of the infected patient. Measurements: the filtration efficiency at 5.5cm/s. Temperature, humidity and cough/sneeze counts were also recorded. Paired t-tests were used for within-group comparisons.	or a cotton mask (p-value < 0.05 in both settings). - The concentration of particles did not significantly differ between a triple-layered cotton mask and a surgical mask in either setting.
Asadi 2020 (7) Quasi-experiment USA Sep 2020	To assess the efficacy of unvented KN95 respirators, vented N95 respirators, surgical masks, homemade single layer paper towel, homemade single layer and double layer t-shirt cotton masks at reducing aerosol particle emission rates from breathing, speaking and coughing by healthy individuals (n=10), study participants were asked to sit with their mouths positioned in front of a funnel attached to an aerodynamic particle sizer (particle counter). They then performed different expiratory activities while wearing or not wearing masks.	- Compared to no mask, both surgical masks and non-fit tested unvented KN95 respirators, reduced the average outward particle emission rates during speaking by 90% and during coughing by 74%. - Cotton masks were difficult to assess. Shedding of non-expiratory micron-scale particulates from fibers in homemade cotton-fabric masks confounded explicit determination of their efficacy as measured particle emission rate for the double-layered mask was not statistically different than no mask at all and single-layered cotton mask was much higher than that of no mask at all.
Fischer 2020 (15) Quasi-experiment USA Sep 2020	Used a simple optical measurement method to evaluate the efficacy of masks to reduce the transmission of respiratory droplets during speech. One human volunteer wore a face mask and spoke into the direction of an expanded laser beam inside a dark enclosure. A cell phone camera recorded droplets that propagated through the laser beam scatter light. A simple computer algorithm was used to then count the droplets. Masks tested included: surgical, valved N95, knitted, polypropylene, Poly/cotton, Maxima AT,	- The fitted N95 mask performed the best with a droplet transmission fraction of 0.1%> surgical > cotton/polypropylene/cotton, 2 layer polypropylene > mask material+ polypropylene swath (loose fit) > 4 different double layer cotton masks, valved N95 > MAxAT, single layer cotton > knitted > bandana > none > neck gaiter. - The neck gaiter performed the worst with a droplet transmission fraction of 110% as the fabric broke larger droplets into a multitude of smaller droplets. - This study has an extremely small sample size and should be used with caution.

	four double-layered cotton masks, one single-layered cotton mask, a neck gaiter, bandana and a fitted N95 (no valve).	
Swain 2020 (14) Quasi-experiment United Kingdom Jul 2020	Humidity was used as a quantitative approximation of viral shedding. At measured distances from a sensor, 4 healthcare staff wearing a mask or no mask were assessed for the change in relative humidity and oxygen saturation, in 3 scenarios over 2 minutes: 1) Hard breathing 65mm 2) Quiet breathing 20cm 3) Hard breathing 20cm The masks tested included a prototype mask from AngelMed (no valve), a standard NHS clinical mask and a FFP2V mask (one-way valve). Homemade masks materials tested included a t-shirt, a double-layered Buff, sock masks (both with and without paper filters, and a homemade mask designed to enable lip-reading (made from a thick material surrounding a clear window).	- Compared to no mask, the AngelMed mask, standard NHS clinical mask and FFP2V mask all significantly prevented a change in humidity. - The t-shirt and double-layered buff were the same as no mask change in humidity for hard breathing @ 65mm scenario (5.4% and 5.1%, respectively). - A two-layer sock mask performed better than a single-layered sock (15.3% vs 9.5%). - The home-made lip-reading mask prevented any increase in relative humidity. However, this mask restricted breathing and was found to reduce oxygen saturation in participants. - Findings are preliminary and caution should be taken when interpreting the results.
Viola 2020 (6) *Preprint* Quasi-experiment United Kingdom May 2020	To compare the air flow ejected by a person wearing no or 7 different face covers while quietly and heavily breathing or coughing, using a Background Oriented Schlieren technique. A human volunteer (n=1) and a manikin were used in the study. Five face masks were studied: FFP1, FFP2, respirator, surgical mask, hand-made mask and two face shields.	- With no face mask, the air jet extended beyond the boundary of the field of view at 562 mm from the mouth after breathing or coughing. - The FFP2 mask was the most effective in reducing all exhaled air dispersal. When not properly sealed to the nose, leakage was observed towards the crown. - The respirator had a valve system that did not stop the displacement of the front through flow, thus offering no prevention of virus dispersion from the wearer.

		- The handmade mask (composition not described) was the least effective in stopping air leakage, and the surgical mask was the least effective in preventing backward jet flow. - Findings are preliminary and caution should be taken when interpreting the results.
Bandiera 2020 (9) *Preprint* Quasi experiment United Kingdom Aug 2020	Assessed effectiveness of surgical masks and single layer cotton masks at mitigating large respiratory droplet dispersion with speaking and coughing simulations in manikins. The number of droplets from the manikin/air compressor were quantified using laser sheet illumination and UV-light for those that had landed at table height at up to 2m. For human volunteers (n=6) wearing surgical masks during speaking and coughing, expiratory droplets were caught on a microscope slide 5cm from the mouth.	- Estimated that a person standing 2m from someone coughing without a mask is exposed to over 1000 times more respiratory droplets than from someone standing 5cm away wearing a basic single layer mask. - Face coverings show consistent efficacy at blocking respiratory droplets of 20-30µm for speaking and coughing simulations ($p<0.05$). - No statistically significant difference in droplet deposition was seen between the surgical mask and the single layer cotton mask. - No droplet deposition occurred with wearing a surgical mask by the volunteers.
Stubington 2020 (11) Quasi experiment United Kingdom Aug 2020	A single volunteer wore several masks and was filmed exhaling visible water vapour, to test the trajectory of exhaled material from a masked individual.	- Flexible pleated and solid FFP masks directed exhaled material downwards, exceeding 25cm. - Duckbill masks directed exhaled material laterally, producing a smaller plume. - Wearing a visor provided no reduction in plume size of exhaled vapour for any mask type. - Fluid repellent material reduced the exhaled material traveling downwards.
Rodriguez-Palacios 2020 (10) Quasi Experiment	The effectiveness of cotton masks in retaining/reducing the risk of environmental contamination by oral/saliva droplets produced by one of the investigators (a healthy volunteer) during a speech trial (counting from 1	- The same cotton mask on a human volunteer, demonstrated even a single layer of the material reduced the risk of environmental contamination by oral/saliva droplets compared to no mask.

USA Aug 2020	to 100 in English) conducted at 30cm over a sterile TSA agar plate. (Table 2 has the protective effect animal model experiment).	
Bahl 2020 (12) Quasi Experiment Australia Jul 2020	This study evaluated the effectiveness of the Centers for Disease Control and Prevention (CDC) recommended one- and two-layer cloth face covering against a three-ply surgical mask. The single-layer covering was made using 'quick cut T-shirt face covering (no-sew method)' and the two-layer covering was prepared using a no sew method recommended by CDC. To provide visual evidence of the efficacy of face coverings, a tailored LED lighting system along with a high-speed camera were used to capture the light scattered by droplets and aerosols expelled during speaking, coughing and sneezing by a single volunteer.	- Based on visualizations (photos in the paper and no analysis) of speaking, coughing and sneezing, a single-layer cloth face mask reduced the droplet spread, a double-layer covering performed significantly better with very little visible droplets upon sneezing only, and the surgical mask performed best by preventing droplet spread from any respiratory emission.
Pan 2020 (4) *Preprint* Simulation experiment USA Nov 2020	Evaluated the effectiveness of 11 face masks in a manikin model for material filtration, inward and outward protection across broad aerosol size range 0.04-135µm. Challenge particles were generated from a 2% NaCl solution. They evaluated both inward and outward protection efficiency of face masks using two manikins mounted on opposite sides of a 57-L acrylic chamber. The "exhaling" manikin was connected to a nebulizer and the "inhaling" manikin was connected to a vacuum. A mask was worn by the inhaling manikin and then the exhaling manikin, to measure the number of	- Filtration efficiency increased with increasing particle size and prevented droplets larger than 20µm from spreading 33 cm away. - Particles 2µm had >90% efficiency using the vacuum bag, microfiber cloth, surgical mask, and MERV 12 filter. - The vacuum bag and microfiber had the highest filtration efficiencies, with a range of 60-90%, surgical masks ~50-75%, coffee filter 10-75% over particle sizes (0.04-1µm). - The thin cotton mask and bandana (2 ply), had low efficiencies (30-50%), with even lower efficiencies (5-40%) for submicron particles.

	particles that passed through the mask, respectively. Face mask: Vacuum bag, surgical mask, MERV 12 filter, Bandana, 200-thread count cotton pillowcase, cotton t-shirt, microfiber cloth, coffee filter, thin cotton, thin acrylic and a plastic face shield.	- Inward protection efficiency and outward protection efficiency were similar for most of the masks. - Loose fitting masks (e.g., the bandana) did not perform as well for source control. - The thin acrylic mask performed the worst. - The combined effects of reduced gaps and reduced air velocity resulted in a high outward protection efficiency for the CDC non-sewn mask made from a 200-thread count cotton pillowcase.
Lindsley 2020 (16) *Preprint* Simulation experiment USA Nov 2020	A cough aerosol simulator with a pliable skin manikin headform was used to propel small aerosol particles (<0.6 to 7 µm) into a N95 respirator, a medical grade procedure mask, a 3-layered cotton cloth mask, a polyester neck gaiter and a face shield. The simulated cough aerosol was generated by nebulizing a solution of 14% KCl and 0.4% sodium fluorescein. Fit tests were conducted using a PortaCount.	- All face masks significantly reduced the aerosol released into the environment ($p<0.0001$), except for the face shield. - The N95 respiratory blocked 99% of aerosols, the medical procedure mask blocked 59%, the cloth mask blocked 51%, the single-layer gaiter blocked 47%, the double-layer gaiter blocked 60% and the face shield only blocked 2%. - Blocking efficiencies for all masks increased with increasing particle size. - The N95 respirator had the best fit, followed by the medical procedure mask, the double-layer gaiter, the single-layer gaiter and the cloth mask.
Kähler 2020 (5) Simulation experiment Germany Oct 2020	Quantitative particle image velocimetry measurements helped determine the spread of exhaled air, the velocity of the exhaled droplets and the turbulence properties of the flow. A single human volunteer was used to observe the flow field generated by coughing without and with a surgical mask using smoke to demonstrate the effect of the gap around the mask edge (surgical and FFP2 masks).	- A surgical mask limited the spread of air and aerosol when speaking or coughing. - Mouth-and-nose covers and surgical masks did not fit tightly enough on the face to protect against droplet infection, as demonstrated by photographic evidence of droplets passing unhindered through the mask. - Masks made from toilet paper with 4 layers, paper towel, coffee filters, fleece and microfiber cloth had low filtration.

	The filtering performance of the different materials on small aerosols (0.3–2µm) was observed with a digital camera in front of and behind the filter material.	- Vacuum cleaner bags with fine dust filters demonstrated comparable filtering effect to FFP2/N95/KN95 masks, but are not suitable for use.
Ueki 2020 (2) Simulation experiment Japan Oct 2020	This study describes an airborne transmission simulator of infectious SARS-CoV-2-containing droplets/aerosols produced by human respiration and coughs. It is used to assess the transmissibility of the infectious droplets/aerosols and the ability of various types of face masks to block the transmission. A test chamber utilized 2 manikin heads placed facing each other connected to a customized compressor nebulizer. Cotton masks, surgical masks and N95 masks were evaluated.	- The N95 mask had the highest protective efficacy (reduced exposure to infectious particles by 80-90%). - Surgical masks and N95 masks were not able to completely block the transmission of virus droplets/aerosols even when completely sealed. The viral load passing through a fitted N95 mask when worn by the spreader was 0.3 $\log_{10}$ copies and when worn by the receiver was 10 $\log_{10}$ copies. - A cotton mask (no description of composition) led to a 20-40% reduction in virus uptake compared to no mask. - Cotton and surgical masks were better at blocking virus dispersion by the wearer (>50%) (i.e., as a form of source control) than protection. - There was a synergistic effect when both the virus receiver and virus spreader wore masks (cotton masks or surgical masks). For example, when the receiver wore a cotton mask the viral load passing through the mask was 63 $\log_{10}$ copies, when the spreader wore a mask the viral load passing through was 42 $\log_{10}$ copies and when both the receiver and spreader wore a mask the viral load was the lowest at 33 $\log_{10}$ copies. See graphs in paper.
Edwards 2020 (3) *Preprint*	This randomized effectiveness study used a 10% NaCl nebulized polydisperse particle solution (0.3 µm up to 10 µm in size) delivered by an exhalation simulator and manikins to conduct 94 experiment runs with	- Non-medical grade mask designs or fabric combinations are statistically significant in reducing airborne dispersion of particles from exhalation compared to no mask. - Fabric, mask design and the interaction of fabric and exhalation breath level have a

Simulation experiment USA Aug 2020	combinations of 8 different fabrics, 5 mask designs and airflows for both talking and coughing. Two novel metrics of Filtration Efficiency Indicator (FEI) and Expiratory Flow Dispersion Factor (EDF) are established in this study to present quantitative values that give relative indicators to the dispersion control performance of non-medical masks. Higher values in both these metrics indicates better filtration and performance with more reduction in particle velocities, respectively.	significant effect on filtration efficiency of exhaled particles. - The best overall performing mask design was a surgical style with internal non-woven layers. - The best overall fabric depends on a reduction in velocity, change in direction or increased filtration performance. - The FEI values for various materials from best to worst were: Bath towel > Sweat pant > T-shirt > Bandana > Microfiber towel > Pillow case > Mover blanket > Dress shirt. - The EDF values for various materials from best to worst were: Pillow case > Microfiber towel > Sweat pant > Bath towel > T-shirt > Dress shirt > Mover blanket > Bandana.
Verma 2020 (8) Simulation experiment USA Jun 2020	This study uses qualitative visualizations of emulated coughs and sneezes using a manikin head to examine how material- and design-choices impact the extent to which droplet-laden respiratory jets are blocked.	- Loosely folded face masks and bandana-style coverings provide minimal stopping-capability for the smallest aerosolized respiratory droplets. - Well-fitted homemade masks with multiple layers of quilting fabric, and off-the-shelf cone style masks, proved to be the most effective in reducing droplet dispersal. These masks did have some leakage through the mask material and from small gaps along the edges.
Filter holder studies to assess source control characteristics of mask materials (n=7)		
Aydin 2020 (21) Simulation experiment USA Jul 2020	This study investigated the performance of 11 household fabrics reducing droplet dispersion, using a commercial medical mask as a benchmark. Also assessed was their breathability (air permeability), texture, fiber composition and water absorption properties. Filtration efficiency of large, high-velocity droplets was assessed by	- Most single-layered fabrics had a relatively high droplet blocking efficiency (median values>70%) when challenged with high velocity droplets representative of sneezing, coughing or speaking. - The medical mask had a blocking efficiency of 98.5%. - Two or 3 layers of fabric, such as T-shirt cloth, blocked droplets with an efficacy similar to

	placing the fabrics 25mm in front of the nozzle of an inhaler, loaded with a suspension of 100nm fluorescent beads. Low-momentum droplets were assessed by placing the fabric 300mm from the inhaler. Air permeability was assessed using a plug flow tube experiment. Test fabrics included: polypropylene medical mask, 100% cotton t-shirts, 100% cotton quilt cloth, cotton and polyester blend t-shirts, polyester bed sheet, polyester and polyamide blend dishcloth, and silk shirts.	that of medical masks (>94%), while still maintaining comparable breathability. - Blocking efficiency by T-shirt fabric is much higher for low-velocity droplets than high velocity droplets. - Less breathable fabrics are more effective in blocking droplets.
Xiao 2020 (18) Simulation experiment Japan Jun 2020	Efficiency of surgical masks, gauze masks, gauze, cotton, silk, linen and tissue paper on blocking micro-droplet sized starch particles (average 8.2µm) and latex microspheres (0.75µm) with a velocity of 44.4m/s (high-velocity sneeze conditions) created by centrifugation was qualitatively analyzed using imaging-based analysis.	- The cotton gauze mask was the most efficient at blocking starch particles (90.4% blocking efficiency), followed by 2 layers of cotton (89.0%). Other materials ranged from 76.4%-87.9% efficiencies, while 8 layers of gauze performed very poorly (36.7%). The surgical mask blocked 78.2% of particles. - When latex microspheres were used to mimic aerosol-sized particles, materials with the best blocking efficiencies were the 4 layers of silk (93.8%), likely because of electrostatic charge, the gauze mask (78.5%) and the 2 layers of cotton (74.6%). - Multi-layered linen performed significantly better than a single layer (66.5% vs. 53.2%).
O'Kelly 2020 (19) Simulation experiment USA	In this study, 20 commonly available fabrics and materials were evaluated for their ability to reduce air concentrations of ultrafine particles (0.1µm and smaller in diameter) at a face velocity of 16.5m/s (coughing velocity). Further assessment was made on the filtration ability of select fabrics while damp and of fabric combinations which might be	- Ultrafine particles used in this study lead to a low 'baseline' for filtration efficiency. - The N95 mask (52.47%), surgical mask (47.46%), and disposable HEPA vacuum (60.86%) had had the highest filtration efficiencies.

Jun 2020	used to construct homemade masks. Breathing resistance was estimated based on qualitative feedback. In this study, filtration efficiency represents the percent of particles a filter medium can block. Fabrics tested included: Felt, Lycra, washable vacuum bags, and quilt batting/wadding and various weaves of cotton commonly available, including quilting cotton, shirting cotton and cotton jersey knit.	- Denim jeans (45.94%) and windbreaker fabric (47.12%) were efficient, but lacked breathability. - High filtration efficiency and low breathing resistance materials included felted wool (35.87%), quilting cotton (34.54%), and cotton flannel (28.50%). - Common fabrics were able to achieve much higher levels of ultrafine particle filtration when layered (60%), but were less breathable. - Vacuum bags were effective, but are unsafe for use.
Foschini 2020 (17) *Preprint* Simulation experiment Brazil May 2020	This study compares the relative efficiencies of commercial respiratory masks (medical masks) and homemade fabric masks. A nebulizer was used to create the aerosol from distilled water. For the optical scattering measurements 2 different techniques were used simultaneously to compare the intensity of light dispersion by the droplets between the windows before and after the sample.	- The N95 respirator and surgical mask (99.7%) had the highest blocking efficiencies. - The coffee filter also had high blocking efficiency (99.6%) but low breathability and degraded with increasing humidity, making paper products a poor choice for mask material. - Confectioner masks (51.0%), do not have as many layers as surgical masks, thus reducing their efficiency. - Conventional fabrics with a higher cotton content were the most effective of the household fabrics (1-layer: 46.5%). Double layering increased the blocking efficiency (2-layers: 66%).
Lustig 2020 (20) Simulation experiment USA May 2020	In this study, over 70 different common fabric combinations and masks were evaluated under steady-state, forced convection air flux with pulsed aerosols that simulate forceful respiration.	- Effective materials (lower fractional transmission estimates) comprise both absorbent, hydrophilic layers and barrier, hydrophobic layers. - Effective designs are noted with absorbent layers (double-layered) comprising terry cloth towel, quilting cotton, and flannel. These commonly available mask materials exhibit

		fractional transmissions within 10% of the five-layer N95 respirator. - Effective designs had barrier layers comprising nonwoven polypropylene, polyester and polyaramid. - Many masks made from either a single-layer or one type of fabric exhibited higher fractional transmissions than the N95 respirator.
Rodriguez-Palacios 2020 (22) Simulation experiment USA May 2020	This study assessed household textiles to quantify their potential as effective environmental droplet barriers. They used a bacterial-suspension spray simulation model of droplet ejection (mimicking a sneeze) to quantify the extent to household clothing fabrics reduce the dispersion of droplets onto surface within 1.8m (the minimum distance recommended for COVID-19 "social distancing"). Textiles tested included: 100% combed cotton (T-shirt material), 100% polyester microfiber 300-thread count fabric (pillow case), 2 loosely woven "homespun" 100% cotton fabrics, and "dry technology" 100% polyester common in sport jerseys. These textiles were compared to no "mask", and medical/surgical mask material.	- When no mask was used, a simulated sneeze could transport bacteria-carrying droplets farther than 1.8m. - All single-layered textiles were able to significantly reduce the ejection of macro-droplets and micro-droplets to <25.5-34cm. - Double-layered textiles (of 100%-combed cotton and 100% polyester) completely prevented the ejection of large macro-droplets, and reduced the ejection of micro-droplets by 97.2% (P<0.020) vs. single-layers and dispersion to <10cm. Even the least effective single-layered textile (loosely woven homespun 100% cotton) achieved a 90-99% droplet retention improvement when double-layered. - Double-layered textiles were as effective as medical/surgical mask material for preventing droplet dispersion.
Amendola 2020 (23) Simulation experiment Italy	The experiment simulated respiratory action measuring the distribution of aqueous-based aerosol particles. The average filtration efficiency was reported taking into account the particles with diameters greater than 0.28µm. The face masks were tested in both the inhalation and exhalation direction.	- The medical face mask demonstrated filtration efficiencies higher than 97%. - Only the face masks fabricated with 3 layers mainly constituted by non-woven fabric material were able to reach values higher than 95% including triple-layer TNT, TNT-cotton-TNT mask.

May 2020	TNT= A non-woven material made of fabric-based polypropylene and viscose

NON-MEDICAL MASKS FOR PROTECTION FROM INHALING SARS-COV-2

Human, manikin and animal model studies (n=17):

Studies on human volunteers (n=7), manikins (n=10) and experimental germ-free mice (n=1) have been conducted. Manikins do not perfectly mimic humans (i.e. impacting fit) or respiratory activities as the air travels in only one direction (4). Thus, caution should be used when extrapolating the manikin results to human face mask wearers.

While non-medical masks have been shown to function better as a form of source control (i.e. limiting transmission from infected individuals) (2, 4, 5), they have also been shown to offer some protection to the wearer (Table 2). The most effective transmission-reducing scenario is one when everyone (both healthy and infected) wears a face mask (2).

- Proper fitting N95 respirators offer the highest degree of protection (>95%) (2, 24-31). Improper fitting N95 respirator offer a range of protection, in some cases comparable to surgical and cloth masks (24, 30).
- Surgical masks have better filtration efficiencies than non-medical masks (range: 19.94%->95%) (4, 25-28).
- Cloth masks generally had lower filtration efficiencies compared to medical masks although certain fabrics and layers performed comparably to medical masks (4, 25, 27, 28).
    - Mask performance (filtration of respiratory droplets, minimal air leakage) was higher for tighter fitting masks (5, 24-26, 30, 32) and for multi-layered masks (29, 31, 33). Filtration efficiency was higher for larger particles (4).
- Silk was found to be very hydrophobic and effective at impeding penetration of water droplets during spray tests (34).
- Bandana's and single-layered cotton fabrics were found to fit and perform poorly (<15-30% efficiency) (4, 27-29, 31).
- Surgical-style non-medical cloth masks did not perform as well as cone or duckbill shaped masks (26, 35).
- In an animal model study, when protected by two layers 100% combed cotton, all mice were 100% protected from becoming contaminated by the bacteria contained in the microdroplets (10).

Filter holder studies (n=20):

Under experimental conditions (i.e. measurements taken while fabric was sealed to a holder) the filtration efficiencies were higher compared to the studies cited above where masks were tested while on a wearer (36-42). Thus, these experimental simulations overestimate the efficacy of household fabrics in protecting potential wearers from SARS-CoV-2 because they do not directly assess breathability or fit, but they do help to understand the relative filtration efficiency of one fabric compared to another.

- Increasing the number of layers increases the filtration efficiency, but increases air resistance (and therefore lowers breathability). Non-medical masks should have an air resistance <40 Pa/cm2) (41-49). All samples tested with <four layers had breathability values below the maximum NIOSH recommendations set for medical masks (50). Samples fabricated with three or more layers were able to reach filtration efficiencies >90% (23, 37, 40, 42-44, 50, 51).
- Simulated leaks in the fabric (to indirectly measure the effect of fit) have been shown to strongly impact filtration efficiency (44, 52). Thus, fit is very important for adequate protection.
- Non-medical masks did not perform as well as medical masks. However, the addition of an activated carbon filter as a middle layer in a cotton mask significantly improved the filtration efficiency (46, 53). One study found that treating household materials with a NaCl solution may be useful in increasing the filtration ability of non-medical masks (54).
- Huge filtration efficiency differences were found between house-hold materials and for different particle sizes, ranging from <10% to >95%. Filtration efficiencies were higher for slower-moving particles produced during talking vs. faster moving particles produced during coughing or sneezing (46).
- Quality of fabric (i.e. tight weave, low porosity) was just as important as the number of layers (43, 44, 46).
- Some fabrics have electrostatic charges that attract and bind nanometer-sized particles, resulting in increased filtration efficiency (44, 52, 55). Combining layers and leveraging mechanical and electrostatic filtering may be effective in maximizing filtration efficiency in a non-medical mask (44, 52). Layered materials, including a hydrophobic outer layer (e.g., polyester, spunbound polypropylene, or polyaramid), an inner layer of high quality cotton fabric and a middle layer of non-woven or electrostatically charged materials (e.g., natural silk, chiffon or polyester) would be an ideal combination to maximize both the transmission-reducing potential and protection capacity of non-medical masks.
- While vacuum cleaner bags have been shown to have filtration efficiencies comparable to medical masks (4, 5, 40, 42, 46, 50), they are not certified clinical products and may contain unhealthy ingredients and harmful fibers. It is not recommended to use the material for homemade masks (5).

Table 2: Studies that assess the protective characteristics of non-medical masks (n=37)

STUDY*	METHOD	KEY OUTCOMES
Experiments conducted with a human volunteer(s), manikins, or animal models (n=17)		
Park 2020 (31) Quasi-experiment USA Aug 2020	In this mask development study, 10 different samples of various material configurations were evaluated for air permeability, particle size filtration efficiency and pressure drop, to arrive at a mask design with optimal comfort and barrier efficacy. One human subject wore the test mask for extended periods of time simulating a typical workday and assessed its performance. Air permeability was assessed with method ASTM D737-96, and filtration and pressure drop were assessed with ASTM F2299-03 with particle sizes 0.2-1µm and air flow of 8.7cm/s.	- Medical masks had the highest filtration efficiency while handkerchief fabric was found to perform the worst (highest air permeability and a filtration efficiency of only 19% even with 4 layers). - The barrier configuration deemed optimal was 'Filter 2 (Pile Up)' between two 100% polyester barrier layers. This mask performed better for filtration and permeability than the commercial double-layer knitted mask evaluated. - Filtration efficiency was better for larger challenge particles than smaller particles.
O'Kelly 2020 (24) *Preprint* Quasi-experiment USA Aug 2020	Seven human volunteers were used to quantitatively evaluate the level of fit offered by various types of masks (N95 masks, a KN95 mask, a surgical mask and fabric masks), and most importantly, assess the accuracy of implementing fit checks by comparing fit check results to quantitative fit testing results. Quantitative fit testing simultaneously assesses the number of particles inside and outside a mask Fit factor scores were derived from the number of particles filtered by the mask.	- N95 masks offered the highest degree of protection. Averaged fit scores across different models ranged from 13.2-72.3. - Poorly fit N95 masks offered a range of protection, in some cases comparable with surgical and cloth masks. - The KN95 and surgical mask showed an average fit score of 3.2 and 2.2., respectively. - The fabric face masks tested produced similar fit scores to KN95 masks and surgical masks. - Improved design coupled with the use of better materials would likely raise the effectiveness of these masks.

	Each participant completed one quantitative fit test and one subjective fit-check per mask.	
Mueller 2020 (26) Quasi-experiment USA May 2020	Quantified the efficacy of community- and commercially-produced fabric masks as personal protective equipment with the use of two particle counter that concurrently sampled ambient air and air inside different types of masks worn by a single volunteer. Mask performance was then evaluated by mean particle (size < 0.3µm) removal efficiency and statistical variability when worn as designed and with a nylon over layer, to independently assess fit and material.	- The properly fitted N95 mask had the greatest mean removal efficiency (99%) and a high fit factor. - When a poor fitting N95 mask was used, the removal efficiency and fit factor decreased to 90.6% and 10.6, respectively. - Standard surgical masks and 4 layer masks with a charcoal layer had a mean removal efficiency of 50-75%. - Cloth mask particle removal efficiencies ranged from <30% to 90%. The best performing cloth masks were cone shaped and included a layer of melt blown filter fabric between fabric cover layers. - Surgical-style cloth masks did not perform as well as cone shaped masks, but were enhanced by a nylon over layer. - A nylon over layer did not provide significant filtration efficiency, but improved the snugness of the fit of the mask underneath.
Ueki 2020 (2) Quasi experiment Japan Oct 2020	This study describes an airborne transmission simulator of infectious SARS-CoV-2-containing droplets/aerosols produced by human respiration and coughs. It is used to assess the transmissibility of the infectious droplets/aerosols and the ability of various types of face masks to block the transmission. A test chamber utilized 2 manikin heads placed facing each other connected to a customized compressor nebulizer.	- The N95 mask had the highest protective efficacy (reduced exposure to infectious particles by 80-90%). - Surgical masks and N95 masks were not able to completely block the transmission of virus droplets/aerosols even when completely sealed. The viral load passing through a fitted N95 mask when worn by the spreader was 0.3 $\log_{10}$ copies and when worn by the receiver was 10 $\log_{10}$ copies. - A cotton mask led to a 20-40% reduction in virus uptake compared to no mask. - Cotton and surgical masks performed much better at blocking virus dispersion by the

		wearer (>50%) (i.e. as a form of source control) than protection. - There was a synergistic effect when both the virus receiver and virus spreader wore masks (cotton masks or surgical masks). For example, when the receiver wore a cotton mask the viral load passing through the mask was 63 log_{10} copies, when the spreader wore a mask the viral load passing through was 42 log_{10} copies and when both the receiver and spreader wore a mask the viral load was the lowest at 33 log_{10} copies. See graphs in paper.
Teesing 2020 (35) Quasi experiment Netherlands Oct 2020	A closed particle chamber was built to test potential filter materials found to be recommended by governments for homemade masks. Materials were tested alone, as well as between 2 layers of cotton, simulating a homemade mask. Various mask designs were tested: folded, pleated, round, flat and duckbill shapes. Mask fit was tested with an AccuFIT 9000 Respirator Fit Test apparatus and a human volunteer. A pressure test was conducted to quantify breathability of designs and materials for those passing the fit test.	- Particle testing of materials was compared to N95/FFP2/KN95 masks; and the best performing material was ePM_1 85%, while from readily available materials top performance came from leather, followed by a folded coffee filter between cotton layers, a folded paper towel between cotton and microfiber fabric. - None of the cotton masks with an inserted filter passed the fit test conducted. The duckbill model was found to have a satisfactory fit. - The duckbill design pressure drop was tested and the single and folded tea towel showed comparable breathability to the 3M reference mask.
Mboowa 2020 (41) *Preprint* Quasi experiment Uganda	Eight commercially available masks were tested for filtration efficiency breathability, microbial cleanliness, and re-usability. Mycobacterium smegmatis was aerosolized by a hand-held sprayer and directed at sections of filter-	- The filterability was best in surgical face masks > local double-layered face mask > double-layered cloth masks. - Treatment with 70% ethanol decreased fitness and re-usability. - Double-layered masks had the best fit as evidenced by the saccharine taste test. It took

Sep 2020	holder mounted face masks. The filtered air was inoculated on agar media. Volunteers wearing face masks were challenged with saccharine (taste test) to evaluate mask fit. Tests were repeated after washing or 70% ethanol treatment to assess re-usability. Masks tested included: polypropylene, "thick" material, kitengi (inside)/cotton (outside), cloth, surgical and face scrub cloth.	more sprays for the volunteer to taste the saccharine when wearing double-layered mask than a single-layered masks. - Caution should be used in interpreting these results, the methodology is unclear.
Rodriguez-Palacios 2020 (10) Quasi experiment USA Aug 2020	This study reported an *in vivo* experiment with bacteria-carrying microdroplets (probiotic-cultured dairy product bacteria) to determine to what extent double-layered 100% combed cotton (common T-shirt material) prevented contamination of germ-free mice using a spray simulation method. Two different fabric densities were tested: 120 and 200 g/m2. (Table 1 reports on the source control experiment)	- When protected by 2 layers 100% combed cotton, all mice were 100% protected from becoming contaminated by the bacteria contained in the microdroplets (2mL spray). - When exposed to 10x the spray volume (20mL) textile barriers still protected all mice (even with low textile density; heavy vs. light fabric, paired t-test, p = 0.002) against high droplet doses. - The same experiments on partly covered cages resulted in microbial contamination of all mice.
Pan 2020 (4) *Preprint* Simulation experiment USA Nov 2020	Evaluated the filtration efficacy of 11 face masks in a manikin model for inward and outward protection across a broad range of aerosols 0.04-135 µm. Challenge particles were generated from a 2% NaCl solution. Two manikins mounted on opposite sides of a 57-L acrylic chamber were used. The "exhaling" manikin was connected to a	- Filtration efficiency increased with increasing particle size and prevented droplets larger than 20µm from spreading 33cm away Particles 2µm had >90% efficiency using the vacuum bag, microfiber cloth, surgical mask and MERV 12 filter - The vacuum bag and microfiber had the highest filtration efficiencies, with a range of 60-90%, surgical masks ~50-75%, coffee filter 10-75% over particle sizes (0.04-1 µm).

	nebulizer and the "inhaling" manikin was connected to a vacuum. A mask was worn by the inhaling manikin and then the exhaling manikin, to measure the number of particles that passed through the mask, respectively. Face masks: Vacuum bag, surgical mask, MERV 12 filter, Bandana, 200-thread count cotton pillowcase, cotton t-shirt, microfiber cloth, coffee filter, thin cotton, thin acrylic and a plastic face shield.	- The thin cotton mask and bandana (2-ply), had low efficiencies (30-50%), with even lower efficiencies (5-40%) for submicron particles. - Inward protection efficiency and outward protection efficiency were similar for most of the masks. - Loose fitting masks (e.g., the bandana) did not perform as well for source control. - The thin acrylic mask performed the worst. - The combined effects of reduced gaps and reduced air velocity resulted in a high outward protection efficiency for the CDC non-sewn mask made from a 200-thread count cotton pillowcase.
Kähler 2020 (5) Simulation experiment Germany Oct 2020	Quantitative particle image velocimetry measurements helped determine the spread of exhaled air, the velocity of the exhaled droplets and the turbulence properties of the flow. A single human volunteer was used to observe the flow field generated by coughing with and without a surgical mask using smoke to demonstrate the effect of the gap around the mask edge (surgical and FFP2 masks). The filtering performance of the different materials on small aerosols (0.3–2µm) was observed with a digital camera in front of and behind the filter material.	- A surgical mask limited the spread of air and aerosol when speaking or coughing. - Mouth-and-nose covers and surgical masks did not fit tightly enough on the face to protect against droplet infection, as demonstrated by photographic evidence of droplets passing unhindered through the mask. - Masks made from toilet paper with 4 layers, paper towel, coffee filters, fleece and microfiber cloth had low filtration. - Vacuum cleaner bags with fine dust filters demonstrated comparable filtering effect to FFP2/N95/KN95 masks, but are not suitable for use.
Hill 2020 (30)	Masks are tested to compare efficiency of a material itself (baseline) with the filtration	- Baseline filtration found a single layer of 500 thread count cotton to have the lowest filtration efficiency (26.2% and 17.4% for 60

Simulation experiment USA Sep 2020	efficiency observed for a mask being worn. Silicon dioxide nanoaerosol was created with media diameter of 40nm and added to a stainless steel enclosure. Baseline filtration efficiency was tested with material clamped (no tension) and an airflow of 0.0465 LPM/cm^2. Masks were fitted to a manikin with intake flow fitted to the nose. Particles of 60 and 125nm were sampled at 1 per second for 180 seconds.	and 125nm droplets, respectively). Dust mask, coffee filter, 2 layer cotton and shop towel performed slightly better. - Particulate respirators (KN95, 3M 8511 and FTF467 ULPA) had filtration efficiencies above 98%. - Significant drop in filtration efficiency seen for all materials when tested as a worn mask, compared to material baseline. The addition of a filter layer between a 2 layer cotton mask did not significantly improve filtration due to leakage around the mask. - The filtration efficiency of a poorly fitted or loose mask can drop by more than 60% compared to the filtration efficiency of the material.
Realmuto 2020 (32) Simulation experiment USA Sep 2020	Mask fabrication that requires no sewing by folding a square piece of cloth into a duck-billed style mask is presented and tested using various materials and compared to commercially available N95 and surgical masks. A manikin fit test simulator was used for filtration, breathability and leakage testing. The manikin head with a breathing tube simulator was placed in a chamber with a mixing fan and set testing valves, while salt concentration particles of 50-700 nm were introduced to the chamber. Materials tested: Non-woven polypropylene (NWPP), "Filti" mask material (Polypropylene/ Nanofiber/ Polyester composite filter media), MERV filters, muslin cotton, reusable wipes, oil towel.	- Filtration efficiencies for masks tested, from best to worst: N95 > surgical > 3 layer polypropylene/filti/polypropylene mask > three layer polypropylene/MERV13 or 8/polypropylene> inner ply Halyad H600, 1 ply Filti. - Double-layered masks had higher filtration efficiencies than single-layered. - Experiments showed mask leakage greatly reduces mask efficiency. - Ear loops did not prevent leakage as well as head straps because gaps between the mask and skin could be reduced more easily with head straps.

Parlin 2020 (34) Simulation experiment USA Sep 2020	Various materials (cotton, polyester, silk, paper towel) were compared to surgical masks under laboratory conditions for their hydrophobicity and breathability before and after cleaning. Laboratory-based tests were done as face coverings on manikins.	- Silk is a hydrophobic material that impedes droplets and performed well to impede droplet absorption similar to a single use surgical mask and maintained its breathability better than hydrophilic materials such as cotton. Silk performed well after cleaning. - When challenged with aerosolized droplets in spray tests, silk, cotton and polyester did not differ in their ability to prevent aerosol droplet penetration when the fabric barriers had 1 or 2 layers.
Bhimaraju 2020 (28) *Preprint* Simulation experiment USA Aug 2020	The filtration efficacy of particulate matter below 2.5µm was assessed with an inhalation system and manikin. Masks tested included: N95 respirators, surgical masks, cloth masks, cloth masks with activated carbon air filters, cloth masks with HVAC air filters, lightly starch-enhanced cloth masks and heavily-starched cloth masks.	- Activated carbon masks and HVAC air filter masks were nearly as effective as N95 respirators, followed by surgical masks>heavy starch cloth masks>light starch cloth masks. - Regular cloth masks provided very little filtration for particles <2.5um compared to the other masks.
Shahane-Kapse 2020 (29) *Preprint* Simulation experiment India Aug 2020	This study described a mask made from 2 layers of cotton with a layer of polypropylene coated with polyurethane applied to the outside layer in the middle half of the mask so it is in front of the mouth and nose, N95 respirator, triple-layer surgical masks and a single-layer cotton mask and a face shield. The amount and degree of droplet and aerosol to each mask was evaluated when worn by a manikin with no gas exchange (i.e. breathing). Fluorescent dyes were	- The fluorescent dye did not penetrate to the inner layer of the triple-layered surgical masks or N95. - The triple-layered mask made from 2 layers of cotton with a polypropylene outer layer blocked the fluorescent dye where the impermeable cloth was, however on the lateral sides of the polypropylene, few spots were visible on the outer cotton layer, but they did not penetrate through to the inner cotton layer. - The fluorescent dye penetrated through the single layer cotton mask to the manikin.

	sprayed from a distance of 1 and 2m at 180km/hr.	
Dhanraj 2020 (33) *Preprint* Simulation experiment USA Jul 2020	The objective of this study was to report the characterization results for Swiffer as an alternate filter media material and evaluate the size-dependent filtration efficiency. Two systems were used: one as 47 mm punches in a filter holder assembly systems, and second in a chamber-based system where the home-made mask (Bandana type) with Swiffer material layered between pillowcase fabrics was placed on a manikin.	- The Swiffer material was very efficient in filtering ultra-fine particles (<0.08µm). - The highest filtration efficiencies were seen when two layers of Swiffer material were stacked in between two layers of pillowcase fabric. The efficiency ranged from 45–62% for particle sizes between 0.1–0.5µm from 30-45% with a single Swiffer.
Joshi 2020 (25) *Preprint* Simulation experiment India Jun 2020	Mask efficiency and pressure drop was measured by mounting the face mask to a glass pipe and measuring the particles upstream and downstream across the test sample. The testing parameters include the particle capture efficiency of the mask material, pressure drop and the fit factor (leakage). Experiments were conducted with atomized NaCl test aerosols, on 3 types of face masks: commercial N-95, surgical mask and cloth mask (no info on specific material).	- The average filtration efficiencies for 0.3µm particles for the N-95 respirator, surgical mask, and cloth mask were 96.19%, 40.08% and 14.22%, respectively. - Filtration efficiency for particle sizes small than 0.3µm were did not change for N95 and cloth masks, surgical masks may have better filtration efficiency. - Tighter mask fits had higher filtration efficiencies: N95, surgical mask and cloth mask were 95.60%, 41.65% and 13.79%, respectively; compared to 95.08%, 19.94% and 11.67% when fit was not as tight, respectively.
Sheets 2020 (27) *Preprint* Simulation experiment USA	To quantify breathability, filtration efficiency and sensitivity to fit for a set of proposed filter and mask designs, a steady flow of aerosolized air was directed at a fit tester manikin and a clamp-style materials tester. Protection against water aerosols >0.3µm was	- N95 masks had the highest filtration efficiencies (>95%). - A woven bandana provided little protection (<15%) but had high breathability. - The surgical mask has twice as good filterability as a bandana with similar breathability.

Jun 2020	measured using off-the-shelf particulate, flow and pressure sensors, permitting rapid comparative evaluation of these 3 properties.	- Sterilization wrap (a non-woven material used by healthcare professionals for packaging surgical instruments) has a higher filtration efficiency compared to a surgical mask but is less breathable. - Filtration of aerosols through the KN95 mask fitted as received and properly fitted demonstrated that a proper fit decreased the number of aerosols that passed through the mask from >50% to <20% when fitted properly.
Filter holder studies to assess protective characteristics of mask materials (n=20)		
Bayersdorfer 2020 (48) Simulation experiment USA Dec 2020	Eight mask prototypes were developed and laboratory tested; 4 for bacterial filtration efficiency (BFE) and pressure drop; and the other 4 for particle filtration efficiency (PFE).	- BFE results of 83.0% to 97.7% in one ply masks and 96.3% to 98.1% in two ply masks. - PFE results ranged from 92.3% to 97.7% for 1 and 2 ply masks.
Li 2020 (36) Simulation experiment China Nov 2020	In this study, filtration efficiency of (a 3-layered mask made from 2 pieces of kitchen towels and a piece of 4-ply tissue paper compared to medical masks were tested under laminar flow within a scaled air duct system using nebulised NaCl aerosols sized 6–220nm.	- The filtration efficiency of the home-made masks was similar to that of medical masks at 6–200nm (84.54% vs 86.94%, P = 0.102).
Maher 2020 (47) Simulation experiment USA	Filtration efficacy of 14 common materials was tested by measuring the concentration of aerosol droplets, the pressure difference across each material and the air-flow characteristics.	- Aerosol concentration results indicated the materials broke large particles into multiple smaller particles. - Multiple layers of fabrics increased the filtering efficiency 4-15%, compared to a single layer of the same fabric; but this decreased breathability with a 3-4x increase

Oct 2020		in pressure difference and three layer masks were 2-2.5x higher pressure difference compared to two-layers. - All tested multi-layer materials had a filtration efficiency > 95% for aerosols 1µm to 4.7µm.
Wang 2020 (51) Simulation experiment China Oct 2020	Referring to the national standard for the "Surgical Mask" of China, 17 materials were tested for pressure difference, particle filtration efficiency, bacterial filtration efficiency and resistance to surface wetting. Material tested included: T-shirt, fleece sweater, outdoor jacket, down jacket, sun-protective clothing, jeans, hairy tea towel, granular tea towel, non-woven shopping bag, vacuum cleaner bag, diaper, sanitary pad, pillowcases, medical non-woven fabric, medical gauze.	- Eleven single-layer materials met the standard of pressure difference (≤49 Pa), of which 3 met the standard of resistance to surface wetting (≥3), 1 met the standard of particle filtration efficiency (≥30%), but none met the standard of bacterial filtration efficiency (≥95%). - Three double-layer materials including double-layer medical non-woven fabric, medical non-woven fabric plus non-woven shopping bag, and medical non-woven fabric plus granular tea towel were close to the standard of the bacterial filtration efficiency.
Long 2020 (50) Simulation experiment USA Oct 2020	This study describes the conversion of standard equipment used to fit-test respirators in hospital and industrial settings into a setup that measures quantitative filtration efficiencies of materials based on NIOSH N95 guidelines, and subsequently measure filtration efficiencies of materials found in healthcare and consumer spaces.	- Filtration efficiencies for single-layered materials ranged between 35 and 53%. Two materials (coffee filter and cotton cloth) had the lowest filtration efficiencies while the vacuum bag, which is not safe for use, had the highest with a filtration efficiency of 82%. - Filtration efficiencies up to 90.37% were reported for multi-layered combinations of materials. - All materials had Δp values below the maximum NIOSH-allowed resistance for respirators (35mmH2O).
Whiley 2020 (40)	This study used a standard mask testing method (ASTM F2101-14) and bacteriophage MS2 to test the viral filtration efficiency (VFE) of	- All the fabric masks had a VFE of at least 50% for 6.0 µm aerosols. This improved to 63% against 2.6µm aerosols.

Simulation experiment Australia Sep 2020	fabric masks (purchased form on online retail website) compared with commercially available disposable, surgical, and N95 masks. The masks were challenged with 2 differenent sized aerosols (6µm and 2.6µm) The conduct and measurements in this study are not standardized. Caution should be used in interpreting these results.	- The N95 and surgical masks had >99% filtration efficiency. - A cotton mask with a filter added and a reusable shopping bag/cotton mask performed just as well as the medical masks (~99% VFE). - A triple-layered hemp/poly-membrane/cheesecloth mask also performed well (>89% VFE).
Maurer 2020 (43) Simulation experiment Germany Sep 2020	In this study, community masks of major manufacturers were tested. The filtration efficiency was determined using radioactive aerosol particles. Air resistance (i.e. breathability) was measured using a pneumotachograph.	- Filtration efficiencies (%) for investigated materials from best to worst were as follows: - Triple-layered masks: Medical membrane according to EN > Outside layer of knitted polypropylene/polyamid, midlayer of microfilament fleece, and inside layer of polyester/polyamid > 100% cotton - Double-layered masks: 100% bio-cotton > cotton/polyester > 100% cotton > polyamide/elastan > polyester and fleece polypropylene - Single layer masks: Texlyte Nano > polyester/carbon > 100% cotton > multifilament yarn > 100% polyester - None of the community face masks met the requirements for medical face mask European standards (filtration efficacy >99% and air resistance <40 Pa/cm2). - Triple-layered masks showed the highest filtration efficiencies but (lower breathability. - When it comes to filtration efficacy, the quality of the fabric seems to be more important than the number of layers (1 vs. 2).
Pei, 2020 (55)	This study evaluated commercial respirators and masks, and common household materials for	- Electret masks (filter with electrostatic charges) filtration efficiencies were 70–85%, with efficiencies increasing with particle size.

Simulation experiment USA Sep 2020	filtration efficiency and breathing resistance (pressure drop). All samples were cut to fit the filter holder. They measured the fractional efficiency with monodisperse NaCl particles (0.03-1µm).	- The N95 and KN95 mask had efficiencies above 90%. - The non-electret media masks filtration efficiencies were significantly lower than that of the electret media mask (as low as 20% for particles 0.3–0.4µm, but increased to 40% for 1 µm. - All respirators and masks tested had acceptable breathing resistance. - Vacuum filters had better filtration efficiencies than even the N95 respirator, but 10x the breathing resistance and thus, impractical as a mask material. - Of the common household materials, 2-layer Thinsulate, 5-layer bed sheets, T-shirts, and Swiffer Sweeper had approximately 50% efficiency for particles around 0.3µm. Their efficiency could be further improved by adding more layers. Breathing resistance was high compared to a procedural mask. - Two-layers of coffee filter has the worst filtration efficiency and breathing resistance.
Schilling 2020 (38) Simulation experiment USA Aug 2020	This study examines both aerosol filtration and breathability of 47 "non-regulation masks" by the use of a polydisperse aerosol and assess filtrations efficiencies of 6 N95 respirators and a number of non-regulation masks. Filtration was assessed by particle sizes ranging (0.2–1µm) and a velocity of 10 cm/s and breathability by measuring the pressure drop (in mm H_2O) across a 40mm disk of mask filter material.	- The filtration efficiencies of the 6 N95 respirators tested ranged from 98-99%. - Some "non-regulation" masks had filtration efficiencies similar to the N95 mask for 0.2µm and above, and others had poor filtration efficiencies (i.e. <80%). - All masks were below the NIOSH threshold of 0.0247-mm H_2O/(cm3/s) for breathability.
Hao 2020 (46)	To evaluate the filtration of non-medical materials under different velocities. Breathability was	- The filtration efficiencies from best to worst were: N95 and KN95 respirators > surgical mask > air filters > vacuum bag > activated

Simulation experiment USA Aug 2020	measured via the flow resistance across the materials. Filtration efficiencies were compared against medical masks: N95, KN95 and surgical masks. To simulate different breathing conditions, nebulizer dispersed NaCl-water aerosols were directed into materials under face velocities of 23.2, 15.3, and 9.2 cm s−1.	carbon filter > 1000 thread count pillowcase > Coffee filter > 600 thread count pillowcase > Four layers of scarf > 400 thread count pillowcase > bandana. - Fabrics with denser weaving patterns were able to provide a higher filtration efficiency Filtration efficiency was inversely related to breathability and increasing velocity of particles.
Drewnick 2020 (52) Simulation experiment Germany Aug 2020	To assess particle-size dependent filtration efficiencies for 44 samples of household materials and several medical masks by using a nebulizer generated NaCl aerosol and counting the particles.	- Huge filtration efficiency differences were found between materials and for different particle sizes, ranging from <10% to almost 100%. - Household materials such as French terry, fleece, microfiber cloth, felt, muslin or velour showed high filtration efficiencies, while materials like poplin, surgical gown or silk showed lower filtration efficiencies. - Reasonable filtration efficiency can be achieved by layers but leaks of just 1-2% can strongly impact filtration efficiency.
Carnino 2020 (54) Simulation experiment USA Aug 2020	To enhance the filtration ability of kitchen paper towel, laboratory paper towel and the middle filter layer of a standard surgical mask pretreated with a salt-based solution (which was then dried). After treatment with fluorescent nanoparticles similar in size to the COVID-19 virus, particle penetration was measured via a microscope.	- When untreated, household materials did a poor job at filtering out nanoparticles. - When household materials were presoaked in a NaCl (+/- TWEEN20) solution the penetration of nanoparticles was blocked after just 10 minutes of treatment. - Bacterial inhibition was also noted.
Loupa 2020 (53) *Preprint*	Eight commercially available masks were tested for filterability of aerosols diameters of 0.006µm to 10µm. A velocity equal to human breathing rate was used.	- Simple cloth masks (with 2 layers of cotton) had the lowest filtration efficiency.

Simulation experiment Greece Jul 2020	Five of the masks were triple-layer masks, 1 was a KN95 mask with a "one way valve", and 2 were fabric masks.	- The addition of activated carbon in a cotton mask significantly improved the filtration efficiency. - Apart from the KN95 mask, all other masks were permeable to aerosols in the range of 0.25-0.5µm (<90% filtration efficiency).
Lammers 2020 (49) Simulation experiment USA Jul 2020	Surgical sterilization wrap was assessed by the TSI 8130 automated filter testing, as required for the N95 respirator mask. Single and double layers of the wrap were tested and compared to the penetrance assessment of the N95.	- Filtration efficacy of the wrap was 64.5% and 78.3% for single and double-ply, respectively. This failed to meet the standard testing requirements for an N95 respirator.
Varallyay 2020 (42) Simulation experiment USA Jul 2020	In this study, common household fabrics were tested for filtration efficiency using a fit testing setup with a standard 40nm median diameter particle generator and airflow resistance with pressure gauge setup. Three different levels of layering (1, 2, and 4) were tested.	- Polyester felt demonstrated the highest filtration efficiency ($p<0.0001$), higher than all tested 100% cotton materials as well as surgical masks ($P<0.05$). - Layering increased filtration efficiency and airflow resistance ($p<0.0001$ and $p<0.01$, respectively). - Filtration efficiencies of various woven and knitted materials were from best to worst were: microfiber cloth > tea towel > hospital scrubs > thick fleece > Buff headwear > T-shirt > pillowcase > non-elastic woven fabric > scarf. - Filtration efficiencies of various non-woven materials from best to worst were: N95 respirator > vacuum cleaner bag > surgical mask > felt > paper kitchen towel > surgical gown > paper facial tissue. - Washing plus drying did not alter filtration performance significantly.
Zhao 2020 (39)	To evaluate the filtration properties of natural and synthetic	- The filtration efficiencies for various medical masks and non-medical materials from best

Simulation experiment USA Jun 2020	materials using an Automated Filter Tester with a flow rate of 32 L/min (similar to human breathing). The filtration efficiency is the percentage of NaCl particles filtered by the material and the pressure drop is the air resistance across the filter material. The higher the pressure drop the less breathable the material. Authors note that their results differ from recent work and this may arise from differences in instrumentation, testing method and source of material.	to worst were: N95 respirator > cotton sweater > exercise pants > T-shirt > tissue paper > polyester toddler wrap > paper towel > polypropylene interfacing material > pillow cover > napkin. - Some of the cotton materials had filtration efficiencies comparable to medical face masks (e.g., cotton sweater and T-shirt). - Paper products may be suitable to use as a disposable media in some homemade facial coverings, but their performance in high humidity environments remains to be examined.
Zangmeister 2020 (45) Simulation experiment USA Jun 2020	To assess filtration efficiency, differential pressure (ΔP), quality factor, and construction parameters for 32 cloth materials including multilayered and mixed-material samples of natural, synthetic or natural-synthetic blends. Materials were microimaged and tested against size selected NaCl aerosols with particle mobility diameters between 50 and 825nm. Particles were charge neutralized.	- Woven 100% cotton with high to moderate yarn counts, and 2 woven synthetic fabrics of moderate yarn count performed the best. - The filtration efficiency of 2 layers of a high performing cloth (32%) was lower than high-density medical-grade wraps (86%), and the N95 mask (>99.9%), and the HEPA vacuum bag (94%). - The fabric with the lowest filtration efficiency was polyester (lightweight chiffon), followed by cotton (muslin), polyester (knit), rayon and 65% polyester/35% cotton blend. - Filtration efficiency and ΔP increased with the number of cloth layers; 4 layers exceeded the recommended ΔP (breathability).
Amendola 2020 (23) Simulation experiment Italy	The experiment simulated respiratory action measuring the distribution of aqueous-based aerosol particles. The average filtration efficiency was reported taking into account the particles with diameters greater than 0.28μm. The face masks were	- The medical face mask demonstrated filtration efficiencies higher than 97%. - Only the face masks fabricated with three layers mainly constituted by non-woven fabric material were able to reach values higher than 95% including triple layer TNT, TNT-cotton-TNT mask.

May 2020	tested in both the inhalation and exhalation direction. TNT= A non-woven material made of fabric-based polypropylene and viscose	
Konda 2020 (44) Simulation experiment USA Apr 2020	To assess filtration efficiencies of several common fabrics including cotton, silk, chiffon, flannel, various synthetics and their combinations as a function of polydispersed NaCl aerosol particulate sizes 10nm-10µm. To simulate fit, holes were drilled in the connecting tube onto which the fabric was mounted resulting in openings of area ~0.5–2% of the active sample area.	- The ranges below represent the filtration efficiency for small particle sizes (<300nm) to larger particle size (>300nm). - A moderate thread count cotton fabric (80 threads per inch) demonstrated inferior efficiency (5-55%) compared to a high thread count cotton fabric (65->90%). - A quilt, with a fibrous cotton batting, provided excellent filtration efficiency (80->90%). - In contrast to the cotton fabrics, the 3 fabrics expected to possess electrostatic charges, silk, chiffon, and flannel, performed better for smaller particles (<300nm) than larger particles (>300nm). - Increasing the number of layers increased filtration efficiency. - Three hybrid combinations were tested: 1 layer 600 TPI cotton with 2 layers of silk, 2 layers of chiffon, and 1 layer of flannel. All combinations performed well, with filtration efficiencies 80%->90%, comparable to that of N95 masks. - In tests where the effect of "leakage" was tested, the openings resulted in up to a 60% drop in filtration efficiency.
Ma 2020 (37) Simulation experiment	The efficacy of 3 types of masks was evaluated using the avian influenza virus to mock the coronavirus. A nebulizer was used to produce aerosols <5.0 um.	- Compared with 1 layer of polyester cloth, the N95 mask blocked 99.98% of the virus, the surgical mask blocked 97.14%, and the homemade mask blocked 95.15%.

China Mar 2020	The top parts of 60mL syringes were removed and then wrapped with the tested masks: 1 layer polyester cloth, a homemade mask made of 1 layer polyester cloth plus 4 layers of kitchen paper, a surgical mask and an N95 mask. A sponge was set inside the syringe behind the mask to collect the virus that passed through the masks.

Methods:

A daily scan of the literature (published and pre-published) is conducted by the Knowledge Synthesis team in the Emerging Science Group, Public Health Agency of Canada. The scan has compiled COVID-19 literature since the beginning of the outbreak and is updated daily. Searches to retrieve relevant COVID-19 literature are conducted in Pubmed, Scopus, BioRxiv, MedRxiv, ArXiv, SSRN, Research Square and COVID-19 information centers run by Lancet, BMJ, Elsevier, Nature and Wiley. The cumulative scan results are maintained in a Refworks database and an excel list that can be searched. Details on this search strategy are available upon request. From this database and excel list, article titles and summaries were systematically searched for the following key words: mask* OR (face AND cover*). Each potentially relevant primary research reference was analyzed to confirm its relevance and data was extracted into the review. Several reviews and synthesis research of variable quality were identified that covered mask composition to some degree, however most included pre-pandemic research only and thus were excluded from this summary as they were missing recent research. This review contains primary research published up until December 2, 2020.

Nouveaux éléments de preuve sur la COVID-19

Revue rapide sur les caractéristiques des masques non médicaux ou des couvre-visages efficaces pour réduire le risque de transmission du SRAS-CoV-2

Introduction

Quelles sont les données probantes en ce qui concerne les caractéristiques (par exemple, conception, matériau, ajustement) et l'efficacité des masques non médicaux ou des couvre-visage pour réduire la transmission du SRAS-CoV-2? (En un mot, à quel point sont-ils efficaces pour prévenir la propagation du SRAS-CoV-2 lorsqu'ils sont portés par une personne confirmée contagieuse ou quel type de protection offrent-ils contre l'inhalation du SRAS-CoV-2 à la personne qui les porte)

De nombreuses organisations de santé publique dans le monde, incluant l'Organisation mondiale de la santé, recommandent le port du masque ou du couvre-visage dans les espaces publics pour se protéger contre la COVID-19. Les masques non médicaux ou couvre-visages (qu'ils soient faits maison ou aient été fabriqués) ne sont pas réglementés comme équipement de protection individuelle, car ils n'ont pas été testés à l'aide d'un ensemble de méthodes de test normalisées (par exemple, NIOSH, ASTM F2100 ou EN 14683) comme le sont les masques médicaux (par exemple, les masques N95 et les masques chirurgicaux). Il n'est donc pas recommandé aux professionnels de la santé et aux personnes présentant un risque accru d'infection de les porter dans les situations où le respect de la distanciation physique n'est pas possible (1).

Cette revue rapide a donc porté sur l'efficacité des masques non médicaux ou des couvre-visages portés par la population en général pendant la pandémie de COVID-19. Ainsi, les articles qui n'évaluaient que des masques comme les N95 ou des masques chirurgicaux n'ont pas été inclus dans la présente revue. Ceux qui comparaient le rendement des masques N95 ou des masques chirurgicaux à celui des masques non médicaux ou des couvre-visages sont inclus et l'analyse comparative de ces différents masques ou couvre-visage a permis de comprendre le contraste entre différents masques non médicaux ou couvre-visages et les masques médicaux. La présente revue rapide contient des recherches publiées jusqu'au 2 décembre 2020 portant sur les caractéristiques des masques non médicaux ou des couvre-visages, ce qui inclut le matériau, la conception et l'ajustement qui permettent aux masques ou aux couvre-visage de filtrer efficacement le SRAS-CoV-2 tout en conservant un niveau approprié de respirabilité. Dans le contexte de la pandémie COVID-19 et de la présente revue, les études ont examiné les masques ou couvre-visages tant comme forme de contrôle à la source (c'est-à-dire pour empêcher la propagation du SRAS-CoV-2 s'ils sont portés par une personne confirmée contagieuse) que comme protection contre l'inhalation du SRAS-CoV-2. Il y a un effet synergique lorsque le récepteur et le propagateur du virus portent tous deux un masque ou couvre-visage (2).

Points clés

- Parmi les cinquante-quatre articles de recherche originale sélectionnés, 22 études portaient sur la prévention de la propagation du SRAS-CoV-2 par des masques non médicaux ou des couvre-visages portés par une personne confirmée contagieuse (contrôle à la source) alors que 37 autres portaient sur la protection qu'offrent les masques non médicaux ou couvre-visages à une personne non infectée contre l'inhalation du SRAS-CoV-2. Les études ont été effectuées sur des volontaires humains (n = 15), des mannequins (n = 15), des porte-filtres (n = 34) et des modèles animaux (n = 1).
- Des études expérimentales de simulation ont montré que les masques non médicaux ou couvre-visages sont plus efficaces comme méthode de contrôle à la source (tableau 1) que pour protéger les personnes non infectées (tableau 2). Il y a un effet synergique lorsque tant la personne non infectée que la personne infectée portent un masque (2).
- Un masque ou couvre-visage peut limiter de manière significative la distance que parcourent les gouttelettes de salive pendant l'élocution, la toux ou les éternuements à l'intérieur, mais l'efficacité de ces masques non médicaux dépend de trois caractéristiques : 1) l'efficacité de filtration, 2) la respirabilité, et 3) l'ajustement.
- L'efficacité de filtration dépend du type, de la taille et de la vitesse des gouttelettes de salive et de la qualité du tissu (étanchéité du tissage, diamètre de la fibre ou du fil) et des caractéristiques inhérentes au tissu (par exemple, charge électrostatique et hydrophobie).
- Lorsqu'ils sont faits en tissu de haute qualité à plusieurs épaisseurs qui s'adaptent parfaitement à la bouche et au nez, les masques non médicaux ou couvre-visages peuvent réduire le risque de propagation ou d'exposition au SRAS-CoV-2, même si cette réduction est inférieure à celle qu'offrent les masques médicaux.
    - Les masques double épaisseur bien ajustés et en différents types de matériaux (par exemple, coton peigné et polyester) ou les masques comportant un seul type de matériau, mais avec plus de deux épaisseurs, présentaient une efficacité en blocage vers l'extérieur semblable à celle des masques médicaux (> 90 %) tout en conservant une respirabilité comparable.
    - Il a été démontré que le fait de ne pas bien ajuster le masque ou couvre-visage sur la peau en réduit considérablement l'efficacité, réduction qui a atteint plus de 50 % dans l'efficacité de filtration.
- L'efficacité de filtration de divers masques non médicaux et de différents matériaux a été évaluée dans 42 études et a permis d'obtenir un vaste éventail de résultats (< 10 % à > 95 %)</10 %>.
    - Le fait que les masques ou couvre-visages en tissu comportent de multiples épaisseurs augmente l'efficacité de filtration, mais le nombre d'épaisseurs entraîne également une diminution de la respirabilité. Ainsi, les recherches montrent que le fait d'avoir plus de trois

épaisseurs de tissu réduit considérablement la respirabilité. Certains échantillons comportant trois épaisseurs ont cependant permis d'atteindre une efficacité de filtration supérieure à 90 %.

- Le niveau d'efficacité de filtration de la plupart des textiles de maison était plus grand pour les grosses gouttelettes et pour les gouttelettes expulsées à plus basse vitesse.

- Des études montrent que le type de tissu et le fait d'utiliser un mélange de tissus améliorent la filtrabilité, la respirabilité et la longévité (c'est-à-dire la capacité à réutiliser le masque ou couvre-visage).
    - Les masques ou couvre-visages devraient être faits d'un tissu fin ou tissé serré. Certains tissus sont hydrophobes (par exemple, le polyester, le polypropylène lacé par filage ou le polyaramide) ou peuvent capturer des particules chargées électriquement grâce à une certaine forme d'électricité statique (par exemple, le polyester ou la soie), alors que d'autres peuvent avoir des propriétés hydrophiles qui en améliorent le confort et la longévité (par exemple, le coton).
    - De multiples études ont montré qu'un masque ou couvre-visage trois épaisseurs, composé d'une couche externe hydrophobe, d'une couche centrale en tissu mélangé non-tissé et d'une couche intérieure hydrophile, était la combinaison idéale pour optimiser tant le potentiel de réduction de transmission que la capacité de protection offerte par les masques non médicaux ou couvre-visages.
- Certains tissus ne sont cependant pas recommandés comme masques non médicaux ou couvre-visages.
    - Il a ainsi été démontré que les sacs pour aspirateur ont une efficacité de filtration comparable à celle des masques médicaux, mais il ne s'agit cependant pas de produits cliniques certifiés et peuvent contenir des ingrédients malsains et des fibres nocives.
    - Les masques ou couvre-visages pliés, mais non ajustés, les masques ou couvre-visage de type bandana et les guêtres simple épaisseur pour le cou bloquent mal les gouttelettes de salive et offrent donc peu de protection. Les données probantes sont très variables en ce qui concerne les guêtres de cou. En fait, plusieurs études ont montré qu'elles n'offraient aucune protection, une a montré une plus grande production d'aérosols alors qu'une autre étude a indiqué des efficacités de blocage similaires à celles d'un masque ou d'un couvre-visage en coton.
    - Les masques ou respirateurs munis d'une soupape ou d'un évent expiratoire peuvent protéger la personne qui les porte contre le SRAS-CoV-2, mais n'empêcheront cependant pas la dispersion du virus et ne sont donc pas efficaces pour le contrôle à la source.

Vue d'ensemble des éléments de preuve

Cette revue rapide comprenait donc 54 articles de recherche originale portant sur les caractéristiques et l'efficacité des masques non médicaux ou des couvre-visage afin de réduire le risque de transmission du SRAS-CoV-2. Elle portait principalement sur l'efficacité des masques non médicaux ou des couvre-visages portés par la population en général. Ainsi, les articles qui n'évaluaient que des masques comme les N95 ou des masques chirurgicaux n'ont pas été inclus dans la présente revue. Les articles qui comparaient le rendement des masques N95 ou des masques chirurgicaux à ceux des masques non médicaux ou des couvre-visages sont inclus. L'analyse comparative de ces différents masques ou couvre-visages a permis de comparer différents masques non médicaux ou couvre-visages aux masques médicaux réglementés. Une revue rapide sur le port des masques ou des couvre-visage pour prévenir la COVID-19 dans les milieux communautaires a été réalisée et est disponible auprès du Secrétariat des sciences émergentes.

La majorité des études incluses dans cette revue rapide étaient des quasi-expériences et des expériences de simulation visant à étudier l'efficacité de blocage et de filtration, la respirabilité et l'ajustement (c'est-à-dire une mesure de la façon dont le masque s'adapte au visage et laisse un minimum d'espace entre le masque ou couvre-visage et la peau) des masques non médicaux ou des couvre-visages en différents matériaux et avec différents styles en utilisant pour ce faire des volontaires humains, des mannequins, des modèles animaux et des porte-filtres en tissu. Ces expériences sont donc une approximation d'une situation réelle et sont soumises aux limites des modèles utilisés. Les mannequins n'imitent pas parfaitement les formes d'un visage humain, les mouvements (c'est-à-dire l'incidence qu'ils peuvent avoir sur l'ajustement) ou les activités respiratoires, ce qui veut dire qu'il faut faire preuve de prudence au moment d'extrapoler ces résultats aux humains. De même, les expériences effectuées avec des porte-filtres surestiment l'efficacité des masques, puisqu'elles n'évaluent que la filtrabilité du tissu et non l'ajustement d'un masque ou d'un couvre-visage sur une personne. Ainsi, l'efficacité d'un masque ou couvre-visage porté par des volontaires ou des mannequins devrait être plus faible en raison des fuites tout autour du masque. Aucune des études recensées n'évalue l'efficacité des types spécifiques de masques non médicaux ou de couvre-visage dans le monde réel. Les résultats de la présente revue rapide ne présentent donc que des données sur l'efficacité de différents masques évalués dans des conditions expérimentales contrôlées. En outre, s'il était possible de comparer et de classer différents modèles, matériaux et ajustements dans les diverses études, les différences dans les méthodologies et les combinaisons de matériaux auraient rendu difficiles les comparaisons entre les différentes études.

Un virion du SRAS-CoV-2 a un diamètre de 0,1 µm, mais il est généralement transporté par d'autres particules comme les particules respirables qui ont un continuum de tailles allant de < 1 µm à > 5 µm. Veuillez demander la revue sur la transmission des aérosols pour plus d'information à cet égard. La taille et la vitesse des particules n'étaient pas cohérentes d'une étude à l'autre alors que la filtration des particules de tailles différentes variait d'un tissu à l'autre, ce qui rend les efficacités de filtration difficiles à comparer ou à synthétiser. Bon nombre d'études n'ont pas utilisé de véritables gouttelettes de salive ou particules chargées de virus et ont plutôt utilisé la dispersion en aérosol de particules alternatives (par exemple, NaCl, amidon,

bactéries, latex, dioxyde de silicium). Les recherches actuelles sur l'efficacité des masques non médicaux ou des couvre-visages sont donc de qualité médiocre et les résultats changeront probablement après des recherches supplémentaires.

TABLE DES MATIÈRES

MASQUES NON MÉDICAUX OU COUVRE-VISAGE POUR LE CONTRÔLE À LA SOURCE

Études sur les humains et les mannequins (n = 15) :

L'efficacité des interventions non pharmaceutiques, telles que la distanciation sociale, peut être augmentée en réduisant le niveau de gouttelettes ou d'aérosols infectieux qui circule dans l'air des espaces communs (3). Compte tenu du fait que les personnes infectées par la COVID-19 peuvent être asymptomatiques ou présymptomatiques, le fait de toujours porter un masque ou couvre-visage dans les lieux publics est recommandé comme moyen de contrôle à la source pour réduire la dispersion, la vitesse et la transmission potentielle des particules expirées.

Des études ont été menées sur des volontaires humains (n = 10) et des mannequins (n = 7). Les mannequins n'imitent cependant pas parfaitement la peau humaine ni les mouvements (c'est-à-dire l'incidence sur l'ajustement du masque ou du couvre-visage) ou les activités respiratoires, puisque l'air ne se déplace généralement que dans une seule direction (4).

Les masques non médicaux ou couvre-visages sont plus efficaces pour le contrôle à la source (blocage des gouttelettes ou des aérosols viraux, c'est-à-dire qu'ils limitent la transmission à partir d'une personne infectée) (tableau 1) que pour la protection des personnes non infectées (tableau 2) (2, 4, 5).

- Les masques ou couvre-visages en tissu, comme ceux en coton, ne sont pas aussi efficaces que les masques médicaux pour réduire la dispersion des gouttelettes ou des aérosols vers l'extérieur (6, 7). Cela est probablement dû au tissu utilisé pour fabriquer le masque ainsi qu'à l'augmentation des fuites d'air résultant d'un ajustement moins serré (6, 8).

- Comparativement aux données obtenues sans masque ou couvre-visage, le fait de porter un masque réduit la dispersion des gouttelettes ou aérosols vers l'extérieur, mais l'importance de la réduction varie cependant selon la composition du masque et les caractéristiques spécifiques de l'expérience (tableau 1) :

  - un masque ou couvre-visage en tissu (tissu/composition non indiquée) a permis de réduire la distance du jet respiratoire lors de la respiration et de la toux d'un champ de vision expérimental de 562 mm (sans masque ou couvre-visage) à 150 mm (similaire à un masque chirurgical) (6);

  - un masque en coton matelassé a, quant à lui, réduit la distance du jet respiratoire de 243,84 cm (8 pi) à 5,08 cm (2,5 po) (8);

  - une personne qui se tient à 2 mètres d'une personne qui tousse sans masque sera exposée à plus de 1 000 fois plus de gouttelettes de salive qu'une personne qui se tiendrait à 5 cm de distance et porterait un masque simple épaisseur (9).

- Les masques chirurgicaux bien ajustés (composés de plusieurs couches dont du tissu 100 % coton et des couches intermédiaires en polypropylène non-tissé) sont très efficaces pour réduire la dispersion des gouttelettes (3, 10). Les masques en bec de canard ont, quant à eux, démontré un ajustement satisfaisant et une efficacité de blocage (11). Les études n'ont pas évalué la respirabilité de ces masques. Des exemples des différents styles de masques sont présentés en annexe.

- Les masques ou couvre-visages double épaisseur bloquent mieux les gouttelettes ou aérosols en cas d'élocution, de toux ou d'éternuement que les masques ou couvre-visages faits d'une seule couche de tissu (12).

- Un masque en coton trois épaisseurs s'est révélé tout aussi efficace qu'un masque chirurgical pour supprimer la dispersion des gouttelettes de salive (86,4 % et 99,9 %, $p > 0,05$, respectivement) (13).

- L'ajout d'une couche filtrante comme un essuie-tout pourrait réduire considérablement le potentiel de transmission (14).

- Les masques ou couvre-visages pliés non ajustés et les masques ou couvre-visages de type bandana ne bloquent pas bien les gouttelettes de salive (8). Quant aux guêtres de cou en polyester, lorsqu'elles sont utilisées comme couvre-visage simple épaisseur, elles ne sont pas efficaces pour empêcher la dispersion des gouttelettes ou des aérosols (14, 15). Cependant, lorsqu'elles sont utilisées en double épaisseur, elles offrent une efficacité de blocage similaire à celle des masques ou des couvre-visage en tissu (16).

- Les respirateurs munis d'un évent n'empêchent pas la dispersion du virus par la personne qui le porte (6, 15).

Études sur les porte-filtres (n = 7) :

Les études sur les porte-filtres ont utilisé des échantillons de tissu maintenus en place par un porte-filtre et ne tiennent donc pas compte de l'ajustement d'un visage humain, ce qui veut dire qu'elles peuvent surestimer l'efficacité des masques ou des couvre-visage.

- Les masques double épaisseur ont démonté une plus grande efficacité de blocage que les masques simple épaisseur (17 à 19). En outre, les masques double épaisseur faits de différents types de matériaux (par exemple, coton peigné et polyester) ou les masques comportant un seul type de matériau tissé serré (par exemple, coton), mais avec plus de deux épaisseurs, ont démontré une efficacité en blocage similaire à celle des masques médicaux (> 90 %) tout en conservant un niveau de respirabilité comparable (20 à 23).
- L'efficacité de blocage est beaucoup plus élevée pour les gouttelettes à faible vitesse (par exemple, créées lors de la parole) que pour les gouttelettes à grande vitesse (par exemple, générées par les éternuements) (21).
- Les compositions de tissu qui ont donné les meilleurs résultats comprenaient des matériaux hydrophiles comme le tissu éponge, le coton piqué ou la flanelle utilisés en combinaison avec une couche barrière hydrophobe faite de polypropylène non-tissé, de polyester ou de polyaramide qui empêchera davantage d'aérosols de passer à travers le masque (20).
- Les normes N95 sont établies en fonction d'une fourchette de taille des particules allant de 0,1 à 0,3 µm. La majorité des études sur les masques non médicaux ou couvre-visages ont également utilisé un éventail de tailles de particules similaires dans leurs expériences. L'efficacité de filtration des masques médicaux et de bon nombre de textiles de maison s'est révélée plus faible pour les petites particules que pour les grosses gouttelettes. Une expérience réalisée sur les particules ultrafines (< 0,1 µm) a montré que les masques N95 et les masques chirurgicaux obtenaient une efficacité de filtration de 52,5 % et de 47,5 %, respectivement (19). En comparaison, la laine feutrée (35,87 %), le piqué de coton (34,54 %) et la flanelle de coton (28,50 %) avaient des rendements de filtration inférieurs pour les très petites particules (19).
- Un masque ou couvre-visage fait de plusieurs couches de soie a obtenu une efficacité de filtration de 94 % contre les petites particules de la taille d'un aérosol (0,75 µm), probablement en raison de sa charge électrostatique (18). La soie n'était cependant pas aussi performante pour les plus grosses particules.
- Une combinaison de plusieurs épaisseurs de matériaux, avec une couche externe hydrophobe (par exemple, du polyester, du polypropylène lacé par filage ou de la polyaramide), une couche intérieure en tissu de coton de haute qualité et une couche intermédiaire faite de matériaux non-tissés ou chargés électrostatiquement (par exemple, soie naturelle, mousseline ou polyester), serait donc idéale pour optimiser tant la capacité de protection que le potentiel de réduction de transmission des masques non médicaux ou des couvre-visages.

- Un vaste éventail de matériaux a été étudié dans différentes études, dont certains ne peuvent cependant pas être utilisés de façon sécuritaire comme masque ou couvre-visage. Les sacs pour aspirateurs, par exemple, se sont avérés efficaces pour filtrer dans plus d'une étude, mais ils peuvent inclure des composants qui ne sont pas sécuritaires lorsque vient le moment d'inhaler ou s'ils entrent en contact étroit avec le visage (19).

Tableau 1 : Études qui examinent les caractéristiques du contrôle à la source des masques non médicaux ou des couvre-visages (n = 22)

ÉTUDE*	MÉTHODE	PRINCIPAUX RÉSULTATS
Expériences effectuées avec des volontaires humains et des mannequins (n = 15)		
Ho 2020 (13) Quasi-expérience Chine Septembre 2020	Évaluation de l'efficacité de filtration des masques en coton trois épaisseurs et des masques chirurgicaux portés par des patients adultes (n = 211) avec grippe confirmée (n = 208) et infection possible à la COVID-19 (n = 6) dans deux milieux climatisés, soit une chambre et une voiture. Les résultats ont ensuite été comparés à ceux obtenus lorsque des personnes sans masque ont été exposées à une concentration de fond dans un espace inoccupé. Un compteur de particules installé à moins de 1 m de chaque patient infecté a réalisé quatre mesures en une heure. Mesure obtenue : efficacité de filtration à 5,5 cm/s. La température, l'humidité, ainsi que le nombre d'éternuements et de toux ont également été enregistrés. Des tests t pour échantillons appariés ont été utilisés pour effectuer les comparaisons dans les groupes.	- L'efficacité de filtration du masque en coton trois épaisseurs a atteint 86,4 % alors qu'avec le masque chirurgical, elle était plutôt de 99,9 %. - Dans les espaces climatisés, soit dans la chambre à coucher et dans la voiture, la concentration moyenne de particules chez les volontaires qui ne portaient pas de masque était considérablement plus élevée que chez ceux qui portaient un masque chirurgical ou un masque en coton (valeur p < 0,05 dans les deux cas). - La concentration de particules obtenue avec un masque en coton trois épaisseurs et un masque chirurgical dans les deux milieux était sensiblement la même.
Asadi 2020 (7) Quasi-expérience	Évaluation de l'efficacité des masques KN95 sans évent respiratoire, des masques N95 avec évent, des masques chirurgicaux, des couvre-visage faits maison avec une épaisseur	- Comparativement à l'absence de masque, les masques chirurgicaux et les masques KN95 sans évent ont réduit de 90 % le taux moyen d'émission de particules vers l'extérieur

États-Unis Septembre 2020	d'essuie-tout comme filtre et des masques faits maison à l'aide d'un t-shirt en coton simple épaisseur et double épaisseur à réduire les taux d'émission de particules d'aérosol lorsque des personnes en bonne santé (n = 10) respirent, parlent et toussent. On a demandé aux participants à l'étude de s'asseoir et de mettre leur bouche devant un entonnoir fixé à un mesureur de particules aérodynamiques (compteur de particules). Ils devaient ensuite effectuer différentes activités expiratoires avec ou sans masque.	lorsque la personne parlait et cette réduction a atteint 74 % lorsqu'elle toussait. - Il a été difficile d'évaluer l'efficacité des masques en coton. La dispersion des particules autres qu'expiratoires à l'échelle du micron dans les fibres des masques en coton faits maison a cependant brouillé la détermination explicite de leur efficacité, car les taux d'émission de particules mesurés avec un masque double épaisseur et sans masque n'étaient pas statistiquement différents alors que le taux était beaucoup plus élevé chez les participants qui ont porté un masque simple épaisseur en coton comparativement à ceux qui n'en portaient pas.
Fischer 2020 (15) Quasi-expérience États-Unis Septembre 2020	Évaluation de l'efficacité des masques à réduire la transmission des gouttelettes de salive lors de l'élocution grâce à une méthode de mesure optique simple. Un volontaire humain qui portait un masque ou couvre-visage a parlé dans la direction d'un faisceau laser étendu dans une enceinte sombre. Une caméra de téléphone cellulaire a été utilisée pour enregistrer la propagation des gouttelettes dans le faisceau de lumière laser diffusée. Puis, un algorithme informatique simple a permis de compter les gouttelettes. Les masques testés comprenaient des masques chirurgicaux, des masques N95 avec évent, des masques en tricot, en polypropylène, en polypropylène et en coton, des masques Maxima AT, quatre masques en coton double épaisseur, un masque en coton simple épaisseur, une	- Le masque N95 ajusté est celui qui a donné les meilleurs résultats avec une transmission fractionnelle des gouttelettes de 0,1 %, suivi du masque chirurgical, du masque en mélange de coton et de polypropylène, du masque en polypropylène double épaisseur, du masque avec matériel et spica (non ajusté), des quatre différents types de masques en coton double épaisseur, du masque N95 avec évent, du masque Maxima AT, du masque en coton simple épaisseur, du masque en tricot, du bandana, de l'absence de masque et de la guêtre de cou. - La guêtre de cou a donné les pires résultats avec une transmission fractionnelle de gouttelettes de 110 %, résultat obtenu parce que le tissu a brisé les plus grosses gouttelettes en une multitude de plus petites. - Puisque cette étude comprenait un échantillon extrêmement petit, elle devrait donc être utilisée avec prudence.

	guêtre de cou, un bandana et un masque N95 ajusté (sans évent).	
Swain 2020 (14) Quasi-expérience Royaume-Uni Juillet 2020	Utilisation de l'humidité comme méthode pour évaluer l'excrétion virale. Un capteur a été utilisé pour mesurer à des distances précises tout changement dans l'humidité relative et la saturation en oxygène qui se sont produits chez quatre membres du personnel médical qui portaient ou non un masque pendant trois scénarios qui duraient chacun deux minutes : 1) Respiration forte, 65 mm 2) Respiration normale, 20 cm 3) Respiration forte, 20 cm Les masques testés comprenaient un prototype fourni par AngelMed (sans évent), un masque clinique standard approuvé par NHS et un masque FFP2V (évent unidirectionnel). Les masques faits maison testés se composaient de différents tissus, soit t-shirt, chaussettes (avec et sans filtre en papier), masque double épaisseur avec chamois ainsi qu'un masque fait maison conçu pour permettre la lecture sur les lèvres (fait d'un matériau épais avec fenêtre transparente).	- Comparativement aux résultats obtenus lorsqu'aucun masque n'était porté, le masque AngelMed, le masque clinique standard approuvé par NHS et le masque FFP2V ont tous empêché de manière significative les variations dans l'humidité. - Le masque en t-shirt et le masque double épaisseur avec chamois ont donné les mêmes résultats puisqu'ils n'ont entraîné aucune variation dans le niveau d'humidité lors du test avec respiration forte à 65 mm (5,4 % et 5,1 % respectivement). - Le masque double épaisseur fait avec des chaussettes a donné de meilleurs résultats qu'un masque simple épaisseur fait du même tissu (15,3 % contre 9,5 %). - Le masque conçu pour permettre la lecture sur les lèvres a, quant à lui, empêché toute augmentation du niveau d'humidité relative. Il limitait cependant la respiration et on a également constaté qu'il réduisait la saturation en oxygène des participants. - Les conclusions de cette étude sont préliminaires et il faut donc faire preuve de prudence dans l'interprétation des résultats.
Viola 2020 (6) *Prépublication* Quasi-expérience Royaume-Uni	Utilisation de la technique Schlieren orientée vers l'arrière-plan pour comparer la quantité d'air expulsée par un participant portant sept types différents de masques et de couvre-visages, dans des situations où il toussait, respirait fort et respirait normalement. La même évaluation a également été effectuée par le même participant, cette fois-ci, sans masque.	- Lorsque le participant toussait ou respirait sans masque, on a pu voir que la quantité d'air expulsée atteignait une distance supérieure à la limite du champ d'exploration fixée à 562 mm de sa bouche. - Le masque FFP2 a été le plus efficace pour réduire la dispersion de l'air expiré. On pouvait cependant voir des fuites d'air près du nez lorsqu'il n'était pas bien ajusté.

Mai 2020	Un volontaire humain (n = 1) et un mannequin ont été utilisés dans cette étude. Cinq masques ou couvre-visage ont été évalués, soit un masque FFP1, un FFP2, un respirateur, un masque chirurgical, un masque fait maison et deux écrans faciaux.	- Comme le respirateur comportait un évent et n'était donc pas conçu pour arrêter le déplacement de l'air vers l'avant, il ne pouvait donc pas empêcher la dispersion du virus. - Le masque fait maison (dont la composition n'a pas été précisée) a celui qui a été le moins efficace pour arrêter les fuites d'air alors que le masque chirurgical a été le moins efficace pour empêcher l'air de fuir vers l'arrière du masque. - Les conclusions de cette étude sont préliminaires et il faut donc faire preuve de prudence dans l'interprétation des résultats.
Bandiera 2020 (9) *Prépublication* Quasi-expérience Royaume-Uni Août 2020	Évaluation de l'efficacité des masques chirurgicaux et des masques en coton simple épaisseur à atténuer la dispersion des grosses gouttelettes de salive lors de simulations d'élocution et de toux avec des mannequins. L'étude a utilisé un faisceau laser pour quantifier le nombre de gouttelettes émis par le mannequin ou le compresseur d'air alors que la lumière UV a servi à évaluer la quantité de gouttelettes ayant atterri à la hauteur d'une table, soit à un maximum de deux mètres. En ce qui concerne les volontaires humains (n = 6) qui ont parlé et toussé alors qu'ils portaient un masque chirurgical, une lame de microscope a été installée à 5 cm de leur bouche pour récupérer les gouttelettes expiratoires.	- On estime qu'une personne qui se trouve à 2 m d'une personne qui tousse sans masque sera exposée à au moins 1 000 fois plus de gouttelettes de salive qu'une personne qui se trouve à 5 m de celle-ci et qui porte un masque simple épaisseur de base. - Les masques ou couvre-visages se sont toujours révélés efficaces pour bloquer les gouttelettes de salive de 20 à 30 µm dans les simulations d'élocution et de toux ($p < 0,05$). - Aucune différence statistiquement significative dans la quantité de gouttelettes se trouvant sur le masque n'a été observée entre le masque chirurgical et le masque en coton simple épaisseur. - Aucune gouttelette ne s'est cependant déposée sur les masques chirurgicaux portés par les volontaires.
Stubington 2020 (11) Quasi-expérience	Examen de la trajectoire que prennent les particules expirées par une personne qui porte un masque. Cette étude a filmé un seul volontaire expirant de la vapeur d'eau visible alors qu'il portait différents masques ou couvre-visages.	- Les masques FFP souples, plissés et solides envoient les particules expirées vers le bas, à une distance supérieure à 25 cm. - Les masques en bec de canard dirigent, quant à eux, les particules expirées vers le côté, ce qui produit un panache plus petit.

Royaume-Uni Août 2020		- Le port d'une visière ne réduit aucunement la taille du panache de vapeur expiré, quel que soit le type de masque utilisé. - Les matériaux hydrofuges réduisent, quant à eux, le mouvement vers le bas des particules expirées.
Rodriguez-Palacios 2020 (10) Quasi-expérience États-Unis Août 2020	Évaluation de l'efficacité des masques ou des couvre-visage en coton à réduire le risque de contamination de l'environnement associé aux gouttelettes de salive ou aux goulettes orales produites par une personne ou retenir ces gouttelettes. Cette évaluation exige que l'un des enquêteurs (un volontaire sain) compte de 1 à 100 alors qu'il se trouve à 30 cm d'une plaque de gélose TSA stérile. (Le tableau 2 présente l'expérience portant sur l'effet de protection effectuée sur un modèle animal).	- Le même masque en coton porté par un volontaire humain a démontré que, comparativement à l'absence de masque, même une seule épaisseur de matériau réduisait le risque de contamination de l'environnement par les gouttelettes de salive.
Bahl 2020 (12) Quasi-expérience Australie Juillet 2020	Comparaison entre l'efficacité des masques simple et double épaisseur en tissu recommandés par le Center for Disease Control and Prevention (CDC) et les masques chirurgicaux trois épaisseurs. Les masques ou couvre-visages simple épaisseur ont été fabriqués selon la méthode qui permettait de « créer un masque ou couvre-visage rapidement, simplement en coupant un t-shirt (méthode sans couture) » alors que le masque double épaisseur a été fabriqué selon une méthode sans couture recommandée par le CDC. Afin d'avoir des preuves visuelles de l'efficacité des différents masques, un système d'éclairage à DEL sur mesure et une caméra haute vitesse	- Grâce aux visualisations obtenues (photos sur le papier, aucune analyse) pour la parole, la toux et l'éternuement, l'étude a pu démontrer que le port d'un masque en tissu simple épaisseur permettait de réduire la propagation des gouttelettes et qu'il suffisait de mettre un masque double épaisseur pour obtenir des résultats encore meilleurs, avec un très faible nombre de goulettes et que seules celles qui étaient associées aux éternuements étaient visibles. Quant au masque chirurgical, c'est celui qui a permis d'obtenir les meilleurs résultats puisqu'il a pu empêcher la propagation des gouttelettes, quel que soit le type d'émission examiné.

	ont été utilisés pour capter la lumière diffusée par les gouttelettes et les aérosols expulsés par un seul volontaire alors qu'il parlait, toussait et éternuait.	
Pan 2020 (4) *Prépublication* Expérience de simulation États-Unis Novembre 2020	Évaluation de l'efficacité de 11 masques ou couvre-visage sur un mannequin afin de connaître le niveau de filtration de chacun des matériaux et le niveau de protection lors de l'inspiration et de l'expiration pour une vaste gamme d'aérosols dont la taille variait de 0,04 à 135 µm. Les particules utilisées dans l'étude provenaient d'une solution de NaCl à 2 %. L'étude visait à évaluer l'efficacité de la protection des masques ou des couvre-visages lors de l'inspiration et de l'expiration à l'aide de deux mannequins installés des côtés opposés d'une chambre en acrylique de 57 litres. Le mannequin qui « expirait » était relié à un nébuliseur alors que celui qui « inhalait » était relié à un aspirateur. Un masque était d'abord porté par le mannequin qui inhalait, puis par le mannequin qui expirait, afin de mesurer le nombre de particules qui traversaient le masque dans chacun des cas. Masque ou couvre-visage utilisé : sac pour aspirateur, masque chirurgical, filtre MERV 12, bandana, taie d'oreiller en coton 200 fils au pouce, t-shirt en coton, chiffon en microfibre, filtre à café, coton mince, acrylique mince et écran facial en plastique.	- L'efficacité de filtration a augmenté avec la taille des particules et a ainsi empêché les gouttelettes de plus de 20µm de parcourir plus de 33 cm. - Le sac pour aspirateur, le chiffon en microfibre, le masque chirurgical et le filtre MERV 12 ont été les plus efficaces pour bloquer les particules de 2 µm avec un taux d'efficacité supérieur à 90 %. - Le sac pour aspirateur et le chiffon en microfibre sont ceux qui ont obtenu l'efficacité de filtration la plus élevée avec une plage de 60 à 90 %, alors que ce niveau variait entre 50 et 75 % pour les masques chirurgicaux. Le filtre à café a, quant à lui, obtenu une efficacité de filtration qui variait entre 10 et 75 % pour des particules de 0,04 à 1 µm. - Le masque en coton mince et le bandana (double épaisseur) avaient un faible niveau d'efficacité (30 à 50 %) et ce niveau était encore plus bas (5 à 40 %) pour les particules submicroniques. - L'efficacité de la protection lors de l'inspiration et de l'expiration était semblable pour la plupart des masques. - Les masques mal ajustés (p. ex., le bandana) n'ont pas donné d'aussi bons résultats en ce qui concerne le contrôle à la source. - L'écran en acrylique mince est celui qui a donné les plus mauvais résultats. - Le fait d'avoir pu réduire le jeu entre la peau et le masque et la vitesse de l'air a permis de

		grandement améliorer la protection en expiration du masque sans couture mentionné par le CDC et fabriqué à l'aide d'une taie d'oreiller en coton de 200 fils au pouce.
Lindsley 2020 (16) *Prépublication* Expérience de simulation États-Unis Novembre 2020	Étude qui combine un simulateur capable de générer des aérosols semblables à ceux de la toux afin de propulser de petites particules d'aérosol (< 0,6 à 7 µm) sur une fausse tête de mannequin souple et pliable portant différents masques, soit un masque N95, un masque de procédure de qualité médicale, un masque en coton trois épaisseurs, une guêtre en polyester et un écran facial. Les aérosols associés à la toux simulée ont été générés par la nébulisation d'une solution avec KCl à 14 % et fluorescéine sodique à 0,4 %. Les tests d'ajustement ont été effectués à l'aide d'un PortaCount.	- Tous les masques ou couvre-visages, à l'exception de l'écran facial, ont considérablement réduit les aérosols rejetés dans l'environnement ($p < 0,0001$). - Le masque N95 a bloqué 99 % des aérosols, le masque de procédure de qualité médicale en a bloqué 59 %, le masque en tissu en a bloqué 51 %, la guêtre simple épaisseur en a bloqué 47 % et la guêtre double épaisseur en a bloqué 60 % alors que l'écran facial n'en a bloqué que 2 %. - Lorsque la taille des particules augmentait, l'efficacité de blocage de tous les masques augmentait aussi. - Le masque N95 est celui qui a offert le meilleur ajustement, suivi du masque de procédure médicale, de la guêtre double épaisseur, de la guêtre simple épaisseur et du masque en tissu.
Kähler 2020 (5) Expérience de simulation Allemagne Octobre 2020	Utilisation des mesures vélocimétriques associées à l'image quantitative des particules pour évaluer la propagation de l'air expiré, la vitesse des gouttelettes expirées et les propriétés de turbulence du flux d'air. Dans cette étude, un seul volontaire humain a été utilisé pour examiner le champ d'écoulement associé à la toux. Les tests ont été effectués avec et sans masque chirurgical et ont utilisé de la fumée pour démontrer l'effet de l'espace qui se crée entre la peau et la bordure du masque lorsqu'un masque	- Le masque chirurgical limite la propagation de l'air et des aérosols lors de l'élocution ou de la toux. - Les masques ou couvre-visages qui recouvrent la bouche et le nez et les masques chirurgicaux n'étaient pas suffisamment ajustés sur le visage pour protéger contre l'infection par gouttelettes, comme le démontrent les preuves photographiques dans lesquelles les gouttelettes passent facilement à travers le masque. - Les masques faits avec du papier hygiénique quatre épaisseur, des essuie-tout, des filtres à

	est mal ajusté (masques chirurgicaux et FFP2). Une caméra numérique installée devant et derrière le matériau filtrant a été utilisée pour déterminer la capacité de filtration des différents matériaux sur les petits aérosols (0,3 à 2µm).	café, du molleton et du tissu en microfibre présentaient tous un bas niveau de filtration. - Les sacs pour aspirateur avec filtre pour poussière fine ont démontré un effet de filtrage comparable aux masques FFP2/N95/KN95, mais ils ne sont pas conçus pour une telle utilisation.
Ueki 2020 (2) Expérience de simulation Japon Octobre 2020	Description d'une simulation dans laquelle des gouttelettes et des aérosols contenant le virus infectieux SRAS-CoV-2 produits par la respiration humaine et la toux sont transmis dans l'air. Le simulateur a été utilisé pour évaluer la transmissibilité des gouttelettes et des aérosols infectieux et la capacité de différents types de masques à bloquer cette transmission. La simulation, qui utilise deux têtes de mannequin installées face à face et connectées à un nébuliseur de compresseur sur mesure, a permis d'évaluer différents masques, dont des masques en coton, des masques chirurgicaux et des masques N95.	- Le masque N95 présente l'efficacité de protection la plus élevée (il entraîne une réduction de l'exposition aux particules infectieuses variant entre 80 et 90 %). - Les masques chirurgicaux et les masques N95 n'ont, quant à eux, pas pu bloquer complètement la transmission des gouttelettes de virus et des aérosols, même lorsqu'ils étaient absolument étanches. La charge virale qui traverse un masque N95 ajusté, porté par le propagateur, était de 0,3 copie $\log_{10}$ alors qu'elle était de 10 copies $\log_{10}$ lorsque ce même masque était porté par le récepteur. - Comparativement à l'absence de masque ou de couvre-visage, un masque ou couvre-visage en coton (sans description de la composition) a entraîné une réduction de 20 à 40 % de l'absorption du virus. - Les résultats de l'étude indiquent que les masques ou couvre-visages en coton et les masques chirurgicaux conviennent mieux pour bloquer la dispersion du virus que pour protéger la personne qui les porte (> 50 %) (c.-à-d. comme forme de contrôle de la source). - Il y avait un effet synergique lorsque le récepteur et le propagateur du virus portaient tous deux des masques ou des couvre-visages (masques de coton ou masques chirurgicaux). Par exemple, lorsque le récepteur portait un masque ou couvre-

		visage en coton, la charge virale qui traversait le masque était de 63 copies log_{10} alors que lorsque le propagateur portait un masque, la charge virale qui traversait le masque était de 42 copies log_{10}. Quand, tant le receveur que le propagateur portaient un masque, la charge virale était plus faible, soit à 33 copies log_{10}. Voir les graphiques dans le document.
Edwards 2020 (3) *Prépublication* Expérience de simulation États-Unis Août 2020	Étude d'efficacité randomisée ayant utilisé une solution de particules polydispersées nébulisées de NaCl à 10 % (de 0,3 µm à 10 µm) administrée par un simulateur d'expiration ainsi que des mannequins pour effectuer 94 tests avec élocution et toux sur huit types de tissus différents, cinq types de masques différents et différents débit d'air. L'étude a également permis de créer deux nouvelles mesures associées à l'indicateur d'efficacité de la filtration (EEF) et au facteur de dispersion du débit expiratoire (FDDE) qui seront utilisées pour présenter des valeurs quantitatives ou indicateurs pour le rendement des masques non médicaux dans le contrôle de dispersion. Des valeurs plus élevées pour ces deux mesures indiquent une meilleure filtration et un meilleur rendement, ainsi qu'une plus grande réduction de la vitesse des particules, respectivement.	- Par rapport à l'absence de masque, les masques de qualité non médicale ou les combinaisons de tissus ont permis une réduction statistiquement significative de la dispersion atmosphérique des particules après l'expiration. - Le tissu, la conception du masque et l'interaction entre le tissu et le niveau de l'expiration ont des incidences majeures sur l'efficacité de la filtration des particules expirées. - Le masque chirurgical avec couches internes non-tissées est celui qui a été le plus performant. - L'évaluation qui permet de trouver le meilleur matériau doit, quant à elle, dépend de plusieurs éléments, à savoir quel matériau réussit à réduire la vitesse des particules, lequel force les particules à changer de direction ou encore, lequel offre un rendement accru en matière de filtration. - Voici donc les valeurs EEF pour différents matériaux, du meilleur au pire : Serviette de bain > Pantalon en molleton > t-shirt > Bandana > Serviette en microfibre > Taie d'oreiller > Couverture de déménageur > Chemise habillée. - Quant aux valeurs FDDE pour divers matériaux, en voici la liste, du meilleur au

		pire : Taie d'oreiller > Serviette en microfibre > Pantalon en molleton > Serviette de bain > t-shirt > Chemise habillée > Couverture de déménageur > Bandana.
Verma 2020 (8) Expérience de simulation États-Unis Juin 2020	Étude qui utilise des visualisations qualitatives pour la toux et les éternuements émulés avec une tête de mannequin pour examiner de quelle manière les choix de matériaux et de conception influent sur la mesure dans laquelle les jets respiratoires chargés de gouttelettes sont bloqués.	- Les masques ou couvre-visages masques pliés et non ajustés ainsi que les masques ou couvre-visages de style bandana offrent une capacité de blocage minimale pour les plus petites gouttelettes aérosolisées. - Une fois bien ajustés, les masques faits maison dans lesquels on retrouve plusieurs épaisseurs d'étoffe matelassée et les masques de type cône que l'on peut acheter en magasin se sont avérés les plus efficaces pour réduire la dispersion des gouttelettes. Ces masques ont cependant généré certaines fuites tant parce que les particules réussissent à traverser le matériau qu'en raison des petits jeux que l'on retrouve entre le bord du masque ou couvre-visage et la peau.
Études sur les porte-filtres utilisés pour évaluer les caractéristiques de contrôle à la source des matériaux utilisés dans la fabrication des masques (n = 7)		
Aydin 2020 (21) Expérience de simulation États-Unis Juillet 2020	Examen de l'efficacité de 11 types de textiles de maison pour réduire la dispersion des gouttelettes, en utilisant comme référence un masque médical commercial. L'étude a également évalué la respirabilité (perméabilité à l'air), la texture, la composition des fibres et les propriétés en matière d'absorption d'eau de ces textiles. L'efficacité de filtration des grosses gouttelettes à grande vitesse a été évaluée en plaçant les tissus à une distance de 25 mm de la buse d'un inhalateur dans lequel se trouvait une suspension de billes fluorescentes de	- En ce qui concerne les gouttelettes à haute vitesse (comme celles que l'on retrouve dans l'élocution, la toux ou les éternuements), la plupart des tissus ont obtenu une efficacité de blocage des gouttelettes relativement élevée (valeurs médianes > 70 %). - Le masque médical avait une efficacité de blocage de 98,5 %. - Deux ou trois épaisseurs de matériau, comme dans le cas du tissu pour t-shirt, permettent de bloquer les gouttelettes avec une efficacité similaire à celle des masques médicaux (>94 %), tout en conservant une respirabilité comparable.

	100 nm. Les gouttelettes à faible vitesse ont, quant à elles, été évaluées en installant le tissu à 300 mm de l'inhalateur. La perméabilité à l'air a été évaluée à l'aide d'un tube d'écoulement par bouchon. Un masque médical en polypropylène, des t-shirts 100 % coton, un tissu matelassé 100 % coton, des t-shirts en mélange de coton et de polyester, un drap en polyester, un linge à vaisselle en polyester et en mélange de polyamide, ainsi que des chemises en soie ont tous été testés.	- L'efficacité de blocage du tissu pour t-shirt est beaucoup plus élevée pour les gouttelettes à faible vitesse que pour les gouttelettes à grande vitesse. - Les tissus moins perméables à l'air sont plus efficaces pour bloquer les gouttelettes.
Xiao 2020 (18) Expérience de simulation Japon Juin 2020	Étude qui a utilisé l'analyse par imagerie pour effectuer analyser qualitativement l'efficacité des masques chirurgicaux, des masques de gaze, de la gaze, du coton, de la soie, du lin et des mouchoirs de papier face à des particules d'amidon dont la taille correspond à celle des microgouttelettes (moyenne de 8,2µm) et des microsphères de latex (0,75µm) lancés sur les masques à une vitesse de 44,4 m/s (conditions d'éternuements à grande vitesse) créée par centrifugation.	- Le masque de gaze de coton a été le plus efficace pour bloquer les particules d'amidon (90,4 % d'efficacité de blocage), suivi par le masque de coton double épaisseur (89,0 %). Le rendement des autres matériaux variait de 76,4 % à 87,9 %, alors que le rendement des huit épaisseurs de gaze était très bas (36,7 %). Le masque chirurgical a, quant à lui, bloqué 78,2 % des particules. - Lorsque des microsphères de latex ont été utilisées pour imiter des particules de la taille des aérosols, les matériaux qui ont offert la meilleure efficacité de blocage étaient les quatre épaisseurs de soie (93,8 %) (probablement en raison de leur charge électrostatique), le masque de gaze (78,5 %) et le coton double épaisseur (74,6 %). - Les masques faits de plusieurs épaisseurs de lin ont donné de bien meilleurs résultats que lorsqu'une seule épaisseur était utilisée (66,5 % contre 53,2 %).
O'Kelly 2020 (19)	Évaluation de la capacité de 20 tissus et matériaux faciles à trouver à réduire les concentrations atmosphériques de	- Les particules ultrafines utilisées dans cette étude ont entraîné une « base de référence »

Expérience de simulation États-Unis Juin 2020	particules ultrafines (0,1 µm et diamètre inférieur) à une vitesse nominale de 16,5 m/s (vitesse de la toux). Une évaluation plus poussée a été effectuée afin de connaître la capacité de filtration de certains tissus humides et de combinaisons de tissus qui pourraient être utilisées pour fabriquer des masques faits maison. La résistance respiratoire a été estimée à partir des commentaires qualitatifs. Dans cette étude, l'efficacité de filtration représente le pourcentage de particules qu'un milieu filtrant peut bloquer. Les tissus testés comprenaient : feutre, Lycra, sacs pour aspirateur lavables, ouatine matelassée/ouate à piquer et divers types de tissage de coton faciles à trouver comme l'étoffe matelassée, le coton pour chemise et le tricot pour chandail de coton.	faible en ce qui concerne l'efficacité de filtration. - Le masque N95 (52,47 %), le masque chirurgical (47,46 %) et le sac pour aspirateur HEPA jetable (60,86 %) ont obtenu les meilleurs rendements en ce qui concerne la filtration. - Les jeans en denim (45,94 %) et le tissu pour coupe-vent (47,12 %) étaient efficaces, mais manquaient de respirabilité. - Les matériaux à haute efficacité de filtration et à faible résistance respiratoire incluaient la laine feutrée (35,87 %), l'étoffe matelassée (34,54 %) et la flanelle de coton (28,50 %). - Les tissus utilisés de façon courante pouvaient atteindre des niveaux beaucoup plus élevés de filtration des particules ultrafines lorsqu'ils étaient utilisés en couches (60 %), mais ils étaient alors moins perméables à l'air. - Les sacs pour aspirateur étaient efficaces, mais leur utilisation n'est pas sécuritaire.
Foschini 2020 (17) *Prépublication* Expérience de simulation Brésil Mai 2020	Comparaison de l'efficacité relative des masques commerciaux (masques médicaux) et des masques en tissu faits maison. Un nébuliseur a été utilisé pour créer des aérosols composés d'eau distillée. En ce qui concerne les mesures de diffusion optique, deux techniques différentes ont été utilisées simultanément pour comparer l'intensité de la dispersion de la lumière par les gouttelettes entre les fenêtres avant et après l'échantillon.	- Le masque N95 et le masque chirurgical (99,7 %) sont ceux qui ont obtenu la plus grande efficacité de blocage. - Alors que le filtre à café a aussi obtenu une grande efficacité de blocage (99,6 %), il comportait cependant une faible respirabilité et s'est rapidement dégradé avec l'augmentation du niveau d'humidité, ce qui n'en fait pas un bon choix comme matériau dans un masque. - Comme les masques faits maison (51,0 %) ne comportaient pas autant d'épaisseurs que les masques chirurgicaux, cela a réduit leur efficacité.

		- Les tissus conventionnels à plus forte teneur en coton étaient les plus efficaces parmi les textiles de maison ayant été étudiés (une épaisseur : 46,5 %). Ajouter une deuxième épaisseur a cependant permis d'augmenter l'efficacité de blocage (double épaisseur : 66 %).
Lustig 2020 (20) Expérience de simulation États-Unis Mai 2020	Évaluation de plus de 70 combinaisons différentes de tissus et de masques dans un débit d'air permanent forcé par convexion avec aérosols pulsés simulant une respiration forcée.	- Parmi les matériaux efficaces (estimations plus basses en ce qui concerne la transmission fractionnelle), on trouvait tant des couches absorbantes hydrophiles que des couches barrière hydrophobes. - Les conceptions efficaces indiquées dans l'étude comportaient toutes des couches absorbantes (deux épaisseurs), soit des serviettes en éponge, du coton pour courtepointe et de la flanelle. Ces différents matériaux faciles à trouver ont tous permis d'obtenir une transmission fractionnelle à moins de 10 % de celle qu'offre le masque N95 à cinq épaisseurs. - Les conceptions efficaces comprenaient des couches barrières en polypropylène non-tissé, en polyester et en polyaramide. - De nombreux masques simple épaisseur ou faits d'un seul type de tissu présentaient des transmissions fractionnelles plus élevées que celles du masque N95.
Rodriguez-Palacios 2020 (22) Expérience de simulation États-Unis	Évaluation de différents textiles de maison pour en quantifier le potentiel comme barrières environnementales efficaces. Les auteurs ont utilisé un modèle de simulation qui pulvérise des gouttelettes avec suspension bactérienne (imitant un éternuement) pour quantifier la mesure dans laquelle les textiles domestiques utilisés pour fabriquer des vêtements réduisent la	- Lorsqu'aucun masque n'était porté, un éternuement simulé pouvait envoyer des gouttelettes porteuses de bactéries à plus de 1,8 m. - Tous les textiles simple épaisseur ont permis de réduire considérablement la distance parcourue par les macro-gouttelettes et les microgouttelettes, soit un maximum de 25,5 à 34 cm.

Mai 2020	dispersion des gouttelettes sur une surface se trouvant à moins de 1,8 m (la distance minimale recommandée pour la « distanciation sociale » selon de COVID-19). Les textiles testés comprenaient un tissu fait uniquement de coton peigné (tissu pour t-shirt), un tissu en microfibre 300 fils au pouce 100 % polyester (taie d'oreiller), deux tissus 100 % coton à tissage non serré filé à la main et un tissu de type « technologie qui garde au sec » 100 % polyester que l'on trouve souvent dans les maillots de sport. L'efficacité de ces textiles a été comparée au résultat obtenu avec un masque médical/chirurgical et sans masque.	- Les textiles deux épaisseurs (100 % coton peigné et 100 % polyester) ont bloqué complètement l'éjection des grosses macrogouttelettes et réduit de 97,2 % (P < 0,020) le déplacement des microgouttelettes par rapport aux tissus simple épaisseur et ont ainsi permis d'obtenir une dispersion inférieure à 10 cm. Même le tissu simple épaisseur le moins efficace (le tissu 100 % coton à tissage non serré filé à la main) a réussi à retenir de 90 à 99 % des gouttelettes lorsque deux épaisseurs étaient utilisées. - Les textiles double épaisseur étaient aussi efficaces que les masques médicaux et chirurgicaux pour prévenir la dispersion des gouttelettes.
Amendola 2020 (23) Expérience de simulation Italie Mai 2020	Expérience qui a simulé l'action respiratoire en mesurant la distribution des particules d'aérosol à base aqueuse. L'efficacité de filtration moyenne indiquée tenait compte des particules ayant un diamètre supérieur à 0,28 µm. Les masques ou couvre-visages ont été testés tant pour l'inhalation que l'expiration. TNT= matériau non-tissé fait de polypropylène et de viscose à base de tissu	- Le masque médical a démontré une efficacité de filtration supérieure à 97 %. - Seuls les masques faciaux triple épaisseur comprenant principalement du tissu non-tissé ont pu atteindre des valeurs supérieures à 95 %, y compris le TNT triple épaisseur et le TNT-coton-TNT.

*Le lieu ou la date de l'étude a été estimé en fonction des affiliations des auteurs et/ou de la date de publication.

MASQUES NON MÉDICAUX UTILISÉS POUR EMPÊCHER L'INHALATION DU SRAS-COV-2

Études de modélisation sur les humains, les mannequins et les animaux (n = 17) :

Des études ont été menées sur des volontaires humains (n = 7), des mannequins (n = 10) et des souris axéniques expérimentales (n = 1). Les mannequins ne reproduisent pas parfaitement les mimiques des humains (c.-à-d. incidence sur l'ajustement) ou les activités respiratoires puisque l'air ne se déplace que dans une seule direction (4). Par conséquent, il faut faire preuve de prudence lorsqu'on extrapole aux humains les résultats obtenus avec des mannequins pour les masques ou couvre-visages.

Bien qu'il ait été démontré que les masques non médicaux ou couvre-visages donnent de meilleurs résultats comme forme de contrôle à la source (c.-à-d. en limitant la transmission des personnes infectées) (2, 4, 5), il a également été démontré qu'ils offrent une certaine protection à la personne qui les porte (tableau 2). Le scénario de réduction de la transmission le plus efficace est celui dans lequel tout le monde (tant les gens sains qu'infectés) porte un masque ou couvre-visage (2).

- Les masques N95 bien ajustés offrent le plus haut degré de protection (>95 %) (2, 24-31). Un masque N95 mal ajusté offre différents niveaux de protection, dans certains cas, des niveaux comparables à ceux qu'offrent les masques chirurgicaux et les masques en tissu (24, 30).
- Les masques chirurgicaux ont une meilleure efficacité de filtration que les masques non médicaux (plage : 19,94 % à 95 %) (4, 25 à 28).
- Les masques en tissu avaient généralement une efficacité de filtration inférieure à celle des masques médicaux, bien que certains tissus et épaisseurs obtiennent un rendement comparable à celui des masques médicaux (4, 25, 27, 28).
    - Le rendement du masque (filtration des gouttelettes de salive, fuite d'air minimale) était plus élevé pour les masques plus ajustés (5, 24-26, 30, 32) et pour les masques multicouche (29, 31, 33). L'efficacité de filtration était plus élevée pour les grosses particules (4).
- On a constaté que la soie était très hydrophobe et efficace pour empêcher la pénétration des gouttelettes d'eau pendant les tests de pulvérisation (34).
- On a également constaté que le bandana et les tissus de coton simple épaisseur s'ajustaient mal et donnaient de mauvais résultats (efficacité inférieure à 15 à 30 %) (4, 27-29, 31).
- Les masques en tissu non médical de style chirurgical n'étaient pas aussi efficaces que les masques en forme de cône ou en bec de canard (26, 35).
- Dans une étude de modélisation avec des animaux, lorsqu'elles étaient protégées par deux couches de coton peigné à 100 %, toutes les souris étaient protégées à 100 % contre la contamination par les bactéries contenues dans les microgouttelettes (10).

Études des porte-filtres (n = 20) :

Dans des conditions expérimentales (c'est-à-dire lorsque les mesures étaient prises alors que le tissu était scellé sur un support), les efficacités de filtration étaient plus élevées que dans les études citées ci-dessus dans lesquelles les masques étaient testés alors qu'ils étaient portés par une personne (36 à 42). Par conséquent, ces simulations expérimentales surestiment l'efficacité des textiles de maison en ce qui concerne la protection potentielle contre le SRAS-CoV-2 des personnes qui les portent parce qu'elles n'évaluent pas directement la respirabilité ou l'ajustement, mais elles aident cependant à comprendre l'efficacité relative de filtration d'un tissu par rapport à un autre.

- L'augmentation du nombre d'épaisseurs augmente l'efficacité de filtration, mais augmente également la résistance à l'air (et réduit la respirabilité). Les masques non médicaux doivent avoir une résistance à l'air inférieure à 40 Pa/cm^2 (41 à 49). Les valeurs de perméabilité à l'air de tous les échantillons comprenant moins de quatre épaisseurs qui ont été analysés étaient inférieures aux valeurs maximales recommandées par le NIOSH pour les masques médicaux (50). Les échantillons comprenant trois épaisseurs ou plus ont réussi à obtenir une efficacité de filtration supérieure à 90 % (23, 37, 40, 42-44, 50, 51).
- Il a été démontré que les fuites simulées dans le tissu (visant à mesurer indirectement l'effet de l'ajustement) ont une grande incidence sur l'efficacité de filtration (44, 52). L'ajustement est donc très important pour assurer une protection adéquate.
- Les masques non médicaux ne donnaient pas d'aussi bons résultats que les masques médicaux. Cependant, l'ajout d'un filtre à charbon actif comme couche intermédiaire dans un masque de coton a considérablement amélioré l'efficacité de filtration (46, 53). Une étude a révélé que le fait de traiter les textiles de maison avec une solution de NaCl pouvait permettre d'accroître la capacité de filtration des masques non médicaux (54).
- D'énormes différences dans l'efficacité de filtration ont été observées tant entre les textiles de maison qu'en raison des tailles de particules, avec un écart allant d'un taux inférieur à 10 % à un taux supérieur à 95 %. L'efficacité de filtration était plus élevée pour les particules à déplacement plus lent produites pendant l'élocution que pour les particules à déplacement plus rapide produites pendant la toux ou l'éternuement (46).
- La qualité du tissu (c.-à-d. tissage serré, faible porosité) était tout aussi importante que le nombre d'épaisseurs (43, 44, 46).
- Certains tissus comportent des charges électrostatiques qui attirent et lient des particules de la taille d'un nanomètre, ce qui augmente l'efficacité de filtration (44, 52, 55). Combiner différentes épaisseurs de tissu et optimiser le filtrage mécanique et électrostatique peut être efficace pour maximiser l'efficacité de filtration dans un masque non médical (44, 52). Une combinaison de plusieurs épaisseurs de matériaux, avec une couche externe hydrophobe (par exemple, du polyester, du polypropylène lacé par filage ou de la polyaramide), une couche intérieure en tissu de coton de haute qualité et une

couche intermédiaire faite de matériaux non-tissés ou chargés électrostatiquement (par exemple, soie naturelle, mousseline ou polyester) serait donc idéale pour optimiser tant la capacité de protection que le potentiel de réduction de transmission des masques non médicaux ou des couvre-visages.

- Bien qu'il ait été démontré que les sacs pour aspirateur ont une efficacité de filtration comparable à celle des masques médicaux (4, 5, 40, 42, 46, 50), ce ne sont pas des produits cliniques certifiés, ce qui signifie qu'ils peuvent donc contenir des ingrédients malsains et des fibres nocives. Il n'est donc pas recommandé de les utiliser dans les masques faits maison (5).

Tableau 2 : Études qui évaluent les caractéristiques de protection des masques non médicaux ou des couvre-visage (n = 37)

ÉTUDE*	MÉTHODE	PRINCIPAUX RÉSULTATS
Expériences menées avec un ou plusieurs volontaires humains, des mannequins ou des modèles animaux (n = 17)		
Park 2020 (31) Quasi-expérience États-Unis Août 2020	Étude sur le développement de masques qui a évalué 10 échantillons différents de diverses configurations de matériaux afin d'en déterminer la perméabilité à l'air, l'efficacité de filtration selon la taille des particules et la chute de pression, pour en arriver à une conception de masque offrant un confort optimal et une efficacité barrière optimale. Un sujet humain a porté le masque à l'essai pendant de longues périodes alors qu'il simulait une journée de travail type, puis en a évalué le rendement. La perméabilité à l'air a été évaluée à l'aide de la méthode ASTM D737-96 alors que la filtration et la chute de pression ont été évaluées avec la méthode ASTM F2299-03 avec des particules de 0,2 à 1 µm et un débit d'air de 8,7 cm/s.	- Les masques médicaux ont obtenu la plus grande efficacité de filtration, alors que le tissu utilisé pour faire des mouchoirs était le moins performant (perméabilité à l'air la plus élevée, mais avec une efficacité de filtration de seulement 19 % même avec quatre épaisseurs). - La configuration de blocage jugée optimale était « filtre 2 (superposition) » entre deux couches de tissu barrière 100 % polyester. Ce masque a obtenu de meilleurs résultats en ce qui concerne la filtration et la perméabilité que le masque commercial en tricot double épaisseur évalué. - L'efficacité de filtration était meilleure pour les particules de plus grande taille que pour les particules plus petites.

O'Kelly 2020 (24) *Prépublication* Quasi-expérience États-Unis Août 2020	Sept volontaires humains ont été utilisés pour évaluer quantitativement le niveau d'ajustement de divers types de masques (masques N95, masques KN95, masques chirurgicaux et masques en tissu), et surtout, pour examiner l'exactitude des vérifications d'ajustement effectuées en comparant les résultats des vérifications d'ajustement aux résultats quantitatifs des essais d'ajustement. Les tests d'ajustement quantitatifs évaluent simultanément le nombre de particules qui se trouvent à l'intérieur et à l'extérieur d'un masque. Les notes indiquées pour le facteur d'ajustement proviennent du nombre de particules filtrées par le masque. Chaque participant a effectué un test quantitatif d'ajustement et une vérification subjective de l'ajustement pour chacun des masques.	- Les masques N95 offraient le plus haut degré de protection avec des notes moyennes pour l'ajustement des différents modèles variant entre 13,2 et 72,3. - Les masques N95 mal ajustés offraient différents niveaux de protection, dans certains cas comparables aux masques chirurgicaux et aux masques en tissu. - Le KN95 et le masque chirurgical ont obtenu une note d'ajustement moyenne de 3,2 et de 2,2, respectivement. - Les masques ou couvre-visages en tissu ont quant à eux donné des résultats semblables à ceux des masques KN95 et des masques chirurgicaux. - Une conception améliorée combinée à l'utilisation de meilleurs matériaux accroîtrait probablement l'efficacité de ces masques.
Mueller 2020 (26) Quasi-expérience États-Unis Mai 2020	Quantification de l'efficacité des masques en tissu produits dans la collectivité et dans le commerce comme équipement de protection individuelle grâce à deux compteurs de particules qui échantillonnent simultanément l'air ambiant et l'air à l'intérieur de différents types de masques portés par un seul volontaire. Le rendement du masque a ensuite	- Un masque N95 bien ajusté présentait l'efficacité d'élimination moyenne la plus élevée (99 %), ainsi qu'un facteur d'ajustement élevé. - Lorsqu'un masque N95 mal ajusté a été utilisé, l'efficacité d'élimination des particules et le facteur d'ajustement ont diminué pour atteindre 90,6 % et 10,6, respectivement. - Les masques chirurgicaux standards et les masques quatre épaisseurs avec une couche de charbon de bois avaient une efficacité

	été évalué selon l'efficacité d'élimination des particules (taille inférieure à 0,3 µm) et la variabilité statistique lorsqu'il est porté comme prévu, ainsi qu'avec une épaisseur de nylon, pour ainsi en évaluer de façon indépendante l'ajustement et le matériau.	moyenne d'élimination variant entre 50 et 75 %. - L'efficacité d'élimination des particules du masque en tissu variait entre une valeur inférieure à 30 % et 90 %. Les masques en tissu les plus performants étaient en forme de cône et comprenaient une couche de tissu filtrant soufflé par fusion entre les couches de tissu. - Les masques en tissu de style chirurgical n'étaient pas aussi efficaces que les masques en forme de cône, mais ils étaient rehaussés d'une épaisseur de nylon. - L'épaisseur de nylon n'a pas eu une efficacité de filtration significative, mais a amélioré l'ajustement du masque en dessous.
Ueki 2020 (2) Quasi-expérience Japon Octobre 2020	Description d'une simulation dans laquelle des gouttelettes et des aérosols contenant le virus infectieux SRAS-CoV-2 produits par la respiration humaine et la toux sont transmis dans l'air. Le simulateur a été utilisé pour évaluer la transmissibilité des gouttelettes et des aérosols infectieux et la capacité de différents types de masques à bloquer cette transmission. Ce simulateur comprend deux têtes de mannequin installées l'une face à l'autre et reliées à un nébuliseur de compresseur sur mesure.	- Le masque N95 présente l'efficacité de protection la plus élevée (il entraîne une réduction de l'exposition aux particules infectieuses variant entre 80 et 90 %). - Les masques chirurgicaux et les masques N95 n'ont, quant à eux, pas pu bloquer complètement la transmission des gouttelettes de virus et des aérosols, même lorsqu'ils étaient absolument étanches. La charge virale qui traverse un masque N95 ajusté, porté par le propagateur, était de 0,3 copie $\log_{10}$ alors qu'elle était de 10 copies $\log_{10}$ lorsque ce même masque était porté par le récepteur. - Comparativement à l'absence de masque ou de couvre-visage, un masque ou couvre-visage en coton a entraîné une réduction de 20 à 40 % de l'absorption du virus. - Les masques ou couvre-visages en coton et les masques chirurgicaux conviennent beaucoup mieux pour bloquer la dispersion du virus que pour protéger la personne qui

		les porte (> 50 %) (c.-à-d. comme forme de contrôle de la source). - Il y avait un effet synergique lorsque le récepteur et le propagateur du virus portaient tous deux des masques ou des couvre-visages (masques de coton ou masques chirurgicaux). Par exemple, lorsque le récepteur portait un masque ou couvre-visage en coton, la charge virale qui traversait le masque était de 63 copies $\log_{10}$ alors que lorsque le propagateur portait un masque, la charge virale qui traversait le masque était de 42 copies $\log_{10}$. Quand, tant le récepteur que le propagateur portaient un masque, la charge virale était la plus faible à 33 copies $\log_{10}$. Voir les graphiques dans le document.
Teesing 2020 (35) Quasi-expérience Pays-Bas Octobre 2020	Étude qui a utilisé chambre à particules fermée construite pour tester les matériaux filtrants potentiels recommandés par les gouvernements pour les masques faits maison. Les matériaux ont été testés seuls, ainsi qu'entre deux couches de coton, comme dans un masque fait maison. Divers modèles de masques ont été testés, soit des masques pliés, plissés, ronds, plats et en bec de canard. L'ajustement du masque a été testé avec un appareil AccuFIT 9000 pour ajustement de masque et un volontaire humain. Un test de pression a été effectué pour quantifier la perméabilité à l'air des différents matériaux et	- Les résultats des tests avec particules effectués sur les différents matériaux ont été comparés à ceux obtenus avec les masques N95/FFP2/KN95, et le matériau le plus performant était l'ePM$_1$ avec un résultat de 85 %. Certains autres matériaux facilement disponibles qui ont obtenu de bons rendements incluaient le cuir, un filtre à café plié entre des épaisseurs de coton, ainsi qu'un essuie-tout plié entre du coton et le tissu en microfibre. - Aucun des masques en coton avec filtre n'a réussi l'essai d'ajustement effectué. Le modèle en bec de canard a été jugé satisfaisant. - La chute de pression associée au masque en bec de canard a été testée et le linge à vaisselle simple épaisseur plié a démontré une respirabilité comparable à celle du masque 3M de référence.

	conceptions après un test d'ajustement réussi.	
Mboowa 2020 (41) *Prépublication* Quasi-expérience Ouganda Septembre 2020	Étude qui a testé huit masques offerts sur le marché afin d'en connaître l'efficacité de filtration, la propreté microbienne et la capacité de réutilisation. Du *Mycobacterium smegmatis* a été aérosolisé par un pulvérisateur portatif et envoyé sur des sections de masques installés sur des porte-filtres. L'air filtré a ensuite été inoculé sur de la gélose. De la saccharine (test de goût) a été utilisée pour évaluer l'ajustement du masque des volontaires. Après un lavage ou un traitement avec éthanol à 70 %, ces mêmes tests ont été refaits afin d'évaluer la réutilisabilité des masques ou couvre-visage. Des masques chirurgicaux, ainsi que des masques en polypropylène, faits d'un tissu « épais », en kitengi (intérieur)/coton (extérieur), en chiffon et faits avec une débarbouillette ont également été testés.	- Les masques chirurgicaux, suivis des masques double épaisseur en tissu local et des masques double épaisseur en tissu ont obtenu la meilleure filtrabilité. - L'ajout du traitement avec éthanol à 70 % a réduit tant l'ajustement que la capacité de réutilisation du masque. - Comme l'a montré le test de goût avec la saccharine, les masques double épaisseur étaient les mieux ajustés puisqu'il a fallu un plus grand nombre de pulvérisations, comparativement au masque simple épaisseur, pour que le bénévole qui le portait goûte la saccharine. - Il faut cependant interpréter ces résultats avec prudence, car la méthodologie utilisée n'est pas claire.
Rodriguez-Palacios 2020 (10) Quasi-expérience États-Unis Août 2020	Étude qui a fait état d'une expérience *in vivo* utilisant une méthode avec pulvérisation simulée de microgouttelettes porteuses de bactéries (bactéries de produits laitiers avec probiotiques) pour déterminer dans quelle mesure le tissu 100 % coton peigné double épaisseur (un	- Lorsque deux épaisseurs de tissu 100 % coton peigné ont été utilisées pour protéger les souris, aucune d'entre elles n'a été contaminée par les bactéries contenues dans les microgouttelettes (vaporisation de 2 ml). - Une fois exposées à 10 fois le volume de pulvérisation (20 ml), les barrières textiles ont continué à protéger toutes les souris (même avec un textile de faible densité; tissu épais

	tissu pour t-shirt couramment utilisé) a empêché la contamination chez des souris axéniques. Deux densités de tissu différentes ont été testées, soit 120 et 200 g/m^2. (Le tableau 1 présente l'expérience avec contrôle à la source)	ou mince, tests t pour échantillons appariés, p = 0,002) contre des doses élevées de gouttelettes. - Lorsque les mêmes expériences ont été effectuées sur des cages partiellement couvertes, toutes les souris ont été contaminées.
Pan 2020 (4) *Prépublication* Expérience de simulation États-Unis Novembre 2020	Évaluation de l'efficacité de filtration de 11 masques ou couvre-visages sur des mannequins pour connaître le niveau de protection de chacun lors de l'inspiration et de l'expiration. Ce test a été réalisé avec une vaste gamme d'aérosols allant de 0,04 à 135 µm. Les particules utilisées dans l'étude provenaient d'une solution de NaCl à 2 %. Deux mannequins installés sur des côtés opposés d'une chambre en acrylique de 57 L ont été utilisés. Le mannequin qui « expirait » était relié à un nébuliseur alors que celui qui « inhalait » était relié à un aspirateur. Un masque était d'abord porté par le mannequin qui inhalait, puis par le mannequin qui expirait, afin de mesurer le nombre de particules qui traversaient le masque dans chacun des cas. masques ou couvre-visage testés : sac pour aspirateur, masque chirurgical, filtre MERV 12, bandana, taie d'oreiller en coton 200 fils au pouce, t-shirt en coton,	- Comme l'efficacité de filtration augmentait lorsque la taille des particules augmentait, ce qui a empêché les gouttelettes de plus de 20µm d'aller à plus de 33 cm. Le sac pour aspirateur, le chiffon en microfibre, le masque chirurgical et le filtre MERV 12 ont été les plus efficaces pour bloquer les particules de 2 µm avec une efficacité supérieure à 90 %. - Le sac pour aspirateur et le chiffon en microfibre sont ceux qui ont obtenu l'efficacité de filtration la plus élevée avec une plage de 60 à 90 %, alors que ce niveau variait entre 50 et 75 % pour les masques chirurgicaux. Le filtre à café a, quant à lui, obtenu une efficacité de filtration qui variait entre 10 et 75 % pour des particules de 0,04 à 1 µm. - Le masque en coton mince et le bandana (double épaisseur) avaient un bas niveau d'efficacité (30 à 50 %) qui a encore descendu (5 à 40 %) avec les particules submicroniques. - L'efficacité de la protection lors de l'inspiration et de l'expiration était semblable pour la plupart des masques. - Les masques mal ajustés (p. ex., le bandana) n'ont pas donné d'aussi bons résultats en matière de contrôle à la source.

	tissu en microfibre, filtre à café, coton mince, acrylique mince et écran facial en plastique.	- L'écran en acrylique mince est celui qui a donné les plus mauvais résultats. - Le fait d'avoir pu réduire le jeu entre la peau et le masque et la vitesse de l'air a permis d'améliorer grandement la protection en expiration du masque sans couture mentionné par le CDC et fabriqué avec une taie d'oreiller en coton de 200 fils au pouce.
Kähler 2020 (5) Expérience de simulation Allemagne Octobre 2020	Utilisation des mesures vélocimétriques associées à l'image quantitative des particules pour évaluer la propagation de l'air expiré, la vitesse des gouttelettes expirées et les propriétés de turbulence du flux d'air. Dans cette étude, un seul volontaire humain a été utilisé pour examiner le champ d'écoulement associé à la toux. Les tests ont été effectués avec et sans masque chirurgical et ont utilisé de la fumée pour démontrer l'effet de l'espace qui se crée entre la peau et la bordure du masque lorsqu'un masque est mal ajusté (masques chirurgicaux et FFP2). Une caméra numérique installée devant et derrière le matériau filtrant a été utilisée pour déterminer la capacité de filtration des différents matériaux sur les petits aérosols (0,3 à 2 µm).	- Le masque chirurgical limite la propagation de l'air et des aérosols lors de l'élocution ou de la toux. - Les masques ou couvre-visages qui recouvrent la bouche et le nez et les masques chirurgicaux n'étaient pas suffisamment ajustés sur le visage pour protéger contre l'infection par gouttelettes, comme le démontrent les preuves photographiques dans lesquelles les gouttelettes passent facilement à travers le masque. - Les masques faits avec du papier hygiénique quatre épaisseur, des essuie-tout, des filtres à café, du molleton et du tissu en microfibre présentaient tous un bas niveau de filtration. - Les sacs pour aspirateur avec filtre pour poussière fine ont démontré un effet de filtrage comparable aux masques FFP2/N95/KN95, mais ils ne sont pas conçus pour une telle utilisation.
Colline 2020 (30) Expérience de simulation	Étude qui a testé des masques afin de comparer l'efficacité d'un matériau neuf (référence) et l'efficacité de filtration de ce même matériau, une fois le masque déjà porté.	- La filtration de référence a révélé qu'une seule épaisseur de coton 500 fils par pouce avait l'efficacité de filtration la plus faible (26,2 % et 17,4 % pour les gouttelettes de 60 et de 125 nm, respectivement). Le masque protecteur contre la poussière, le filtre à café,

États-Unis Septembre 2020	Un nanoaérosol avec dioxyde de silicium d'un diamètre moyen de 40 nm a ensuite été ajouté à une enceinte en acier inoxydable. L'efficacité de filtration de base a été testée avec un matériau attaché (sans tension) et un débit d'air de 0,0465 LPM/cm^2. Des masques ont ensuite été installés sur un mannequin auquel un débit d'admission était installé sur le nez. Des particules de 60 et de 125 nm ont été échantillonnées à raison de 1 par seconde pendant 180 secondes.	le coton double épaisseur et la serviette d'atelier ont donné des résultats un peu meilleurs. - Les appareils de protection respiratoire à filtres à particules (KN95, 3M 8511 et FTF467 ULPA) avaient une efficacité de filtration supérieure à 98 %. - Comparativement aux matériaux de référence, on a noté une importante baisse de l'efficacité de filtration pour tous les matériaux testés comme lorsque ce même masque avait déjà été porté. L'ajout d'une couche filtrante dans un masque en coton double épaisseur n'a pas permis d'améliorer considérablement la filtration en raison des fuites autour du masque. - L'efficacité de filtration d'un masque mal ajusté ou non serré peut donc chuter de plus de 60 % par rapport à l'efficacité de filtration du matériau.
Realmuto 2020 (32) Expérience de simulation États-Unis Septembre 2020	Étude qui a comparé des tests effectués sur un masque en bec de canard (masque sans couture obtenu simplement en pliant un morceau de tissu carré pour former un masque) faits de différents matériaux aux masques chirurgicaux et aux masques N95 disponibles dans le commerce. Un simulateur d'essai d'ajustement sur mannequin a été utilisé pour les tests de filtration, de perméabilité à l'air et de fuite. La tête du mannequin sur laquelle un simulateur de tube respiratoire a été installé a ensuite été mise dans une chambre avec un ventilateur de mélange et des valves d'essai	- Efficacité de filtration des masques testés, du meilleur au pire : masque N95 > chirurgical > triple épaisseur en polypropylène/Filti/polypropylène > triple épaisseur en polypropylène/MERV 13 ou huit/polypropylène> couche intérieure en Halyad H600, Filti simple épaisseur. - Les masques double épaisseur avaient une plus grande efficacité de filtration que les masques simple épaisseur. - Les expériences ont montré que les fuites dans les masques réduisaient considérablement l'efficacité de ce dernier. - Les résultats obtenus avec les sangles de tête étaient meilleurs que ceux obtenus avec les boucles d'attache dernière les oreilles, car l'espace entre le masque et la peau était plus facile à réduire avec ce type de sangle.

	alors que des particules avec une concentration de sel variant entre 50 et 700 nm étaient introduites dans la chambre. Matériaux testés : polypropylène non-tissé, matériau de masque « Filti » (polypropylène/nanofibre/matériau filtrant en polyester composite), filtres MERV, mousseline de coton, lingettes réutilisables, serviettes d'atelier pour l'huile.	
Parlin 2020 (34) Expérience de simulation États-Unis Septembre 2020	Comparaison de divers matériaux (coton, polyester, soie, essuie-tout) à des masques chirurgicaux dans des conditions de laboratoire afin d'en évaluer l'hydrophobie et la respirabilité avant et après un nettoyage. Des tests en laboratoire ont été effectués avec des masques installés sur des mannequins.	- La soie est un matériau hydrophobe qui bloque les gouttelettes et qui a réussi à empêcher l'absorption des gouttelettes comme le fait un masque chirurgical à usage unique, en plus de mieux conserver sa respirabilité que les matériaux hydrophiles comme le coton. La soie a également donné de bons résultats après avoir été nettoyée. - Lorsque la soie, le coton et le polyester ont été soumis à des tests de pulvérisation avec gouttelettes aérosolisées, la capacité de bloquer la pénétration des goulettes dans les aérosols n'a pas varié, que la barrière utilisée ait été simple ou double épaisseur.
Bhimaraju 2020 (28) *Prépublication* Expérience de simulation États-Unis Août 2020	Étude qui a utilisé un mannequin et un système d'inhalation pour évaluer l'efficacité de filtration des particules de moins de 2,5 µm. Les masques testés comprenaient : masques N95, masques chirurgicaux, masques en tissu, masques en tissu avec filtres à air au charbon actif, masques en tissu avec filtres à air de type CVCA, masques en tissu légèrement	- Les masques au charbon actif et les masques avec filtre à air de type CVCA étaient presque aussi efficaces que les masques N95, suivis des masques chirurgicaux, des masques en tissu fortement amidonnés et des masques en tissu légèrement revêtus d'amidon. - Le niveau de filtration des masques ordinaires en tissu pour les particules < 2,5 um était très bas par rapport aux autres masques.

	revêtus d'amidon et masques en tissu fortement amidonnés.	
Shahane-Kapse 2020 (29) *Prépublication* Expérience de simulation Inde Août 2020	Comparaison entre un masque double épaisseur en coton avec une couche de polypropylène enduit de polyuréthane appliqué sur l'extérieur du masque au centre du masque (afin qu'elle recouvre la bouche et le nez), un masque N95, des masques chirurgicaux triple épaisseur, un masque ou couvre-visage en coton et un écran facial. La quantité et le degré de gouttelettes et d'aérosols dans chacun des masques ont été évalués lorsque ceux-ci étaient portés par un mannequin, mais cette étude ne comportait cependant aucun échange gazeux (c.-à-d. respiration). Des colorants fluorescents ont été pulvérisés d'une distance de 1 et de 2 m à 180 km/h.	- Le colorant fluorescent n'a pas pénétré la couche intérieure des masques chirurgicaux trois épaisseurs ou des N95. - Le masque trois épaisseurs composé de deux couches de coton et d'une couche extérieure en polypropylène a bloqué le colorant fluorescent aux endroits où le tissu était imperméable. On pouvait cependant voir quelques taches sur la couche extérieure en coton sur les côtés du polypropylène, mais le colorant n'a cependant pas pénétré la couche de coton intérieure. - Le colorant fluorescent a cependant pénétré le masque en coton simple épaisseur et s'est retrouvé sur le mannequin.
Dhanraj 2020 (33) *Prépublication* Expérience de simulation États-Unis Juillet 2020	Étude visant à présenter les résultats de la caractérisation du Swiffer comme matériau filtrant de rechange et à évaluer l'efficacité de filtration de ce matériau selon la taille des particules. Deux systèmes ont été utilisés. Dans l'un, des confettis ronds de 47 mm étaient envoyés sur un système avec porte-filtre alors que dans l'autre, un masque (de type bandana) fait maison avec des Swiffer intercalés entre du tissu de taie d'oreiller, a été placé sur un mannequin dans une chambre.	- Le Swiffer a été très efficace pour filtrer les particules ultrafines (< 0,08 µm). - On a observé de plus grandes efficacités de filtration lorsque deux épaisseurs de Swiffer étaient intercalées entre deux couches de tissu de taie d'oreiller. Ainsi, avec deux épaisseurs de Swiffer, l'efficacité variait entre 45 et 62 % pour les particules de 0,1 à 0,5 µm alors qu'elle atteignait 30 à 45 % avec un seul Swiffer.

Joshi 2020 (25) *Prépublication* Expérience de simulation Inde Juin 2020	Étude qui a mesuré l'efficacité et la chute de pression du masque en installant le masque ou couvre-visage sur un tuyau en verre et en mesurant les particules en amont et en aval présentes dans l'échantillon. Les paramètres du test incluaient l'efficacité de capture des particules du matériau du masque, la chute de pression et le facteur d'ajustement (fuite). Des expériences ont été menées avec des aérosols faits de NaCl atomisé sur trois types de masques, soit le N95 commercial, le masque chirurgical et le masque en tissu (aucune information sur un matériau particulier utilisé).	- L'efficacité de filtration moyenne pour les particules de 0,3 µm pour le masque N95, le masque chirurgical et le masque en tissu était de 96,19 %, de 40,08 % et de 14,22 % respectivement. - L'efficacité de filtration pour les particules de moins de 0,3 µm n'a pas changé pour le N95 et les masques en tissu, mais les masques chirurgicaux pourraient, quant à eux, avoir une meilleure efficacité de filtration. - Les masques plus serrés avaient une plus grande efficacité de filtration. Ainsi, le N95, le masque chirurgical et le masque en tissu ont obtenu 95,60 %, 41,65 % et 13,79 %, comparativement à 95,08 %, 19,94 % et 11,67 %, respectivement, lorsque l'ajustement n'était pas aussi serré.
Sheets 2020 (27) *Prépublication* Expérience de simulation États-Unis Juin 2020	Étude qui utilise un débit constant d'air aérosolisé envoyé vers un mannequin test pour l'ajustement des masques et vers un essayeur de matériaux à pince afin de quantifier la perméabilité à l'air, l'efficacité de filtration et la sensibilité de l'ajustement d'un ensemble particulier de types de conceptions de masques et de filtres. Des capteurs de particules, de débit et de pression disponibles dans le commerce ont été utilisés pour mesurer la protection contre les aérosols aqueux d'une taille supérieure à 0,3 µm, ce qui a permis d'évaluer rapidement ces trois propriétés.	- Les masques N95 présentaient l'efficacité de filtration la plus élevée (> 95 %). - Le bandana tissé offrait peu de protection (< 15 %), mais avait une grande respirabilité. - Le masque chirurgical a une filtrabilité deux fois plus élevée qu'un bandana ayant la même respirabilité. - L'emballage pour stérilisation (un matériau non-tissé utilisé par les professionnels de la santé pour emballer les instruments chirurgicaux) a une plus grande efficacité de filtration que le masque chirurgical, mais est moins perméable à l'air. - La filtration des aérosols à travers le masque KN95 installé tel que reçu et correctement ajusté a démontré qu'un ajustement correct a réduit le nombre d'aérosols qui traversaient le masque de > 50 % à < 20 % lorsqu'il était bien ajusté.

Études sur les porte-filtres utilisés pour évaluer les caractéristiques de protection des matériaux utilisés dans la fabrication des masques (n = 20)		
Bayersdorfer 2020 (48) Expérience de simulation États-Unis Décembre 2020	Huit prototypes de masque ont été mis au point et testés en laboratoire. De ceux-ci, quatre ont été utilisés pour évaluer l'efficacité de filtration bactérienne (EFB) et la chute de pression alors que les l'efficacité de filtration des particules (EFP) a été évaluée avec les quatre autres.	- Les résultats en ce qui concerne l'EFB sont de 83,0 % à 97,7 % pour les masques simple épaisseur et de 96,3 % à 98,1 % pour les masques double épaisseur. - Les résultats pour l'EFP variaient de 92,3 % à 97,7 % pour les masques simple et double épaisseur.
Li 2020 (36) Expérience de simulation Chine Novembre 2020	Étude qui a évalué l'efficacité de filtration d'un masque triple épaisseur (fait avec deux serviettes de cuisine et des mouchoirs en papier quatre épaisseurs) comparativement à celle des masques médicaux sous flux laminaire dans un système de conduits d'air à plusieurs niveaux avec des aérosols de NaCl nébulisés de 6 à 220 nm.	- L'efficacité de filtration des masques faits maison était semblable à celle des masques médicaux pour les particules de 6 à 200 nm (84,54 % contre 86,94 %, P = 0,102).
Maher 2020 (47) Expérience de simulation États-Unis Octobre 2020	Étude qui a utilisé la concentration des gouttelettes d'aérosol, la différence de pression entre chaque matériau et les caractéristiques du débit d'air pour mesurer l'efficacité de filtration de 14 matériaux courants.	- Les résultats obtenus en ce qui concerne la concentration en aérosols ont indiqué que les matériaux divisaient les grosses particules en plusieurs particules plus petites. - Les couches multiples de tissu augmentaient l'efficacité du filtrage de 4 à 15 %, comparativement à une seule épaisseur du même tissu, mais cela diminuait la perméabilité à l'air et augmentait de 3 à 4 fois la différence de pression. Les masques triple épaisseur ont donc obtenu une pression 2 à 2,5 fois plus élevée que les masques double épaisseur.

		- Tous les matériaux multicouche testés avaient une efficacité de filtration > 95 % pour les aérosols de 1 µm à 4,7 µm.
Wang 2020 (51) Expérience de simulation Chine Octobre 2020	Étude réalisée en conformité avec la norme nationale chinoise qui oblige le port du « masque chirurgical » et a testé 17 matériaux pour en évaluer la différence de pression, l'efficacité de filtration des particules, l'efficacité de filtration bactérienne et la résistance à l'humidité de surface. Les matériaux testés comprenaient : t-shirt, chandail en molleton, manteau d'extérieur, manteau en duvet, vêtements de protection solaire, jeans, linge à vaisselle pelucheux, linge à vaisselle à texture granuleuse, sac à provisions non-tissé, sac pour aspirateur, couche, serviette hygiénique, taies d'oreiller, tissu médical non-tissé, gaze médicale.	- Parmi les onze matériaux simple épaisseur ont satisfait la norme de différence de pression (≥ 49 Pa), trois correspondaient à la norme de résistance à l'humidité de surface (≥ 3), un a satisfait la norme d'efficacité de filtration des particules (≥ 30 %), mais aucun ne répondait à la norme d'efficacité de filtration bactérienne (≥ 95 %). - Trois matériaux double épaisseur, y compris un tissu médical non-tissé, un tissu médical non-tissé et un sac à provisions non-tissé, et un tissu médical non-tissé et une serviette à thé à texture granuleuse, ont cependant obtenu des résultats proches de la norme d'efficacité de filtration bactérienne.
Long 2020 (50) Expérience de simulation États-Unis Octobre 2020	Étude qui décrit la conversion de l'équipement standard utilisé pour effectuer les tests d'ajustement des respirateurs en milieu hospitalier et industriel en une installation qui mesure l'efficacité de filtration quantitative des matériaux en fonction des lignes directrices du NIOSH pour les masques N95, ainsi que l'efficacité de filtration des matériaux que l'on retrouve dans le secteur des soins de santé et de consommation générique.	- L'efficacité de filtration des matériaux simple épaisseur variait entre 35 et 53 %. Deux matériaux (filtre à café et chiffon en coton) présentaient les plus faibles efficacités de filtration, tandis que le sac pour aspirateur, dont l'utilisation comme masque n'est pas sécuritaire, affichait la plus grande efficacité avec une efficacité de filtration de 82 %. - Des efficacités de filtration pouvant atteindre 90,37 % ont été déclarées pour les combinaisons de matériaux multicouche. - Tous les matériaux présentaient des valeurs Δp inférieures à la résistance maximale

		autorisée par le NIOSH pour les respirateurs (35 mm H_2O).
Whiley 2020 (40) Expérience de simulation Australie Septembre 2020	Étude qui a utilisé une méthode standard d'essai pour les masques (ASTM F2101-14) et la méthode avec bactériophage MS2 pour tester l'efficacité de filtration virale (EFV) des masques en tissu (achetés sur un site Web de vente au détail en ligne) comparativement aux masques jetables, chirurgicaux et N95 disponibles dans le commerce. Deux types d'aérosols de taille différente, soit 6 µm et 2,6 µm, ont été utilisés pour tester les masques. Ni le déroulement de cette étude ni les mesures qui y sont présentées ne sont normalisés. Il faut donc interpréter ces résultats avec prudence.	- Tous les masques en tissu présentaient une EFV d'au moins 50 % pour les aérosols de 6,0 µm. Ce taux est passé à 63 % pour les aérosols de 2,6 µm. - Les masques N95 et chirurgicaux avaient une efficacité de filtration supérieure à 99 %. - Un masque en coton avec filtre ajouté et un sac à provisions/masque en coton réutilisable ont obtenu des résultats aussi bons que ceux obtenus avec les masques médicaux (EFV d'environ 99 %). - Un masque triple épaisseur en chanvre, en polymembrane et en coton a également donné de bons résultats (EFV supérieure à 89 %).
Maurer 2020 (43) Expérience de simulation Allemagne Septembre 2020	Étude qui a évalué des masques de type communautaire fournis par de grands fabricants. L'efficacité de filtration a été déterminée avec des particules aérosol radioactives. La résistance à l'air (c.-à-d. la perméabilité à l'air) a été mesurée avec un pneumotachographe.	- Les efficacités de filtration (%) des matériaux étudiés, de la meilleure à la pire, étaient les suivantes : - Masques triple épaisseur : membrane médicale selon EN > Couche extérieure en tricot de polypropylène/polyamide, couche médiane en microfilaments de molleton et couche intérieure en polyester/polyamide > 100 % coton - Masques double épaisseur : 100 % coton biologique > coton/polyester > 100 % coton > polyamide/élasthanne > polyester et polypropylène avec molleton - Masques simple épaisseur : Texlyte Nano > polyester/carbone > 100 % coton > fil multifilament > 100 % polyester

		- Aucun des masques ou des couvre-visage de type communautaire n'était conforme aux normes européennes pour les masques médicaux (efficacité de filtration supérieure à 99 % et résistance de l'air inférieure à 40 Pa/cm^2). - Les masques triple épaisseur présentaient l'efficacité de filtration la plus élevée, mais avaient une respirabilité réduite. - En ce qui concerne l'efficacité de filtration, la qualité du tissu semble plus importante que le nombre d'épaisseurs (simple et double).
Pei, 2020 (55) Expérience de simulation États-Unis Septembre 2020	Étude qui visait à évaluer l'efficacité de filtration et la résistance à la respiration (chute de pression) des respirateurs et des masques commerciaux, ainsi que des matériaux domestiques courants. Tous les échantillons ont été coupés pour s'adapter au porte-filtre. L'efficacité fractionnelle a été mesurée avec des particules monodispersées de NaCl (entre 0,03 et 1 µm).	- Les masques électrets (filtre à charges électrostatiques) ont une efficacité de filtration de 70 à 85 % et l'efficacité augmente avec la taille des particules. - Les masques N95 et KN95 avaient une efficacité supérieure à 90 %. - L'efficacité de filtration des masques avec filtre non-électret était nettement inférieure à celle du masque avec filtre électret (aussi faible que 20 % pour les particules de 0,3 à 0,4 µm, mais qui augmente à 40 % pour 1 µm). - Tous les respirateurs et masques testés avaient une résistance respiratoire acceptable. - Les filtres pour aspirateur avaient une meilleure efficacité de filtration que le respirateur N95, mais ils avaient une résistance respiratoire 10 fois supérieure et se sont donc révélés peu pratiques comme matériau pour fabriquer des masques. - Parmi les textiles de maison courants, le Thinsulate double épaisseur, les draps cinq épaisseurs, les t-shirts et le Swiffer Sweeper avaient une efficacité d'environ 50 % pour les particules d'environ 0,3 µm. Leur efficacité

		pourrait être améliorée en ajoutant d'autres épaisseurs. La résistance à la respiration était élevée comparativement à un masque de procédure. - Deux épaisseurs de filtre à café offrent la pire efficacité de filtration et la pire résistance à la respiration.
Schilling 2020 (38) Expérience de simulation États-Unis Août 2020	Étude qui a examiné la filtration des aérosols et la respirabilité de 47 « masques non réglementaires » en utilisant des aérosols polydispersés. Elle a également évalué l'efficacité de filtration de six masques N95 et d'un certain nombre de masques non réglementaires. La filtration a été évaluée en fonction de la taille des particules (0,2 à 1 µm) à une vitesse de 10 cm/s et de la perméabilité à l'air en mesurant pour ce faire la chute de pression (en mm H_2O) sur un disque de 40 mm conçu avec le même matériau que celui du masque.	- L'efficacité de filtration des six masques N95 testés variait de 98 à 99 %. - Certains masques « non réglementaires » ont obtenu des efficacités de filtration semblables à celles du masque N95 pour les particules de 0,2µm et plus, alors que d'autres avaient des efficacités de filtration médiocres (c.-à-d. < 80 %). - Tous les masques étaient sous le seuil établi par le NIOSH pour la respirabilité, soit de 0,0247 mm $H_2O/(cm^3/s)$.
Hao 2020 (46) Expérience de simulation États-Unis Août 2020	Étude qui a évalué la filtration de matériaux non médicaux à des vitesses différentes. La perméabilité à l'air a été mesurée par la résistance à l'écoulement des matériaux. L'efficacité de filtration a été comparée à celle des masques médicaux, soit les masques N95, KN95 et chirurgicaux. Pour simuler différentes conditions respiratoires, des aérosols d'eau avec NaCl dispersés par nébuliseur ont été dirigés vers des matériaux	- L'efficacité de filtration du meilleur au pire était la suivante : masques N95 et KN95 > masque chirurgical > filtres à air > sacs pour aspirateur > filtre à charbon actif > taie d'oreiller 1 000 fils au pouce > filtre à café > taie d'oreiller 600 fils au pouce > quatre épaisseurs de foulard > taie d'oreiller à 400 fils au pouce > bandana. - Les tissus qui avaient des motifs de tissage plus denses ont offert une plus grande efficacité de filtration. Cette efficacité était cependant inversement liée à la respirabilité et à la vitesse croissante des particules.

	à des vitesses de 23,2, de 15,3 et de 9,2 cm/s-1.	
Drewnick 2020 (52) Expérience de simulation Allemagne Août 2020	Étude qui a évalué l'efficacité de filtration selon la taille des particules de 44 échantillons de textiles de maison et de plusieurs masques médicaux avec un nébuliseur produisant un aérosol de NaCl et avec un compteur de particules.	- D'énormes différences dans l'efficacité de filtration ont été observées tant entre les textiles de maison qu'en raison des tailles de particules, avec un écart allant de < 10 % à > 100 %. - Les matériaux ménagers comme le jersey bouclette, le molleton, la microfibre, le feutre, la mousseline ou le velours ont montré une efficacité de filtration élevée, tandis que des matériaux comme la popeline, la blouse de chirurgie ou la soie ont montré une efficacité de filtration moindre. - Une efficacité de filtration raisonnable peut être obtenue en empilant plusieurs épaisseurs, mais des fuites de seulement 1 à 2 % peuvent avoir un impact important sur l'efficacité de filtration.
Carnino 2020 (54) Expérience de simulation États-Unis Août 2020	Étude qui a évalué si un prétraitement à base de sel sur des tissus qui ont ensuite été asséchés permettait d'augmenter la capacité de filtration de l'essuie-tout de cuisine, de l'essuie-tout de laboratoire et de la couche filtrante centrale d'un masque chirurgical standard. Après un traitement avec des nanoparticules fluorescentes de taille similaire à celle du virus COVID-19, la pénétration des particules a été mesurée au microscope.	- En l'absence de traitement, les textiles de maison ont mal filtré les nanoparticules. - Lorsque ces textiles ont été trempés dans une solution de NaCl (+/- TWEEN20), la pénétration des nanoparticules était bloquée après seulement 10 minutes de traitement. - L'inhibition bactérienne a également été mentionnée.
Loupa 2020 (53) *Prépublication*	Étude qui a évalué huit masques disponibles dans le commerce afin d'en vérifier la filtrabilité à des aérosols d'un diamètre compris entre 0,006 µm et 10 µm. On a	- Les masques ou couvre-visages en tissu simples (avec deux épaisseurs de coton) ont obtenu l'efficacité de filtration la plus faible.

Expérience de simulation Grèce Juillet 2020	utilisé une vitesse égale à la fréquence respiratoire humaine. Cinq des masques avaient trois épaisseurs, un était un masque KN95 avec un « évent antiretour » et deux étaient des masques ou des couvre-visages en tissu.	- L'ajout de charbon actif dans un masque en coton a considérablement amélioré l'efficacité de filtration. - Mis à part le masque KN95, tous les autres masques étaient perméables aux aérosols de l'ordre de 0,25 à 0,5 µm (< 90 % d'efficacité de filtration).
Lammers 2020 (49) Expérience de simulation États-Unis Juillet 2020	Étude qui a évalué l'emballage chirurgical pour stérilisation dans un test automatisé pour filtre TSI 8130, comme cela est exigé pour le masque N95. Des couches simples et doubles de l'emballage ont été testées et comparées à l'évaluation d'imprégnation du masque N95.	- L'efficacité de filtration de l'emballage était de 64,5 % et de 78,3 % pour les épaisseurs simple et double, respectivement. Cela ne respectait pas les exigences d'essai standard pour un masque N95.
Varallyay 2020 (42) Expérience de simulation États-Unis Juillet 2020	Étude qui a évalué l'efficacité de filtration des textiles de maison courants avec une configuration de test d'ajustement et générateur de particules standard de diamètre médian (40 nm) et résistance du débit d'air avec un manomètre. Trois niveaux différents de superposition (1, 2 et 4) ont été testés.	- Le feutre de polyester a démontré la plus grande efficacité de filtration ($p < 0,0001$), supérieure à tous les matériaux 100 % coton testés, ainsi qu'aux masques chirurgicaux ($P < 0,05$). - La superposition a augmenté l'efficacité de filtration et la résistance au débit d'air ($p < 0,0001$ et $p < 0,01$, respectivement). - L'efficacité de filtration de divers matériaux tissés et de tricot variait. Elle est indiquée ici, de la plus grande à la plus faible, soit tissu en microfibre > linge à vaisselle > uniforme d'hôpital > molleton épais > chapeau en chamois > t-shirt > taie d'oreiller > matériel tissé sans plastique > foulard. - L'efficacité de filtration de divers matériaux non-tissés a également varié et figure ici, de la plus grande à la plus faible : masque N95 > sac pour aspirateur > masque chirurgical > feutre > essuie-tout de cuisine > blouse chirurgicale > mouchoirs en papier.

		- Le lavage et le séchage n'ont pas modifié de façon significative les performances de filtration.
Zhao 2020 (39) Expérience de simulation États-Unis Juin 2020	Étude qui a évalué les propriétés de filtration des matériaux naturels et synthétiques à l'aide d'un testeur de filtre automatisé à un débit de 32 L/min (semblable à la respiration humaine). L'efficacité de filtration est le pourcentage de particules de NaCl filtrées par le matériau alors que la chute de pression est la résistance de l'air à travers le matériau filtrant. Plus la pression est élevée, moins le matériau est perméable à l'air. Les auteurs font remarquer que leurs résultats diffèrent des travaux récents et que cela peut découler de différences dans l'instrumentation, la méthode d'essai et la source du matériel.	- Voici l'efficacité de filtration pour divers masques médicaux et textiles non médicaux, du meilleur au pire : masque N95 > chandail en coton > pantalon de sport > t-shirt > mouchoirs en papier > cache-couche en polyester > essuie-tout > matériau d'interface en polypropylène > housse d'oreiller > serviette en papier. - Certains des matériaux en coton présentaient des efficacités de filtration comparables à celles des masques médicaux ou des couvre-visages (p. ex., chandail et t-shirt en coton). - Les produits en papier peuvent être utilisés comme support jetable dans certains masques ou couvre-visage maison, mais leur performance dans des environnements très humides reste à examiner.
Zangmeister 2020 (45) Expérience de simulation États-Unis Juin 2020	Étude qui a évalué l'efficacité de filtration, la pression différentielle (ΔP), le facteur de qualité et les paramètres de fabrication de 32 tissus, y compris des échantillons multicouches et mixtes faits de mélanges naturels, synthétiques ou synthétiques naturels. Les matériaux ont fait l'objet de microimages et de tests avec des aérosols de NaCl de taille choisie, avec des diamètres de mobilité des particules variant entre 50 et 825 nm. La charge des particules a été neutralisée.	- Les tissus 100 % coton à teneur élevée ou modérée en fils et deux tissus synthétiques à teneur moyenne en fils sont ceux qui ont donné les meilleurs résultats. - L'efficacité de filtration de deux couches d'un tissu très performant (32 %) était inférieure à celle des emballages de qualité médicale à haute densité (86 %), du masque N95 (> 99,9 %) et du sac pour aspirateur HEPA (94 %). - Le tissu le moins filtrant était le polyester (chiffon léger), suivi du coton (mousseline), du polyester (tricot), de la rayonne et du mélange 65 % polyester/35 % coton. - L'efficacité de filtration et la ΔP augmentaient avec le nombre d'épaisseurs de tissu. Ainsi,

		les masques quatre épaisseurs ont dépassé la ΔP recommandée (perméabilité à l'air).
Amendola 2020 (23) Expérience de simulation Italie Mai 2020	Expérience qui a simulé l'action respiratoire en mesurant la distribution des particules d'aérosol à base aqueuse. L'efficacité de filtration moyenne indiquée tenait compte des particules ayant un diamètre supérieur à 0,28 µm. Les masques ou couvre-visages ont été testés tant pour l'inhalation que l'expiration. TNT= matériau non-tissé fait de polypropylène et de viscose à base de tissu	- Le masque médical a démontré une efficacité de filtration supérieure à 97 %. - Seuls les masques faciaux fabriqués avec trois épaisseurs constituées principalement de tissu non-tissé ont pu atteindre des valeurs supérieures à 95 %, y compris le TNT triple épaisseur et le TNT-coton-TNT.
Konda 2020 (44) Expérience de simulation États-Unis Avril 2020	Évaluation de l'efficacité de filtration de plusieurs tissus courants, y compris le coton, la soie, le chiffon, la flanelle, divers tissus synthétiques et leurs combinaisons à l'aide de particules d'aérosols de NaCl polydispersées dont la taille variait entre 10 nm et 10 µm. Pour simuler l'ajustement, on a percé des trous dans le tube de raccordement sur lequel le tissu était installé, ce qui a entraîné des ouvertures de ~0,5 à 2 % dans la zone d'échantillonnage active.	- Les plages ci-dessous représentent l'efficacité de filtration pour les particules de petite taille (< 300 nm) à plus grande taille (> 300 nm). - Un tissu de coton à contexture modérée (80 fils au pouce) a démontré une efficacité inférieure (entre 5 et 55 %) comparativement à un tissu de coton à contexture élevée (entre 65 et 90 %). - Une courtepointe, avec de la ouate de coton fibreuse, a offert une excellente efficacité de filtration (entre 80 et 90 %). - Contrairement aux tissus de coton, les trois tissus qui devraient posséder des charges électrostatiques, soit la soie, le chiffon et la flanelle, ont obtenu un meilleur rendement pour les plus petites particules (< 300 nm) que pour les plus grandes particules (> 300 nm). - L'augmentation du nombre de couches a augmenté l'efficacité de filtration.

		- Trois combinaisons hybrides ont été testées, soit une épaisseur de coton TPI 600 avec deux épaisseurs de soie, deux épaisseurs de chiffon et une épaisseur de flanelle. Toutes les combinaisons ont donné de bons résultats, avec une efficacité de filtration variant entre 80 % et 90 %, comparable à celle des masques N95. - Dans les tests où l'effet de « fuite » a été testé, les ouvertures ont réduit l'efficacité de filtration de 60 %.
Ma 2020 (37) Expérience de simulation Chine Mars 2020	Évaluation de l'efficacité de trois types de masques en utilisant le virus de la grippe aviaire pour simuler le coronavirus. Un nébuliseur a été utilisé pour produire des aérosols de taille inférieure à 5,0 um. Les parties supérieures des seringues de 60 ml ont été retirées, puis enveloppées dans des masques testés, soit une épaisseur de tissu de polyester, un masque maison fait d'une épaisseur de polyester et de quatre épaisseurs d'essuie-tout de cuisine, un masque chirurgical et un masque N95. Une éponge a été insérée dans la seringue derrière le masque pour recueillir les virus qui passaient à travers les masques.	- Comparativement au polyester simple épaisseur, le masque N95 a bloqué 99,98 % du virus, le masque chirurgical en a bloqué 97,14 % et le masque fait maison en a bloqué 95,15 %.

Méthodologie :

Une analyse documentaire quotidienne (ouvrages publiés et en prépublication) est effectuée par le Groupe des sciences émergentes de l'ASPC. L'analyse a compilé les ouvrages sur la COVID-19 depuis le début de l'éclosion et est mise à jour quotidiennement. Les recherches visant à extraire les ouvrages pertinents sur la COVID-19 sont menées dans Pubmed, Scopus, BioRxiv, MedRxiv, ArXiv, SSRN, Research Square et dans les centres d'information de la COVID-19 gérés par Lancet, BMJ, Elsevier et Wiley. Les résultats cumulatifs de l'analyse sont conservés dans une base de données Refworks et une liste Excel consultable. Des détails sur cette stratégie de recherche sont disponibles sur demande. Une recherche ciblée par mot-clé dans les titres et les résumés des articles a été effectuée dans ces bases de données et dans la liste en Excel. Les termes de recherche utilisés comprenaient : mask* OU (face ET cover*). Chaque référence de recherche originale potentiellement pertinente a été examinée pour confirmer qu'elle comportait des données pertinentes, qui ont été extraites dans la revue. Parmi les examens et synthèses de recherche de qualité variable portant sur la composition des masques ou des couvre-visages qui ont été sélectionnés, la plupart n'incluaient que la recherche pré-pandémique et ont donc été exclus de ce résumé car ils manquaient de recherches récentes. La présente revue contient des recherches originales publiées jusqu'au 2 décembre 2020.

Don't have Emerging Evidence on COVID-19

Evidence Brief of Multisystem Inflammatory Syndrome in Adults (MIS-A)

Introduction

What are the epidemiological and clinical characteristics of multisystem inflammatory syndrome in adults (MIS-A)?

Numerous cases of Multisystem Inflammatory Syndrome in Children (MIS-C) have been described worldwide since the beginning of the COVID-19 pandemic. More recently, clinical features similar to MIS-C have been described in adults. A definition for Multisystem Inflammatory Syndrome in Adults (MIS-A) does not exist; therefore, case selection has been based on the definition of MIS-C excluding the age criteria.

There are at least four definitions of MIS-C. The World Health Organisation (WHO) (1) definition of MIS-C includes children and adolescents below the age of 19, a positive COVID-19 test or likely contact with COVID-19 positive individuals and several signs and symptoms, which include fever lasting for more than 3 days and two of the following:

- Rash
- Bilateral non-purulent conjunctivitis
- Signs of muco-cutaneous inflammation signs (in the mouth or on the hands or feet)
- Hypotension or shock
- Myocardial dysfunction, pericarditis, valvulitis or coronary abnormalities (including echocardiogram findings or elevated Troponin/NT-proBNP)
- Coagulopathy (increased prothrombin time, activated partial thromboplastin time, elevated D-Dimers)
- Acute gastrointestinal problems (diarrhoea, vomiting, or abdominal pain).

There must be laboratory evidence of inflammation, such as an elevated erythrocyte sedimentation rate (ESR), C-reactive protein (CRP), or procalcitonin, and other obvious microbial causes of inflammation such as bacterial sepsis, staphylococcal or streptococcal shock syndromes must be excluded as a plausible diagnosis.

The Centers for Disease Control (CDC) (2) Health Advisory defines an MIS-C case as an individual below the age of 21 presenting with fever lasting for more than 24 hours and laboratory evidence of inflammation such as an elevated C-reactive protein (CRP), erythrocyte sedimentation rate (ESR), fibrinogen, procalcitonin, D-dimer, ferritin, lactic acid dehydrogenase (LDH), or interleukin 6 (IL-6), elevated neutrophils, reduced lymphocytes and low albumin. The patient must also have an evidence of clinically severe illness requiring hospitalization, with multisystem organ involvement and no alternative plausible diagnoses. The patient must be positive for current or recent SARS-CoV-2 infection by RT-PCR, serology, or antigen test; or must have been exposed to a suspected or confirmed COVID-19 case within the 4 weeks prior to the onset of symptoms.

According to the Royal College of Paediatrics and Child Health (RCPCH) (3) a case MIS-C is a child presenting with persistent fever, inflammation (neutrophilia, elevated CRP and lymphopaenia) and evidence of single or multi-organ dysfunction (shock, cardiac, respiratory, renal, gastrointestinal or neurological disorder) with persistent fever over 38.5 °C, most of the time, oxygen requirement, hypotension, and other additional features. The laboratory tests must show abnormal fibrinogen, absence of potential causative organisms (other than SARS-CoV-2), high CRP, high D-Dimers, high ferritin, hypoalbuminaemia, and/or lymphopenia. This may include children fulfilling full or partial criteria for Kawasaki disease. Any other microbial cause, including bacterial sepsis, staphylococcal or streptococcal shock syndromes, infections associated with myocarditis such as enterovirus must be excluded. The SARS-CoV-2 PCR testing may be positive or negative.

Finally, the Canadian Pediatric Society (CPS) (4) defines MIS-C as the presence of high and persistent fever (≥3 days) unexplained by other causes. Fever together with laboratory evidence of marked systemic inflammation and temporal association with COVID-19 having been present in the community should raise the index of suspicion for MIS-C. The clinical presentations described to date have included fever with hyperinflammation; a Kawasaki-like syndrome; and shock or toxic shock-like states, with signs of hypotension and poor perfusion related to severe myocardial dysfunction. GI distress, that may or may not occur with neurological signs such as neck stiffness, altered mental status, or lethargy.

This review describes the first reported cases of MIS-A in order to identify common features of the disease and raise the awareness of clinicians regarding the appropriate management of cases. It summarizes literature until November 13, 2020.

Key Points

Demographic characteristics, COVID status, and comorbidities

- All nine MIS-A cases described were relatively young adults, with a median age of 31 years and IQR [25-45]. Six cases (67%) were male (5-10) and three cases (33%) were female (11-13). Six out of nine studies reported ethnicity. Three cases (33%) had African origins (5,7,12), two cases (22%) were of Hispanic origin (10,13) one (11%) was Caucasian (9). In the three remaining cases (33%) ethnicity was not reported.
- All nine cases underwent a RT-PCR test. Five cases (56%) had negative RT-PCR results, but positive serology tests (5-7,9,13). One case (11%) had a negative PCR result with a history of a positive RT-PCR result a few days earlier (12). Results of RT-PCR swab test and serology were both positive in one case (11%)(11). The two remaining cases (22%) had a positive RT-PCR test but did not undergo serology test (8,10).These findings suggested that MIS-A generally occurred (n=6; 67%) during viral clearance.
- Seven out of nine studies reported on comorbidity. Two cases (22%) had both hypertension and obesity (5,12) of which one of them also had diabetes (12). Five cases (56%) had no known comorbidity (8,10,13) and in two (22%) the comorbidity status was not reported.

Clinical and laboratory findings

- All cases had fever; seven cases had fever for 5-7 days prior to hospital admission; two cases did not report on the duration of fever (4,11).
- The majority of cases (n=8; 89%) had digestive symptoms upon admission. The most common digestive symptom was diarrhea (n=6; 67%) followed by vomiting (n=4; 44%), rash (n=4; 44%) and neck pain (n=4; 44%) with or without lymphadenopathy. One case (11%) had bilaterally enlarged parotid glands.
- All cases had multi-organ involvement. Cardiovascular system involvement was the most common (n=7; 78%)(5,6,8-11,13), represented via echocardiography by acute myocardial dysfunction with left ventricular systolic dysfunction and pericardial effusion (n=4, 44%), ventricular fibrillation, dilated inferior vena cava (n=2; 22%) with overloaded right ventricular pressure and mild enlargement of the main pulmonary artery and hyperkinetic left ventricle (n=1; 11%).
- All cases had elevated inflammatory markers. The most common elevated inflammatory marker was C-reactive-protein CRP (n=8; 89%) (5,6,8-11), followed by D-dimers (n=6; 67%) (6,8,10-13) and troponin (n=6; 67%) (5-10). Lymphopenia was also common (n=6; 67%) (7-11).

Treatment and outcome

- Intravenous immunoglobulin (n=3; 33%) (7,10,11), prednisolone (n=3; 33%) (7,8,13) and aspirin (n=3; 33%) (6,11,13) were the most common treatments given. Immunoglobulin was not given in one case because the patient responded well to aspirin. In another case, prednisolone was not given because the patient had a concomitant tracheal aspiration positive for *Enterobacter aerogenes* that was then treated with Trimethoprim Sulfamethoxazole (5). One patient did not receive any specific treatment; as she died while being evaluated for admission and could not be resuscitated (12).
- Seven cases (77%) survived hospitalization. Three cases (33%) had severe symptoms, requiring admission to the ICU but recovered (5,6,11). Two cases (22%) presented with hypotension and tachycardia upon admission but did not require admission to intensive care unit (ICU) and recovered (9,10,13). One case (11%) presented with vasoplegic shock upon admission, had a length of stay (LOS) in hospital of 8 days and recovered under treatment (9). One case (11%) did not demonstrate shock-like signs and recovered under treatment (8). One case died in hospital (11%). The case that died had been previously hospitalized for COVID-19 and discharged 12 days earlier, upon readmission she presented with rapid onset of fever and developed hemodynamic instability and ventricular fibrillation and could not be resuscitated. The outcome of one patient (11%) was not reported (7).

Overview of the Evidence

Nine case reports of MIS-A were identified in the literature. Five cases were identified in the United-States, two in France and two in the United Kingdom. The case descriptions revealed similarities in clinical features such as occurrence after viral clearance, fever, digestive symptoms, cardiac involvement and elevated inflammatory markers. All cases where hospitalized, two required admission to the ICU and one died. The most common treatments were intravenous immunoglobulin, prednisolone and aspirin. The findings suggest early recognition of MIS-A may improve outcome.

Limitations

Only case reports were identified in this review. Although case reports can help in the identification of new trends or diseases, they have a number of limitations. They are difficult to compare since cases have different backgrounds and are not representative of a population. Therefore these findings are very preliminary; as more studies become available we will learn more about the common epidemiological and clinical characteristics of this condition.

Data gaps

It appears MIS-A is a rare complication of COVID-19 disease. Studies to date include a total of 9 MIS-A cases and were limited to three countries, United-States, France and the United-Kingdom. There is no definition of MIS-A; using the MIS-C case definition (minus age) has challenges as there are at least 4 definitions and in the cases reviewed, how they met the case definition was not always clear. For example, the authors did not always specify how they excluded all other potential causes of the multi system inflammatory syndrome and the duration of fever or presence of comorbidities were not always reported. More systematic description of ethnicity and Severity of the disease is needed. For example, when hypotension was identified, the presence or not of shock-like syndrome was not always specified.

A case definition for MIS-A is needed to help standardize reporting. Future studies of MIS-A are also indicated to learn more about this disease and the effectiveness of treatment.

Table: Summary of case reports on Multisystem Inflammatory Syndrome in Adults (MIS-A) (n=9)

STUDY	METHOD	KEY OUTCOMES
Case reports (n=9)		
Boudhabhay (2020) (5) Case report France 16 Sept 2020*	A case of MIS-A was described, including clinical and laboratory characteristics, treatment and outcome. The case met only RCPCH definition, since the duration of the fever was not specified.	*Demographic characteristics and past medical history* • The patient was a 46 years old male of African descent. • History of hypertension and obesity *MIS-A characteristics* Fever and other signs and symptoms • Admitted for hypertensive emergency (189/123 mmHg) and fever (duration not reported). Evidence of coagulopathy and renal involvement • Acute kidney injury (AKI): Serum creatinine (sCr) level was 169µmol/L associated with 1g per day proteinuria, aseptic pyuria, no hematuria and low natriuresis (< 20mmol/L) • Renal biopsy light microscopy revealed typical lesions of thrombotic micro angiopathy TMA including fibrin thrombi within glomeruli and myxoid intimal alterations of arterioles and small-to-medium sized renal arteries • On day four the patient presented evanescent facial erythema and developed acute myocardial dysfunction with reduced left ventricular ejection fraction to 40%, pericardial effusion. On day five the patient presented a neurological impairment. Abnormal supratentorial periventricular MRI signals responsible for a restriction of the diffusion due to an acute vasculitis. PCR and serology for SARS-CoV-2 • RT-PCR negative, IgM negative and IgG positive (no previous COVID-19 symptoms were reported) Inflammatory markers • C-Reactive protein (CRP) level was 312 mg/L • Thrombocytopenia: neutrophil count was 18.7 G/L • High sensitive Troponin (hsTroponin) elevation

		Treatment • No immunosuppressive treatment was introduced because of concomitant tracheal aspiration positive for *Enterobacter aerogenes* treated with trimethoprim sulfamethoxazole. • Dobutamine and renal replacement therapy (RRT). • Specific complement inhibition with Eculizumab therapy (900mg) *Severity and outcome* • On day 5 hospitalization neurological impairment appeared with coma leading to intubation and mechanical ventilation. • The patient was discharged after 30 days in hospital.
Chowdhary (2020) (6) Case report United Kingdom Sept 2020*	A case of MIS-A was described, including clinical and laboratory characteristics, treatment and outcome. The case met RCPCH, CDC, CPS and WHO definitions.	*Demographic characteristics and past medical history* • 26 years old male • Ethnicity was not reported. • The presence or absence of comorbidity was not reported. • Exposure to SARS-CoV-2 was reported. *MIS-A characteristics* Fever and other signs and symptoms • Patient was admitted after five days of fever • Dry cough, myalgia, diarrhoea, vomiting, and abdominal pain • Patient was hypotensive and hypoxic upon admission One or more organ involved (pulmonary, cardiac, digestive) • Computed tomography (CT) showed bilateral pulmonary basal ground-glass changes and bowel oedema • Initial transthoracic echocardiography demonstrated severe left ventricular (LV) systolic dysfunction with pericardial effusion. • CT of the abdomen demonstrating mesenteric lymphadenopathy and small bowel oedema PCR and serology for SARS-CoV-2 • RT-PCR negative, IgG and IgM positive serology Inflammatory markers • C-reactive protein (CRP) 419 mg/L • Ferritin 3275 lg/L (<322 µg/L)

		• Procalcitonin 164 lg/L (<50 µg/L) • Troponin I 2030 ng/L (<57 ng/L) • D-dimer 2722 ng/mL (<220 ng/mL) Treatment • Vasopressor therapy, high-dose aspirin, and broad-spectrum antibiotics in intensive care • Immunomodulatory therapy was not given due to the good response to aspirin. *Severity and outcome* • The case was admitted to ICU and recovered over 10 days.
Fox (2020) (12) Case report United States July 2020*	A case of MIS-A was described, including clinical and laboratory characteristics, treatment and outcome. The case met only RCPCH definition, since the duration of the fever was not specified.	*Demographic characteristics and past medical history* • The patient was a 31 years old African American female. • Comorbidities: hypertension with lisinopril, diabetes with poor adherence to metformin and glizide, and obesity (BMI=36.1 kg/m^2) • She had been discharged 12 days earlier after a hospitalization for COVID-19 disease with a positive RT-PCR. *MIS-A characteristics* • Admitted for sudden fever 39.8 °C (duration not specified), tachycardia 120 beats/min, left-sided neck pain, nausea and vomiting Inflammatory markers • D-dimer level of 2.48 nmol/L • C-reactive protein levels 165 mg/L then 580 mg/L • Ferritin level, 114.2 µg/L • Lactic acid level, 3.1 mmol/L • Lymphopenia One or more organ involved (pulmonary, cardiac, parotids, renal) • Computed tomography scan of her neck showed bilaterally enlarged parotid glands and swelling in the posterior nasopharynx to oropharynx. • Computed tomography scan of her chest showed interval improvement of bibasilar ground-glass opacities, with cervical and anterior mediastinal lymphadenopathy

		• Creatinine level 202.44 µmol/L; glomerular filtration rate 32 mL/min/1.73 m^2 PCR and serology for SARS-CoV-2 • RT-PCR was positive 12 days prior to re-admission MISC-A, RT-PCR was negative at re-admission and serology was not performed *Treatment, severity and outcome* • Patient developed hemodynamic instability and ventricular fibrillation during evaluation for hospital admission and died.
Jones (2020)(7) Case report United Kingdom The date the study was conducted was not reported Sept 2020*	A case of MIS-A was described, including clinical and laboratory characteristics, treatment and outcome. The case met RCPCH, CDC, CPS and WHO definitions.	*Demographic characteristics and past medical history* • The case was a 21 years old male of African descent. • The presence or absence of comorbidity was not reported. *MIS-A characteristics* Fever and other signs or symptoms • 6 days of fever • Admitted for abdominal pain associated with constipation, anorexia • Transient maculopapular palmar rash 4 days into illness • Non-exudative conjunctivitis, • Cervical lymphadenopathy, • Cracked lips, and prominent lingual papillae PCR and serology for SARS-CoV-2 • RT-PCR negative and serology was strongly positive, suggesting recent exposure to SARS-CoV-2 One organ or more involved • Rash • Conjunctivitis • Cervical lymphadenopathy • Cracked lips, and prominent lingual papillae Inflammatory markers • Lymphopenia • Elevated inflammatory and elevated troponin T • Other infective and inflammatory conditions were excluded

		Treatment • Intravenous immunoglobulin • Methylprednisolone *Severity and outcome* • The patient was discharged after a length of stay in hospital of 8 days.
Kofman(2020) (11) Case report United States The date the study was conducted was not reported Sept 2020*	A case of MIS-A was described, including clinical and laboratory characteristics, treatment and outcome. The case met RCPCH, CDC, CPS and WHO definitions.	*Demographic characteristics and past medical history* • The case was a 25 years old female. • Ethnicity was not reported. • She was non-smoker, not a drug user, no medications, no known allergies. • She had taken ibuprofen and acetaminophen over the prior week for symptomatic relief. *MIS-A characteristics* Fever and other signs and symptoms • One week of low grade fever, weakness, dyspnea, fatigue • Also developed mild cough, sore throat, vomiting, diarrhea, and lymph node swelling • Upon admission o She was afebrile, with mild hypotension (blood pressure 98/56 mmHg) o Oxygen saturation was normal on room air. o She appeared ill, with tender cervical lymphadenopathy o Significant conjunctival injection without perilimbal sparing; injected, erythematous, and cracked lips o Tenderness to palpation in the left lower abdominal quadrant One or more organ involved (renal, cardiac, digestive, ocular) • Acute kidney injury: Creatinine 7.74 mg/dL (Normal: 0.5 -1.2 mg/dL) and leukocytosis • Point-of-care echocardiogram revealed a dilated inferior vena cava andoverloaded right ventricular pressure • CT angiogram of the chest showed mild enlargement of the main pulmonary artery • CT abdomen/pelvis demonstrated mild peripancreatic fat stranding, felt to possibly represent acute uncomplicated

		pancreatitis, as well as nonspecific bilateral perinephric fat stranding • Conjunctivitis PCR and serology for SARS-CoV-2 • Positive RT-PCR and IgG serology Inflammatory markers • C-reactive protein 90 mg/L (Normal: 0-10 mg/L) • D-dimer 960 mg/L (Normal : 0-574 mg/L) • Ferritin 798 ng/ml (Normal : 11-307 ng/ml) • Lymphocytes 3% (Normal: 19-53) Treatment: • Aggressive fluid resuscitation and vasopressor • Intravenous immunoglobulin (IVIG), 2 g/kg split equally between hospital days 2 and 3 • Aspirin 325 mg daily for 7 days • Patient was offered remdesivir under an Emergency Use Authorization (EUA) basis, but declined • At discharge she was prescribed a 7-day course of apixaban for COVID-19-associated coagulopathy per Emory University Hospital COVID-19 treatment guidelines Severity and outcome • The patient was admitted to ICU twice during her hospital stay and was discharged day 5.
Lidder (2020) (8) Case report United States May 2020	A case of MIS-A was described, including clinical and laboratory characteristics, treatment and outcome. The case met RCPCH, CDC, CPS and WHO definitions.	*Demographic characteristics and past medical history* • The case was a 45 years old male with no comorbidities. • Ethnicity was not reported. *MIS-A characteristics* Fever and other signs and symptoms • He had fever for 5 days, sore throat, diarrhea, eye redness, eyelid swelling, and a diffuse rash including bilateral upper and lower eyelids. One or more organ involved (renal, cardiac, digestive, ophthalmological)

		• A transthoracic echocardiogram demonstrated global hypokinesis and a reduced ejection fraction of 40%.
		• CT imaging showed unilateral cervical lymphadenopathy with a lymph node measuring 1.8 cm.
		• Photophobia and swollen eyelids. No vision changes including blurry vision and eye pain.
		• Uncorrected near visual acuity was 20/20 bilaterally
		  ○ Bilateral superficial punctate keratitis, symmetric anterior chamber (AC) inflammation with 10–15 cells per high power field, and normal intraocular pressure. Dilated fundus exam was notable only for one small peripheral cotton wool spot in each eye.
		• Punch biopsy of his erythema multiforme-like rash
		  ○ Showed sparse superficial perivascular infiltrate of lymphocytes with neutrophils and scattered eosinophils, suggestive of toxic shock syndrome.
		
		Excluding other cause
		• Testing for myositis and HIV was negative.
		• An exhaustive rheumatologic workup including ANA, RF, anti-CCP, anti-Smith, anti-dsDNA, p-ANCA/MPO, c-ANCA/PR3 was also negative.
		• Blood cultures were negative.
		
		PCR and serology for SARS-CoV-2
		• Positive RT-PCR
		
		Inflammatory markers
		• Lymphopenia
		• Ferritin, CRP, ESR, D-dimer and troponin were elevated
		
		Treatment:
		• Ophthalmic lubricating therapy in addition to prednisolone acetate 1% eye drops four times daily for his photophobia in the setting of AC inflammation
		• IVIG and an IL-6 inhibitor (tocilizumab) in addition to using a topical triamcinolone ointment for his diffuse rash

		Severity and outcome • The length of stay in hospital was not reported but the patient did not demonstrate shock-like signs.

Moghadam (2020) (9)
 	
Case report
 	
France
 	
The date the study was conducted was not reported
 	
July 2020*
	A case of MIS-A was described, including clinical and laboratory characteristics, treatment and outcome.
	
	The case met RCPCH, CDC and WHO definitions.
		Demographic characteristics and past medical history
		• The case was a 21 years old Caucasian male.
		• The presence or absence of comorbidity was not reported.
		
		MIS-A characteristics
		Fever and other signs and symptoms
		• He had fever and non-bloody watery diarrhea lasting for 7 days.
		• Asymptomatic rash over his trunk and palms, consisting of erythematous round-shaped macules with a darker and raised rim, 1-3 cm in diameter
		• Bilateral conjunctivitis
		• Blood pressure 80/40 mmHg
		• Respiratory rate was 38 breaths/min, and oxygen saturation was 97% on ambient air
		
		One or more organ involved (cardiac, digestive, pleural)
		• Electrocardiogram showed diffuse negative T waves, and echocardiography displayed hyperkinetic left ventricle with normal ejection fraction, normal right cavities, and dilated non-compressible inferior vena cava.
		• Thoraco-abdominal computed tomography (CT) scan did show
		  ○ Signs of congestive heart failure
		  ○ Bilateral pleural effusion
		  ○ Wall thickening of the right colon
		• Respiratory function deterioration
		
		PCR and serology for SARS-CoV-2
		• Negative RT-PCR and IgG positive serology
		
		Inflammatory markers
		• Lymphocytes of 900/mm3
		• C-reactive protein 365 mg/L
		• Procalcitonin was 3.4 ng/mL
		• Ferritin was 1282 mg/L (normal <30)
		• Lactate 2.4 mmol/L (normal <1.6)

		• Troponin level was 550 ng/L (normal <34) • Cutaneous biopsy showed a slightly inflammatory infiltrate in upper dermis, and direct cutaneous immunofluorescence was negative. Exclusion of other causes • Patient denied any drug intake • He did not smoke tobacco, or use illicit drugs • Extensive infectious inquiry and search for antinuclear antibodies were negative • The rash was particular and diagnosis of erythema multiforma and subacute lupus erythematosus were ruled out. Treatment: • Volume resuscitation • Noradrenaline • Antibiotics (ie, ceftriaxone and amikacin) • High-flow nasal oxygenation Severity and outcome • The length of stay in ICU was 8 days.
Sokolovsky(2020) (13) Case report United States The date the study was conducted was not reported June 2020*	A case of MIS-A was described, including clinical and laboratory characteristics, treatment and outcome. The case met RCPCH, CDC, CPS and WHO definitions.	*Demographic characteristics and past medical history* • The case was a 36 years old Hispanic female. • She had no known comorbidity. *MIS-A characteristics* Fever and other signs and symptoms • One week of fever, abdominal pain, vomiting, and diarrhea • Two days of a diffuse rash and arthralgias • Tachycardia, tachypnea, hypotensive • Classic phenotype of complete Kawasaki's Disease: bilateral nonexudative conjunctivitis mucositis wit cracked lips, edema of the bilateral hands and feet; a diffuse maculopapular rash and cervical lymphadenopathy One or more organ involved (cardiac, digestive) • CT angiogram of the chest: normal lung parenchyma and a trace right pleural effusion

		• CT abdomen/pelvis illustrated mild circumferential gallbladder wall thickening and a small area of colitis • Echocardiogram after treatment with ○ IVIG revealed an EF of 65% with moderate tricuspid valve regurgitation. Subsequent CTA coronaries was normal except for a trace pericardial effusion. PCR and serology for SARS-CoV-2 • Negative RT-PCR and IgG positive serology Inflammatory markers • CRP: 30 mg/dL (0.0–0.9) • D-dimer: 652 ng/mL (<318) Exclusion of other cause • Anti-dsDNA, anti-smith, anti-RNP, SSB, RF, CCP, ANCA, ASO, and anti-Jo-1 antibodies were negative • HIV and hepatitis panels were negative Treatment: • Fluid resuscitation for shock • A single dose of aspirin 650 mg • IVIG 2 g/kg • Methylprednisolone 2 mg/kg for 5 days followed by a prednisone taper Severity and outcome • She stayed at least 6 days in hospital.
Shaigany (2020) (10) Case report United States The date the study was conducted was not reported	A case of MIS-A was described, including clinical and laboratory characteristics, treatment and outcome. The case met RCPCH, CDC,	*Demographic characteristics and past medical history* • The case was a 45 years old Hispanic male. • He had no known comorbidity. *MIS-A characteristics* Fever and other signs and symptoms • Six days of fever, sore throat, diarrhoea, bilateral lower extremity pain, conjunctivitis, and diffuse exanthema • Exposure to SARS-CoV-2 infection 2 weeks earlier • Respiratory rate was 25–33 breaths per min • Hypotension (systolic blood pressure 80–90 mm Hg)

July 2020	CPS and WHO definitions.	• Tachycardia with episodes of atrial fibrillation with rapid ventricular response
		• Bilateral, nonexudative conjunctival injection,
		• Tender left neck swelling with palpable lymphadenopathy, periorbital oedema with overlying erythema, lip cheilitis, and targetoid erythematous papules and plaques with central duskiness involving the back, palms, neck, scalp, anterior trunk, and upper thighs
		
		One or more organ involved (renal, cardiac, digestive, ophthalmological)
		• CT of the neck revealed inflammation and oedema involving the bilateral lower eyelid and pre-septal space, as well as sub-occipital reactive lymphadenopathy.
		• Electrocardiogram demonstrated:
		  ○ ST elevations in the anterolateral leads,
		  ○ Global hypokinesis of the left ventricular wall with a mild to moderately reduced ejection fraction of 40%
		• Diffuse conjunctivitis with chemosis, as well as the presence of inflammatory cells within the anterior chamber, indicative of uveitis
		• A 4-mm punch biopsy of the skin was performed on a papule on the back, with histology revealing rare intraepithelial collections of neutrophils with necrotic keratinocytes and a sparse interstitial, mixed-cell dermal infiltrate with vacuolar interface changes.
		
		PCR and serology for SARS-CoV-2
		• Positive RT-PCR
		
		Inflammatory markers
		• Lymphopenia (0–700 lymphocytes per µL)
		• Erythrocyte sedimentation rate of 120 mm/hr
		• Ferritin of 21 196 ng/mL
		• C-reactive protein of 546·7 mg/L
		• D-dimer of 2977 ng/mL
		• Procalcitonin of 31·79 ng/mL
		• Interleukin-6 (IL-6) 117 pg/mL
		• Troponin 8·05 g/mL)

		Exclusion of other causes • HIV-1 and HIV-2 antibodies were negative • Bacterial blood cultures were negative Treatment: • Therapeutic dose low molecular weight heparin • Intravenous immunoglobulin (2 g/kg) over 2 days • A single intravenous dose of the IL-6 inhibitor tocilizumab (400 mg) Severity and outcome • The patient was 8 days in hospital and did not require vasopressor support or intensive care unit level of care.

*The date was based on the publication date as the date the case occurred was not reported

Methods:

A daily scan of the literature (published and pre-published) is conducted by the Emerging Science Group, PHAC. The scan has compiled COVID-19 literature since the beginning of the outbreak and is updated daily. Searches to retrieve relevant COVID-19 literature are conducted in Pubmed, Scopus, BioRxiv, MedRxiv, ArXiv, SSRN, Research Square and cross-referenced with the COVID-19 information centers run by Lancet, BMJ, Elsevier, Nature and Wiley. The daily summary and full scan results are maintained in a refworks database and an excel list that can be searched. Targeted keyword searching is conducted within these databases to identify relevant citations on COVID-19 and SARS-COV-2. Search terms used included: "MIS-A", "Kawasaki", "multisystem inflame", "multi-system inflam", "inflammatory multisystem", "inflammatory multi-system", and "inflammatory disease" , "Kawasaki-like", "COVID-19 linked disease. This review contains research published up to November 13, 2020.
Each potentially relevant reference was examined to confirm it had relevant data and relevant data is extracted into the review.

Nouveaux éléments de preuve sur la COVID-19

Sommaire des éléments de preuve sur le syndrome inflammatoire multisystémique chez l'adulte (MIS-A)

Introduction

Quelles sont les caractéristiques épidémiologiques et cliniques du syndrome inflammatoire multisystémique chez l'adulte (MIS-A) ?

Depuis le début de la pandémie de COVID-19, de nombreux cas de syndrome inflammatoire multisystémique chez les enfants (MIS-C) à l'échelle mondiale ont été décrits. Plus récemment, des caractéristiques cliniques similaires à celles du MIS-C ont été signalées chez les adultes. Comme il n'existe aucune définition du syndrome inflammatoire multisystémique chez l'adulte (MIS-A); la sélection des cas a donc été basée sur la définition du MIS-C, en excluant les critères d'âge.

Il existe au moins quatre définitions du MIS-C. La définition du MIS-C selon l'Organisation mondiale de la santé (OMS) (1) comprend les enfants et les adolescents de moins de 19 ans, un test COVID-19 positif ou un contact probable avec des personnes positives à la COVID-19, ainsi que plusieurs signes et symptômes, dont une fièvre qui dure plus de 3 jours et deux des éléments suivants :

- Éruption
- Conjonctivite bilatérale non purulente
- Signes d'inflammation muco-cutanée (dans la bouche ou sur les mains ou les pieds)
- Hypotension ou choc
- Dysfonctionnement du myocarde, péricardite, valvulite ou anomalies coronariennes (notamment constatation suite à un échocardiogramme ou niveau élevé de troponine/NT-proBNP)
- Coagulopathie (augmentation du temps de prothrombine, temps de thromboplastine partielle activée, D-dimères élevés)
- Troubles gastro-intestinaux aigus (diarrhées, vomissements ou douleurs abdominales).

Il est nécessaire de disposer de résultats de laboratoire indiquant une inflammation, tels qu'une augmentation de la vitesse de sédimentation des érythrocytes (VS), du taux de protéine C réactive (CRP) ou de la procalcitonine, et d'exclure les autres causes microbiennes évidentes d'inflammation telles que la septicémie bactérienne, les syndromes de choc staphylococcique ou streptococcique, comme diagnostic plausible.

Un avis de santé publique émis par les centres de contrôle des maladies (CDC) (2) définit un cas de MIS-C comme étant un individu de moins de 21 ans présentant une fièvre de plus de 24 heures accompagnée de signes inflammatoires attestés par des résultats de laboratoire tels qu'une augmentation du taux de protéine C-réactive (CRP), de la vitesse de sédimentation des érythrocytes (VS), du taux de fibrinogène, de la procalcitonine, des D-dimères, de la ferritine, de l'acide lactique déshydrogénase (LDH) ou de l'interleukine 6

(IL-6), ainsi qu'une hausse du nombre de neutrophiles, des lymphocytes réduits et une faible teneur en albumine. Le patient doit également présenter les signes d'une maladie cliniquement grave nécessitant une hospitalisation, avec une atteinte multisystémique des organes et sans autre diagnostic plausible. La contamination actuelle ou récente du patient par le CoV-2 - SRAS doit avoir été établie par RT-PCR, sérologie ou test d'antigène; ou le patient doit avoir été exposé à un cas suspecté ou confirmé de COVID-19 dans les 4 semaines précédant l'apparition des symptômes.

Selon le Royal College of Paediatrics and Child Health (RCPCH) (3), un cas de MIS-C est un enfant présentant une fièvre persistante, une inflammation (neutrophilie, CRP élevée et lymphopénie) ainsi que des signes de dysfonctionnement d'un ou de plusieurs organes (choc, trouble cardiaque, respiratoire, rénal, gastro-intestinal ou neurologique) avec le plus souvent, une fièvre persistante supérieure à 38,5 °C, un besoin en oxygène, une hypotension et d'autres caractéristiques. Les tests de laboratoire doivent indiquer un taux de fibrinogène anormal, une absence d'organismes potentiellement responsables (autres que le SRAS-CoV-2), une augmentation de la CRP élevée, des D-dimères, de la ferritine, une hypoalbuminémie et/ou une lymphopénie. Cela peut concerner des enfants qui remplissent tous ou certains des critères de la maladie de Kawasaki. Toute autre cause microbienne, notamment la septicémie bactérienne, les syndromes de choc staphylococcique ou streptococcique, les infections associées à la myocardite telles que l'entérovirus doivent être exclues. Le test PCR pour le SRAS-CoV-2 peut être positif ou négatif.

Enfin, la Société canadienne de pédiatrie (SCP) (4) définit la MIS-C comme caractérisée par une fièvre élevée et persistante (≥3 jours) inexpliquée par d'autres causes. La fièvre associée à des résultats de laboratoire attestant d'une inflammation systémique marquée et à un lien temporel avec la présence de COVID-19 dans la communauté sont des indices qui doivent orienter le diagnostic vers un éventuel MIS-C. Les cas cliniques décrits à ce jour comprennent de la fièvre associée à une hyperinflammation, un syndrome de Kawasaki et des états de choc ou de choc toxique, avec des signes d'hypotension et de mauvaise perfusion liés à un dysfonctionnement myocardique grave. Les troubles gastro-intestinaux, susceptibles ou non de se manifester, peuvent être accompagnés de symptômes neurologiques tels qu'une raideur de la nuque, une altération de l'état mental ou une léthargie.

Cette étude décrit les premiers cas de MIS-A signalés afin d'identifier les caractéristiques communes de la maladie et de sensibiliser les cliniciens à la gestion appropriée des cas. Il résume la littérature jusqu'au 13 novembre 2020.

Points clés

Caractéristiques démographiques, COVID et facteurs de comorbidité

- Les neuf cas de MIS-A décrits concernaient tous des adultes relativement jeunes, dont l'âge médian était de 31 ans et l'EI était [25-45]. Six cas (67 %) étaient des hommes (5-10) et trois cas (33 %) étaient des femmes (11-13). Six études sur neuf faisaient état de l'ethnicité. Trois cas (33 %) étaient d'origine

africaine (5,7,12) deux cas (22 %) étaient d'origine hispanique (10,13) un cas (11 %) était de type caucasien (9). Pour les trois autres cas (33 %), l'appartenance ethnique n'a pas été signalée.

- Les neuf cas ont été soumis à un test RT-PCR. Le test RT-PCR était négatif pour cinq cas (56 %), mais leurs tests sérologiques étaient positifs (5-7,9,13). Un cas (11 %) a obtenu un résultat PCR négatif associé à un historique de résultat RT-PCR positif quelques jours plus tôt (12). Les résultats du test RT-PCR et de la sérologie étaient positifs pour un cas (11 %)(11). Les deux cas restants (22 %) ont obtenu un test RT-PCR positif, mais n'ont pas été soumis à un test sérologique (8,10) ■ Ces résultats suggèrent que le MIS-A s'est globalement déclaré (n=6; 67 %) pendant la clairance virale.
- Sept études sur neuf ont rapporté l'existence de facteurs de comorbidité. Deux cas (22 %) présentaient à la fois de l'hypertension et des problèmes d'obésité (5,12) et l'un d'entre eux était également diabétique (12). Cinq cas (56 %) ne présentaient aucun facteur de comorbidité connu (8,10,13) et dans deux cas (22 %), la présence de facteurs de comorbidité n'a pas été indiquée.

Résultats cliniques et de laboratoire

- Tous les cas présentaient de la fièvre; pour sept cas la fièvre a duré de 5 à 7 jours avant leur admission à l'hôpital; deux cas n'ont pas indiqué la durée de la fièvre (4,11).
- La majorité des cas (n=8; 89 %) présentaient des symptômes digestifs à l'admission. Le symptôme digestif le plus fréquent était la diarrhée (n=6; 67 %), suivi par des vomissements (n=4; 44 %), des éruptions cutanées (n=4; 44 %) et des douleurs cervicales (n=4; 44 %) avec ou sans lymphadénopathie. Un cas (11 %) présentait une hypertrophie bilatérale des glandes parotides.
- Tous les cas impliquaient plusieurs organes. L'atteinte du système cardiovasculaire était la plus fréquente (n=7; 78 %)(5,6,8-11,13), elle était représentée par échocardiographie et caractérisée par un dysfonctionnement myocardique aigu avec dysfonctionnement systolique du ventricule gauche et épanchement péricardique (n=4, 44 %), fibrillation ventriculaire, veine cave inférieure dilatée (n=2; 22 %) avec pression ventriculaire droite surchargée et léger élargissement de l'artère pulmonaire principale et ventricule gauche hyperkinétique (n=1; 11 %).
- Tous les cas présentaient un niveau élevé des marqueurs inflammatoires. Le marqueur inflammatoire élevé le plus courant était la protéine C-réactive CRP (n=8; 89 %) (5,6,8-11), suivi par les D-dimères (n=6; 67 %) (6,8,10-13) et la troponine (n=6; 67 %) (5-10). La lymphopénie était également fréquente (n=6; 67 %) (7-11).

Traitement et résultats

- L'immunoglobuline par intraveineuse (n=3; 33 %) (7,10,11), la prednisolone (n=3; 33 %) (7,8,13) et l'aspirine (n=3; 33 %) (6,11,13) ont été les traitements les plus couramment administrés. Dans un cas,

l'immunoglobuline n'a pas été administrée, car le patient a bien répondu à l'aspirine. Dans un autre cas, la prednisolone n'a pas été administrée, car le patient était sous aspiration trachéale concomitante en raison de la contamination par *Enterobacter aerogenes* qui a ensuite été traitée avec du Triméthoprime Sulfaméthoxazole (5). Une patiente n'a pas reçu de traitement spécifique, car elle est décédée pendant l'évaluation en vue de son admission et n'a pas pu être réanimée (12).

- Sept cas (77 %) ont survécu à l'hospitalisation. Trois cas (33 %) présentaient des symptômes graves, nécessitant une admission en soins intensifs, mais ils se sont rétablis (5,6,11). Deux cas (22 %) présentaient une hypotension et une tachycardie à l'admission, mais n'ont pas nécessité d'être admis en unité de soins intensifs (USI) et se sont rétablis (9,10,13). Un cas (11 %) présentait un choc vasoplégique à l'admission, son séjour à l'hôpital a duré 8 jours et il s'est rétabli sous traitement (9). Un cas (11 %) ne présentait aucun signe de choc et s'est rétabli sous traitement (8). Un cas est mort à l'hôpital (11 %). Le patient décédé avait été hospitalisé pour la COVID-19 et avait quitté l'hôpital 12 jours plus tôt. Lors de sa réadmission, il a subi une brusque poussée de fièvre puis a développé une instabilité hémodynamique et une fibrillation ventriculaire, il n'a pas pu être réanimé. L'issue de l'état de santé d'un patient (11 %) n'a pas été communiquée (7).

Vue d'ensemble des éléments de preuve

Neuf cas de MIS-A ont été identifiés dans la littérature. Cinq cas ont été identifiés aux États-Unis, deux en France et deux au Royaume-Uni. Les descriptions des cas ont révélé des similitudes dans les caractéristiques cliniques telles que la déclaration du syndrome après la clairance virale, de la fièvre, des troubles digestifs, l'atteinte cardiaque et un niveau anormalement élevé des marqueurs inflammatoires. Tous les cas ont été hospitalisés, deux ont nécessité une admission en soins intensifs et un est décédé. Les traitements les plus couramment administrés ont été l'immunoglobuline par intraveineuse, la prednisolone et l'aspirine. Les résultats indiquent qu'une reconnaissance précoce du MIS-A pourrait améliorer les chances des patients.

Limites

Seuls des rapports de cas ont été identifiés dans le cadre de cette étude. Bien qu'ils puissent contribuer à identifier de nouvelles tendances ou maladies, les rapports de cas présentent un certain nombre de limites. Il est difficile d'établir une comparaison, car les origines des cas sont différentes et ils ne sont pas représentatifs d'une population. Ces résultats sont donc très préliminaires; à mesure que d'autres études seront disponibles, nous en apprendrons davantage sur les caractéristiques épidémiologiques et cliniques communes de cette maladie.

Lacunes dans les données

Il semble que le MIS-A soit une complication rare de la maladie COVID-19. Les études menées à ce jour portent sur un total de 9 cas de MIS-A et ont été limitées à trois pays, les États-Unis, la France et le Royaume-Uni. Il n'existe aucune définition du MIS-A; l'utilisation de la définition des cas de MIS-C (sans tenir compte de l'âge)

est problématique, car il existe au moins 4 définitions et dans les cas examinés, la manière dont ils ont répondu à la définition de cas n'était pas toujours claire. Par exemple, les auteurs n'ont pas toujours précisé la manière dont ils excluaient toutes les autres causes potentielles du syndrome inflammatoire multisystémique, et la durée de la fièvre ou la présence de facteurs de comorbidité n'étaient pas toujours signalées. Une description plus systématique de l'ethnicité et de la gravité de la maladie est nécessaire. Par exemple, lorsque l'hypotension a été identifiée, la présence ou non d'un syndrome de choc n'a pas toujours été précisée.

Une définition de cas du MIS-A est nécessaire pour contribuer à normaliser le signalement. Il est également indiqué que de futures études portent sur le MIS-A pour en savoir plus sur cette maladie et sur l'efficacité du traitement.

Tableau : Résumé des rapports de cas sur le syndrome inflammatoire multisystémique chez l'adulte (MIS-A) (n=9)

ÉTUDE	MÉTHODE	PRINCIPAUX RÉSULTATS
Rapports de cas (n=9)		
Boudhabhay (2020) (5) Rapport de cas France 16 Sept 2020*	Un cas de MIS-A a été décrit, il comprenait les caractéristiques cliniques et de laboratoire, le traitement et le résultat. Le cas satisfaisait uniquement à la définition du RCPCH, puisque la durée de la fièvre n'était pas précisée.	*Caractéristiques démographiques et antécédents médicaux* • Le patient était un homme de 46 ans, d'origine africaine. • Antécédents d'hypertension et d'obésité *Caractéristiques du MIS-A* Fièvre et autres signes et symptômes • Admis pour une urgence hypertensive (189/123 mmHg) et de la fièvre (durée non précisée). Coagulopathie et atteinte rénale établies • Lésion rénale aiguë (AKI) : le taux de créatinine sérique (sCr) était de 169 µmol/L associé à 1 g par jour de protéinurie, pyurie aseptique, absence d'hématurie et faible natriurèse (< 20 mmol/L) • La biopsie rénale au microscope optique a révélé des lésions typiques de la microangiopathie thrombotique (MAT), notamment des thrombus de fibrine dans les glomérules et des altérations de l'intimité myxoïde des artérioles et des artères rénales de petite et moyenne taille • Le quatrième jour, le patient a présenté un érythème facial évanescent et a développé un dysfonctionnement myocardique aigu avec une diminution de 40 % de la fraction d'éjection ventriculaire gauche, un épanchement péricardique. Le cinquième jour, le patient a développé une déficience neurologique. Signaux d'IRM périventriculaires supratentoriels anormaux responsables d'une restriction de la diffusion due à une vascularite aiguë. PCR et sérologie pour le SRAS-CoV-2 • Test RT-PCR négatif, test IgM négatif et test IgG positif (aucun symptôme antérieur de la COVID-19 n'a été signalé) Marqueurs inflammatoires • Le niveau de protéine C réactive (CRP) était de 312 mg/L • Thrombocytopénie : le nombre de neutrophiles était de 18,7 G/L

		• Augmentation du dosage de troponine hautement sensible (hsTroponine) *Traitement* • Aucun traitement immunosuppresseur n'a été administré en raison d'une aspiration trachéale concomitante positive pour une contamination par *Enterobacter aerogenes* traitée avec du triméthoprime sulfaméthoxazole. • Dobutamine et thérapie de remplacement rénal (TRR). • Inhibition du complément spécifique avec thérapie à l'Eculizumab (900 mg) *Gravité et résultats* • Au cinquième jour de l'hospitalisation, une atteinte neurologique est apparue avec un coma entraînant une intubation et une ventilation mécanique. • Le patient a reçu son congé au bout de 30 jours d'hospitalisation.
Chowdhary (2020) (6) Rapport de cas Royaume-Uni Sept 2020*	Un cas de MIS-A a été décrit, il comprenait les caractéristiques cliniques et de laboratoire, le traitement et le résultat. Le cas satisfaisait uniquement aux définitions du RCPCH, des CDC, du CPS et de l'OMS.	*Caractéristiques démographiques et antécédents médicaux* • Homme de 26 ans • L'origine ethnique n'a pas été indiquée. • La présence ou l'absence de facteurs de comorbidité n'a pas été communiquée. • Une exposition au SRAS-CoV-2 a été signalée. *Caractéristiques du MIS-A* Fièvre et autres signes et symptômes • Le patient a été admis après cinq jours de fièvre • Toux sèche, myalgie, diarrhée, vomissements et douleurs abdominales • Au moment de son admission, le patient était hypotendu et hypoxique Un ou plusieurs organes étaient atteints (système pulmonaire, cardiaque, digestif) • La tomographie informatisée a indiqué la présence de plages de verre dépoli bilatérales basales et un œdème intestinal

		• L'échocardiographie transthoracique initiale a mis en évidence un dysfonctionnement systolique grave du ventricule gauche (VG) avec épanchement péricardique. • Le CT de l'abdomen a révélé une lymphadénopathie mésentérique et un œdème de l'intestin grêle PCR et sérologie pour le SRAS-CoV-2 • Sérologie RT-PCR négative, IgG et IgM positive Marqueurs inflammatoires • Protéine C-réactive (CRP), 419 mg/L • Ferritine, 3 275 lg/L (<322 µg/L) • Procalcitonine, 164 lg/L (<50 µg/L) • Troponine I, 2 030 ng/L (<57 ng/L) • D-dimères, 2 722 ng/mL (<220 ng/mL) Traitement • Thérapie vasopressive, aspirine à forte dose et antibiotiques à large spectre en soins intensifs • La thérapie immunomodulatoire n'a pas été administrée en raison de la bonne réaction à l'aspirine. *Gravité et résultats* • Le cas a été admis en USI et a été récupéré en 10 jours.
Fox (2020) (12) Rapport de cas États-Unis Juillet 2020*	Un cas de MIS-A a été décrit, il comprenait les caractéristiques cliniques et de laboratoire, le traitement et le résultat. Le cas satisfaisait uniquement à la définition du RCPCH, puisque la durée de la	*Caractéristiques démographiques et antécédents médicaux* • La patiente était une Afro-Américaine de 31 ans. • Facteurs de comorbidité : hypertension avec lisinopril, diabète avec mauvaise adhérence à la metformine et au glizide, et obésité (IMC = 36,1 kg/m2) • Elle avait reçu son congé 12 jours plus tôt, après une hospitalisation pour maladie de COVID-19 avec un RT-PCR positif. *Caractéristiques du MIS-A* • Admis pour fièvre soudaine 39,8 °C (durée non précisée), tachycardie 120 battements/min, douleur au cou du côté gauche, nausées et vomissements Marqueurs inflammatoires

	fièvre n'était pas précisée.	• Dosage des D dimères, 2,48 nmol/L • Taux de protéine C réactive, 165 mg/L, puis 580 mg/L • Niveau de ferritine, 114,2 µg/L • Niveau d'acide lactique, 3,1 mmol/L • Lymphopénie Un ou plusieurs organes atteints (système pulmonaire, cardiaque, parotidien, rénal) • La tomographie informatisée de son cou a révélé une hypertrophie bilatérale des glandes parotides et un gonflement du nasopharynx postérieur à l'oropharynx. • La tomographie informatisée de sa poitrine a indiqué une amélioration de l'intervalle des plages de verre dépoli bilatérales basales, avec une lymphadénopathie médiastinale cervicale et antérieure • Taux de créatinine 202,44 µmol/L; taux de filtration glomérulaire 32 mL/min/1,73 m^2 PCR et sérologie pour le SRAS-CoV-2 • La RT-PCR était positive 12 jours avant la réadmission pour MISC-A, la RT-PCR était négative à la réadmission et la sérologie n'a pas été effectuée *Traitement, gravité et résultats* • La patiente a développé une instabilité hémodynamique et une fibrillation ventriculaire pendant l'évaluation en vue de son admission à l'hôpital et elle est décédée.
Jones (2020)(7) Rapport de cas Royaume-Uni La date à laquelle l'étude a été menée n'a pas été communiquée	Un cas de MIS-A a été décrit, il comprenait les caractéristiques cliniques et de laboratoire, le traitement et le résultat. Le cas satisfaisait uniquement aux	*Caractéristiques démographiques et antécédents médicaux* • Le cas concernait un homme de 21 ans d'origine africaine. • La présence ou l'absence de facteurs de comorbidité n'a pas été communiquée. *Caractéristiques du MIS-A* Fièvre et autres signes ou symptômes • 6 jours de fièvre • Admis pour des douleurs abdominales associées à une constipation, de l'anorexie • Éruption palmaire maculopapuleuse transitoire 4 jours après le début de la maladie

Sept 2020*	définitions du RCPCH, des CDC, du CPS et de l'OMS.	• Conjonctivite non exsudative, • Lymphadénopathie cervicale, • Lèvres fendues et papilles linguales proéminentes PCR et sérologie pour le SRAS-CoV-2 • RT-PCR négative et sérologie fortement positive, ce qui suggère une exposition récente au SARS-CoV-2 Un ou plusieurs organes atteints • Éruption • Conjonctivite • Lymphadénopathie cervicale • Lèvres fendues et papilles linguales proéminentes Marqueurs inflammatoires • Lymphopénie • Niveau élevé des marqueurs inflammatoires et de la troponine T • Les autres causes infectieuses et inflammatoires ont été exclues Traitement • Immunoglobuline en intraveineuse • Méthylprednisolone *Gravité et résultats* • Le patient a reçu son congé de l'hôpital au bout de 8 jours.
Kofman(2020) (11) Rapport de cas États-Unis La date à laquelle l'étude a été menée n'a pas été communiquée	Un cas de MIS-A a été décrit, il comprenait les caractéristiques cliniques et de laboratoire, le traitement et le résultat. Le cas satisfaisait uniquement aux définitions du	*Caractéristiques démographiques et antécédents médicaux* • Le cas comprenait une femme de 25 ans. • L'origine ethnique n'a pas été indiquée. • Elle ne fumait pas, ne se droguait pas, ne prenait pas de médicaments et n'avait pas d'allergies connues. • Elle avait pris de l'ibuprofène et de l'acétaminophène au cours de la semaine précédente pour soulager ses symptômes. *Caractéristiques du MIS-A* Fièvre et autres signes et symptômes • Une semaine de fièvre légère, accompagnée de faiblesse, dyspnée et fatigue

Sept 2020*	RCPCH, des CDC, du CPS et de l'OMS.	• Elle a également développé une légère toux, un mal de gorge, des vomissements, de la diarrhée et un gonflement des ganglions lymphatiques
		• Lors de l'admission
		  ○ Elle était fébrile, avec une légère hypotension (pression sanguine 98/56 mmHg)
		  ○ La saturation en oxygène était normale dans l'air ambiant.
		  ○ Elle semblait malade et présentait une lymphadénopathie cervicale sensible
		  ○ Injection conjonctivale importante sans épargner le périlimbe; lèvres injectées, érythémateuses et fissurées
		  ○ Sensibilité à la palpation dans le quadrant inférieur gauche de l'abdomen
		
		Un ou plusieurs organes étaient atteints (système rénal, cardiaque, digestif, oculaire)
		• Lésion rénale aiguë : Créatinine, 7,74 mg/dL (normal : 0,5 - 1,2 mg/dL) et leucocytose
		• L'échocardiogramme au point de service a révélé une dilatation de la veine cave inférieure et une surcharge de la pression ventriculaire droite
		• L'angiographie CT du thorax a indiqué une légère hypertrophie de l'artère pulmonaire principale
		• Le scanner de l'abdomen et du bassin a mis en évidence une légère infiltration de graisse péripancréatique, qui pourrait représenter une pancréatite aiguë sans complication, ainsi qu'une infiltration de graisse périnéphrétique bilatérale non spécifique
		• Conjonctivite
		
		PCR et sérologie pour le SRAS-CoV-2
		• Sérologie RT-PCR et IgG positive
		
		Marqueurs inflammatoires
		• Protéine C-réactive, 90 mg/L (normal : 0-10 mg/L)
		• D-dimères,960 mg/L (normal : 0-574 mg/L)
		• Ferritine, 798 ng/ml (normal : 11-307 ng/ml)
		• Lymphocytes, 3 % (normal : 19-53)

		Traitement : • Réanimation liquidienne énergique et vasopresseur • Immunoglobuline en intraveineuse (IVIG), 2 g/kg répartis à parts égales entre les jours d'hospitalisation 2 et 3 • Aspirine, 325 mg par jour pendant 7 jours • La patiente s'est vu proposer le remdesivir dans le cadre d'une autorisation d'utilisation d'urgence (AUE), mais a refusé • À sa sortie, on lui a prescrit un traitement de 7 jours d'apixaban pour la coagulopathie associée à la COVID-19, conformément aux directives de traitement de la COVID-19 de l'hôpital universitaire Emory Gravité et résultats • La patiente a été admise deux fois en soins intensifs pendant son séjour à l'hôpital et a reçu son congé le cinquième jour.
Lidder (2020) (8) Rapport de cas États-Unis Mai 2020	Un cas de MIS-A a été décrit, il comprenait les caractéristiques cliniques et de laboratoire, le traitement et le résultat. Le cas satisfaisait uniquement aux définitions du RCPCH, des CDC, du CPS et de l'OMS.	*Caractéristiques démographiques et antécédents médicaux* • Le cas concernait un homme de 45 ans sans facteurs de comorbidité. • L'origine ethnique n'a pas été indiquée. *Caractéristiques du MIS-A* Fièvre et autres signes et symptômes • Il a eu de la fièvre pendant 5 jours, un mal de gorge, de la diarrhée, une rougeur des yeux, un gonflement des paupières et une éruption diffuse comprenant les paupières supérieures et inférieures bilatérales. Un ou plusieurs organes atteints (système rénal, cardiaque, digestif, ophtalmologique) • Un échocardiogramme transthoracique a révélé une hypokinésie globale et une diminution de 40 % de la fraction d'éjection. • La tomodensitométrie a indiqué une lymphadénopathie cervicale unilatérale avec un ganglion lymphatique de 1,8 cm. • Photophobie et gonflement des paupières. Aucune modification de la vision, y compris vision floue et douleurs oculaires.

		• L'acuité visuelle de près non corrigée était de 20/20 des deux côtés
		  ○ Kératite ponctuée superficielle bilatérale, inflammation symétrique de la chambre antérieure (CA) avec 10-15 cellules par champ de haute puissance, et pression intraoculaire normale. L'examen du fond d'œil dilaté notable uniquement pour une petite tâche périphérique d'ouate dans chaque œil.
		• Biopsie par perforation de son érythème polymorphe
		  ○ Présence d'un infiltrat périvasculaire superficiel épars lymphocitaire avec dispersion de neutrophiles et d'éosinophiles, suggérant un syndrome de choc toxique.
		
		À l'exclusion de toute autre cause
		• Les tests de dépistage de la myosite et du VIH étaient négatifs.
		• Le bilan rhumatologique exhaustif incluant les ANA, RF, anti-CCP, anti-Smith, anti-ADN, p-ANCA/MPO, c-ANCA/PR3 était également négatif.
		• Les hémocultures étaient négatives.
		
		PCR et sérologie pour le SRAS-CoV-2
		• Test RT-PCR positif
		
		Marqueurs inflammatoires
		• Lymphopénie
		• Dosage élevé de ferritine, CRP, ESR, D-dimères et troponine
		
		Traitement :
		• Thérapie ophtalmique lubrifiante en plus de l'acétate de prednisolone 1 % en gouttes oculaires quatre fois par jour pour sa photophobie dans le cadre de l'inflammation AC
		• IVIG et un inhibiteur de l'IL-6 (tocilizumab) en plus de l'utilisation d'une pommade topique à base de triamcinolone pour son éruption diffuse
		
		Gravité et résultats

		• La durée du séjour à l'hôpital n'a pas été communiquée, mais le patient n'a présenté aucun signe de choc.
Moghadam (2020) (9) Rapport de cas France La date à laquelle l'étude a été menée n'a pas été communiquée Juillet 2020*	Un cas de MIS-A a été décrit, il comprenait les caractéristiques cliniques et de laboratoire, le traitement et le résultat. Le cas satisfaisait aux définitions du RCPCH, des CDC et de l'OMS.	*Caractéristiques démographiques et antécédents médicaux* • Le cas concernait un homme caucasien de 21 ans. • La présence ou l'absence de facteurs de comorbidité n'a pas été communiquée. *Caractéristiques du MIS-A* Fièvre et autres signes et symptômes • Il a eu de la fièvre et une diarrhée aqueuse non sanglante pendant 7 jours. • Éruption asymptomatique sur le tronc et les paumes des mains, consistant en macules érythémateuses de forme ronde avec un bord plus foncé et surélevé, de 1 à 3 cm de diamètre • Conjonctivite bilatérale • Tension artérielle 80/40 mmHg • La fréquence respiratoire était de 38 respirations/min, et la saturation en oxygène était de 97 % dans l'air ambiant Un ou plusieurs organes étaient atteints (système cardiaque, digestif, pleural) • L'électrocardiogramme a révélé des ondes T négatives diffuses, et l'échocardiographie a indiqué un ventricule gauche hyperkinétique avec une fraction d'éjection normale, des cavités droites normales et une veine cave inférieure dilatée et non compressible. • La tomodensitométrie thoraco-abdominale (CT) a indiqué o Des signes d'insuffisance cardiaque congestive o Un épanchement pleural bilatéral o Un épaississement de la paroi du côlon droit • Détérioration de la fonction respiratoire PCR et sérologie pour le SRAS-CoV-2 • Sérologie RT-PCR négative et IgG positive Marqueurs inflammatoires • Lymphocytes de 900/mm3 • Protéine C réactive, 365 mg/L • La procalcitonine était de 3,4 ng/mL

		• La ferritine était de 1 282 mg/L (normale <30) • Lactate, 2,4 mmol/L (normal <1,6) • Le taux de troponine était de 550 ng/L (normal <34) • La biopsie cutanée a révélé un infiltrat légèrement inflammatoire dans le derme supérieur, et l'immunofluorescence cutanée directe était négative. Exclusion d'autres causes • Le patient s'est vu refuser toute prise de médicament • Il ne fumait pas de tabac et ne consommait pas de drogues illicites • L'analyse infectieuse approfondie et la recherche d'anticorps antinucléaires n'ont donné aucun résultat • L'éruption était particulière et le diagnostic d'érythème polymorphe et de lupus érythémateux subaigu a été écarté. Traitement : • Volume réanimation • Noradrénaline • Antibiotiques (ceftriaxone et amikacine) • Oxygénation nasale à haut débit Gravité et résultats • Le séjour en USI a duré 8 jours.
Sokolovsky(2020) (13) Rapport de cas États-Unis La date à laquelle l'étude a été menée n'a pas été communiquée Juin 2020*	Un cas de MIS-A a été décrit, il comprenait les caractéristiques cliniques et de laboratoire, le traitement et le résultat. Le cas satisfaisait uniquement aux définitions du RCPCH, des	*Caractéristiques démographiques et antécédents médicaux* • Le cas concernait une femme hispanique de 36 ans. • Elle ne présentait aucun facteur de comorbidité connu. *Caractéristiques du MIS-A* Fièvre et autres signes et symptômes • Une semaine de fièvre, de douleurs abdominales, de vomissements et de diarrhée • Deux jours d'éruption diffuse et d'arthralgies • Tachycardie, tachypnée, hypotension • Phénotype classique de la maladie de Kawasaki complète : conjonctivite mucosite bilatérale non exsudative avec lèvres fissurées, œdème bilatéral des mains et des pieds; éruption maculopapuleuse diffuse et lymphadénopathie cervicale

	CDC, du CPS et de l'OMS.	Un ou plusieurs organes étaient atteints (système cardiaque, digestif) • Angiographie CT du thorax : parenchyme pulmonaire normal et trace d'épanchement pleural droit • Le scanner de l'abdomen et du bassin a révélé un léger épaississement de la paroi circonférentielle de la vésicule biliaire et une petite zone de colite • Échocardiogramme après traitement par o IVIG a révélé une FE de 65 % avec une régurgitation modérée de la valve tricuspide. Les coronaires CTA subséquents étaient normaux, à l'exception d'une trace d'épanchement péricardique. PCR et sérologie pour le SRAS-CoV-2 • Sérologie RT-PCR négative et IgG positive Marqueurs inflammatoires • CRP : 30 mg/dL (0,0-0,9) • D-dimères : 652 ng/mL (<318) Exclusion d'une autre cause • Le dosage des anticorps anti-ADNdb, anti-Smith, anti-RNP, SSB, RF, CCP, ANCA, ASO et anti-Jo-1 était négatif • Les panels de VIH et hépatite étaient négatifs Traitement : • Réanimation liquidienne pour choc • Une dose unique d'aspirine 650 mg • IVIG 2 g/kg • Méthylprednisolone 2 mg/kg pendant 5 jours, suivi d'une cure de prednisone Gravité et résultats • Elle est restée au moins 6 jours à l'hôpital.
Shaigany (2020) (10) Rapport de cas États-Unis	Un cas de MIS-A a été décrit, il comprenait les caractéristiques cliniques et de laboratoire, le	*Caractéristiques démographiques et antécédents médicaux* • Le cas concernait un homme hispanique de 45 ans. • Il ne présentait aucun facteur de comorbidité connu. *Caractéristiques du MIS-A* Fièvre et autres signes et symptômes

La date à laquelle l'étude a été menée n'a pas été communiquée Juillet 2020	traitement et le résultat. Le cas satisfaisait uniquement aux définitions du RCPCH, des CDC, du CPS et de l'OMS.	• Six jours de fièvre, de maux de gorge, de diarrhée, de douleurs bilatérales aux membres inférieurs, de conjonctivite et d'exanthème diffus • Exposition à l'infection par le SRAS-CoV-2 2 semaines plus tôt • La fréquence respiratoire était de 25-33 respirations par minute • Hypotension (pression artérielle systolique 80-90 mm Hg) • Tachycardie avec épisodes de fibrillation auriculaire et réponse ventriculaire rapide • Injection conjonctivale bilatérale, non exsudative, • Gonflement sensible de la partie gauche du cou avec lymphadénopathie palpable, œdème périorbitaire avec érythème sus-jacent, chéilite labiale et papules et plaques érythémateuses ciblées avec crépuscule central touchant le dos, les paumes, le cou, le cuir chevelu, le tronc antérieur et le haut des cuisses Un ou plusieurs organes étaient atteints (système rénal, cardiaque, digestif, ophtalmologique) • Le scanner du cou a révélé une inflammation et un œdème impliquant les deux paupières inférieures et l'espace pré-septal, ainsi qu'une lymphadénopathie réactive sous-occipitale. • L'électrocardiogramme a révélé : o Élévations ST dans les voies antérolatérales, o Hypokinésie globale de la paroi ventriculaire gauche avec une diminution légère à modérée de 40 % de la fraction d'éjection • Conjonctivite diffuse avec chimiose et présence de cellules inflammatoires dans la chambre antérieure, indiquant une uvéite • Une biopsie cutanée à l'aide d'un poinçon de 4 mm a été réalisée sur une papule dans le dos, l'histologie a révélé de rares collections intraépithéliales de neutrophiles avec des kératinocytes nécrosés et un infiltrat cutané interstitiel peu abondant à cellules mixtes avec des modifications de l'interface vacuolaire. PCR et sérologie pour le SRAS-CoV-2

		• Test RT-PCR positif Marqueurs inflammatoires • Lymphopénie (0-700 lymphocytes par µL) • Vitesse de sédimentation des érythrocytes de 120 mm/h • Ferritine de 21 196 ng/mL • Protéine C-réactive de 546-7 mg/L • D-dimères de 2 977 ng/mL • Procalcitonine de 31-79 ng/mL • Interleukine-6 (IL-6) 117 pg/mL • Troponine 8-05 g/mL) Exclusion d'autres causes • Le dosage des anticorps du VIH-1 et du VIH-2 était négatif • Les hémocultures bactériennes étaient négatives Traitement : • Héparine de faible poids moléculaire à dose thérapeutique • Immunoglobuline en intraveineuse (2 g/kg) sur 2 jours • Une dose unique de tocilizumab en intraveineuse, un inhibiteur de l'IL-6 (400 mg) Gravité et résultats • Le patient a été hospitalisé pendant 8 jours et n'a pas eu besoin de soutien vasopresseur ou de niveau de soins d'unité de soins intensifs.

*La date est basée sur la date de publication, car la date à laquelle le cas s'est déclaré n'a pas été communiquée

Méthodes :

Un balayage quotidien de la littérature (publiée et pré-publiée) est effectué par le Groupe des sciences émergentes de l'ASPC. L'analyse a compilé la littérature sur la COVID-19 depuis le début de l'épidémie et est mise à jour quotidiennement. Les recherches pour trouver la littérature pertinente sur la COVID-19 sont effectuées dans Pubmed, Scopus, BioRxiv, MedRxiv, ArXiv, SSRN, Research Square et croisées avec les centres d'information sur la COVID-19 gérés par Lancet, BMJ, Elsevier, Nature et Wiley. Le résumé quotidien et les résultats complets de l'analyse sont conservés dans une base de données Refworks et une liste excel qui peut être consultée. Une recherche ciblée par mot-clé est effectuée dans ces bases de données pour identifier les citations pertinentes sur COVID-19 et SARS-COV-2. Les termes de recherche utilisés comprenaient : « MIS-A »,

« Kawasaki », « multisystem inflame », « multi-system inflam », « inflammatory multisystem », « inflammatory multi-system », et « inflammatory disease », « Kawasaki-like », « COVID-19 linked disease ». Cette étude contient les recherches publiées jusqu'au 13 novembre 2020.
Chaque référence potentiellement pertinente a été examinée pour confirmer qu'elle contenait des données pertinentes et les données pertinentes sont extraites dans l'étude.

Nouvelles données probantes sur la COVID-19

Examen rapide du syndrome inflammatoire multisystémique chez les enfants (MIS-C)

INTRODUCTION

Quelles sont les caractéristiques épidémiologiques du syndrome inflammatoire multisystémique chez les enfants?

L'objectif de cet examen est de résumer les caractéristiques épidémiologiques du syndrome inflammatoire multisystémique chez les enfants, également appelé le Paediatric Inflammatory Multisystem Syndrome (PIMS). Le syndrome inflammatoire multisystémique chez les enfants est une maladie émergente qui a été identifiée lors de la pandémie de COVID-19. Des cas d'enfants présentant des signes de la maladie de Kawasaki suite à un résultat positif à un test de dépistage de la COVID-19 ont été signalés pour la première fois au Royaume-Uni le 27 avril 2020 (1). Des définitions de cas ont depuis été publiées par l'Organisation mondiale de la santé (2), les Centres de contrôle et de prévention des maladies des États-Unis (3) et le Royal College of Paediatrics and Child Health au Royaume-Uni (4). Comme l'illustre l'annexe, les trois définitions de cas sont similaires, mais pas identiques.

Dans cet examen, le nom syndrome inflammatoire multisystémique chez les enfants (MIS-C) est utilisé pour des raisons de cohérence, mais il désigne globalement le syndrome connu sous le nom de PIMS. Il n'existe pas de test de diagnostic définitif pour le MIS-C. Il est considéré comme un syndrome distinct, mais apparenté à la forme complète, incomplète ou atypique de la maladie de Kawasaki, au Kawasaki disease shock syndrome (KDSS), au syndrome de choc toxique (SCT) et au syndrome d'activation macrophagique, avec de nombreuses caractéristiques qui se chevauchent (5). L'examen comprend des données probantes provenant d'articles où l'une des trois définitions a été appliquée, ou la maladie de Kawasaki ou un syndrome inflammatoire lié à la COVID-19 a été diagnostiqué.

La grande majorité des articles sur le MIS-C étaient des rapports de cas et des études par cohorte. Pour donner une indication approximative de la solidité des données probantes, les articles ont ensuite été organisés en trois catégories : important, moyen et petit, en fonction du nombre de patients atteints du MIS-C présentés dans l'article ≥50, 6-49 et ≤5, respectivement. Les résultats liés à l'épidémiologie du MIS-C ont été résumés, notamment : les données démographiques des patients atteints de MIS-C (âge, sexe, origine ethnique/race et comorbidités), les résultats de gravité commune (admission en unité de soins intensifs [USI], ventilation mécanique et utilisation de l'oxygénation extracorporelle), la mortalité liée au MIS-C et le moment par rapport à la forme grave de la COVID-19. Notez que des cas similaires de syndrome inflammatoire multisystémique ont été signalés chez les adultes (connu sous le nom de MIS-A), qui font l'objet d'un examen séparé disponible sur demande : phac.evidence-donnees.probantes.aspc@canada.ca

POINTS CLÉS

Il y a eu 102 articles recensés. Onze articles étaient des vastes études de cohortes, décrivant chacune plus de 50 cas de MIS-C. Quarante-trois articles étaient de taille moyenne, décrivant chacun 6 à 49 cas de MIS-C. Quarante-huit articles étaient des rapports de cas où le nombre de cas de MIS-C décrits allait de un à cinq.

Prévalence parmi les cas de COVID-19 chez les enfants

Une vaste étude internationale menée sur plusieurs emplacements a estimé que le MIS-C touchait entre 0,5 % et 3,1 % de tous les enfants ayant un diagnostic de COVID-19 et entre 0,9 % et 7,6 % des enfants atteints de la COVID-19 hospitalisés et âgés de moins de 18 ans (6). Trois autres articles ont examiné la fréquence du MIS-C parmi les cas de COVID-19 chez les enfants hospitalisés, avec des estimations variant de 6 % au Pérou (7) à 9 % et 11 % aux États-Unis (8,9).

Âge

Le MIS-C peut toucher les enfants de tout âge, comme l'indiquent les intervalles entre les articles. Cependant, l'âge médian des cas était de 7 à 11 ans. Cela a été constant avec les articles importants, moyens et petits.

Sexe

Dans les articles importants, moyens et petits, de 57 à 58 % des cas étaient de sexe masculin.

Comorbidités

Dans les articles qui ont fait état de comorbidités, la définition de la comorbidité était incohérente. La comorbidité la plus souvent signalée est l'obésité. Les taux d'obésité étaient cohérents, mais plus faibles dans les petits articles (8 %) que dans les articles moyens (22 %) et importants (24-29 %). Une autre comorbidité courante était l'asthme (6 à 18 %). Les patients présentant au moins une comorbidité allaient de 19 % lorsque l'obésité était exclue à 29 % lorsque l'obésité était incluse. Peu d'articles ont comparé les taux d'une comorbidité donnée à la prévalence de cette comorbidité dans la population pédiatrique générale. Un article a révélé que la proportion de patients atteints du MIS-C et obèses est légèrement plus élevée que celle rapportée dans la population avec des problèmes sous-jacents (10).

Aucun article n'a tenté de démêler la relation entre une condition donnée, l'infection à la COVID-19 et le développement du MIS-C. Par exemple, les enfants obèses ou asthmatiques pourraient être plus susceptibles de contracter la COVID-19, et seraient donc surreprésentés dans les cas de MIS-C, sans être spécifiquement prédisposés au MIS-C. Cette relation est largement inexplorée et doit être étudiée davantage.

Origine ethnique

Bien que certains articles aient traité de l'origine ethnique ou de la race, peu d'entre eux ont fourni des comparaisons avec la composition de la population avec des problèmes sous-jacents. Cependant, dans 14 articles de taille moyenne des États-Unis, les enfants noirs et hispaniques représentaient la plus grande partie des patients, avec respectivement 36 % et 29 %. Un important article des États-Unis fait état de

données démographiques similaires (33 % hispaniques et 27 % noirs) (10). Les Centres de contrôle et de prévention des maladies des États-Unis indiquent que, par rapport aux Blancs, les Noirs ont 2,6 fois plus de risques et les Hispaniques 2,8 fois plus de risques d'être infectés par la COVID-19 (11). Cela peut expliquer en partie ou en totalité les taux disproportionnellement élevés de MIS-C parmi ces populations. Cette relation complexe doit être étudiée davantage.

Déclenchement du MIS-C par rapport à l'infection par le SRAS-CoV-2

Les données de cas cliniques suggèrent qu'il y a un retard dans l'apparition du MIS-C après une infection grave causée par le SRAS-CoV-2. Dans trois articles qui ont documenté le moment de l'infection de la forme grave de la COVID-19 pour chaque patient du MIS-C, l'apparition du MIS-C est survenue de 15 à 24 jours après l'apparition des symptômes de la forme grave de la COVID-19. Une poignée d'articles (n=6) ont déterminé que le délai entre le pic des cas de MIS-C était d'environ deux à cinq semaines après le pic des cas de COVID-19 à l'échelle de l'état ou du pays. Le retard dans l'apparition des symptômes est encore renforcé par les faibles taux de positivité (<50 %) avec le modèle RT-PCR par rapport au test sérologique d'anticorps IgG (>75 %). Cela suggère que le MIS-C est souvent un syndrome après-infection, ayant une apparition retardée après la forme grave de la COVID-19.

Résultats de la gravité

Les données probantes suggèrent que les patients atteints de MIS-C ont souvent besoin de soins intensifs, mais que le taux de survie global est élevé. Huit importants articles ont fait état d'un taux d'admission aux soins intensifs de 21 à 80 %, ce qui correspond à un taux de 65 % pour les articles de taille moyenne et de 74 % pour les petits articles. En outre, entre 25 et 40 % des cas de MIS-C ont été intubés et de 5 à 11 % ont nécessité une oxygénation extracorporelle. Dans les articles importants, le taux de mortalité variait de 0 à 2,2 % des patients hospitalisés et 2,6 % des patients atteints du MIS-C admis aux soins intensifs. Cela correspond aux articles de taille moyenne qui font état d'un taux de mortalité de 2 %, mais qui est inférieur au taux de 7 % de mortalité signalés dans les petits articles. Il se peut que des cas et des décès en double soient inclus dans ces totaux, mais le nombre de décès pourrait également être une sous-estimation, car tous les cas n'ont pas été résolus au moment de la publication des documents.

VUE D'ENSEMBLE DES DONNÉES PROBANTES

Lors d'une recherche documentaire effectuée jusqu'au 10 novembre 2020, 102 articles contenant des renseignements sur les caractéristiques épidémiologiques du MIS-C ont été trouvés. Presque tous ces articles étaient des rapports de cas ou des études de cohortes rétrospectives.

Il y avait 11 importants articles qui étaient pour la plupart des études de cohortes rétrospectives. Notamment deux études de plusieurs pays, quatre articles des États-Unis, trois du Royaume-Uni et deux du continent européen (tableau 1).

Il y avait 43 articles de taille moyenne (avec un total de 861 cas de MIS-C) qui ont été inclus dans cet examen. Il s'agissait de séries de cas et d'études de cohortes rétrospectives. Au total, 18 provenaient des États-Unis (379 cas), 13 d'Europe (314 cas), quatre d'Amérique du Sud (50 cas), deux du Moyen-Orient (53 cas), deux de l'Inde (42 cas) et un d'Afrique du Sud (23 cas) (tableau 2).

Les rapports de cas ont tendance à être publiés lorsqu'une nouvelle maladie est identifiée. Ils sont bons pour générer des hypothèses, mais sont généralement considérés comme des données probantes faibles. Ces 48 rapports de cas s'inscrivent dans cette tendance puisqu'ils reprennent certains des rapports de cas antérieurs du MIS-C, avant la reconnaissance officielle du syndrome et pour mettre en évidence l'éventail des pays qui ont signalé des cas de MIS-C : 20 provenaient des États-Unis, 13 d'Europe, et le reste de l'Inde (6 articles), du Moyen-Orient (5 articles), de l'Amérique du Sud (2 articles), de l'Afrique (1 article) et du Canada (1 article) (tableau 3).

Limites

- La majorité des articles de cet examen proviennent des États-Unis et d'Europe. En revanche, seuls deux articles proviennent d'Afrique, et seule une partie d'un examen a tiré des données en Asie. Il n'y a qu'un seul rapport de cas en provenance du Canada.
- Il y a un problème de double comptage des patients, car certains articles provenaient des mêmes hôpitaux, régions ou sources de données. Cela pourrait fausser les résultats. Lorsque signalé par l'auteur, il est inscrit dans les tableaux ci-dessous. Afin d'éviter un double comptage important, les examens systématiques et autres types n'ont pas été inclus.
- De nombreux articles comportaient des données incomplètes, en particulier des données sur la comorbidité et l'origine ethnique, qui n'étaient souvent recueillies que pour une partie des cas.
- Comme il s'agit d'un syndrome émergent, les définitions de cas et les critères d'inclusion ont évolué au fil du temps. Chaque cas peut ou non répondre à l'une des trois définitions de cas standard, ou aux exigences relatives à la maladie de Kawasaki.
- Aucun des articles ne prévoit de suivi des patients après leur rétablissement du MIC-C grave. Par conséquent, les séquelles ou les complications ultérieures sont encore inconnues.

TABLE DES MATIÈRES

Pour chaque étude incluse dans les tableaux des données probantes ci-dessous, les renseignements suivants sur le MIS-C sont fournis lorsqu'ils sont disponibles : Âge, sexe, origine ethnique/race, comorbidités, résultats

de la gravité (admission en USI, intubation, oxygénation extracorporelle et décès), résultats des tests PCR et sérologique pour le SRAS-CoV-2, et intervalle entre la forme grave de la COVID-19 et l'apparition du MIS-C. Ces variables ne sont pas incluses lorsqu'elles n'ont pas été déclarées.

ARTICLES IMPORTANTS

Tableau 1 : Articles décrivant 50 cas ou plus de MIS-C, par ordre décroissant de taille

Étude	Méthode	Principales conclusions
Godfred-Cato (2020) (10) Étude de cohorte rétrospective États-Unis Mars-juillet 2020	Les données relatives à 570 cas de MIS-C ont été recueillies auprès de 40 départements de la santé des États du District de Columbia et de la ville de New York	- Âge médian = 8 ans (fourchette = 2 semaines - 20 ans) - 316/570 (55 %) de sexe masculin - 187 (33 %) étaient hispaniques, 153 (27 %) noirs, 61 (11 %) blancs, 13 (2 %) asiatiques, 48 (8 %) d'une autre origine ethnique et 108 (19 %) d'une origine ethnique inconnue. Cette étude révèle que la proportion de patients hispaniques, noirs et blancs atteints du MIS-C et obèses est légèrement plus élevée que celle rapportée dans la population. - 146 (26 %) étaient obèses, 48 (8 %) étaient atteints d'une maladie pulmonaire chronique. - 364 (64 %) admis aux soins intensifs, 69 (12 %) nécessitant une ventilation mécanique. - 10 (2 %) décès. - Tous sauf 5 ont été testés positifs pour la COVID-19 par l'un ou l'autre ou les deux tests PCR ou sérologique et les 5 autres avaient un lien épidémiologique avec un cas connu de COVID-19.
Feldstein (2020) (12) Étude de cohorte rétrospective États-Unis Mars-mai 2020	Surveillance prospective et rétrospective de 186 patients atteints de MIS-C admis dans les centres de santé participants dans 26 États des États-Unis.	- Âge médian = 8,3 ans (EI = 3,3-12,5 ans) - 115/186 (62 %) de sexe masculin - 57 (31 %) étaient hispaniques, 46 (25 %) noirs, 35 (19 %) asiatiques, 9 (5 %) d'une autre origine ethnique et 41 (22 %) d'une origine ethnique inconnue. - 45 (24 %) étaient obèses. De plus, 51 (27 %) présentaient une comorbidité, dont 33 (18 %) avec des maladies respiratoires, 5 (3 %) avec des maladies cardiaques, 10 (5 %) avec des maladies liées au système immunitaire et 20 (11 %) avec d'autres maladies.

		- 148 (80 %) admis aux soins intensifs, 37 (20 %) nécessitant une ventilation mécanique, 8 (4 %) nécessitant une oxygénation extracorporelle. - Quatre (2 %) décès. - 131 personnes ont obtenu un résultat positif pour la COVID-19 par l'un ou l'autre, ou les deux tests, PCR ou sérologique et les 5 autres avaient un lien épidémiologique avec un cas connu de COVID-19. - Les cas de MIS-C sont survenus en moyenne 25 jours (intervalle = 6-51 jours) après la forme grave de la COVID-19.
Deep (2020) (13) Étude de cohorte rétrospective Royaume-Uni Mars-mai 2020 Remarque : 78 des enfants de cette étude avaient déjà fait partie d'un rapport.	116 enfants admis dans 24 unités de soins intensifs au Royaume-Uni ont été traités pour une insuffisance rénale aiguë. Les patients atteints de maladie du rein existante ont été exclus.	- Âge médian = 11 ans (EI = 7-14 ans) - 76/116 (66 %) de sexe masculin - 51 (45 %) étaient noirs, 29 (26 %) asiatiques, 24 (21 %) blancs, 9 (8 %) d'autres origines ethniques. - 20 (17 %) avaient une comorbidité, dont 5 (4 %) asthmatiques, 3 (3 %) atteints de fibrose kystique, 1 (1 %) d'une maladie pulmonaire chronique, 1 (1 %) autiste, 10 (9 %) atteints d'une autre maladie. - 116 (100 %) admis en soins intensifs (selon le modèle d'étude), 41 (35 %) nécessitant une ventilation mécanique, 3 (3 %) nécessitant une oxygénation extracorporelle. - Deux (2 %) décès.
Belot (2020) (14) Étude de cohorte rétrospective France Mars-mai 2020	Tous les services de pédiatrie en France ont déclaré 108 cas de MIS-C diagnostiqués après le 1er mars 2020, pour estimer la charge de cette affection en France.	- Âge médian = 8 ans (EI = 5-11 ans) - 53/108 (49 %) de sexe masculin - 72 (67 %) admis aux soins intensifs, 46 (43 %) nécessitant une ventilation mécanique. - Un (1 %) décès. - Un total de 79 personnes ont obtenu un résultat positif pour la COVID-19 par l'un ou l'autre, ou les deux tests, PCR ou sérologique. 16 ont eu un contact avéré avec des cas de COVID-19 et 13 ont été suspectés d'avoir eu la COVID-19 sur la base des symptômes et des antécédents.

		- Les cas de MIS-C ont atteint un pic 4 à 5 semaines après le pic des cas locaux de COVID-19.
Dufort (2020) (15) Étude de cohorte rétrospective États-Unis Mars-mai 2020	Les hôpitaux de l'État de New York qui fournissent des soins pédiatriques ont signalé 99 cas potentiels de MIS-C.	- Des catégories d'âge ont été données : 31 (31 %) étaient âgés de 0 à 5 ans, 42 (42 %) de 6 à 12 ans et 26 (26 %) de 3 à 20 ans. - 53/99 (54 %) de sexe masculin. - 31 (31 %) étaient hispaniques, 29 (29 %) blancs, 4 (4 %) asiatiques, 14 (14 %) d'une autre origine ethnique et 21 (21 %) d'une origine ethnique inconnue. - 36 (36 %) avaient une comorbidité, dont 29 (29 %) étaient obèses et 14 (14 %) étaient atteints d'une maladie pulmonaire chronique. - 79 (80 %) admis en soins intensifs, 10 (10 %) nécessitant une ventilation mécanique, 1 (1 %) nécessitant une oxygénation extracorporelle. - Deux (2 %) décès. - 76/77 (99 %) ont obtenu un résultat positif au test sérologique et 50/99 (56 %) ont obtenu un résultat positif au test PCR. - Les cas de MIS-C ont atteint un pic 31 jours après le pic des cas locaux de COVID-19.
Antunez-Montes (2020) (16) Cohorte ambidirectionnelle Mexique, Colombie, Pérou, Costa Rica et Brésil Juillet-août, 2020	Un groupe de médecins d'Amérique centrale et du Sud a recueilli 95 cas de MIS-C parmi 409 cas pédiatriques confirmés. Infections par le SRAS-CoV-2	- 95 cas de MIS-C ont été identifiés parmi 409 enfants admis à l'hôpital avec un résultat positif de la COVID-19 (23 %). - Âge médian = 7 ans (intervalle = 1 mois - 17 ans). Les patients atteints du MIS-C étaient nettement plus âgés que les enfants non atteints du MIS-C admis à l'hôpital avec la COVID-19. - 52/95 (55 %) de sexe masculin. - 11 (12 %) présentaient des comorbidités et avaient un statut socioéconomique nettement inférieur à celui des enfants admis avec la forme grave de la COVID-19. - 20 (21 %) admis aux soins intensifs, 9 (9 %) nécessitant une ventilation mécanique. - Deux (2 %) décès.

		- Tous ont obtenu un résultat positif pour la COVID-19 par l'un ou l'autre, ou les deux tests, PCR ou sérologique.
Davies (2020) (17) Étude de cohorte rétrospective Royaume-Uni Avril-mai 2020 Remarque : Huit des enfants inclus dans cette étude avaient déjà fait partie d'un rapport.	Une description de 78 cas de PIMS, âgés de 17 ans et moins, admis dans les unités de soins intensifs au Royaume-Uni	- Avant l'arrivée de la COVID-19, les données historiques concernant des maladies inflammatoires similaires faisaient état d'une admission moyenne aux soins intensifs par semaine (IC à 95 %; 0,85 à 1,22). En comparaison, il y avait une moyenne de 14 cas par semaine pour le PIMS, et un pic de 32 admissions par semaine pendant la période d'étude. - Âge médian = 11 ans (EI = 8-14 ans) - 52/78 (67 %) de sexe masculin. - 37 (47 %) étaient noirs, 22 (28 %) asiatiques, 17 (22 %) blancs, 2 (3 %) d'autres origines ethniques. - 17 (22 %) présentaient des comorbidités, dont 2 (3 %) avec des maladies graves préexistantes. - 78 (100 %) admis en soins intensifs (requis pour faire partie de l'étude), 36 (46 %) nécessitant une ventilation mécanique, 3 (4 %) nécessitant une oxygénation extracorporelle. - Deux (3 %) décès. - 33/35 (94 %) ont obtenu un résultat positif au test sérologique et 17/78 (22 %) ont obtenu un résultat positif au test PCR.
Jonat (2020) (18) Étude de cohorte rétrospective États-Unis Mars-juin 2020	Une description des 54 cas de MIS-C identifiés dans un seul hôpital dans la période donnée.	- Âge médian = 7 ans (intervalle = 10 mois - 20 ans) - 25/54 (46 %) de sexe masculin. - 19 (35 %) étaient blancs, 10 (19 %) noirs, 8 (15 %) d'une autre origine ethnique, 17 (31 %) d'une origine ethnique inconnue. - Sept avaient des conditions préexistantes (à l'exclusion de l'obésité). - 31 (57 %) ont été admis aux soins intensifs. Aucun patient n'a eu besoin de ventilation mécanique ou d'oxygénation extracorporelle. - Aucun décès.

		- 41/54 (97 %) ont obtenu un résultat positif au test sérologique et 20/54 (34 %) ont obtenu un résultat positif au test PCR.
Cattalini (2020) (19) *(préimpression)* Étude de cohorte rétrospective Italie Février-mai 2020	Un sondage envoyé à la société italienne de pédiatrie; 53 patients avaient les caractéristiques d'un diagnostic de « KawaCOVID » (équivalent du MIS-C).	- L'âge médian des cas de KawaCOVID = 7 ans (EI : 4,5-11 ans), alors que l'âge médian des cas de Kawasaki = 2 ans (EI : 1-4 ans). L'âge médian est significativement différent (p<0,0001). - Il n'y a pas eu de différence significative dans le sex-ratio de KawaCOVID par rapport à la maladie de Kawasaki. - L'admission aux soins intensifs était plus fréquente dans les cas de KawaCOVID que dans ceux de la maladie de Kawasaki (23,1 % par rapport à 1,1 %; p<0,0001) - Les cas de KawaCOVID présentaient une atteinte cardiaque plus grave que les cas de Kawasaki - myocardite (60,4 % par rapport à 3,1 %; p<0,0001), péricardite (26,4 % par rapport à 7,3 %; p=0-0013), insuffisance cardiaque (35,8 % par rapport à 1 %; p<0,00001) et autres. - Tous les patients atteints de KawaCOVID ont obtenu un résultat positif pour la COVID-19 par PCR ou par un test sérologique, ou les deux (31 ont été obtenu un résultat positif au test sérologique et 14 par PCR). - Aucun décès.
Whittaker (2020) (20) Étude de cohorte rétrospective Royaume-Uni Mars-mai 2020 Remarque : Huit des enfants inclus dans cette étude avaient déjà fait partie d'un rapport.	Un sondage en ligne avec des données sur 58 enfants qui ont été admis dans huit hôpitaux en Angleterre avec le PIMS (MIS-C).	- Âge médian = 9 ans (EI = 5,7-14 ans, intervalle = 3 mois - 17 ans) - 38/58 (66 %) de sexe masculin. - Sept (12 %) présentaient des comorbidités, dont 3 (5 %) asthmatiques, et 1 chacun (2 %) avec un trouble du développement neurologique, de l'épilepsie, le trait drépanocytaire et l'alopécie. - 29 (50 %) des patients admis aux soins intensifs, 25 (43 %) nécessitant une ventilation mécanique, 2 (3 %) nécessitant une oxygénation extracorporelle. - Un (2 %) décès. - 40/46 (87 %) ont obtenu un résultat positif au test sérologique et 15/58 (26 %) ont obtenu un résultat positif au test PCR.

Duarte-Salles (2020) (6) *(préimpression)* Étude de cohorte rétrospective États-Unis, Espagne, France, Allemagne et Corée du Sud Janvier-juin 2020	Sur la base des dossiers médicaux, des données de facturation des hôpitaux et des données relatives aux demandes d'assurance aux États-Unis, en Europe et en Asie, les enfants diagnostiqués ou hospitalisés avec la COVID-19 ont été comparés à une précédente cohorte de grippe saisonnière.	- Cette étude porte sur 55 270 enfants et adolescents atteints de la COVID-19, dont 3 693 ont été hospitalisés avec la COVID-19 et ont été comparés à une cohorte historique de 1 952 693 enfants atteints de la grippe. - Le MIS-C était relativement peu fréquent, touchant entre 0,5 % et 3,1 % des patients atteints de la COVID-19, et entre 0,9 % et 7,6 % des patients hospitalisés avec la COVID-19. - On pensait que le MIS-C était lié à la COVID-19, car des syndromes similaires sont beaucoup moins fréquents dans la cohorte historique de la grippe.

ARTICLES DE TAILLE MOYENNE

Tableau 2 : Articles décrivant de 6 à 49 cas de MIS-C, par ordre décroissant de taille

ÉTUDE	MÉTHODE	PRINCIPAUX RÉSULTATS
Mamishi (2020) (21) Étude de cohorte rétrospective Iran Mars-juin 2020	45 cas de MIS-C sont décrits.	- Âge médian = 7 ans (intervalle = 10 mois - 17 ans) - 24/45 (46 %) de sexe masculin. - Six (13 %) avaient des maladies préexistantes - Cinq (11 %) décès - quatre d'entre eux avaient des maladies sous-jacentes (leucémie aiguë lymphoblastique, néphropathie chronique, paralysie cérébrale et syndrome de Budd-Chiari). - 35 tests sérologiques positifs, 10 tests PCR positifs
Miller (2020) (22) Étude de cohorte rétrospective États-Unis Avril-mai 2020	44 cas de MIS-C sont décrits.	- Âge médian = 7,3 ans (EI = 4,98 ans, intervalle = 7 mois - 20 ans) - 20/44 (45 %) de sexe masculin. - 15 (34 %) étaient hispaniques, 9 (20 %) noirs, 9 (20 %) blancs, 11 (25 %) origines ethniques inconnues.

		- 16 (36 %) étaient en surpoids. - Un (2 %) a nécessité de la ventilation mécanique. - Aucun décès. - 31/32 ont été testés positifs avec un test sérologique et 15/44 avec un test PCR.
Belhadjer (2020) (23) Étude de cohorte rétrospective France Mars-avril 2020	35 cas de MIS-C ayant eu une implication cardiaque et nécessitant une admission en soins intensifs sont décrits.	- Âge médian = 10 ans (intervalle = 2-16 ans) - 18/35 (51 %) de sexe masculin. - Six (17 %) étaient en surpoids, 3 (9 %) asthmatiques, 1 (3 %) atteint de lupus. - 35 (100 %) admis aux soins intensifs, 22 (63 %) nécessitant une ventilation mécanique, 10 (29 %) nécessitant une oxygénation extracorporelle. - Aucun décès. - 14 ont eu un résultat positif au test PCR, tandis que 30 patients ont eu un résultat positif au test sérologique (28 positifs pour les anticorps IgG et 2 positifs pour les anticorps IgM).
Hameed (2020) (24) Étude de cohorte rétrospective Royaume-Uni Avril-mai 2020 Remarque : Huit patients ont fait partie d'autres études.	35 cas de MIS-C de moins de 17 ans sont décrits.	- Âge médian = 11 ans (EI = 8 ans) - 27/35 (77 %) de sexe masculin. - 24 (69 %) admis aux soins intensifs, 7 (20 %) nécessitant une ventilation mécanique, 2 (6 %) nécessitant une oxygénation extracorporelle. - Un (3 %) décès. - 25 ont été testés positifs pour les anticorps IgG et 23 pour les anticorps IgM.
Sethuraman (2020) (25) Étude de cohorte rétrospective États-Unis Avril-juillet 2020	34 cas de MIS-C sont décrits.	- Âge médian = 6 ans (EI = 8 ans) - 16/34 (47 %) de sexe masculin. - 23 (68 %) étaient noirs, autre origine ethnique/race non déclarée. - Deux (6 %) étaient obèses et 9 (26 %) étaient asthmatiques. 24 (71 %) admis aux soins intensifs, 8 (24 %) nécessitant une ventilation mécanique, 2 (6 %) nécessitant une oxygénation extracorporelle.

		- Aucun décès. - 18/25 testés positifs pour les anticorps IgG, 8/34 testés positifs au test PCR. - Les cas de MIS-C ont atteint un pic 3 semaines après le pic des cas locaux de COVID-19.
Minocha (2020) (26) Étude de cohorte rétrospective États-Unis Mars-juin 2020	33 cas de MIS-C sont décrits.	- Âge médian = 2,8 ans (EI = 1,4-9 ans) - 19/33 (56 %) de sexe masculin. - 12 (36 %) hispaniques, 10 (30 %) blancs, 7 (21 %) noirs, 4 (12 %) asiatiques. - Sept (21 %) étaient obèses, 5 (15 %) étaient asthmatiques, 1 (3 %) est né prématurément. - 11 (33 %) ont été admis aux soins intensifs. - Aucun décès. - 14/23 testés positifs pour les anticorps IgG, 11/33 testés positifs au test PCR.
Kaushik, Aydin, (2020) (27) Étude de cohorte rétrospective États-Unis Avril-mai 2020 Remarque : Quatre patients ont fait partie d'autres études.	33 cas de MIS-C qui ont été admis aux soins intensifs sont décrits.	- Âge médian = 10 ans (EI = 6-13 ans) - 20/33 (61 %) de sexe masculin. - 15 (45 %) étaient hispaniques, 13 (39 %) noirs, 3 (9 %) blancs, 1 (3 %) asiatique, 1 (3 %) d'une autre origine ethnique. - 16 (48 %) des patients présentaient des comorbidités - 4 (12 %) étaient obèses, 2 (6 %) étaient en surpoids, 5 (15 %) étaient asthmatiques, 3 (9 %) avaient des allergies/eczémas, 2 (6 %) avaient des problèmes cardiaques, 2 (6 %) avaient des problèmes hématologiques - 33 (100 %) admis aux soins intensifs, 5 (15 %) nécessitant une ventilation mécanique, 1 (3 %) nécessitant une oxygénation extracorporelle. - Un (3 %) décès. - 11 tests PCR positifs et 27 tests sérologiques positifs.
Capone (2020) (28) Étude de cohorte rétrospective États-Unis	33 cas de MIS-C sont décrits.	- Âge médian = 8,6 ans (EI = 5,5-12,6 ans) - 20/33 (61 %) de sexe masculin. - Huit (24 %) étaient noirs, 3 (9 %) blancs, 3 (9 %) asiatiques, 19 (58 %) autres origines ethniques ou

Avril-mai 2020		inconnues. Les taux de l'ethnicité dans les cas de MIS-C étaient similaires aux taux de l'ethnicité de la population hospitalisée. - 12 (36 %) étaient obèses, 2 (6 %) étaient en surpoids. Le taux d'obésité infantile dans la région est de 18 %, les patients obèses sont donc surreprésentés dans les cas de MIS-C dans cette étude. - 26 (79 %) admis aux soins intensifs, 6 (18 %) nécessitant une ventilation mécanique. - Aucun décès. - 30 personnes testées positives pour les anticorps IgG. - Les cas de MIS-C ont atteint un pic 5 semaines après le pic d'hospitalisation local de la COVID-19.
Moraleda (2020) (29) Étude de cohorte rétrospective Espagne Mars-juin 2020	31 cas de MIS-C sont décrits.	- Âge médian = 7,6 ans (EI = 4,5-11,5 ans) - 18/31 (58 %) de sexe masculin. - Trois (10 %) étaient obèses, 4 (13 %) étaient asthmatiques et 1 chacun (3 %) était atteint d'une maladie cardiaque chronique, d'une maladie hématologique et d'un cancer. - 20 (65 %) admis aux soins intensifs, 6 (19 %) nécessitant une ventilation mécanique. - Un (3 %) décès. - 17 ont été positifs au test PCR, 10 tests positifs pour les anticorps IgM et 19 tests positifs pour les anticorps IgG. - Les cas de MIS-C ont atteint un pic un mois après le pic d'hospitalisation local de la COVID-19.
Aulnes (2020) (30) Étude de cohorte rétrospective Royaume-Uni Mars-mai 2020	31 cas de MIS-C sont décrits.	- Âge médian = 10,1 ans (intervalle = 8,7-13,9 ans) - 21/31 (68 %) de sexe masculin. - 14 (45 %) étaient noirs, 9 (29 %) asiatiques, 4 (13 %) blancs, 3 (10 %) d'origine mixte, 1 (3 %) d'origine ethnique inconnue. - Cinq (16 %) étaient en surpoids et 7 (23 %) étaient obèses - 14 (45 %) nécessitant une ventilation mécanique, 1 (3 %) nécessitant une oxygénation extracorporelle. - Aucun décès.

		- 20 tests PCR positifs et 28 tests sérologiques positifs.
Felsenstein (2020) (31) Étude de cohorte rétrospective Royaume-Uni Mars-juin 2020	29 cas de MIS-C sont décrits.	- Âge médian = 6 ans (EI = 3,8-9,9 ans) - 20/29 (69 %) de sexe masculin. - 12 (41 %) étaient blancs, 6 (21 %) d'Asie du Sud-Est, 4 (14 %) noirs, 2 (7 %) d'Asie de l'Est, 5 (17 %) d'origine ethnique inconnue. - Aucun décès. - 14 tests sérologiques positifs, 3 tests PCR positifs. - Les cas de MIS-C ont atteint un pic 4 semaines après le pic des cas locaux de COVID-19.
Lee (2020) (32) Étude de cohorte rétrospective États-Unis Mars-juin 2020	28 cas de MIS-C sont décrits.	- Âge médian = 9 ans (échelle = 1 mois - 17 ans) - 16/28 (57 %) de sexe masculin. - 12 (43 %) étaient hispaniques, 10 (36 %) blancs, 5 (18 %) noirs. - 14 (50 %) présentaient des comorbidités; 4 (14 %) étaient obèses, 3 (11 %) étaient asthmatiques et 1 chacun (4 %) était atteint de cardiopathie congénitale, de drépanocytose et de trouble mitochondrial. - 17 (61 %) ont été admis aux soins intensifs, aucun n'a nécessité de ventilation mécanique ou d'oxygénation extracorporelle. - Aucun décès. - 17 tests PCR positifs et 18 tests sérologiques positifs.
Matsubara (2020) (33) Étude de cohorte rétrospective États-Unis Avril-juin 2020	28 cas de MIS-C sont décrits.	- Âge médian = 11,4 ans (EI = 8-13, 7 ans) - 14/28 (50 %) de sexe masculin. - 13 (46 %) étaient noirs, 7 (25 %) blancs, 4 (14 %) hispaniques, 1 (4 %) asiatique, 3 (11 %) d'origine ethnique inconnue. - Huit personnes testées positives pour les anticorps IgG.
Torres (2020) (34) Étude de cohorte rétrospective Chili Mai-juin 2020	27 cas de MIS-C chez des enfants de jusqu'à 14 ans sont décrits.	- Âge médian = 6 ans (intervalle = 0-14 ans) - 14/27 (52 %) de sexe masculin. - 23 (85 %) des parents étaient chiliens, 2 (7 %) vénézuéliens, 1 (4 %) haïtien, 1 (4 %) péruvien. - Quatre (15 %) étaient en surpoids ou obèses, 1 (4 %) était asthmatique, 1 (4 %) était immunodéprimé.

		- 16 (59 %) admis aux soins intensifs, 12 (44 %) nécessitant une ventilation mécanique. - Aucun décès. - 14 tests PCR positifs et 10 tests sérologiques positifs.
Carter (2020) (35) Étude de cohorte prospective Royaume-Uni Avril-mai 2020	25 cas de MIS-C sont décrits.	- Âge médian = 12,5 ans (intervalle = 7,7-14,4 ans) - 15/25 (60 %) de sexe masculin. - 10 (40 %) étaient blancs, 9 (36 %) noirs, 5 (20 %) asiatiques, 1 (4 %) d'une autre origine ethnique. - Cinq (20 %) présentaient des comorbidités, dont 2 (8 %) asthmatiques (1 également autiste et 1 avec de l'eczéma), 1 (4 %) avec une allergie alimentaire, 1 (4 %) porteur du trait de l'hémoglobine C, et 1 (4 %) atteint d'anémie aplastique et immunodéprimé. - 21 (84 %) admis aux soins intensifs, 2 (8 %) nécessitant une ventilation mécanique. - Aucun décès. - 18 tests sérologiques positifs et 1 test PCR positif.
Dionne (2020) (36) Étude de cohorte rétrospective États-Unis Mars-mai 2020	25 cas de MIS-C sont décrits.	- Âge médian = 9,7 ans (EI = 2,7-15,0 ans) - 15/25 (60 %) de sexe masculin. - Quatre (16 %) étaient obèses, 4 (16 %) étaient asthmatiques et 1 chacun (4 %) atteint de drépanocytose, de trouble mitochondrial, de prématurité ou d'insuffisance respiratoire. - 14 (56 %) admis aux soins intensifs, 1 (4 %) nécessitant une ventilation mécanique. - Aucun décès. - 15 tests PCR positifs et 13 tests sérologiques positifs.
Jain (2020) (37) Étude de cohorte rétrospective Inde Mai-juillet 2020	23 cas de MIS-C sont décrits.	- Âge médian = 7,2 ans (intervalle = 0,8-14 ans) - 11/23 (48 %) de sexe masculin. - Neuf (39 %) ont nécessité de la ventilation mécanique. - Un décès (4 %). - Sept tests sérologiques positifs, 9 tests PCR positifs. - Les cas de MIS-C ont atteint un pic 2 à 4 semaines après le pic des cas locaux de COVID-19.

Webb (2020) (38) Étude de cohorte rétrospective Afrique du Sud Juin-juillet 2020	23 cas suspects de MIS-C sont décrits dans une zone où les tests de dépistage pour la COVID-19 sont limités.	- Âge moyen = 6,6 ans (IC à 95 %; 4,8-8,4 ans) - 17/23 (74 %) de sexe masculin. - 18 (78 %) étaient noirs, 5 (22 %) étaient noirs et d'origine sud-africaine. - Deux (9 %) étaient obèses, 4 (17 %) ont été exposés au VIH avant la naissance, mais séronégatifs, 1 (4 %) était asthmatique, 1 (4 %) était atteint de leucémie. - 12 (52 %) admis aux soins intensifs, 6 (26 %) nécessitant une ventilation mécanique. - Aucun décès. - Quatre tests PCR positifs. - En moyenne, les cas de MIS-C sont survenus 24 jours après la forme grave de COVID-19 (IC à 95 %; 9-39 jours).
Toubiana (2020) (39) Cohorte ambidirectionnelle France Avril-mai 2020	21 cas de MIS-C sont décrits.	- 21 cas de MIS-C sont décrits. - Âge médian = 7,9 ans (intervalle = 3,7-16,6 ans) - 24 (57 %) des parents étaient noirs, 12 (29 %) blancs, 4 (10 %) asiatiques, 2 (5 %) du Moyen-Orient. - 24 % des patients avaient un poids dépassant le 75^{e} percentile. - 17 (81 %) admis aux soins intensifs, 11 (53 %) nécessitant une ventilation mécanique. - Aucun décès. - 19 testés positifs pour les anticorps IgG, 34 tests positifs au test PCR.
Grimaud (2020) (40) Étude de cohorte rétrospective France Avril 2020	20 cas de MIS-C admis aux soins intensifs sont décrits.	- Âge médian = 10 ans (intervalle = 2,9-15 ans) - 10/20 (50 %) de sexe masculin. - 20 (100 %) admis aux soins intensifs, 8 (40 %) nécessitant une ventilation mécanique, aucun ne nécessitant l'oxygénation extracorporelle. - Aucun décès. - 15 tests sérologiques positifs, 10 tests PCR positifs.
Dhanalakshmi (2020) (41)	19 cas de MIS-C sont décrits.	- Âge médian = 6 ans (intervalle = 13 mois - 16 ans) - 8/19 (42 %) de sexe masculin. - Un (5 %) a connu des retards de développement.

Étude de cohorte rétrospective Inde Mai-juillet 2020		- 12 (63 %) ont été admis aux soins intensifs, aucun n'a nécessité de ventilation mécanique ni oxygénation extracorporelle. - Aucun décès. - Huit tests sérologiques positifs, 4 tests PCR positifs.
Blumfield & Levin (42) Étude de cohorte rétrospective États-Unis Février-mars 2020	19 cas de MIS-C sont décrits.	- Âge médian = 8 ans (intervalle = 2 mois - 18 ans) - 10/19 (53 %) de sexe masculin. - Trois (16 %) étaient obèses, 5 (26 %) présentaient des troubles neurologiques et 1 chacun (5 %) était atteint de cardiopathie congénitale, de cardiomyopathie, de cancer, d'asthme, d'hypertension, de drépanocytose, du syndrome de l'X fragile et un a connu des événements thromboemboliques antérieurs. - 14 (74 %) admis aux soins intensifs, 8 (42 %) nécessitant une ventilation mécanique. - Deux décès (11 %) - les deux avaient des comorbidités. - 18 tests PCR positifs.
Yonker (2020) (8) Étude de cohorte rétrospective États-Unis Août 2020*	18 cas de MIS-C sont décrits sur un total de 192 cas pédiatriques de COVID-19 hospitalisés.	- 18/192 (9 %) enfants se présentant à l'urgence ou hospitalisés en lien avec la COVID-19 étaient atteints du MIS-C. - Âge moyen = 7,7 ans (ET = 7 ans) - 14/18 (78 %) de sexe masculin. - Neuf (50 %) étaient blancs, 6 (33 %) hispaniques, 2 (11 %) blancs et 1 (6 %) asiatique. - Deux (11 %) étaient obèses, 1 chacun (6 %) était atteint d'une maladie inflammatoire chronique de l'intestin, de TDAH et d'autisme.
Cheung (2020) (43) Étude de cohorte rétrospective États-Unis Avril-mai 2020	17 cas de MIS-C sont décrits.	- Âge médian = 8 ans (intervalle = 1,8-16 ans) - 8/17 (47 %) de sexe masculin. - Trois (18 %) étaient asthmatiques. - Un (6 %) ont été admis aux soins intensifs, aucun n'a nécessité de ventilation mécanique ni oxygénation extracorporelle. - Aucun décès.

		- Neuf ont été testés positifs avec un test sérologique et 44 avec un test PCR.
Pouletty (2020) (44) Étude de cohorte rétrospective France Avril 2020	16 cas de MIS-C sont décrits.	- Âge médian = 12 ans (intervalle = 4,7-12,5 ans) - 8/16 (50 %) de sexe masculin. - Quatre (25 %) étaient en surpoids, 2 (13 %) étaient asthmatiques. - Sept (44 %) admis aux soins intensifs, 2 (13 %) nécessitant une ventilation mécanique, aucun ne nécessitant l'oxygénation extracorporelle. - Aucun décès. - 7/8 testés positifs pour les anticorps IgG, 11/16 testés positifs au test PCR.
Ramcharan (2020) (45) Étude de cohorte rétrospective Royaume-Uni Avril-mai 2020	15 cas de MIS-C sont décrits.	- Âge médian = 8,8 ans (EI = 6,4-11,2 ans) - 11/15 (73 %) de sexe masculin. - Six (40 %) étaient noirs, 6 (40 %) sud-asiatiques, 3 (20 %) d'autres origines ethniques. - Quatre (27 %) ont nécessité une ventilation mécanique, aucun n'a nécessité l'oxygénation extracorporelle. - Aucun décès. - 12 tests sérologiques positifs, 2 tests PCR positifs.
Riollano-Cruz (2020) (46) Étude de cohorte rétrospective États-Unis Avril-juin 2020	15 cas de MIS-C sont décrits.	- Âge médian = 12 ans (intervalle = 3-20 ans) - 11/15 (73 %) de sexe masculin. - 10 (67 %) étaient hispaniques, 2 (13 %) noirs, 2 (13 %) blancs et 1 (7 %) d'origine ethnique inconnue. - Deux (13 %) étaient obèses, 2 (13 %) étaient en surpoids, 4 (27 %) étaient asthmatiques et 1 (7 %) était atteint d'hypothyroïdie. - 15 (100 %) admis aux soins intensifs, 3 (20 %) nécessitant une ventilation mécanique, 1 (7 %) nécessitant une oxygénation extracorporelle. - Un (7 %) décès. - 15 ont été testés positifs avec un test sérologique et 9 avec un test PCR. - L'apparition du MIS-C a commencé 21 jours après la forme grave de COVID-19 (EI = 21-24 jours).

Rosat Consiglio (2020) (47) Étude de cohorte rétrospective Italie, Suède Mars-mai 2020	13 cas de MIS-C sont décrits.	- Âge médian = 106 mois (EI = 71-165 mois). - 8/11 (73 %) de sexe masculin (2 manquants). - 3/4 (75 %) ont été testés positifs pour les anticorps IgG.
Gaitonde (2020) (48) Étude cas/témoins États-Unis Mars-juin 2020	12 cas de MIS-C sont décrits.	- Âge médian = 8 ans (EI = 5,5-11,5 ans). - 9/12 (75 %) de sexe masculin. - Huit (80 %) étaient noirs, 3 (30 %) blancs, 1 (10 %) d'une autre origine ethnique. - Aucun décès.
de Farias (2020) (49) Étude de cohorte prospective Brésil Avril-juin 2020	11 cas de MIS-C sont décrits.	- Âge médian = 4 ans (intervalle = 7 mois - 11 ans) - 9/11 (82 %) de sexe masculin. - Deux (18 %) souffraient de malnutrition, 3 (27 %) étaient obèses, 3 (27 %) étaient en surpoids. - 11 admis aux soins intensifs - requis pour l'inclusion (100 %), 3 (27 %) ont nécessité une ventilation mécanique. - Deux (18 %) décès - tous deux souffraient de malnutrition. - Neuf tests sérologiques positifs, 2 tests PCR positifs. - L'apparition du MIS-C a commencé 15 jours après la forme grave de COVID-19 (intervalle = 21-60 jours).
Ouldali (2020) (50) Essai accidentel France Décembre 2005-mai 2021	10 cas de MIS-C sont décrits après le début de la pandémie de COVID-19, et comparés aux cas de Kawasaki avant avril 2020.	- Avant avril 2020, le taux d'hospitalisation pour la maladie de Kawasaki était de 1,2 cas par mois. En avril 2020, ce chiffre est passé à 6 cas par mois (soit une augmentation de 497 %). Un autre pic en décembre 2009 a atteint 6 cas par mois (soit une augmentation de 365 %) au moment de la pandémie de grippe A H1N1. - Âge médian = 11,5 ans (intervalle = 1-15 ans) - 4/10 (40 %) de sexe masculin. - Six (60 %) ont été admis aux soins intensifs, aucun n'a nécessité de ventilation mécanique ni oxygénation extracorporelle. - Aucun décès.

		- 5/10 testés positifs pour les anticorps IgG, 5/9 testés positifs au test PCR. - Les cas de MIS-C ont atteint un pic 2 semaines après le pic des cas locaux de COVID-19.
Verdoni (2020) (51) Essai accidentel Italie Février-avril 2020	10 cas de MIS-C sont décrits après le début de la pandémie de COVID-19, et comparés aux cas de Kawasaki avant février 2020.	- Il s'agit d'une étude précoce qui a permis de comparer les taux de la maladie de Kawasaki entre le 1er janvier 2015 et le 17 février 2020 (19 patients) avec ceux entre le 18 février 2020 et le 20 avril 2020 (10 patients). L'étude a révélé une multiplication par 30 de la maladie de Kawasaki au début de 2020 en Italie. - Âge médian = 7,5 ans (ET = 3,5 ans). - 7/10 (70 %) de sexe masculin. - Huit testés positifs pour les anticorps IgG, 2 testés positifs pour les anticorps IgM, 2 positifs au test PCR.
Rostad (2020) (52) Cohorte ambidirectionnelle États-Unis Mars-mai 2020	10 cas de MIS-C sont décrits.	- Âge médian = 106 mois (intervalle = 71-165 mois). - 6/10 (60 %) de sexe masculin. - 6 (60 %) étaient noirs, 3 (30 %) blancs, 1 (10 %) d'une autre origine ethnique. - 3 (30 %) étaient atteints de maladies respiratoires sous-jacentes. - 10 (100 %) ont été admis aux soins intensifs. - Tous testés positifs pour les anticorps IgG et IgM, 2 tests PCR positifs.
Gruber (2020) (53) Étude de cohorte rétrospective États-Unis Avril-juin 2020	9 cas de MIS-C sont décrits.	- Âge médian = 11,5 ans. - 4/9 (44 %) de sexe masculin. - Six (67 %) étaient hispaniques, 2 (22 %) noirs, 1 (11 %) d'origine ethnique inconnue. - Deux (22 %) étaient asthmatiques, 1 (11 %) atteint de TSPT. - Aucun décès. - Neuf tests sérologiques positifs, 3 tests PCR positifs.
Kim (2020) (9) Étude de cohorte rétrospective États-Unis	9 cas de MIS-C sont décrits sur un total de 83 cas pédiatriques de	- Sur 83 enfants hospitalisés pour la COVID-19, 9 ont eu un diagnostic de MIS-C (11 % des enfants hospitalisés avec la COVID-19). - Âge : 0-2 ans (1), 2-4 ans (5), 5-17 ans (3).

Mars-juillet 2020	COVID-19 hospitalisés.	
Khan & Ullah (2020) (54) Étude de série de cas Pakistan Août 2020*	8 cas de MIS-C sont décrits avec des données issues de rapports.	- Intervalle d'âges = 5-15 ans. - Tous les tests sérologiques étaient positifs.
Riphagen (2020) (55) Étude de cohorte rétrospective Royaume-Uni Avril 2020	8 cas de MIS-C sont décrits.	- Âge médian = 8 ans (intervalle = 4-14 ans) - 5/8 (63 %) de sexe masculin. - Six (75 %) étaient noirs, 1 (13 %) asiatique, 1 (13 %) du Moyen-Orient. - Deux (25 %) étaient obèses, 1 (13 %) en surpoids, 1 (13 %) autiste, 1 (13 %) avait le rhume des foins. - 8 (100 %) admis aux soins intensifs, 5 (63 %) nécessitant une ventilation mécanique, 1 (13 %) nécessitant une oxygénation extracorporelle. - Un décès (13 %).
Perez-Toledo (2020) (56) *(préimpression)* Étude de cohorte rétrospective Royaume-Uni Avril-mai 2020	8 cas de MIS-C sont décrits, où les patients ont eu un résultat négatif au test PCR, mais un test sérologique positif.	- Âge médian = 9 ans (intervalle 7-14 ans). - 5/8 (63 %) de sexe masculin. - Six (75 %) ont été admis aux soins intensifs. - Aucun décès.
Syrimi (2020) (57) *(préimpression)* Étude de cohorte rétrospective Royaume-Uni Avril-mai 2020	7 cas de MIS-C sont décrits.	- Âges : <5 ans (1), 5-10 ans (3), 10-15 ans (3). - 4/7 (57 %) de sexe masculin. - Quatre (57 %) étaient noirs, 2 (29 %) asiatiques, 1 (14 %) blanc. - Six (86 %) ont été admis aux soins intensifs.
Pereira (2020) (58) Étude de cohorte rétrospective Brésil	6 cas de MIS-C sont décrits à partir d'un groupe de 66 cas pédiatriques de	- Sur 66 enfants hospitalisés pour la COVID-19, 6 ont eu un diagnostic de MIS-C (9 % des enfants hospitalisés avec la COVID-19). - Âge médian = 7,8 ans (intervalle = 0,01-17,6 ans)

Avril-juin 2020	COVID-19 hospitalisés.	- 5/6 (83 %) de sexe masculin. - Cinq (83 %) avaient une maladie sous-jacente, 4 étaient immunodéprimés, 3 étaient atteints d'un cancer, 1 était atteint d'une néphropathie chronique. - Six (100 %) admis aux soins intensifs, 5 (83 %) nécessitant une ventilation mécanique. - Quatre (67 %) décès.
Chiara-Chilet (2020) (7) *(préimpression)* Étude de cohorte rétrospective Pérou Mars-juillet 2020	6 cas de MIS-C sont décrits sur un total de 91 cas pédiatriques de COVID-19 hospitalisés.	- Sur 91 enfants hospitalisés pour la COVID-19, 6 ont eu un diagnostic de MIS-C (7 % des enfants hospitalisés avec la COVID-19). - Deux (33 %) ont été admis aux soins intensifs.
Chiotos (2020) (59) Étude de série de cas États-Unis Mai 2020*	6 cas de MIS-C qui ont été admis aux soins intensifs sont décrits.	- Âge médian = 7,5 ans (intervalle = 5-14 ans) - 1/6 (17 %) de sexe masculin. - Deux (33 %) étaient noirs, 2 (33 %) blancs, 2 (33 %) d'origine ethnique inconnue. - Six (100 %) admis aux soins intensifs, 3 (50 %) nécessitant une ventilation mécanique, et aucun ne nécessitant l'oxygénation extracorporelle. - Aucun décès. - Cinq testés positifs pour les anticorps IgG, 2 testés positifs au test PCR.
Diorio (2020) (60) Étude de cohorte prospective États-Unis Avril-mai 2020	6 cas de MIS-C sont décrits.	- Âge médian = 6 ans (EI = 5-7 ans). - 2/6 (33 %) de sexe masculin. - Quatre (66 %) étaient blancs, 1 (17 %) noir, 1 (17 %) d'une autre origine ethnique. - Cinq (83 %) admis aux soins intensifs, 2 (33 %) nécessitant une ventilation mécanique, et aucun ne nécessitant l'oxygénation extracorporelle. - Aucun décès.

* Date de publication de l'article parce que les dates des cas ne sont pas disponibles.

PETITS ARTICLES

Tableau 3 : Articles décrivant de un à cinq cas de MIS-C, par pays et par taille d'étude

ÉTUDE	MÉTHODE	PRINCIPAUX RÉSULTATS
ÉTUDE DE SÉRIE DE CAS		
Blondiaux (2020) (61) Étude de série de cas France Avril 2020	Étude de série de cas descriptive de quatre patients atteints du MIS-C.	- Trois filles de 6, 8 et 11 ans; un garçon de 12 ans. - Les quatre ont été admis aux soins intensifs, un a été intubé, aucun n'a été placé sous oxygénation extracorporelle. - Aucun décès. - Tous les tests PCR étaient négatifs et positifs pour les anticorps IgG, 1 test positif pour les anticorps IgM.
Labé (2020) (62) Étude de série de cas France Mai 2020*	Étude de série de cas descriptive de deux patients atteints du MIS-C.	- Deux garçons de 3 et 6 ans. - Aucune admission aux soins intensifs, aucune intubation ni oxygénation extracorporelle. - Aucun décès. - Un test PCR positif, aucun résultat de test sérologique.
Licciardi (2020) (63) Étude de série de cas Italie Avril 2020	Étude de série de cas descriptive de deux patients atteints du MIS-C.	- Deux garçons, âgés de 7 et 12 ans, aucun n'ayant de comorbidités. - Les deux ont été admis aux soins intensifs; aucune intubation, aucune oxygénation extracorporelle. - Aucun décès. - Les deux ont eu un résultat négatif au test PCR, mais les tests étaient positifs pour les anticorps IgG et IgM.
Pang (2020) (64) Étude de série de cas Royaume-Uni Mars-mai 2020	Étude de série de cas descriptive de cinq patients atteints du MIS-C.	- Trois garçons de 8, 12 et 14 ans; deux filles de 5 et 15 ans. - Deux étaient asiatiques, un noir, un blanc et un métis. - Deux étaient atteints d'épilepsie. - Quatre ont été admis en soins intensifs et intubés. - Aucun décès. - Tous ont eu un résultat positif au test PCR, aucun résultat de test sérologique.
Ng (2020) (65) Étude de série de cas Royaume-Uni Avril-mai 2020	Étude de série de cas descriptive de trois patients atteints du MIS-C.	- Deux garçons de 13 et 17 ans; une fille de 16 ans. - Deux étaient noirs, un était asiatique. - Un était obèse. - Tous les trois ont été admis aux soins intensifs; un a été intubé; aucune oxygénation extracorporelle. - Aucun décès.

		- Les trois ont eu un résultat positif pour les anticorps IgG, un a eu un résultat positif au test PCR.
Del Greco (2020) (66) Étude de série de cas États-Unis Octobre 2020*	Étude de série de cas descriptive de quatre patients atteints du MIS-C.	- Trois filles de 4, 10 et 16 ans; un garçon de 13 ans. - Un était asthmatique, les autres n'avaient pas de comorbidité. - Deux ont été admis aux soins intensifs; aucune intubation, aucune oxygénation extracorporelle. - Aucun décès. - Les quatre tests sérologiques étaient positifs, un résultat positif au test PCR.
Rogo (2020) (67) Étude de série de cas États-Unis Avril-mai 2020	Étude de série de cas descriptive de quatre patients atteints du MIS-C.	- Trois garçons de 5, 17 et 20 ans; une fille de 3 ans. - Quatre admis aux soins intensifs, deux ont été intubés, un a nécessité de l'oxygénation extracorporelle. - Un décès. - Quatre résultats négatifs au test PCR et les résultats pour les anticorps IgG étaient positifs.
Waltuch (2020) (68) Étude de série de cas États-Unis Mai 2020	Étude de série de cas descriptive de quatre patients atteints du MIS-C.	- Trois garçons de 5, 10 et 13 ans; une fille de 12 ans. - Un était atteint d'hypothyroïdie, un autre était asthmatique. - Quatre ont été admis aux soins intensifs; aucune intubation, aucune oxygénation extracorporelle. - Aucun décès. - Les quatre tests sérologiques étaient positifs, un résultat positif au test PCR.
Heidemann (2020) (69) Étude de série de cas États-Unis Août 2020*	Étude de série de cas descriptive de trois patients atteints du MIS-C.	- Deux garçons de 5 et 7 ans; une fille de 6 ans, sans comorbidité. - Deux admis aux soins intensifs et intubés, un a nécessité de l'oxygénation extracorporelle. - Un décès. - Un test PCR positif et trois tests sérologiques positifs.
Schupper (2020) (70) Étude de série de cas États-Unis Juin 2020*	Étude de série de cas descriptive de deux patients atteints du MIS-C.	- Deux garçons âgés de 2 mois, 5 ans - Un atteint de trachéomalacie. - Les deux ont été admis aux soins intensifs, intubés et ont nécessité de l'oxygénation extracorporelle. - Un décès. - Un test sérologique positif, aucun résultat de test PCR.
Spencer (2020) (71) Étude de série de cas États-Unis	Étude de série de cas descriptive de	- Une fille de 7 ans; un garçon de 11 ans. - Un patient a eu une crise d'épilepsie.

Septembre 2020*	deux patients atteints du MIS-C.	- Un a été admis aux soins intensifs; aucune intubation, aucune oxygénation extracorporelle. - Aucun décès. - Les deux ont eu un résultat positif au test PCR, aucun résultat sérologique.
ÉTUDE DE CAS		
Khesrani (2020) (72) Étude de cas Algérie Août 2020*	Étude de cas descriptive d'un patient atteint du MIS-C.	- Fille de 9 ans atteinte d'aphasie médullaire idiopathique. - A été admise aux soins intensifs; aucune intubation, aucune oxygénation extracorporelle. - La patiente est décédée. - La patiente a eu un résultat positif au test PCR, aucun résultat de test sérologique.
De Paulis (2020) (73) Étude de cas Brésil Mai 2020	Étude de cas descriptive d'un patient atteint du MIS-C.	- Fille de 4 ans sans comorbidité. - A été admise aux soins intensifs; aucune intubation, aucune oxygénation extracorporelle. - La patiente a survécu. - La patiente a eu un résultat négatif au PCR, un résultat négatif pour les anticorps IgM, mais un résultat positif pour les anticorps IgG.
Tam (2020) (74) Étude de cas Canada Septembre 2020*	Étude de cas descriptive d'un patient atteint du MIS-C.	- Garçon de 10 ans sans comorbidité. - A été admis aux soins intensifs; aucune intubation, aucune oxygénation extracorporelle. - Le patient a survécu. - Le patient a eu un résultat négatif au test PCR, mais un test sérologique positif.
Klocperk (2020) (75) Étude de cas Tchéquie Juillet 2020*	Étude de cas descriptive d'un patient atteint du MIS-C.	- Fille de 8 ans sans comorbidité. - Aucune admission aux soins intensifs, aucune intubation ni oxygénation extracorporelle. - La patiente a survécu. - La patiente a eu un résultat positif au PCR et un résultat positif pour les anticorps IgG.
Acharyya (2020) (76) *(préimpression)* Étude de cas Inde Mai 2020*	Étude de cas descriptive d'un patient atteint du MIS-C.	- Garçon de 4 mois sans comorbidité. - Aucune admission aux soins intensifs, aucune intubation ni oxygénation extracorporelle. - Le patient a survécu. - Le patient a eu un résultat positif au test PCR, aucun résultat de test sérologique.

Balasubramanian (2020) (77) Étude de cas Inde Juillet 2020*	Étude de cas descriptive d'un patient atteint du MIS-C.	- Garçon de 8 ans sans comorbidité. - A été admis aux soins intensifs; aucune intubation; aucune oxygénation extracorporelle. - Le patient a survécu. - Le patient a eu un résultat positif au test PCR, aucun résultat de test sérologique.
Gupta (2020) (78) *(préimpression)* Étude de cas Inde Septembre 2020*	Étude de cas descriptive d'un patient atteint du MIS-C.	- Garçon de 2 ans. - Aucune admission aux soins intensifs, aucune intubation ni oxygénation extracorporelle. - Le patient a survécu. - Le patient a eu un résultat négatif au PCR, mais ses parents ont eu un résultat positif pour les anticorps parents IgG.
Rauf (2020) (79) Étude de cas Inde Avril 2020	Étude de cas descriptive d'un patient atteint du MIS-C.	- Garçon de 5 ans sans comorbidité. - A été admis aux soins intensifs; aucune intubation; aucune oxygénation extracorporelle. - Le patient a survécu. - Le patient a eu un résultat négatif au test PCR et pour les tests sérologiques.
Singhi (2020) (80) Étude de cas Inde Octobre 2020*	Étude de cas descriptive d'un patient atteint du MIS-C.	- Fille de 8 ans. - Aucune admission aux soins intensifs, aucune intubation ni oxygénation extracorporelle. - La patiente a survécu. - La patiente a eu un résultat négatif au test PCR, mais un test sérologique positif.
Tiwari (2020) (81) Étude de cas Inde Octobre 2020*	Étude de cas descriptive d'un patient atteint du MIS-C.	- Fille de 9 ans. - A été admise aux soins intensifs; aucune intubation, aucune oxygénation extracorporelle. - La patiente a survécu. - La patiente a eu un résultat négatif au test PCR, mais un test sérologique positif.
Bahrami (2020) (82) Étude de cas Iran Juillet 2020*	Étude de cas descriptive d'un patient atteint du MIS-C.	- Fille de 5 ans sans comorbidité. - Aucune admission aux soins intensifs, aucune intubation ni oxygénation extracorporelle. - La patiente a survécu. - La patiente a eu un résultat négatif au test PCR, mais un test sérologique positif.
Parvaneh & Rahmani (2020) (83)	Étude de cas descriptive d'un	- Garçon de 7 ans. - Le patient a survécu.

(préimpression) Étude de cas Iran Mai 2020	patient atteint du MIS-C.	- Le patient a eu un résultat positif au test PCR, aucun résultat de test sérologique.
Regev (2020) (84) Étude de cas Israël Août 2020*	Étude de cas descriptive d'un patient atteint du MIS-C.	- Garçon de 16 ans sans comorbidité. - A été admis aux soins intensifs; aucune intubation, aucune oxygénation extracorporelle. - Le patient a survécu. - Le patient a eu un résultat positif au test PCR et un résultat positif pour les anticorps IgG.
Schnapp (2020) (85) Étude de cas Israël Juin 2020*	Étude de cas descriptive d'un patient atteint du MIS-C.	- Garçon de 16 ans sans comorbidité. - A été admis aux soins intensifs; aucune intubation, aucune oxygénation extracorporelle. - Le patient a survécu. - Le patient a eu un résultat négatif au test PCR, mais un résultat positif pour les anticorps IgG.
Buonsenso (2020) (86) Étude de cas Italie Avril 2020	Étude de cas descriptive d'un patient atteint du MIS-C.	- Fille de 11 ans. - La patiente a eu un résultat positif au test PCR, aucun résultat de test sérologique.
Giannattasio (2020) (87) Étude de cas Italie Juin 2020*	Étude de cas descriptive d'un patient atteint du MIS-C.	- Garçon de 9 ans. - Aucune admission aux soins intensifs, aucune intubation ni oxygénation extracorporelle. - Le patient a survécu. - Le patient a eu un résultat négatif au test PCR, mais un résultat positif pour les anticorps IgG et IgM.
Yáñez (2020) (88) Étude de cas Pérou Juin 2020	Étude de cas descriptive d'un patient atteint du MIS-C.	- Fille de 3 ans. - Aucune autre information fournie.
Tracewski (2020) (89) Étude de cas Pologne Mai 2020	Étude de cas descriptive d'un patient atteint du MIS-C.	- Garçon de 2 ans. - Aucune admission aux soins intensifs, aucune intubation ni oxygénation extracorporelle. - Le patient a survécu. - Le patient a eu un résultat négatif au test PCR, un résultat négatif pour les anticorps IgM, mais un résultat positif pour les anticorps IgG.
Rodriguez-Gonzalez (2020) (90)	Étude de cas descriptive d'un	- Garçon de 6 mois atteint du syndrome de l'intestin court.

Étude de cas Espagne Juin 2020*	patient atteint du MIS-C.	- A été admis aux soins intensifs; aucune intubation, aucune oxygénation extracorporelle. - Le patient a survécu. - Le patient a eu un résultat négatif au test PCR, mais un résultat positif pour les anticorps IgG.
Bapst (2020) (91) Étude de cas Suisse Avril 2020	Étude de cas descriptive d'un patient atteint du MIS-C.	- Garçon de 13 ans sans comorbidité. - Aucune admission aux soins intensifs, aucune intubation ni oxygénation extracorporelle. - Le patient a survécu. - Le patient a eu un résultat négatif au test PCR, mais un test sérologique positif.
Yozgat (2020) (92) *(préimpression)* Étude de cas Turquie Juillet 2020*	Étude de cas descriptive d'un patient atteint du MIS-C.	- Fille de 3 ans. - La patiente a survécu. - La patiente a eu un résultat négatif au test PCR, aucun résultat de test sérologique.
Domico (2020) (93) Étude de cas Royaume-Uni Avril 2020	Étude de cas descriptive d'un patient atteint du MIS-C.	- Garçon de 11 ans sans comorbidité. - A été admis aux soins intensifs; aucune intubation, aucune oxygénation extracorporelle. - Le patient a survécu. - Le patient a eu un résultat négatif au test PCR, un résultat négatif pour les anticorps IgM, mais un résultat positif pour les anticorps IgG.
Chiu (2020) (94) Étude de cas États-Unis Juin 2020*	Étude de cas descriptive d'un patient atteint du MIS-C.	- Garçon de 10 ans sans comorbidité. - A été admis aux soins intensifs. - Le patient a eu un résultat positif au test PCR, aucun résultat de test sérologique.
Choi (2020) (95) Étude de cas États-Unis Août 2020*	Étude de cas descriptive d'un patient atteint du MIS-C.	- Homme hispanique de 19 ans obèse et atteint d'apnée du sommeil. - A été admis aux soins intensifs; aucune intubation, aucune oxygénation extracorporelle. - Le patient a survécu. - Le patient a eu un résultat positif au test PCR, aucun résultat de test sérologique.
Clouser (2020) (96) Étude de cas États-Unis Mai 2020	Étude de cas descriptive d'un patient atteint du MIS-C.	- Fille noire de 11 ans obèse. - A été admise aux soins intensifs; aucune intubation, aucune oxygénation extracorporelle. - La patiente a survécu.

		- La patiente a eu un résultat positif au test PCR, aucun résultat de test sérologique.
Dasgupta (2020) (97) Étude de cas États-Unis Juin 2020*	Étude de cas descriptive d'un patient atteint du MIS-C.	- Fille métisse de 8 ans sans comorbidité. - A été admise aux soins intensifs. - La patiente a survécu. - La patiente a eu un résultat négatif au test PCR et pour les anticorps IgG.
Deza Leon (2020) (98) Étude de cas États-Unis Mai 2020*	Étude de cas descriptive d'un patient atteint du MIS-C.	- Fille de 6 ans sans comorbidité. - A été admise aux soins intensifs, intubée et a nécessité de l'oxygénation extracorporelle. - La patiente a survécu. - La patiente a eu un résultat positif au test PCR, aucun résultat de test sérologique.
Dolhnikoff (2020) (99) Étude de cas États-Unis Août 2020*	Étude de cas descriptive d'un patient atteint du MIS-C.	- Fille noire de 11 ans sans comorbidité - A été admise aux soins intensifs; aucune intubation, aucune oxygénation extracorporelle. - La patiente est décédée. - La patiente a eu un résultat positif au test PCR, aucun résultat de test sérologique.
Dolinger (2020) (100) Étude de cas États-Unis Mai 2020*	Étude de cas descriptive d'un patient atteint du MIS-C.	- Un garçon de 14 ans atteint de la maladie de Crohn. - Le patient a survécu. - Le patient a eu un résultat positif au test PCR, aucun résultat de test sérologique.
Greene (2020) (101) Étude de cas États-Unis Juin 2020*	Étude de cas descriptive d'un patient atteint du MIS-C.	- Fille de 11 ans sans comorbidité. - A été admise aux soins intensifs; aucune intubation; aucune oxygénation extracorporelle. - La patiente a survécu. - La patiente a eu un résultat positif au test PCR, aucun résultat de test sérologique.
Jones (2020) (102) Étude de cas États-Unis Juin 2020*	Étude de cas descriptive d'un patient atteint du MIS-C.	- Fille de 6 mois sans comorbidité. - Aucune admission aux soins intensifs, aucune intubation ni oxygénation extracorporelle. - La patiente a survécu. - La patiente a eu un résultat positif au test PCR, aucun résultat de test sérologique.
Kaushik, Ahluwalia, (2020) (103) Étude de cas États-Unis	Étude de cas descriptive d'un patient atteint du MIS-C.	- Garçon de 5 ans sans comorbidité. - A été admis aux soins intensifs, intubé et a nécessité de l'oxygénation extracorporelle. - Le patient est décédé.

Septembre 2020*		- Le patient a eu un résultat négatif au test PCR, mais un test sérologique positif.
Nelson (2020) (104) Étude de cas États-Unis Octobre 2020*	Étude de cas descriptive d'un patient atteint du MIS-C.	- Fille de 15 ans sans comorbidité. - Aucune admission aux soins intensifs, aucune intubation ni oxygénation extracorporelle. - La patiente a survécu. - La patiente a eu un résultat négatif au test PCR, aucun résultat de test sérologique.
Rivera-Figueroa (2020) (105) Étude de cas États-Unis Juillet 2020*	Étude de cas descriptive d'un patient atteint du MIS-C.	- Garçon noir de 5 ans sans comorbidité. - A été admis aux soins intensifs; aucune intubation; aucune oxygénation extracorporelle. - Le patient a survécu. - Le patient a eu un résultat positif au test PCR, aucun résultat de test sérologique.
Stevens (2020) (106) Étude de cas États-Unis Avril 2020	Étude de cas descriptive d'un patient atteint du MIS-C.	- Fille noire de 10 ans asthmatique. - A été admise aux soins intensifs; aucune intubation; aucune oxygénation extracorporelle. - La patiente a survécu. - La patiente a eu un résultat négatif au PCR, mais un résultat positif pour les anticorps IgG.
Vari (2020) (107) Étude de cas États-Unis Avril 2020	Étude de cas descriptive d'un patient atteint du MIS-C.	- Garçon de 14 ans. - A été admis aux soins intensifs; aucune intubation, aucune oxygénation extracorporelle. - Le patient a survécu. - Le patient a eu un résultat négatif au test PCR, mais un résultat positif pour les anticorps IgG.
Verkuil (2020) (108) Étude de cas États-Unis Août 2020*	Étude de cas descriptive d'un patient atteint du MIS-C.	- Fille de 14 ans sans comorbidité. - A été admise aux soins intensifs; aucune intubation, aucune oxygénation extracorporelle. - La patiente a survécu. - La patiente a eu un résultat négatif au test PCR, mais un résultat positif pour les anticorps IgG.

* Date de publication de l'article parce que les dates des cas ne sont pas disponibles.

Méthodes

Une analyse documentaire quotidienne (ouvrages publiés et en prépublication) est effectuée par le Groupe des sciences émergentes de l'ASPC. L'analyse a compilé les ouvrages sur la COVID-19 depuis le début de l'éclosion et est mise à jour quotidiennement. Les recherches visant à extraire les ouvrages pertinents sur la COVID-19 sont menées dans Pubmed, Scopus, BioRxiv, MedRxiv, ArXiv, SSRN et Research Square, et les résultats sont recoupés avec les ouvrages figurant sur la liste de la documentation sur la COVID de l'Organisation mondiale de la Santé et des centres d'information sur la COVID-19 gérés par Lancet, BMJ, Elsevier et Wiley. Le résumé quotidien et les résultats complets de l'analyse sont conservés dans une base de données RefWorks et dans une liste Excel consultable.

Une recherche ciblée par mot-clé est effectuée dans ces bases de données pour trouver les citations pertinentes sur la COVID-19 et le SRAS-CoV-2. Les termes de recherche utilisés comprennent : MIS-C, PIMS, Kawasaki, inflammation multisystémique, syndrome inflammatoire multisystémique, inflammation multi-système.

382 articles ont été recensés sur le thème du MIS-C, après élimination des doublons. Chaque référence potentiellement pertinente a été examinée pour confirmer qu'elle comportait des données pertinentes et les données pertinentes sont extraites de l'examen. 102 études recensées comme pertinentes pour le sujet de l'étude. Cet examen contient les recherches publiées jusqu'au 10 novembre 2020.

Préparé par Megan Striha. Déclaration des incidents en laboratoire du Canada, ASPC. phac.evidence-donnees.probantes.aspc@canada.ca

ANNEXE

Définition de cas de MIS-C publiée par les Centres de contrôle et de prévention des maladies des États-Unis (CDC) (3) :

- Un individu âgé de <21 ans présentant de la fièvre (>38 °C pendant ≥24 heures, ou un rapport de fièvre subjective durant ≥24 heures), des preuves en laboratoire d'une inflammation et des preuves d'une maladie cliniquement grave nécessitant une hospitalisation, avec une atteinte de plusieurs (>2) organes (cardiaque, rénal, respiratoire, hématologique, gastro-intestinal, dermatologique ou neurologique);

ET

- Pas d'autres diagnostics plausibles;

ET

- Résultat positif pour une infection actuelle ou récente par le SRAS-CoV-2 à un test RT-PCR, sérologique ou test antigénique; ou exposition à un cas suspecté ou confirmé de COVID-19 dans les quatre semaines précédant l'apparition des symptômes.

Définition du MIS-C publiée par l'Organisation mondiale de la santé (OMS) (2) :

- Enfants et adolescents de 0 à 19 ans ayant de la fièvre > 3 jours;

ET

- deux des éléments suivants :
    - Éruption cutanée ou conjonctivite bilatérale non purulente ou signes d'inflammation cutanéo-muqueux (buccale, mains ou pieds).
    - Hypotension ou choc.
    - Caractéristiques du dysfonctionnement myocardique, de la péricardite, de la valvulite ou des anomalies coronariennes (y compris les anomalies lors d'une échographie ou les taux élevés de troponine/NT-proBNP);
    - Preuve de coagulopathie (par PT, PTT, taux élevés de d-Dimères).
    - Problèmes gastro-intestinaux aigus (diarrhées, vomissements ou douleurs abdominales).

ET

- Des marqueurs d'inflammation élevés comme l'ESR, la protéine C-réactive ou la procalcitonine.

ET

- Aucune autre cause microbienne évidente d'inflammation, y compris la septicémie bactérienne, les syndromes de choc staphylococcique ou streptococcique.

ET

- Preuve de COVID-19 (RT-PCR, résultat positif à un test antigénique ou sérologique), ou contact probable avec des patients atteints de la COVID-19.

Définition du PIMS publiée par le Royal College of Paediatrics and Child Health (RCPCH) du Royaume-Uni (4) :

- Enfant présentant une fièvre persistante, une inflammation (neutrophilie, CRP élevée et lymphopénie) et des signes de dysfonctionnement d'un seul ou de plusieurs organes (choc, trouble cardiaque, respiratoire, rénal, gastro-intestinal ou neurologique) avec des caractéristiques supplémentaires. Il peut s'agir d'enfants qui répondent à tous les critères de la maladie de Kawasaki ou à une partie de ceux-ci.

ET

- Exclusion de toute autre cause microbienne, y compris la septicémie bactérienne, le syndrome de choc toxique staphylococcique ou le syndrome de choc toxique streptococcique, les infections associées à la myocardite comme l'entérovirus (l'attente des résultats de ces investigations ne devrait pas retarder la recherche d'un avis d'expert).

ET

- Le test PCR du SRAS-CoV-2 peut être positif ou négatif.

Emerging Evidence on COVID-19

Evidence Brief of COVID-19 quarantine length reduction strategies and effectiveness, Update 1

Introduction

What is the effectiveness of shortened quarantine with and without testing for SARS-CoV-2?

This evidence brief identifies and summarizes published and pre-published data on alternative quarantine strategies (e.g. combinations of RT-PCR testing and quarantine) to explore the potential trade offs compared to the 14-day quarantine currently used. Studies up to December 3, 2020 are included.

Quarantine was one of several public health interventions adopted early in the COVID-19 pandemic by many jurisdictions. Quarantine period in this brief refers to the length of time that must elapse before a person potentially exposed to SARS-CoV-2 can be considered incapable of developing or transmitting COVID-19. The practice may be applied for incoming travellers to a region, suspected cases and/or known contacts of an index case. While many studies have explored the effectiveness of quarantine in reducing COVID-19 transmission, here we focus on the effectiveness of reduced quarantine length with and without testing. Countries have been managing the COVID-19 pandemic for roughly 10 months, and are now looking for effective interventions to reduce transmission while also limiting the negative impact of quarantine on the individual, society and the economy.

It is estimated that the current incubation period for SARS-CoV-2, the time from exposure to symptom onset averages five days (with a range of 1-14 days). It is also estimated that the infectious period may start 1-2 days before symptom onset and continue in mild cases for approximately 8-10 days (1). Exposed contacts may have knowledge of when they were most likely exposed to a known COVID-19 case, if identified by contact tracing. Travellers entering a country may be at any point in their infection from recently exposed to late in an infection at arrival. Quarantine strategies for case contacts and travellers will likely differ in their approach, but the goal is similar, to prevent transmission of SARS-CoV-2 from infected individuals.

An active SARS-CoV-2 infection is most commonly established by RT-PCR testing of a nasopharyngeal or other respiratory mucous membrane swab. The sensitivity of the RT-PCR test depends on many factors including virus load in the sample. Early in an infection the virus load may be very low and there is a high likelihood of a false negative result, which decreases as virus load increases; an example from a meta-analysis indicates false negative results are ~100% on days 1-3, 67% on day 4, 38% on day 5 (symptom onset) and 20% on day 8 post exposure (2, 3). Models included in this review consider a distribution for the sensitivity of the RT-PCR from exposure through infectious period with sensitivity increasing rapidly two days before infection to over 80% and remains high for eight or more days after symptom onset (4). Usually as infection progresses the viral load will increase, studies show variability in peak viral load timing from just before to up

to five days after symptom onset and gradually decreasing as the infection is cleared. Rapid antigen detection tests (RADT) have also started to emerge as a diagnostic tool for COVID-19 (5). RADT tests are cheaper, quicker and easier to perform than the RT-PCR, but likely suffer from lower sensitivity (5). The field performance of RADTs are less certain than RT-PCR, thus models that explored the use of RADTs as a testing option frequently cited a dearth of data on RADT performance (5). Within this review, the test modelled is mainly RT-PCR with the exception of the most recent models which look at scenarios with RT-PCR separately from RADTs.

Key Points

- Since the first version of this evidence brief, one pre-published model was updated, and one rapid review and thirteen models have been released, eleven of which are prepublications that have not completed a peer review process. The rapid review confirms that there was very little research prior to June 26 on the efficacy of quarantine for SARS-CoV-2 as well as SARS-CoV-1 and MERS. The publications in Table 1 and 2 have been issued since the review was conducted and include eight studies that focus on effective quarantine period strategies in the community for contacts of cases and fourteen studies focus on quarantine strategies for travellers to reduce the risk of importation of SARS-CoV-2.
- Two epidemiological studies in Table 1 and 2 and the rapid review in Table 3 describe observed data about the effectiveness of the 14-day quarantine period for both case contacts and travellers. These studies indicate that the 14-day quarantine was effective and the addition of an RT-PCR improved the effectiveness of the quarantine strategy.
- Quantitative models (n=17) concur the 14-day quarantine strategy is effective and explore several alternative scenarios for quarantine and test strategies in the community (Table 1) and for travellers (Table 2).
    - Shorter quarantines (seven or more days) with at least one test completed near the end of the quarantine were fairly equivalent to 14 days with no test (Table 1 & 2). Scenarios where quarantine was less than seven days were consistently less effective compared to longer quarantine.
    - Without the addition of a test, effectiveness increased over time from seven days (50-60% median range) to ten days (68-84%) compared to fourteen days.
    - Testing travellers on arrival and not quarantining those with a negative result was significantly less effective (~40%) than quarantine strategies of one week or longer with various testing strategies.
    - Testing close to the end of the quarantine period was the most effective time point in most scenarios, because individuals initially in the incubation period have a longer time for virus load to increase and thus be detected. This was particularly true to all quarantine scenarios less

than seven days. For quarantines seven days and longer, a test at seven days was just as effective as a test performed later.

  - Testing multiple times during the quarantine period resulted in minimal reduction in the risk of releasing an infectious person into the community compared to testing one time close to the end of quarantine.

- Evidence from quantitative models suggests that testing and quarantine strategies for community contacts and travellers are similar when considering testing at quarantine lengths greater than one week. For strategies less than one week, test and quarantine strategies are less effective in the community because case contacts may be early in their incubation period and test results would have a high false negative rate. This is less of an issue for travellers that may be at any point in their infection, but there is still a risk of releasing travellers early in their incubation period.
- For both community contacts and travellers, the models captured have started to look at quarantine strategies that use RT-PCR or RADTs. The RADT sensitivity is predicted in most of the models to lag behind the RT-PCR, which translated to optimal test and quarantine model results suggesting that doing an RT-PCR on day five of quarantine or the RADT on day six was equivalent. However, depending on the turn around time for the RT-PCR test (reported to be 24 to 96 hours), the RADT would shorten the quarantine period because results would be obtained on day six assuming there is minimal wait for RADT results.
- Adherence to quarantine was also discussed and modelled in several studies. All studies concluded that adherence is higher with shorter quarantines and the impact of quarantine in real life is likely much lower than reflected in the models due to a lack of compliance.

Overview of the Evidence

The review identified and summarized twenty published and pre-published studies. The limited research focused on quarantine to reduce transmission among case contacts in the community and by traveller introduction of COVID-19.
Seventeen quantitative models and risk assessments were included. These do not identify actual outcomes of strategies that have been tested, but rather present a range of plausible outcomes within theoretical scenarios being studied. Their results are useful to compare different options as part of a decision-making process, however the results should be interpreted with caution as the models will vary on their assumptions, input values based on the epidemic period and region specific parameters used.

Two epidemiological investigations, related to contact tracing or quarantine and surveillance of passengers arriving at the airport were identified. These observational studies have a moderate to high risk of bias due to selection, reporting and follow-up biases.

A single rapid review was conducted, it is considered of moderate quality by AMSTAR because only on person assessed and extracted data from each study. Within this review six additional epidemiological investigations and one model were identified for SARS-CoV-2 with similar biases as noted above.

Important knowledge gaps were identified. The knowledge base on quarantine scenarios is largely supported by models, thus there is a lack of empirical evidence on the impact quarantine has on the epidemic, particularly in a local context. Additional information on adherence to quarantine could help with future decision making on this issue. It was also noted that little performance data exists for new diagnostic tools such as RADTs, thus testing and quarantine scenarios for RADTs may change as data becomes available.

CONTENTS

QUARANTINE EFFECTIVENESS: CASE CONTACTS

Table 1 presents nine studies that examined quarantine within the community. An epidemiological account of the epidemic in Macao is presented that implemented a 14-day quarantine with a test on day 13 which successfully prevented known onward transmission (6). Seven modelling studies and one risk assessment explored the role of quarantine in controlling the epidemic. One model looked at how contact tracing (or delays in contract tracing) and adherence affect the effectiveness of different quarantine strategies ranging from no quarantine with symptom based isolation to 7, 10 or 14 day quarantines with or without one to two RT-PCR tests and concluded a 7-day quarantine with a test was equivalent to a 14-day quarantine (7). Quarantine and test strategies from quantitative models suggests that testing and quarantine strategies for community contacts and travellers is similar when considering testing quarantine lengths greater than one week. However, strategies less than one week, test and quarantine strategies are less effective in the community because case contacts may be early in their incubation period.

Other important considerations, particularly in the most recent studies, were type of test and adherence to quarantine. Models have started to look at quarantine strategies that use RT-PCR or a RADTs and strategy optimization findings were test dependent. Adherence to quarantine was examined and results suggest that adherence is higher with shorter quarantines and the impact of quarantine is likely much lower than reflected in the models due to a lack of compliance.

Table 1: Epidemiologic and modelling studies on quarantine of suspected symptomatic and/or potentially exposed individuals in the community. (n=9)

STUDY	METHOD	KEY OUTCOMES
Epidemiological studies		
Lio (2020) (6) Case investigations Macao Jan-Apr 2020	This paper describes successful quarantine (14 days) of individuals who developed symptoms of COVID-19 or were identified as possibly exposed through contact tracing in Macao, a special administration region of China January 22 through April 8, 2020. A 14-day quarantine with an RT-PCR test on day 13 to confirm negative status was implemented in Macao.	Based on surveillance data no, infectious cases were released from quarantine, two people tested positive on the day 13 RT-PCR test. The total number of people quarantined was not reported.
Modelling studies		
Quilty (2020) (7) *preprint updated* Modelling study UK* 2020*	An agent-based model was developed to simulate different quarantine scenarios for identified contacts of a confirmed index case of COVID-19. The model accounts for the time of identification and contact tracing (average is 4 days) as well as the risk of releasing an infected person from quarantine.	This study explored quarantine scenarios from 3-15 days (in graphs) and effectiveness of quarantine based on adherence. Key outcomes for prevention of onward transmission: • Self isolation based on symptoms (no quarantine) prevents 39% (95%UI; 34 – 45%) onward transmission. • 14-day quarantine prevents 70% (95%UI: 39 – 90%) onward transmission. • A negative RT-PCR upon being traced as a contact (~4 days post exposure) prevents 62% (95%UI: 40 - 84%) onward transmission. • A negative RT-PCR 7 days post exposure prevents 68% (95%UI: 40 - 88%) onward transmission. 10 days 69% (95%UI: 41-90%) and 14 days 70% (95%UI: 40-91%).

		• The 7-day quarantine with 1 test was equivalent to the 14-day quarantine with no test. • Testing upon contact tracing and at the end of quarantine had minimal gains in preventing transmission. • A delay of notifying a contact of exposure of 4 days is estimated to result in transmission potential of 26% (95%UI: 7 - 56%) and halving that to 2 days would decrease the transmission potential to 14% (95%UI: 5 - 42%).
Lewis (2020) (8) *preprint* Risk Assessment USA* 2020*	Using the 14-day quarantine as the benchmark for acceptable risk of a COVID-19 case being released from quarantine (estimated to be 0.5%), the authors use this benchmark to quantitatively explore other quarantine strategies. In this risk assessment the outcome is presented as the likelihood of being infectious given a person was symptom-free in quarantine for *x* days.	• A non-symptomatic person with a negative COVID-19 test at day 7-8 would have a lower risk of being infectious (0.4%) than someone completing a 14-day quarantine. This relationship was robust regardless of someone's initial exposure risk. Type of test received was not explored. • Shorter quarantine would improve compliance, decrease economic burden and may better identify asymptomatic infected individuals.
Peng (2020) (9) *preprint* Modelling study USA* 2020*	Simulations (individual-based forward-time simulation method) of quarantine strategies were used to explore the efficacy of strategies that include one or more tests administered during quarantine. The statistical models developed estimate the transmissibility and viral loads of SARS-CoV-2 infections, and the sensitivities of available SARS-CoV-2 testing methods.	Optimal alternative strategies to the 14-day strategy with no test included: RT-PCR • 10-day quarantine with 1 test 1-2 days before the end of quarantine (90% sensitivity RT-PCR) • 8-day quarantine with 2 tests (day 6-7 and day 8). (both RT-PCRs) • 6-day quarantine with 3 tests (days 4, 5, 6), (95% sensitivity RT-PCR) Antigen • 9-day quarantine with 2 tests (days 7 & 8)

	Tests: They model RT-PCR with 95% and 90% sensitivity and an antigen test with a 1 hour turnaround time.	• 11-day quarantine with 2 tests (days 9 & 10) • Note: Additional strategies presented in Table 2 of the paper
Van der Toorn (2020) (5) *preprint* Modelling study Germany 2020*	This paper describes a model (stochastic transit compartment model) and software interface developed to calculate the reduction in the transmissibility of COVID-19 through quarantine or isolation policies with or without testing strategies. The user chooses between three different modi (i) isolation of infected individuals *(not relevant to this review)*, (ii) management of potentially infected contacts and (iii) quarantine of incoming travelers *(see Table 2).* The user customizes the strategy. The model accounts for infection time, temporal changes in test sensitivity (Antigen test assumed to be 85% sensitivity of RT-PCR due to lack of data), incubation and infectious periods and time to symptom onset.	Outcome is a fold risk reduction (ie: x times less risk). Data is provided for each day of quarantine and test type, however only the strategies that were equivalent to a 14-day quarantine and those associated with a 10-day quarantine are reported below. Contact management with symptom screening: • 14-day quarantine 12.22 (7.88 – 22.13) • 8-day quarantine + RT-PCR test 14.48 (13.39 – 15.80) • 10-day quarantine + RDT test 14.51 (11.89-19.92) • 10-day quarantine with RT-PCR test day 5= 23.20 (19.02-31.50) • 10-day quarantine = 4.65 (3.80 – 6.46) The 14-day quarantine was equal to an 8-day with PCR test or 10 day with an antigen test. Benefits to testing include identification of asymptomatic cases and reduction of uncertainty of the quarantine strategy.
Ashcroft (2020) (10) *preprint* Modelling study Switzerland* Oct 2020*	A mathematical model was developed to explore the impact of quarantine strategies to reduce transmission of COVID-19 based on the empirical data of incubation period, infectivity and generation time. Quarantine strategies explored are for close contacts of a confirmed case that has been traced and	Results are largely presented in graphs: • Optimal duration of quarantine is 6 to 8 days, depending on the delay from exposure to quarantine (estimated to be 0-4 days). • Requiring a negative test result before release on day *n* improves transmission prevention, compared to standard release after *n* days. • Efficacy of test-and-release increases with the time from starting quarantine to testing.

	placed in quarantine for *n* days after their exposure to the case (Traveller quarantine strategies, see Table 2). Scenarios investigated: i) Test-and-release. ii) Release upon negative test with reinforced hygiene.	• Rapid testing reduces quarantine by one day, with equivalent efficacy to RT-PCR testing. For example: Day 6 rapid test (efficacy 80.5%) is equivalent to day 5 RT-PCR test with result obtained day 7 (efficacy 82.4%). • Adherence to quarantine has a large impact on efficacy.
Eilersen (2020) (11) Modelling study Denmark* Oct 2020*	Contact tracing and quarantine strategies within the community are explored to facilitate planning the lifting of a lockdown. To do this, an agent-based SEIR model was developed to simulate a society divided into families, workplace and social groups, with noted connections.	The model shows that quarantine periods longer than 5 days have limited effect on the peak infected fraction throughout the epidemic (figure 3d).
Pak (2020) (12) Modelling study Korea* Sept 2020*	Authors evaluate reasons for variability in incubation period and how that may affect quarantine periods. The authors develop a model for incubation period based on epidemiological data (n=312 cases) reported in the literature. They examined the influence of patient demographics on incubation period of documented cases.	Patients > 42 years of age had, on average, longer incubation periods than patients ≤ 42 years old. Analysis indicates that age-specific quarantine may allow for reduced quarantine duration for those less than 42 years old, without increasing the risk of releasing an infected individual from quarantine. Outcome: risk of infection to others before symptom onset: • 14-day quarantine ≤ 42 years, 8.4% > 42 years. 17.1% • 21-day quarantine ≤ 42 years, 2.2% > 42 years. 5.8% Outcome: quarantine duration required for 90% of cases to manifest symptoms before release: • ≤ 42 years, 13.1 days

		• > 42 years, 17.4 days
Wells (2020) (13) *preprint* Modelling study USA* 2020*	A mathematical model was developed to explore various quarantine scenarios: 1) Quarantine for travel, initiated at random times across the infectious course (see Table 2); 2) Quarantine prompted by contact-tracing and therefore initiated early in the infectious course; Quarantine when the time of exposure is known.	The outcome is the epidemiological equivalence to the standard 14 day quarantine to reduce the probability of post-quarantine transmission (PQT): Scenario (1 &) 2 • Testing on initiation of and exit from quarantine could reduce quarantine time by 50% • Testing at initiation only could reduce quarantine time by one day. • 7 day quarantine with testing on exit from quarantine and 6 day quarantine with testing on initiation and exit was equal to 14 day quarantine • testing during quarantine consistently outperformed testing upon tracing • optimal timing for test was one day prior to end of quarantine for periods < 7 days and on day 7 for longer periods of quarantine Scenario 3 • If testing one day post exposure, an additional test on day 6 was optimal. If entering quarantine >6 days after exposure, testing on day of entry was optimal.

*The location or timing of the study was estimated from the author affiliations and publication date respectively. UI= 95% Uncertainty Interval for super spreading events,

QUARANTINE EFFECTIVENESS: TRAVELLERS

Table 2 presents two epidemiological and twelve models related to quarantine strategies for travellers. The epidemiological studies report on the results of the quarantine program for incoming travellers which was 14 days and incorporated RT-PCR testing. In these studies there were no known infective cases released from quarantine in the reported studies.

Twelve modelling studies explore traveller quarantine lengths from zero through 14 days, with various testing strategies. Compared to a 14-day quarantine period, testing around day 5-7 and being released upon a negative test was shown to be equivalent in six models that examined this scenario. Similarly testing earlier than seven days with quarantine shorter than seven days was generally less protective than 14-day quarantine. Testing as close to the end of quarantine as possible in the less than seven day scenarios was most effective. Testing and releasing negative passengers with no quarantine was not effective.

Having multiple tests within a quarantine period resulted in marginal gains to the predicted efficacy of the quarantine scenario. In scenarios with no testing, a seven day quarantine was shown to be between 50-60% effective. A ten day quarantine was better than seven, but not as effective as fourteen.

Other important considerations, particularly in the most recent studies, were type of test and adherence to quarantine. Models have started to look at quarantine strategies that use RT-PCR or a RADTs and strategy optimization was test dependent. Adherence to quarantine was examined and results suggest that adherence is higher with shorter quarantines and the impact of quarantine is likely much lower than reflected in the models due to a lack of compliance.

TABLE 2: Epidemiologic and modelling studies of quarantine length and testing strategies for travellers (n=14)

STUDY	METHOD	KEY OUTCOMES
Epidemiologic studies		
Laiger (2020) (14) Case investigations France 2020	Repatriated travellers from Wuhan, China (n=337). A 14-day quarantine was observed with RT-PCR testing on arrival and day 5.	0/328 repatriated travellers were positive or developed COVID-19. The other 9 travellers: 1 traveller refused to be tested and 8 were only tested on arrival and had a negative result.
Lio (2020) (6) Case investigations Macao Jan-Apr 2020	This paper describes successful quarantine (14 days) of travellers (n=4347) arriving to Macao, a special administration region of China, January 22 through April 8, 2020. A 14-day quarantine with an RT-PCR test on day 13 to confirm negative status was implemented in Macao.	43/4347 travellers were identified to be infected and successfully isolated. Based on surveillance data no infectious cases were released from quarantine.
Modelling studies		

Clifford (2020) (15) *preprint* Modelling study UK* 2020*	A simulation model (generalized additive model with binomial likelihood and P-spline) of air travellers arriving to the UK from the EU or USA was developed to explore four levels of quarantine stringency: 1) Low - no mandatory quarantine, with and without arrival testing; 2) Moderate - mandatory 3, 5 or 7 day quarantine, with and without a test at end of quarantine; 3) High - mandatory quarantine until two negative tests (taken day 0-2 and 2-6 days after first), or 14 days after a positive test; 4) Maximum - mandatory 14-day quarantine with and without a single test at the end of quarantine. The outcome of the model was the number of infectious individuals who enter the country while infectious in each scenario. That result is converted into the proportion of cases prevented from entering the community due to the quarantine scenarios.	1) All scenarios are compared to no quarantine which in mid-July was predicted to be approximately 23 cases from the USA per week and 12 from the EU per week into the UK. Outcome= the proportion of cases prevented from entering the community due to the quarantine scenarios 2) 7 days, no test = 80% 6 days, test day 5 = 88% 8 days, test day 7= 94% 3) Results not extractable 4) 14 days, no test = 99% 15 days, test day 14= 99% (95%UI 97 – 100%) • There was limited utility of pre-departure testing when testing after arrival was in place. • Testing more than one time had limited benefit. Although the uncertainty interval is not presented in the paper, the figures presented in this paper show that quarantines as short as 8 days with testing on day 7 were almost equivalent to the results of a 14 day quarantine.
Dickens (2020) (4) Modelling study Singapore* 2020*	Six scenarios are simulated for preventing importation of COVID-19 cases into a country using a data-driven framework with information from 153 affected countries. Strategies explored include an arrival test and quarantine positive travellers or prohibit entry vs. quarantine only for 7 or 14 days.	Outcome= the reduction in imported cases. Quarantine scenario: • 7 days – no test = 55.4% • 14 days- no test = 91.2% • 0 days- arrival test and positives denied entry = 77.2%

	This model does not account for varying RT-PCR sensitivity through infection.	• 7 days if positive test on arrival and day 7 test = 90.2% • 14 days if positive test on arrival and test on day 14 = 91.7% 14-day quarantine of all passengers is most effective, but also the highest negative impact to travellers.
Steyn (2020) (3) *preprint* Modelling study New Zealand 2020*	A continuous time branching process model for COVID-19 transmission that includes a time-dependent probability of a false-negative test is used to simulate New Zealand's quarantine facility and each simulation is seeded with a case infected up to 14 days prior to arrival. New Zealand has a 14-day quarantine for all international arrivals that includes a minimum of two tests. The model explores 14-day quarantine without testing, 5-day quarantine with test on day 3 and pre-departure and post-arrival testing as different strategies.	Outcome: the percentage of infected travellers prevented from entering the community assuming no transmission in the quarantine facility. • 14 days, tests on day 3 & 12 = 99.9% • 14 days, no tests = 96% • 14 days, chance of early release on day 7 due to a negative test on day 3 or 8 = 99.9% • 5 days, test on arrival and day 3 = 75% • 0 days, negative test pre-departure and on arrival, positives denied entry = 50% If transmission within the quarantine facility should occur, the effectiveness of quarantine goes down and the importance of multiple tests during quarantine increases to both prevent transmission in the facility and to identify newly infected individuals.
Wells (2020) (13) *preprint* Modelling study USA* 2020*	A mathematical model was developed to explore various quarantine scenarios: 1) Quarantine for travel, initiated at random times across the infectious course; 2) Quarantine prompted by contact-tracing and therefore initiated early in the infectious course (*see Table 1)*,	The outcome is the epidemiological equivalence to the standard 14-day quarantine to reduce the probability of post-quarantine transmission (PQT): Scenario 1 & 2 • Testing on arrival and exit from quarantine could reduce quarantine time by 50%. • Testing on arrival only could reduce quarantine time by one day.

	3) Quarantine when the time of exposure is known (*see Table 1)*.	• 7-day quarantine with testing on exit from quarantine and 6-day quarantine with testing on arrival and exit was equal to 14-day quarantine. • Testing during quarantine consistently outperformed testing on arrival. • Optimal timing for test was one day prior to end of quarantine for periods < 7 days and on day 7 for longer periods of quarantine. Example of oil rig workers: • This was applied to an oil rig screening program with both arrival and exit from quarantine testing. 47/4040 employees were positive by this strategy, 16 would have been missed by entry only testing and could have lead to 9 different outbreaks. No infected worker went unidentified.
Russell (2020) (16) *preprint* Modelling study USA* 2020*	A mathematical model was developed to evaluate quarantine and testing strategies. Web application is accessible. Quarantine length examined in days: 0, 2, 5, 7, 14. Testing scenarios: no test, on arrival, 24 hours before the end of quarantine or both. Outcome is days at risk of community transmission assuming 1/10000 travellers are infected and a transmission risk of 0.5 per person-day at risk of transmission.	• Testing during quarantine consistently outperformed testing on arrival (if quarantine compliance is high). • Testing benefits diminished the longer the quarantine period; median reduction of 0.30, 0.10, and 0.004 days at risk for 2, 7, and 14-day quarantine, respectively. • The benefit of quarantine was highly sensitive to compliance where 40% compliance resulted in 1.7-2.1 days at risk, 100% compliance reduced this to 0.00-0.05 days at risk.
Johansson (2020) (17) *preprint*	A mathematical model was developed to analyze the expected effectiveness of symptom monitoring, testing, and quarantine strategies under different	Outcome: reduction in risk of transmission: • Testing on the day of departure could reduce the transmission risk while

Modelling study USA* 2020*	estimates of the infectious period, test-positivity relative to time of infection, and test sensitivity to reduce the risk of transmission from infected travelers during and after travel.	travelling by 37-61%, but 3 days before was a 5-9% reduction. • Testing and no quarantine 0-77% depending on the day of infectious period the test was performed. • Pre and post arrival test 40-66%. • Testing at arrival and 3-4 days later = 45-70%. • Isolation based on symptom monitoring = 36-52%. • 14-day quarantine = 97-100%. • 10-day quarantine = 84-100%. • 7-day quarantine = 65-95% • 7-day quarantine with a test on day 3-4 = 95-99%.
Taylor (2020) (18) *preprint* Modelling study UK Aug 2020	This study estimated that 895 (95%CI 834-958) infectious travellers were arriving in the UK in a single week in August 2020, 87% were on the UK quarantine list, and no quarantine is required for travellers from destinations not on the list. The quarantine is a 14 day self isolation (assumed to be ~80% effective due to compliance), alternative strategies were explored. They considered symptom screening at airports, self isolation for 7, 10 or 14 days and the addition of RT-PCR tests (a 48h turnaround is assumed on test results). A model was created to estimate different quarantine scenarios, but the methods section of the manuscript has been omitted from the prepublication documents, so it cannot be assessed.	• 14-day self isolation is estimated to be 78% effective (95%CI 74.4-81.6). • Thermal scanners detect 1/128 infectious travellers. • Arrival test is 39.6% effective (95%CI 35.2-43.7) – detects 2/5 infectious travellers. • 6-day quarantine with test at 4 days after arrival is 64.3% effective (95%CI 60.0-68.3). • 6-day quarantine with test at arrival and 4 days is 68.9% effective (95%CI: 64.9-73.0). • 7-day quarantine 51.3% effective (95%CI 47.2 – 55.7). • 10-day quarantine 68.8% effective (95%CI 65.1-72.9). • 9-day quarantine with test on day 7 is 74.3% effective (95%CI: 70.0-78.0).

		• 9-day quarantine with test at arrival and on day 7 is 75.9% effective (95%CI: 72.3-79.6). Strategies with testing on day 7 to clear a traveller were almost as effective as the 14-day quarantine.

Van der Toorn (2020) (5)
preprint
Modelling study
Germany
2020*
	This paper describes a model (stochastic transit compartment model) and software interface developed to calculate the reduction in the transmissibility through quarantine or isolation policies with or without testing strategies.
	
	The user chooses between three different modi
	
	(i) isolation of infected individuals *(not relevant to this review);*
	
	(ii) management of potentially infected contacts *(see Table 1);* and
	(iii) quarantine of incoming travelers.
	
	The user customizes the strategy.
	
	The model accounts for infection time, temporal changes in test sensitivity (Antigen test assumed to be 85% sensitivity of RT-PCR due to lack of data), incubation and infectious periods and time to symptom onset.
		Outcome is a fold risk reduction. (ie: x times less risk)
		
		Travellers with symptom screening:
		
		• Symptom screening and testing at arrival
		  ○ RT-PCR = 4.69 (4.19 – 4.83)
		  ○ rapid test (RDT 87% sensitivity) = 3.59 (3.22-3.69)
		• 14-day quarantine = 43.09 (21.82-94.40)
		• 10-day quarantine = 15.66 (9.77- 27.44)
		• 8-day quarantine + RT-PCR test = 47.56 (33.27-73.34)
		• 10-day quarantine + RDT test = 49.92 (30.54 – 85.67)
		• 10-day quarantine with RT-PCR test day 5 = 78.27 (48.87 – 136.94)
		
		Data is provided for each day of quarantine by test type. The 14-day quarantine was equal to an 8-day with PCR test or 10 day with an antigen test.

Ashcroft (2020) (10) *preprint* Predictive Model Switzerland* Oct 2020*	A mathematical model was developed to explore the impact of quarantine strategies to reduce transmission of COVID-19 based on the empirical data of incubation period, infectivity and generation time. Quarantine strategies explored are for travellers that has been placed in	Results are largely presented in graphs. Outcome: fraction of local transmission prevented: • Quarantine of 10 days upon arrival prevents nearly 100% of local transmission. • Testing on arrival is a poor strategy for limiting transmission: testing upon return

	quarantine for *x* days after their arrival. *(Case contacts, see Table 1).* Scenarios investigated: I. Test-and-release. II. Release upon negative test with reinforced hygiene.	at day zero only prevents 54.1% of local transmission, but testing on day five and releasing on day seven prevents 98.5% of local transmission. • Rapid testing reduces quarantine by one day, with minimal loss to efficacy compared to RT-PCR testing.
Arino (2020) (19) *preprint* Modelling study Canada* Dec 2020*	A stochastic model was developed to simulate a small population, homogeneously mixing, and the potential transmission chains that result after a case importation. Efficacy of quarantine is compared to duration of post-arrival quarantine, including how strictly quarantine is observed. Scenarios of 7, 10 and 14-day quarantines are analyzed.	Probability of preventing local transmission from an imported case increased with duration of quarantine and detection of cases from testing. • The efficacy for 7, 10, and 14-day quarantines are shown graphically (figure 7). • If 10% of cases are undetected, 14-day quarantine efficacy is 90%. • Increasing undetected cases to 90%, 14-day quarantine efficacy is 70%.
Matsinos (2020) (20) *preprint* Modelling study USA* Oct 2020*	A Monte-Carlo model is applied to the effect of quarantine length for travellers returning from high-risk COVID-19 regions. Model distributions: -Travel duration: beta(1-21 days, avg 12) -Infection timing : random -Infection probability: i) constant during travel ii) increasing with time, linear iii) increasing with time, logarithmic The model was run nine times, each simulating one million traveller scenarios.	Outcome: Probability of new infections resulting from infectious travellers being released from quarantine: • 8-day quarantine= 5% • 12-day quarantine= 1% • 16-day quarantine= 0.1% The model results do not support a reduction of quarantine from the current 10-14 day requirement of European countries.
Wilson (2020) (21) *preprint* Modelling study	A stochastic SEIR model was developed to explore the impact of various control measures upon likelihood that an infectious traveller would cause an outbreak when coming from a low	Outcome: average time between outbreaks due to travel into a COVID-19 free country: • No intervention = 1.7 years.

New Zealand* Jun 2020*	prevalence area (Australia) to a COVID-19 free area (New Zealand). Quarantine standard of 14 days and reduced 7 days were modelled as well as utilizing a test-and-release policy.	• 14-day quarantine = 34.5 years or more for all scenarios considered. • 7-day quarantine = 5.8 years. • PCR testing on days 3 & 12, release if both negative = 29.6 years

QUARANTINE EFFECTIVENESS SYNTHESIS RESEARCH

A single rapid review was identified that covered travel-related control measures. Quarantine was a component of this review and included research from SARS-CoV-1, MERS and SARS-CoV-2 up to June 26, 2020. Based on this rapid review there was very little relevant research up to June on quarantine strategies for travellers at the time of the search.

Table 3: Synthesis research related to quarantine length and testing

STUDY	METHOD	KEY OUTCOMES
Burns (2020) (22) Rapid Review Germany* 2020	Rapid review conducted by Cochrane (AMSTAR =moderate quality due to single reviewer) includes 36 studies on travel-related control measures to contain a pandemic. Search up to June 26, 2020 and included relevant studies on SARS-CoV-2 as direct evidence and SARS-CoV-1 and MERS as indirect evidence. The review includes 17 modelling studies, 7 observational screening studies and one observational ecological study on COVID-19, four modelling and six observational studies on SARS, and one modelling study on SARS and MERS, covering a variety of settings and epidemic stages.	For quarantine outcomes: • 1 COVID-19 study was included and concluded that 14-day quarantines reduced the risk of transmission from imported cases and the effectiveness of the quarantine depended on compliance (very low certainty of evidence) (Table 7). • 4 studies on SARS-1 or MERS were reported, however these looked at the impact of quarantine as a public health intervention and did not explore different quarantine strategies (Table 7). • Six COVID-19 observational studies are described particularly for repatriation flights where travellers were quarantined for 14 days and both symptom and

	None appear to have looked at different quarantine strategies, but some speak to the impact and effectiveness of the 14-day quarantine with symptom based screening or testing.	testing during quarantine was conducted. The results generally indicate that the 14 days alone or based on symptoms is not as sensitive as the use of an RT-PCR test during quarantine (no inference about shortening quarantine can be drawn from these studies) (Table 6). Other outcomes covered, but not summarized here: entry/exit symptom screening, border closures, and border restrictions.

*The location or timing of the study was estimated from the author affiliations and publication date respectively.

Methods:

A daily scan of the literature (published and pre-published) related to COVID-19 is conducted by the Emerging Science Group, PHAC; and has been ongoing since the beginning of the outbreak. The literature is retrieved from Pubmed, Scopus, BioRxiv, MedRxiv, ArXiv, SSRN, Research Square and cross-referenced, the WHO COVID literature list, and COVID-19 information centers run by Lancet, BMJ, Elsevier and Wiley. A search to retrieve relevant literature for this evidence summary was conducted in the Refworks database. Targeted keyword searching is conducted within these databases to identify relevant citations on COVID-19 and SARS-CoV-2. The search algorithms used isolation AND length, quarantine AND length, quarantine AND testing AND (reduce OR travel). 414 citations were screened for relevance and data was extracted from relevant articles into the review. This review contains research related to quarantine, and testing as a means to reduce quarantine duration, published up to December 3, 2020.

Nouveaux éléments de preuve sur la COVID-19

Synthèse en bref sur les stratégies visant à réduire la durée de la quarantaine associée à la COVID-19 et leur efficacité, mise à jour 1

Introduction

Quelle est l'efficacité d'une quarantaine plus courte avec et sans test de dépistage pour le SRAS-CoV-2?

Cette synthèse des données probantes détermine et résume les données publiées et prépubliées sur différentes stratégies de rechange à la quarantaine (p. ex., combinaison de test RT-PCR et de quarantaine) afin d'explorer les solutions pouvant être mises en œuvre plutôt que la mise en quarantaine de 14 jours actuellement utilisée. Les études publiées et prépubliées jusqu'au 3 décembre 2020 ont été incluses dans cette synthèse.

La quarantaine a été l'une des nombreuses interventions en santé publique adoptées par de nombreuses administrations au début de la pandémie de COVID-19. Dans la présente synthèse, le terme « quarantaine » fait référence au temps qui doit s'écouler avant qu'une personne potentiellement exposée au SRAS-CoV-2 puisse être jugée incapable de développer ou de transmettre la COVID-19. La quarantaine peut être utilisée pour les voyageurs qui arrivent dans une région, les cas soupçonnés de COVID-19 ou les contacts connus d'un cas de référence. Bien que de nombreuses études aient examiné l'efficacité de la quarantaine pour réduire la transmission de la COVID-19, la présente synthèse porte spécifiquement sur l'efficacité de la réduction de la durée de la quarantaine avec et sans test de dépistage. Comme les pays gèrent la pandémie de COVID-19 depuis environ dix mois, ils cherchent désormais des moyens d'intervention efficaces qui pourront permettre de réduire la transmission tout en limitant les répercussions négatives de la quarantaine sur les personnes, la société et l'économie.

On estime que la période d'incubation actuelle du SRAS-CoV-2, c'est-à-dire le temps entre l'exposition au virus et l'apparition des symptômes, est de 5 jours en moyenne (elle varie cependant entre 1 et 14 jours). On estime également que la période infectieuse peut commencer un à deux jours avant l'apparition des symptômes et se poursuivre pendant environ 8 à 10 jours (1) dans les cas légers. Si elles sont identifiées par une recherche des contacts, les personnes qui ont été en contact avec le virus pourront ainsi savoir à quel moment elles ont été le plus susceptibles d'avoir été exposées à un cas connu de COVID-19. Il ne faut pas non plus oublier que tout voyageur qui arrive dans un pays peut avoir été exposé à l'infection et que cette exposition peut être récente ou remonter à quelques jours. De ce fait, même si les stratégies de mise en quarantaine pour les contacts et les voyageurs utiliseront probablement des approches différentes, elles ont cependant toutes deux le même objectif, soit prévenir la transmission du SRAS-CoV-2 par les personnes infectées.

Une infection active au SRAS-CoV-2 est le plus souvent confirmée par le test RT-PCR, soit un test de prélèvement par écouvillonnage nasopharyngé et oropharyngé qui permet d'obtenir des muqueuses respiratoires. La sensibilité du test RT-PCR dépend cependant de nombreux facteurs, dont la charge virale de l'échantillon. Puisque cette charge virale peut être très faible en début d'infection, il est fort probable qu'une personne qui passerait un test de dépistage au début de l'infection obtiendrait un résultat faussement négatif, probabilité qui diminue cependant lorsque la charge virale augmente. Un exemple tiré d'une méta-analyse indique les pourcentages suivants de faux négatifs, soit 100 % pendant les jours 1 à 3, 67 % le jour 4, 38 % le jour 5 (apparition des symptômes) et 20 % le jour 8 suivant l'exposition (2, 3). Les modèles inclus dans cette revue tiennent compte d'une répartition établie en fonction de la sensibilité du test RT-PCR établie entre le moment où une personne est exposée au virus et la fin de la période infectieuse, sachant que la sensibilité augmente rapidement deux jours avant l'infection pour atteindre plus de 80 % et reste à un niveau élevé pendant huit jours ou plus après l'apparition des symptômes (4). De façon générale, au fur et à mesure que l'infection s'étend, la charge virale augmente. Les études montrent cependant une variabilité dans le pic de la charge virale qui va du moment qui précède l'apparition des symptômes jusqu'à cinq jours après celle-ci, suivi d'une diminution graduelle à mesure que l'infection disparaît. Les tests de détection rapide d'antigènes (RADT) ont également commencé à être utilisés comme outil de diagnostic pour la COVID-19 (5). Bien que ces tests soient moins chers, plus rapides et plus faciles à réaliser que les tests RT-PCR, ils sont probablement moins sensibles que ces derniers (5). Le rendement des RADT sur le terrain est plus incertain que celui des RT-PCR et les modèles qui ont examiné l'utilisation des RADT comme option de test ont souvent mentionné le manque de données sur le rendement de ces tests (5). La présente revue porte principalement sur l'utilisation du RT-PCR, sauf en ce qui concerne les modèles les plus récents qui font une distinction entre les scénarios avec RT-PCR et les scénarios avec RADT.

Points clés

- Depuis la diffusion de la première version de cette revue rapide, une revue rapide a été publiée et un modèle prépublié a été mis à jour. Treize modèles ont également été diffusés dont onze sont des prépublications pour lesquelles aucun processus d'examen par les pairs n'a été effectué. La revue rapide confirme que très peu de recherches ont été effectuées avant le 26 juin sur l'efficacité de la quarantaine pour le SRAS-CoV-2 ainsi que pour le SRAS-CoV-1 et le MERS. Les tableaux 1 et 2 comprennent donc les publications diffusées depuis la publication de cette revue rapide, ce qui inclut huit études qui mettent l'accent sur des stratégies efficaces de quarantaine dans la collectivité pour les contacts avec les cas et quatorze autres qui portent plutôt sur les stratégies de mise en quarantaine des voyageurs afin de réduire le risque d'importation du SRAS-CoV-2.
- Les deux études épidémiologiques qui figurent dans les tableaux 1 et 2 et la revue rapide incluse dans le tableau 3 décrivent les données observées sur l'efficacité de la période de quarantaine de 14 jours pour les voyageurs et pour les personnes ayant été en contact avec des cas. Elles montrent que la quarantaine de 14 jours a été efficace et que l'ajout du test RT-PCR a permis d'augmenter l'efficacité de la stratégie de mise en quarantaine.

- Les modèles quantitatifs (n = 17) conviennent également que la stratégie de quarantaine de 14 jours est efficace, en plus d'explorer plusieurs scénarios de rechange combinant quarantaine et test, tant dans la communauté (tableau 1) que pour les voyageurs (tableau 2).
    - Une quarantaine plus courte (sept jours ou plus) combinée à au moins un test effectué vers la fin de la quarantaine a permis d'obtenir des résultats à peu près équivalents à 14 jours de quarantaine sans test (tableaux 1 et 2). Les scénarios dans lesquels la quarantaine durait moins de sept jours se sont tous révélés moins efficaces que les scénarios dans lesquels une quarantaine plus longue était respectée.
    - Sans l'ajout d'un test, l'efficacité a augmenté avec le temps de sept jours (plage médiane de 50 à 60 %) à dix jours (68 à 84 %) comparativement à quatorze jours.
    - Le fait de soumettre les voyageurs à des tests à l'arrivée et de ne pas mettre en quarantaine ceux dont le résultat était négatif s'est cependant révélé beaucoup moins efficace (~40 %) que les stratégies avec quarantaine d'une semaine ou plus combinées à différentes stratégies de dépistage.
    - La plupart des scénarios indiquent que le moment le plus approprié pour effectuer les tests de dépistage se situe vers la fin de la période de quarantaine puisque ce confinement a permis à la charge virale d'augmenter, ce qui permet de la détecter chez les personnes qui se trouvaient en période d'incubation au moment de leur mise en quarantaine. Cela était particulièrement vrai pour tous les scénarios avec quarantaine durant moins de sept jours. Lorsque la quarantaine dure sept jours et plus, un test effectué après sept jours était tout aussi efficace qu'un test effectué par la suite.
    - Le fait d'effectuer plusieurs tests pendant la quarantaine, plutôt qu'un seul test vers la fin de la quarantaine, a permis de réduire au minimum le risque de contagion dans la collectivité lorsqu'une personne terminait sa quarantaine.
- Les données probantes tirées des modèles quantitatifs indiquent que les stratégies de dépistage et de mise en quarantaine pour les contacts dans la collectivité et les voyageurs sont semblables lorsqu'on envisage d'effectuer des tests et que la quarantaine dure plus d'une semaine. En ce qui concerne les stratégies qui comportent une quarantaine durant moins d'une semaine, les stratégies avec test et quarantaine se sont révélées moins efficaces dans la collectivité parce que les personnes pouvaient être au début de leur période d'incubation et que les résultats des tests entraîneraient alors un taux élevé de faux négatifs. Cela est cependant moins problématique pour les voyageurs qui peuvent en être à quelque phase que ce soit de l'infection, mais il y a toujours un risque associé à la levée de la quarantaine pour ces voyageurs, puisqu'ils pourraient encore être au début de la période d'incubation.
- Tant pour les contacts dans la collectivité que pour les voyageurs, les modèles ont commencé à examiner les stratégies de mise en quarantaine combinée aux tests RT-PCR ou RADT. La plupart des modèles ont prédit que la sensibilité du RADT serait inférieure à celle des tests RT-PCR, ce qui s'est

traduit par des résultats optimaux pour le modèle avec test et quarantaine selon lequel le fait d'effectuer un test RT-PCR le cinquième jour de la quarantaine ou un RADT le sixième jour aurait le même effet. Toutefois, en raison du délai d'exécution du test RT-PCR (entre 24 et 96 heures), le RADT permettrait de réduire la période de quarantaine puisque l'on obtiendrait les résultats le sixième jour, si l'on présume suppose une attente minimale avant d'obtenir ces résultats.

- Le respect de la quarantaine a également été abordé et modélisé dans plusieurs études. Les études ont toutes conclu que le niveau de respect est plus élevé lorsque les quarantaines sont plus courtes et qu'en raison d'un manque de conformité, les répercussions de la quarantaine dans la vie réelle sont probablement beaucoup moins importantes que ce qu'indiquent les modèles.

Vue d'ensemble des éléments de preuve

La revue a permis de cerner et de résumer vingt études publiées et non encore publiées. La recherche, bien que limitée, a donc porté sur le rôle de la quarantaine pour réduire la transmission lors des contacts avec des cas dans la collectivité et à la transmission de la COVID-19 par les voyageurs.
Dix-sept modèles quantitatifs et évaluations du risque ont été inclus. Même si ces modèles n'ont pas permis de déterminer les résultats réels des stratégies mises à l'essai, ils offrent un éventail de résultats plausibles en ce qui concerne les scénarios théoriques à l'étude. Bien que ces résultats soient utiles pour comparer différentes options dans le cadre d'un processus décisionnel, il faut cependant faire preuve de prudence au moment de les interpréter, puisque ces modèles ont utilisé différentes hypothèses de base ainsi que des valeurs variables, notamment la période et les paramètres propres aux régions.

Deux enquêtes épidémiologiques, liées à la recherche des contacts ou à la mise en quarantaine et à la surveillance des passagers qui arrivent dans les aéroports, ont aussi été utilisées. Ces études d'observation présentent un risque modéré à élevé de biais en raison de la méthode de sélection, de la façon de présenter les résultats et du suivi utilisés.

Une seule revue rapide a été effectuée et est jugée être de qualité moyenne par AMSTAR puisqu'une seule personne a évalué et extrait les données utilisées dans chacune des études. Dans le cadre de cette revue, six enquêtes épidémiologiques supplémentaires et un modèle avec des biais semblables à ceux qui sont indiqués ci-dessus ont été utilisés pour le SRAS-CoV-2.

Des lacunes importantes dans les connaissances ont cependant été relevées. La base de connaissances sur les scénarios de quarantaine est largement appuyée par différents modèles, ce qui veut dire qu'il n'y a pas suffisamment de données empiriques sur les répercussions de la quarantaine sur l'épidémie, en particulier dans un contexte local. Des renseignements supplémentaires sur le respect de la quarantaine pourraient permettre de prendre des décisions à l'avenir en ce qui concerne cette question. Il a également été mentionné qu'il existait peu de données sur le rendement pour les nouveaux outils de diagnostic comme les tests RADT, ce qui veut dire que les scénarios de test et de quarantaine pour le RADT pourront changer à mesure que les données deviendront disponibles.

TABLE DES MATIÈRES

EFFICACITÉ DE LA QUARANTAINE : CONTACTS AVEC DES CAS

Le tableau 1 présente neuf études portant sur la quarantaine dans la collectivité. Un compte rendu épidémiologique de l'épidémie à Macao est également présenté. Il comprenait une quarantaine de 14 jours avec test effectué le jour 13 qui a permis d'empêcher la transmission subséquente (6). Sept études de modélisation et une évaluation du risque ont exploré le rôle de la quarantaine dans le contrôle de l'épidémie. Un modèle a notamment examiné la façon dont la recherche des contacts (ou les retards dans cette recherche) et le respect de la quarantaine influent sur l'efficacité des différentes stratégies en matière de quarantaine, ce qui incluait l'absence de quarantaine avec isolement fondée sur les symptômes à des quarantaines de 7, de 10 ou de 14 jours avec ou sans un ou deux tests RT-PCR. Il a conclu qu'une quarantaine de 7 jours avec test équivalait à une quarantaine de 14 jours (7). Les stratégies avec quarantaine et test tirées des modèles quantitatifs indiquent que les stratégies de dépistage et de mise en quarantaine pour les contacts dans la collectivité et les voyageurs sont semblables lorsqu'on prévoit effectuer des tests et que la quarantaine dure plus d'une semaine. Cependant, les stratégies qui s'accompagnent d'une quarantaine durant moins d'une semaine et d'un test combiné à une quarantaine se sont révélées moins efficaces dans la collectivité parce que les contacts avec les cas pouvaient encore être au début de leur période d'incubation.

D'autres éléments importants, particulièrement dans les études les plus récentes, incluaient le type de test et le respect de la quarantaine. Les modèles ont commencé à examiner les stratégies de quarantaine qui utilisent les tests RT-PCR ou RADT et les résultats de l'optimisation de la stratégie dépendaient directement des tests. Le respect de la quarantaine a alors été examiné et les résultats suggèrent que le taux de respect est plus élevé lorsque les quarantaines sont plus courtes et qu'en raison d'un manque de conformité, les répercussions de la quarantaine dans la vie réelle sont probablement beaucoup moins importantes que ce qu'indiquent les modèles.

Tableau 1 : Études épidémiologiques et de modélisation sur la mise en quarantaine dans la collectivité de personnes soupçonnées d'être symptomatiques ou d'avoir été potentiellement exposées au virus. (n = 9)

ÉTUDE	MÉTHODE	RÉSULTATS PERTINENTS
Études épidémiologiques		
Lio (2020) (6) Enquêtes sur les cas Macao Entre janvier et avril 2020	Ce document décrit la mise en quarantaine réussie (14 jours) des personnes qui ont développé des symptômes de COVID-19 ou qui ont été jugées comme ayant été possiblement exposées à la suite d'une recherche de contacts à Macao, une région administrative spéciale de la Chine, entre le 22 janvier et le 8 avril 2020. Une quarantaine de 14 jours avec test RT-PCR effectué le jour 13 pour confirmer le statut négatif a été mise en œuvre à Macao.	Selon les données de surveillance, la quarantaine n'a pas été levée pour aucune personne infectée et deux personnes ont obtenu un résultat positif au test RT-PCR effectué le jour 13. Le nombre total de personnes mises en quarantaine n'a cependant pas été déclaré.
Études de modélisation		
Quilty (2020) (7) *préimpression mise à jour* Étude de modélisation R.-U.* 2020*	Un modèle fondé sur des agents a été développé pour simuler différents scénarios de mise en quarantaine pour les contacts identifiés après un cas de référence confirmé de COVID-19. Le modèle tient compte du moment où la détermination des cas et la recherche des contacts ont été effectuées (la moyenne étant de 4 jours) ainsi que du risque qu'une personne infectée puisse circuler, après la levée de la quarantaine.	Cette étude a examiné différents scénarios dans lesquels la quarantaine variait de 3 à 15 jours (dans les graphiques), ainsi que l'efficacité de la quarantaine en fonction du respect de la quarantaine. Principaux résultats en ce qui concerne la prévention de la transmission subséquente : • L'auto-isolement fondé sur les symptômes (aucune mise en quarantaine) empêche 39 % (II à 95 %, de 34 à 45 %) de la transmission subséquente. • Une quarantaine de 14 jours empêche 70 % (II à 95 %, de 39 à 90 %) de la transmission subséquente.

		• Un résultat négatif au test RT-PCR après recherche de contacts (environ 4 jours après l'exposition) empêche 62 % (II à 95 % : de 40 à 84 %) de la transmission subséquente. • Un résultat négatif au test RT-PCR 7 jours après l'exposition empêche 68 % (II à 95 % : de 40 à 88 %) de la transmission subséquente. Le pourcentage atteint 69 % (II à 95 % : de 41 à 90 %) pour 10 jours et 70 % (II à 95 % : de 40 à 91 %) pour 14 jours. • La quarantaine de 7 jours avec 1 test équivalait à la quarantaine de 14 jours sans test. • Les tests effectués lors de la recherche des contacts et à la fin de la quarantaine ont permis de réduire au minimum la transmission. • On estime qu'un retard de 4 jours avant d'aviser un contact de toute exposition entraîne un potentiel de transmission de 26 % (II à 95 % : de 7 à 56 %) et que le fait de réduire cette période de moitié (soit 2 jours) réduirait à 14 % (II à 95 % : de 5 à 42 %) le potentiel de transmission.
Lewis (2020) (8) *préimpression* Évaluation du risque É.-U.* 2020*	Les auteurs ont utilisé la quarantaine de 14 jours comme point de référence pour définir le niveau de risque acceptable de levée de la quarantaine pour un cas de COVID-19 (estimé à 0,5 %) et explorer quantitativement d'autres stratégies en ce qui concerne la quarantaine. Dans cette évaluation du risque, le résultat est présenté comme la probabilité que le cas soit infectieux lorsqu'une personne n'a pas eu de	• Une personne non symptomatique dont le résultat du test pour la COVID-19 effectué les jours 7 ou 8 présente un risque d'infection inférieur (0,4 %) à celui d'une personne qui termine une quarantaine de 14 jours. Le lien était solide, quel que soit le risque d'exposition initial d'une personne. Le type de test effectué n'a pas été examiné. • Une quarantaine plus courte permettrait donc d'augmenter la conformité et de réduire le fardeau économique, en plus de

	symptômes pendant les *x* jours de sa quarantaine.	permettre de mieux déterminer les personnes infectées et asymptomatiques.
Peng (2020) (9) *préimpression* Étude de modélisation É.-U.* 2020*	Des simulations (méthode individuelle de simulation prospective) de stratégies de quarantaine ont été utilisées pour évaluer l'efficacité des différentes stratégies comprenant un ou plusieurs tests effectués pendant la quarantaine. Les modèles statistiques ont permis d'estimer la transmissibilité et la charge virale des infections par le SRAS-CoV-2, ainsi que la sensibilité des méthodes de dépistage du SRAS-CoV-2 disponibles. Tests : Les auteurs ont modélisé le test RT-PCR avec une sensibilité de 95 % et de 90 % et un test antigénique avec un délai d'exécution d'une heure.	Les stratégies de rechange optimales à la stratégie de 14 jours sans test comprenaient : RT-PCR • Quarantaine de 10 jours avec 1 test 1 à 2 jours avant la fin de la quarantaine (RT-PCR avec sensibilité de 90 %) • Quarantaine de 8 jours avec 2 tests (jour 6 ou 7 et jour 8). (deux RT-PCR) • Quarantaine de 6 jours avec 3 tests (jours 4, 5, 6) (RT-PCR avec sensibilité de 95 %) Antigène • Quarantaine de 9 jours avec 2 tests (jours 7 et 8) • Quarantaine de 11 jours avec 2 tests (jours 9 et 10) • Remarque : Stratégies supplémentaires présentées dans le tableau 2 du document
Van der Toorn (2020) (5) *préimpression* Étude de modélisation Allemagne 2020*	Ce document décrit un modèle (modèle de compartimentation de la transmission) et une interface logicielle conçus pour calculer la réduction dans la transmissibilité de la COVID-19 grâce à des politiques de mise en quarantaine ou d'isolement avec ou sans test. L'utilisateur a le choix entre trois modes différents : (i) isolement des personnes infectées (*non pertinent pour cette revue*), (ii) gestion des contacts potentiellement infectés, et (iii) mise en quarantaine des	Il en résulte une réduction du risque multiplié (c.-à-d. x fois moins de risque). Les données sont fournies pour chaque jour de quarantaine et chaque type de test, mais seules les stratégies qui équivalaient à une quarantaine de 14 jours et celles associées à une quarantaine de 10 jours sont mentionnées ci-dessous. Gestion des contacts avec dépistage des symptômes : • Quarantaine de 14 jours 12,22 (entre 7,88 et 22,13) • Quarantaine de 8 jours + test RT-PCR 14,48 (entre 13,39 et 15,80)

	voyageurs qui arrivent au pays *(voir le tableau 2).* L'utilisateur personnalise ensuite la stratégie. Le modèle tient compte de la durée de l'infection, des changements temporels dans la sensibilité du test (on présume que le test antigénique a une sensibilité de 85 % par rapport au test RT-PCR en raison du manque de données), des périodes d'incubation et d'infection et du temps écoulé avant l'apparition des symptômes.	• Quarantaine de 10 jours + test RDTA 14,51 (entre 11,89 et 19,92) • Quarantaine de 10 jours avec test RT-PCR le jour 5 = 23,20 (de 19,02 à 31,50) • Quarantaine de 10 jours = 4,65 (de 3,80 à 6,46) La quarantaine de 14 jours équivalait à une quarantaine de 8 jours avec test PCR ou à une quarantaine de 10 jours avec test antigénique. Les avantages des tests comprennent la détermination des cas asymptomatiques et la réduction de l'incertitude de la stratégie de quarantaine.
Ashcroft (2020) (10) *préimpression* Étude de modélisation Suisse* Octobre 2020*	Un modèle mathématique a été élaboré pour explorer les répercussions des stratégies de quarantaine visant à réduire la transmission de la COVID-19 en fonction des données empiriques sur la période d'incubation, l'infectiosité et le temps de génération. Les stratégies de quarantaine explorées portent sur les contacts étroits d'un cas confirmé ayant été cherché et mis en quarantaine pendant *n* jours après l'exposition au cas (stratégies de quarantaine pour les voyageurs, voir le tableau 2). Scénarios étudiés : i) test et levée de la quarantaine.	Les résultats sont en grande partie présentés sous forme de graphiques : • La durée optimale de la quarantaine est de 6 à 8 jours, durée établie en fonction du délai entre l'exposition et la quarantaine (estimé entre 0 et 4 jours). • Le fait d'exiger un résultat négatif au test avant la levée de la quarantaine le jour *n* augmente la prévention de la transmission, comparativement à la levée de la quarantaine standard après *n* jours. • L'efficacité des tests et de la levée de la quarantaine augmente avec le temps qui s'est écoulé entre le début de la quarantaine et les tests. • Les tests rapides réduisent la quarantaine d'un jour, avec une efficacité équivalente aux tests RT-PCR. Par exemple : Le test rapide effectué le jour 6 (efficacité de 80,5 %) est équivalent au test RT-PCR effectué le jour 5 lorsque l'on obtient le résultat le jour 7 (efficacité de 82,4 %).

	ii) Levée de la quarantaine après test négatif avec renforcement de l'hygiène.	• Le respect de la quarantaine a une grande incidence sur l'efficacité.
Eilersen (2020) (11) Étude de modélisation Danemark* Octobre 2020*	Les stratégies de recherche des contacts et de quarantaine dans la collectivité sont explorées pour faciliter la planification de la levée du confinement. Pour ce faire, un modèle SEIR (susceptible, exposé, infectieux, éliminé) basé sur les agents a été élaboré pour simuler une société divisée en familles, en milieux de travail et en groupes sociaux, dont les liens entre chaque personne étaient indiqués.	Le modèle montre que les périodes de quarantaine de plus de 5 jours ont un effet limité sur la fraction de crête des infections pendant toute la durée de l'épidémie (figure 3d).
Pak (2020) (12) Étude de modélisation Corée* Septembre 2020*	Les auteurs évaluent les raisons de la variabilité de la période d'incubation et son incidence sur les périodes de quarantaine. Les auteurs ont élaboré un modèle pour la période d'incubation fondé sur des données épidémiologiques (n = 312 cas) mentionnées dans la documentation. Ils ont examiné l'influence des données démographiques des patients sur la période d'incubation dans les cas documentés.	Les patients de plus de 42 ans avaient, en moyenne, des périodes d'incubation plus longues que les patients de 42 ans et moins. L'analyse indique que la durée de la quarantaine établie selon l'âge peut permettre de réduire la durée de la quarantaine pour les personnes de moins de 42 ans, sans augmenter le risque de levée de la quarantaine pour une personne infectée. Résultat : risque d'infection avant l'apparition des symptômes • Quarantaine de 14 jours ≤ 42 ans, 8,4 % > 42 ans. 17,1 % • Quarantaine de 21 jours ≤ 42 ans, 2,2 % > 42 ans. 5,8 % Résultat : durée de quarantaine requise dans 90 % des cas avant l'apparition des symptômes et levée de la quarantaine : • ≤ 42 ans, 13,1 jours

		• > 42 ans, 17,4 jours
Wells (2020) (13) *préimpression* Étude de modélisation É.-U.* 2020*	Un modèle mathématique a été élaboré pour explorer divers scénarios en ce qui concerne la quarantaine : 1) Mise en quarantaine pour les voyages, amorcée à différents moments établis de façon aléatoire pendant toute la phase d'infection (voir le tableau 2); 2) Mise en quarantaine motivée par la recherche des contacts et, par conséquent, amorcée au début de la phase d'infection; Mise en quarantaine lorsque le moment de l'exposition est connu.	Le résultat est l'équivalence épidémiologique avec mise en quarantaine standard de 14 jours afin de réduire la probabilité de transmission après la mise en quarantaine : Scénario (1 et) 2 • Les tests sur la date de début de la quarantaine et la levée de celle-ci pourraient réduire de 50 % la durée de la quarantaine. • Seuls les tests effectués au début de la quarantaine pourraient réduire d'une journée la durée de celle-ci. • Une quarantaine de 7 jours avec test avant la levée de la quarantaine et une quarantaine de 6 jours avec test au début et à la fin équivaut à 14 jours de quarantaine avec tests en fin de quarantaine et à une quarantaine de 6 jours avec tests au début et à la fin équivaut à une quarantaine de 14 jours. • Les tests effectués pendant la quarantaine ont toujours donné des résultats supérieurs aux tests effectués après la recherche • Le moment optimal pour effectuer le test était une journée avant la fin de la quarantaine pour les périodes < 7 jours et le jour 7 pour les périodes de quarantaine plus longues Scénario 3 • Si le test a eu lieu une journée après l'exposition, un autre test effectué le jour 6 était optimal. Si la personne avait été mise en quarantaine plus de 6 jours après l'exposition, les tests effectués le jour de l'entrée en quarantaine étaient optimaux.

*Le lieu ou le moment de l'étude a été estimé à partir des affiliations des auteurs et de la date de publication, respectivement. II= Intervalle d'incertitude à 95 % pour les événements de super propagation

EFFICACITÉ DE LA QUARANTAINE : VOYAGEURS

Le tableau 2 présente deux modèles épidémiologiques et douze modèles portant sur les stratégies de quarantaine pour les voyageurs. Les études épidémiologiques font état des résultats du programme de quarantaine pour les voyageurs qui arrivent au Canada, programme qui comprend 14 jours de quarantaine et des tests RT-PCR. Ces études n'ont relevé aucune personne contagieuse après que la quarantaine ait été levée.

Douze études de modélisation explorent la durée de la quarantaine des voyageurs. Cette durée allait de zéro à 14 jours, avec diverses stratégies de test. Comparativement à une période de quarantaine de 14 jours, les tests effectués autour des jours 5 à 7 et la levée de la quarantaine après un test négatif se sont révélés équivalents dans les six modèles examinés dans ce scénario. De même, les tests effectués avant sept jours lors d'une quarantaine de moins de sept jours offraient généralement une protection moindre que la quarantaine de 14 jours. Les tests les plus efficaces ont été effectués le plus près possible de la fin de la quarantaine dans les scénarios avec quarantaine de moins de sept jours. Il n'a pas été efficace de tester les passagers négatifs qui ne se sont pas mis en quarantaine et pour qui la quarantaine a été levée.

Le fait d'avoir effectué plusieurs tests au cours d'une période de quarantaine a entraîné des gains marginaux dans l'efficacité prévue du scénario de quarantaine. Dans les scénarios sans test, il a été démontré qu'une quarantaine de sept jours avait une efficacité variant entre 50 et 60 %. Une quarantaine de dix jours était préférable à sept jours, mais pas aussi efficace qu'une quarantaine de quatorze jours.

D'autres éléments importants, particulièrement dans les études les plus récentes, incluaient le type de test et le respect de la quarantaine. Les modèles ont commencé à examiner les stratégies de quarantaine qui utilisent les tests RT-PCR ou RADT et établi que l'optimisation de la stratégie dépendait directement des tests. Le respect de la quarantaine a alors été examiné et les résultats suggèrent que le taux de respect est plus élevé lorsque les quarantaines sont plus courtes et qu'en raison d'un manque de conformité, les répercussions de la quarantaine dans la vie réelle sont probablement beaucoup moins importantes que ce qu'indiquent les modèles.

TABLEAU 2 : Études épidémiologiques et de modélisation de la durée de la quarantaine et stratégies de dépistage pour les voyageurs (n = 14)

ÉTUDE	MÉTHODE	RÉSULTATS PERTINENTS
Études épidémiologiques		
Laiger (2020) (14) Enquêtes sur les cas France 2020	Voyageurs rapatriés de Wuhan, Chine (n = 337). Les voyageurs ont dû se soumettre à une quarantaine de 14 jours avec des tests RT-PCR à l'arrivée et au jour 5.	Parmi les 328 voyageurs rapatriés, aucun n'était positif pour la COVID-10 ou avait développé la maladie. En ce qui concerne les neuf autres voyageurs : Un voyageur a refusé de se soumettre à un test et les huit autres n'ont été soumis à un test qu'à leur arrivée et ont obtenu un résultat négatif.
Lio (2020) (6) Enquêtes sur les cas Macao Entre janvier et avril 2020	Ce document décrit la mise en quarantaine réussie (14 jours) de voyageurs (n = 4 347) qui sont arrivés à Macao, une région chinoise sous administration spéciale, entre le 22 janvier et le 8 avril 2020. Une quarantaine de 14 jours avec test RT-PCR effectué le jour 13 pour confirmer le statut négatif a été mise en œuvre à Macao.	43/4 347 voyageurs ont été jugés infectés et ont alors été isolés avec succès. Selon les données de surveillance, lorsque la quarantaine a été levée, aucun cas n'était encore infecté.
Études de modélisation		
Clifford (2020) (15) *préimpression* Étude de modélisation R.-U.* 2020*	Un modèle de simulation (modèle additif généralisé avec probabilité binomiale et courbe splinée avec pénalité) pour les voyageurs aériens qui sont arrivés au Royaume-Uni en provenance de l'Union européenne ou des États-Unis a été élaboré afin d'explorer quatre niveaux de rigueur en matière de quarantaine : 1) Faible - aucune quarantaine obligatoire, avec et sans test à l'arrivée;	1) Tous les scénarios sont comparés à l'absence de quarantaine qui, à la mi-juillet, devait être d'environ 23 cas par semaine à partir des É.-U. vers le R.-U. et de 12 par semaine de l'UE au R.-U. Résultat = la proportion des cas qui ne peuvent ensuite se retrouver dans la collectivité en raison des scénarios de quarantaine 2) 7 jours, aucun test = 80 % 6 jours, test le jour 5 = 88 %

	2) Modérée - mise en quarantaine obligatoire de 3, de 5 ou de 7 jours, avec et sans test à la fin de la quarantaine; 3) Élevée - mise en quarantaine obligatoire jusqu'à ce que deux résultats négatifs aient été obtenus aux tests (les jours 0 à 2 et 2 à 6 après le premier test), ou 14 jours après un résultat positif; 4) Maximum - quarantaine obligatoire de 14 jours avec et sans un seul test à la fin de la quarantaine. Le modèle a indiqué le nombre de personnes contagieuses qui arrivent au pays alors qu'elles sont contagieuses dans chacun des scénarios. Ce résultat est ensuite converti en proportion des cas qui ne peuvent ensuite se retrouver dans la collectivité en raison des scénarios de quarantaine.	8 jours, test le jour 7 = 94 % 3) Résultats non extractibles 4) 14 jours, aucun test = 99 % 15 jours, test le jour 14 = 99 % (II à 95 %, de 97 à 100 %) • L'utilité des tests avant le départ était limitée lorsque des tests étaient effectués après l'arrivée. • Les tests effectués à plus d'une reprise ont eu des avantages limités. Bien que l'intervalle d'incertitude ne soit pas présenté dans le document, les chiffres présentés montrent qu'une quarantaine aussi courte que 8 jours avec test effectué le jour 7 donne des résultats presque équivalents à ceux obtenus après une quarantaine de 14 jours.
Dickens (2020) (4) Étude de modélisation Singapour* 2020*	Six scénarios sont simulés pour empêcher l'importation de cas de COVID-19 dans un pays grâce à un cadre axé sur des données contenant des renseignements provenant de 153 pays touchés. Les stratégies explorées comprennent un test à l'arrivée et la mise en quarantaine des voyageurs déclarés positifs ou l'interdiction d'entrer au pays ou la mise en quarantaine seulement pendant 7 ou 14 jours. Ce modèle ne tient cependant pas compte de la sensibilité du test RT-PCR qui varie selon l'infection.	Résultat = réduction du nombre de cas importés. Scénario de quarantaine : • 7 jours - aucun test = 55,4 % • 14 jours - aucun test = 91,2 % • 0 jour - test à l'arrivée et entrée refusée à ceux dont le résultat était positif = 77,2 % • 7 jours si le résultat du test était positif à l'arrivée et test le jour 7 = 90,2 % • 14 jours si le résultat du test était positif à l'arrivée et test le jour 14 = 91,7 % La mise en quarantaine de 14 jours de tous les passagers était la plus efficace, mais était également celle qui avait le plus de répercussions négatives sur les voyageurs.
Steyn (2020)	Un modèle de processus arborescent chronologique continu pour la	Résultat : le pourcentage de voyageurs infectés qui n'ont pas pu entrer dans la

(3) *préimpression* Étude de modélisation Nouvelle-Zélande 2020*	transmission de la COVID-19 qui comprend une probabilité à dépendance temporelle avec test faussement négatif pour une simulation réalisée dans l'endroit où s'effectue la quarantaine en Nouvelle-Zélande et une simulation dans laquelle on retrouve un cas ayant été infecté jusqu'à 14 jours avant son arrivée au pays. La Nouvelle-Zélande a instauré une quarantaine de 14 jours avec un minimum de deux tests pour tous les voyageurs internationaux qui entrent au pays. Le modèle explore une quarantaine de 14 jours sans test, une quarantaine de 5 jours avec test effectué le jour 3 et des tests avant le départ et après l'arrivée comme autres stratégies.	collectivité en supposant qu'il n'y ait pas de transmission dans l'endroit où s'effectue la quarantaine. • 14 jours, tests les jours 3 et 12 = 99,9 % • 14 jours, aucun test = 96 % • 14 jours, possibilité de levée anticipée de la quarantaine le jour 7 en raison d'un test négatif effectué le jour 3 ou 8 = 99,9 % • 5 jours, test à l'arrivée et le jour 3 = 75 % • 0 jour, test négatif avant le départ et à l'arrivée et entrée refusée à ceux dont le résultat était positif = 50 % Si la transmission devait se faire dans l'endroit où s'effectue la quarantaine, l'efficacité de la quarantaine diminuerait alors et l'importance des tests multiples pendant la quarantaine augmenterait tant pour prévenir la transmission dans l'établissement utilisé à des fins de confinement que pour identifier les personnes nouvellement infectées.
Wells (2020) (13) *préimpression* Étude de modélisation É.-U.* 2020*	Un modèle mathématique a été élaboré pour explorer divers scénarios en ce qui concerne la quarantaine : 1) Mise en quarantaine pour les voyages, amorcée à différents moments établis de façon aléatoire pendant toute la phase d'infection; 2) Mise en quarantaine motivée par la recherche des contacts et, par conséquent, amorcée au début de la phase d'infection (*voir le tableau 1*), 3) Mise en quarantaine lorsque le moment de l'exposition est connu (*voir le tableau 1*).	Le résultat est l'équivalence épidémiologique avec mise en quarantaine standard de 14 jours afin de réduire la probabilité de transmission après la mise en quarantaine : Scénario 1 et 2 • Les tests effectués au début de la quarantaine et à la levée de celle-ci pourraient réduire de 50 % la durée de la quarantaine. • Les tests effectués seulement au début de la quarantaine pourraient réduire d'une journée la durée de celle-ci. • Une quarantaine de 7 jours avec test avant la levée de la quarantaine et une

		quarantaine de 6 jours avec test au début et à la fin équivaut à 14 jours de quarantaine. • Les tests effectués pendant la quarantaine ont toujours donné des résultats supérieurs aux tests effectués au début de la quarantaine. • Le moment optimal pour effectuer le test était une journée avant la fin de la quarantaine pour les périodes de moins de 7 jours et le jour 7 pour les périodes de quarantaine plus longues. Exemple des travailleurs sur les plates-formes pétrolières : • Ce modèle a été appliqué à un programme de contrôle des plates-formes pétrolières avec test et mis en quarantaine à l'arrivée et avant le départ. 47 employés sur 4 040 avaient un avis positif en ce qui concerne cette stratégie, 16 auraient été oubliés si seuls des tests à l'arrivée avaient été effectués, ce qui aurait pu entraîner 9 éclosions différentes. Aucun travailleur infecté n'est passé inaperçu.
Russell (2020) (16) *préimpression* Étude de modélisation É.-U.* 2020*	Un modèle mathématique a été élaboré pour évaluer les stratégies de quarantaine et de test. L'application web est accessible. Durée de la quarantaine examinée, en jours : 0, 2, 5, 7, 14. Scénarios de test : aucun test, à l'arrivée, 24 heures avant la fin de la quarantaine ou les deux. Le résultat est le nombre de jours de risque de transmission dans la collectivité en supposant qu'un voyageur sur	• Les tests effectués pendant la quarantaine ont toujours donné des résultats supérieurs aux tests effectués au début de la quarantaine (lorsque le niveau de respect de la quarantaine est élevé). • Les avantages des tests ont réduit la plus longue durée de la période de quarantaine : réduction médiane de 0,30, de 0,10 et de 0,004 jour à risque pour une quarantaine de 2, de 7 et de 14 jours, respectivement.

	10 000 est infecté et que le risque de transmission est de 0,5 par jour-personne de risque de transmission.	• L'avantage associé à la quarantaine était directement lié à la conformité, puisqu'une conformité de 40 % a entraîné un risque variant entre 1,7 et 2,1 jours alors qu'une conformité de 100 % a réduit ce risque à un maximum de 0,05 jour.
Johansson (2020) (17) *préimpression* Étude de modélisation É.-U.* 2020*	Un modèle mathématique a été élaboré pour analyser l'efficacité prévue du suivi des symptômes, des tests et des stratégies de mise en quarantaine selon les différentes estimations de la période infectieuse et de la positivité des tests par rapport au moment de l'infection, ainsi que pour tester la sensibilité afin de réduire le risque de transmission des voyageurs infectés pendant et après le voyage.	Résultat : réduction du risque de transmission • Les tests effectués le jour du départ pourraient réduire de 37 à 61 % le risque de transmission pendant les voyages, alors que les tests effectués trois jours auparavant ne représentaient qu'une réduction de 5 à 9 %. • Test et aucune mise en quarantaine, entre 0 et 77 % selon le jour de la période infectieuse où le test a été effectué. • Test avant et après l'arrivée, varie entre 40 et 66 %. • Test à l'arrivée et 3 ou 4 jours plus tard = entre 45 et 70 %. • Isolement basé sur la surveillance des symptômes = entre 36 et 52 %. • Quarantaine de 14 jours = entre 97 et 100 %. • Quarantaine de 10 jours = entre 84 et 100 %. • Quarantaine de 7 jours = entre 65 et 95 % • Quarantaine de 7 jours avec test les jours 3 ou 4 = entre 95 et 99 %.

Taylor (2020) (18) *préimpression* Étude de modélisation R.-U. Août 2020	Selon cette étude, 895 voyageurs infectieux (IC à 95 %, de 834 à 958) sont arrivés au Royaume-Uni pendant une seule semaine en août 2020. De ces voyageurs, 87 % figuraient sur la liste de quarantaine du Royaume-Uni, et aucune quarantaine n'est requise pour les voyageurs en provenance de destinations qui ne figurent pas sur la liste. La quarantaine est un auto-isolement de 14 jours (on suppose qu'elle est efficace à environ 80 % en raison de la conformité); d'autres stratégies ont été explorées. Les auteurs ont examiné le dépistage des symptômes dans les aéroports, l'auto-isolement pendant 7, 10 ou 14 jours et l'ajout de tests RT-PCR (un délai de 48 heures est présumé avant d'obtenir les résultats des tests). Un modèle a été créé pour estimer différents scénarios de quarantaine, mais la section sur les méthodes du manuscrit a été omise des documents de prépublication, ce qui empêche de l'évaluer.	• On estime que l'auto-isolement de 14 jours est efficace à 78 % (IC à 95 %, 74,4 à 81,6). • Les thermomètres thermiques détectent 1 voyageur infectieux sur 128. • Le test à l'arrivée est efficace à 39,6 % (IC à 95 %, 35,2 à 43,7) puisqu'il détecte deux voyageurs infectieux sur cinq. • La quarantaine de 6 jours avec test effectué 4 jours après l'arrivée est efficace à 64,3 % (IC à 95 %, 60,0 à 68,3). • La quarantaine de 6 jours avec test à l'arrivée et après 4 jours est efficace à 68,9 % (IC à 95 % : 64,9 à 73,0). • La quarantaine de 7 jours est efficace à 51,3 % (IC à 95 %, 47,2 à 55,7). • La quarantaine de 10 jours est efficace à 68,8 % (IC à 95 %, 65,1 à 72,9). • La quarantaine de 9 jours avec test le jour 7 est efficace à 74,3 % (IC à 95 % : 70,0 à 78,0). • La quarantaine de 9 jours avec test à l'arrivée et le jour 7 est efficace à 75,9 % (IC à 95 % : 72,3 à 79,6). Les stratégies de dépistage utilisées le jour 7 pour permettre à un voyageur de sortir de quarantaine étaient presque aussi efficaces que la quarantaine de 14 jours.
Van der Toorn (2020) (5) *préimpression* Étude de modélisation Allemagne	Ce document décrit un modèle (modèle stochastique de compartiment de transit) avec interface logicielle développé pour calculer la réduction de la transmissibilité par des politiques de quarantaine ou d'isolement avec ou sans stratégies de test.	Il en résulte une réduction du risque multiplié (c.-à-d. x fois moins de risque). Voyageurs avec dépistage des symptômes : • Dépistage des symptômes et tests à l'arrivée ○ RT-PCR = 4,69 (4,19 à 4,83)

2020*	L'utilisateur a le choix entre trois modes différents : (i) isolement des personnes infectées (*non pertinent pour cette revue*); (ii) gestion des contacts potentiellement infectés (*voir le tableau 1)* et (iii) mise en quarantaine des voyageurs qui arrivent au pays. L'utilisateur personnalise ensuite la stratégie. Le modèle tient compte de la durée de l'infection, des changements temporels dans la sensibilité du test (on présume que le test antigénique a une sensibilité de 85 % par rapport au test RT-PCR en raison du manque de données), des périodes d'incubation et d'infection et du temps écoulé avant l'apparition des symptômes.	○ test rapide (sensibilité de 87 % RDT) = 3,59 (3,22 à 3,69) • Quarantaine de 14 jours = 43,09 (21,82 à 94,40) • Quarantaine de 10 jours = 15,66 (9,77 à 27,44) • Quarantaine de 8 jours + test RT-PCR = 47,56 (33,27 à 73,34) • Quarantaine de 10 jours + test RDT = 49,92 (30,54 à 85,67) • Quarantaine de 10 jours avec test RT-PCR le jour 5 = 78,27 (48,87 à 136,94) Les données sont fournies pour chaque jour de quarantaine et chaque type de test. La quarantaine de 14 jours équivalait à une quarantaine de 8 jours avec test PCR ou à une quarantaine de 10 jours avec test antigénique.
Ashcroft (2020) (10) *prépublication* Modèle prédictif Suisse* Octobre 2020*	Un modèle mathématique a été élaboré pour explorer les répercussions des stratégies de quarantaine visant à réduire la transmission de la COVID-19 en fonction des données empiriques sur la période d'incubation, l'infectiosité et le temps de génération. Les stratégies de quarantaine explorées portent sur les voyageurs qui ont été mis en quarantaine pendant *x* jours après leur arrivée. *(Contacts de cas, voir le tableau 1).* Scénarios étudiés : I. test et levée de la quarantaine.	Les résultats sont en grande partie présentés sous forme de graphiques. Résultat : une fraction de la transmission locale a été évitée : • La quarantaine de 10 jours à l'arrivée empêche presque 100 % de la transmission locale. • Le dépistage à l'arrivée est une mauvaise stratégie pour limiter la transmission. Le dépistage au retour au jour 0 n'empêche que 54,1 % de la transmission locale alors que le dépistage au jour 5 et la levée de la quarantaine au jour 7 empêchent 98,5 % de la transmission locale.

	II. Levée de la quarantaine après test négatif avec renforcement de l'hygiène.	• Les tests rapides réduisent la quarantaine d'une journée, avec une perte minimale d'efficacité comparée aux tests RT-PCR.
Arino (2020) (19) *préimpression* Étude de modélisation Canada* Décembre 2020*	Un modèle stochastique a été mis au point pour simuler une petite population formée d'un mélange homogène et les chaînes de transmission potentielles qui résultent de l'importation d'un cas. L'efficacité de la quarantaine est comparée à la durée de la quarantaine après l'arrivée, y compris la façon dont la quarantaine est strictement observée. Les scénarios avec quarantaines d'une durée de 7, de 10 et de 14 jours ont été analysés.	La probabilité d'empêcher la transmission locale à partir d'un cas importé augmente avec la durée de la mise en quarantaine et la détection des cas obtenue grâce aux tests. • L'efficacité des quarantaines d'une durée de 7, de 10 et de 14 jours est illustrée sur un graphique (figure 7). • Si 10 % des cas ne sont pas détectés, une quarantaine de 14 jours a une efficacité de 90 %. • Lorsque le nombre de cas non détectés augmente et atteint 90 %, une quarantaine de 14 jours sera efficace à 70 %.
Matsinos (2020) (20) *préimpression* Étude de modélisation É.-U.* Octobre 2020*	Le modèle de simulation de Monte-Carlo est appliqué à l'effet de la durée de la quarantaine pour les voyageurs qui reviennent de régions dont le risque de COVID-19 est élevé. Distributions dans le modèle : -Durée du voyage : bêta (entre 1 et 21 jours, moyenne de 12) -Moment de l'infection : aléatoire -Probabilité d'infection : i) est constante pendant le voyage ii) augmente avec le temps, de façon linéaire iii) augmente avec le temps, de façon logarithmique Le modèle a été exécuté neuf fois, simulant chacun un million de scénarios avec voyageurs.	Résultat Probabilité de nouvelles infections découlant de voyageurs encore infectieux après la levée de la quarantaine : • Quarantaine de 8 jours = 5 % • Quarantaine de 12 jours = 1 % • Quarantaine de 16 jours = 0,1 % Les résultats du modèle n'appuient pas la réduction de la quarantaine par rapport à l'exigence actuelle qui varie entre 10 et 14 jours dans les pays européens.

Wilson (2020) (21) *préimpression* Étude de modélisation Nouvelle Zélande* Juin 2020*	Un modèle SEIR stochastique a été élaboré pour explorer l'incidence de diverses mesures de contrôle sur la probabilité qu'un voyageur infectieux entraîne une éclosion lorsqu'il vient d'une zone à faible prévalence (Australie) vers une zone exempte de COVID-19 (Nouvelle-Zélande). La mise en quarantaine standard de 14 jours et la quarantaine réduite à 7 jours ont été modélisées, tout comme l'utilisation d'une politique avec test et levée de la quarantaine.	Résultat : temps moyen qui s'est écoulé entre les éclosions à la suite d'un voyage dans un pays sans COVID-19 : • Aucune intervention = 1,7 an. • Quarantaine de 14 jours = 34,5 ans ou plus pour tous les scénarios envisagés. • Quarantaine de 7 jours = 5,8 ans. • Test PCR les jours 3 et 12, levée de la quarantaine si les deux sont négatifs = 29,6 ans

*Le lieu ou le moment de l'étude a été estimé à partir des affiliations des auteurs et de la date de publication, respectivement. R.-U. = Royaume-Uni, É.-U. = États-Unis d'Amérique, UE = Union européenne. II = intervalle d'incertitude, IC à 95 % = intervalle de confiance

RECHERCHE DE SYNTHÈSE SUR L'EFFICACITÉ DE LA QUARANTAINE

Une seule revue rapide portant sur les mesures de contrôle des voyages a été cernée. La quarantaine est l'un des éléments examinés dans cette revue qui comprenait des recherches sur le SRAS-CoV-1, le MERS et le SRAS-CoV-2 jusqu'au 26 juin 2020. Selon cette revue rapide, très peu de recherche pertinente portant sur les stratégies de quarantaine pour les voyageurs avait été effectuée jusqu'en juin, au moment de l'examen des documents disponibles.

Tableau 3 : Recherche de synthèse portant sur la durée de la quarantaine et les tests

ÉTUDE	MÉTHODE	RÉSULTATS PERTINENTS
Burns (2020) (22) Revue rapide Allemagne* 2020	L'examen rapide effectué par Cochrane (AMSTAR = qualité modérée en raison d'un seul examinateur) comprend 36 études portant sur des mesures de contrôle pour les voyages visant à contenir la pandémie. Recherche effectuée jusqu'au 26 juin 2020 comprenant des études pertinentes sur le SRAS-CoV-2 comme preuve directe et le SRAS-CoV-1 et le MERS comme preuve indirecte. La revue comprend 17 études de modélisation, 7 études de dépistage par observation et une étude d'observation écologique sur la COVID-19, quatre études de modélisation et six études d'observation sur le SRAS, ainsi qu'une étude de modélisation sur le SRAS et le MERS, couvrant divers contextes et stades de l'épidémie. Aucune revue ne semble avoir examiné différentes stratégies de quarantaine, mais certaines parlent des répercussions et de l'efficacité d'une quarantaine de 14 jours avec test de dépistage ou tests en fonction des symptômes.	En ce qui concerne les résultats de la quarantaine : • Une étude sur la COVID-19 a été incluse et a conclu que la quarantaine de 14 jours réduisait le risque de transmission des cas importés et que l'efficacité de la quarantaine dépendait de la conformité (très faible certitude de la preuve) (tableau 7). • Quatre études sur le SRAS-1 ou le MERS ont été mentionnées, mais elles examinent les répercussions de la quarantaine comme intervention de santé publique sans explorer d'autres stratégies de quarantaine différentes (tableau 7). • Six études d'observation de la COVID-19 sont décrites et portent plus particulièrement sur les vols de rapatriement dans lesquels les voyageurs ont été mis en quarantaine pendant 14 jours et où les symptômes ont été surveillés et des tests effectués pendant la quarantaine. Les résultats indiquent généralement que la quarantaine de 14 jours, prise seule ou en fonction des symptômes, n'est pas aussi sensible que l'utilisation d'un test RT-PCR pendant la quarantaine (aucune inférence sur la réduction de la durée de la quarantaine ne peut être tirée de ces études) (tableau 6). D'autres résultats ont été abordés, mais ne sont pas résumés ici. Ils portaient notamment

		sur le dépistage des symptômes à l'arrivée au pays et au départ du pays, la fermeture de la frontière et les restrictions imposées aux frontières.

*Le lieu ou le moment de l'étude a été estimé à partir des affiliations des auteurs et de la date de publication, respectivement.

Méthodes :

Une analyse quotidienne de la littérature (publiée et prépubliée) liée à la COVID-19 est effectuée par le Groupe des sciences émergentes de l'ASPC et se continue depuis le début de l'éclosion. La littérature est extraite de Pubmed, de Scopus, de BioRxiv, de MedRxiv, d'ArXiv, de SSRN, de Research Square et croisée avec la liste de littérature sur la COVID de l'OMS et des centres d'information sur la COVID-19 gérés par Lancet, BMJ, Elsevier et Wiley. Une recherche visant à extraire la documentation pertinente pour inclusion dans cette synthèse a été effectuée dans la base de données Refworks. Une recherche ciblée par mot-clé est effectuée dans ces bases de données pour identifier les citations pertinentes sur la COVID-19 et le SRAS-CoV-2. Les algorithmes de recherche ont utilisé isolement ET durée, quarantaine ET durée, quarantaine ET tests ET (réduction OU voyages). La pertinence de 414 citations a été évaluée, et des données ont été tirées d'articles pertinents dans le cadre de cette revue. Cette synthèse contient des recherches liées à la mise en quarantaine et aux tests comme moyen de réduire la durée de la mise en quarantaine, publiées jusqu'au 3 décembre 2020.

Emerging Evidence on COVID-19

Rapid Review on the use of Face Masks to Prevent the Spread of COVID-19 in Community Settings: Update 1

Introduction

What is the evidence on face mask use to prevent COVID-19 in community settings?

Of all the public health measures (PHM) that have been used during the COVID-19 pandemic, the use of face masks in the community is a technically simple one that has had little impact on the economy (1). But is it effective? This rapid review summarizes the empirical evidence on the effectiveness of masks to prevent COVID-19 cases in community settings. It is an update to the earlier *Evidence Brief on the use of Face Masks to Prevent COVID-19 in Community Settings, July 2020* (2). This review does not include experimental data on the filterability of different types of non-medical masks, materials or combinations of materials, as this is being covered as a separate review. It also does not include predictive models that estimate the mitigation effects of wearing a face mask alone or in combination with other public health interventions. This review summarizes literature until November 19, 2020.

Key Points

- Forty nine studies were identified on the effectiveness of face masks to prevent COVID-19 in community settings. There was one experimental study, 15 observational studies, 27 ecological studies and six reviews.
- The majority of studies demonstrate that community masking in observational studies and community mask policy implementation in ecological studies is protective against COVID-19, however the magnitude of this effect varied. Variability could be due to when the study was conducted, confounders, and adherence rates.
- Key findings from individual level observational studies (n=15) and a randomized control trial (n=1) include:
    - In seven observational studies, wearing a face mask was associated with a 7.0-79% decrease in COVID-19 infections.
    - A large randomized control trial (DANMASK-19) in Denmark reported insignificant results for mask usage (OR 0.82, 95% CI: 0.54-1.23, P= 0.33), although this trial suffered from low adherence in the mask group likely due to low levels of community masking during the study (3).
    - Cluster and outbreak investigations consistently reported fewer secondary cases when index cases and/or their contacts wore masks.

  - No evidence was found related to differences in effectiveness of masks between adults and children.

- Twenty-six ecological studies demonstrated that face mask policies were associated with a decrease in COVID-19 infections and deaths. There was some variability in the type of face mask policy implemented, most were universal in public spaces, and three were specific to mask policies for employees.
  - In nine studies the effect of universal face mask policies was calculated and the decrease in COVID-19 infections attributed to the policy ranged from 3.2-48%. There was some variability in the type of face mask policy implemented, most were universal in public spaces, and three were specific to mask policies for employees.
  - One study in Canada was identified, which demonstrated that mask policies in Ontario invoked in Jun-Jul resulted in a 25-31% weekly reduction in COVID-19 cases starting two weeks after implementation (4).
  - A study of COVID-19 case reductions the first month after a universal mask policy in New York demonstrated age-related differences. There was a 20.8% reduction in cases for both 65-74 year olds and 75+ year-olds in the first month, whereas 25-44 and 45-64 year-olds were associated with a 4.5% and 8.1% reduction, respectively (5).
  - Three studies of face mask policies that mandated masks for all employees at all workplaces in an area (county or state) found a decrease in COVID-19 infections and deaths (1, 6, 7), although the results were not consistent in magnitude or statistical significance across different models (1).
  - A USA study found that both early and late mask policies were effective in reducing COVID-19 infections (8).
  - The only study that did not show a significant impact with a mask policy was under lock down conditions -1% (95% CI: -13 to 8%) (9).
  - One study found that countries that had a pre-existing norm that all sick people wear masks, had a lower daily growth rate of COVID-19 cases and deaths compared to countries with no pre-existing mask norm (10).
- Implementing a community mask policy instead of only recommending people wear masks has a significant impact on adherence to mask use in public settings. The study from Ontario indicated there was a 30% increase in mask use after mask policies were implemented (4). A similar study in Australia found a mask policy increased mask use by almost 50% (11). In contrast, a study from the USA showed mask recommendations consistently did not have an impact on COVID-19 fatality rates (1).

Overview of the Evidence

Forty-nine articles pertaining to the effectiveness of face masks to prevent COVID-19 in community settings were identified and included in this review. Of these, 23 are preprints or reports and have not completed the peer-review process. The publications reporting on the effectiveness of face masks include a randomized control trial (n=1), longitudinal studies (n=2), cohort studies (n=2), a natural experiment (n=1), a case-control study (n=1), cross-sectional studies (n=5), cluster and outbreak investigations (n=4), ecological studies (n=27), and systematic or rapid reviews (n=6).

Studies where the inference can be made to the individual include randomized control trials that are the gold standard for measuring the impact of an intervention as the randomization process controls for confounding variables and assuming the sample is representative of the population, by design the RCT should isolate the effect of the intervention. The RCT included in this review was done in a community without a universal mask policy and suffered from lack of adherence to mask wearing in the treatment group, missing data, and lack of blinding. Thus this RCT has some risk of bias that decreases confidence that future research will not change the conclusions.

The 15 observational studies assessed individual level data. Cohort studies, natural experiments, longitudinal studies, and case-control studies can have moderate to high risk of bias depending on whether the sampling strategy is able to obtain a representative sample of the target population. Cross-sectional studies provide a single point in time snap shot of an issue, but cannot establish causation, therefore these studies provide low quality evidence. Retrospective cluster and outbreak investigations are at high risk of bias. In many studies outcomes and risk factors were self-reported so may have recall and social desirability bias. In general observational studies cannot establish causation, but can be useful in developing hypotheses or understanding observed factors for transmission.

The 27 ecological studies assessed population level data. These types of study are inexpensive to conduct and can be done quickly as they largely capitalize on publicly available data. They are at high risk of bias due to the use of disparate population level data and are prone to ecological fallacy (what is true at a population level may not apply at an individual level).

The six reviews were evaluated by the AMSTAR tool for systematic reviews to assess whether the conduct of a review minimized bias. The rapid and systematic reviews ranged from low to high quality, depending on the number of reporting and conduct issues in the study. Despite this, there was good agreement in the results across the review literature.

The literature on COVID-19 is rapidly evolving and with time studies with low risk of bias can be conducted to close existing knowledge gaps. An important knowledge gap is a lack of studies where the inference can be made to an individuals' mask compliance (both adherence and proper use) on SARS-CoV-2 infection in community settings. There is also minimal evidence on effectiveness of wearing a face mask or face mask policies for employees, and in school settings.

CONTENTS

EXPERIMENTAL AND OBSERVATIONAL STUDIES ASSESSING PREVENTION

There were 16 studies identified that assessed the effectiveness of face masks to prevent COVID-19 spread in community settings using individual level data (Table 1). This included one experimental study and 15 observational studies.

- The experimental study was a large randomized control trial (DANMASK-19) from Denmark. It showed that when no face mask policy was in place in the community, recommending mask use was not effective. Although those who wore a mask were 18% less likely be become infected with SARS-CoV-2 compared with those who did not wear a mask, these results were not significant (OR 0.82, 95% CI: 0.54-1.23, P= 0.33). Major limitations to this study were variable adherence to mask wearing, missing data, and a lack of blinding (3).
- The 15 observational studies included two longitudinal studies, two cohort studies, one case-control study, five cross-sectional studies, four cluster and outbreak investigations, and one natural experiment. The majority of studies demonstrated that wearing a face mask was protective against COVID-19, however the magnitude varied across studies.
    - A longitudinal study across 24 countries shows that widespread mask-wearing by 100% of individuals in a country to be associated with a 7% (95% CI: 3.94-9.99%) decline in the daily active cases of COVID-19. Over a 30 day period, this accumulated to an 88.5% (95% CI: 68.7-89.2%) decline in active cases (12).
    - A 7.0-7.9% decrease in COVID-19 cases associated with the use of face masks was also found in three cross-sectional, two cohort, one longitudinal, and one case-control study (12-18).
    - A case-control study in Thailand showed that wearing a mask all of the time versus never wearing a mask was associated with decreased risk for SARS-CoV-2 infection (aOR 0.23, 95% CI: 0.09-0.60), whereas inconsistent use was not associated with decreased risk (aOR 0.87, 95% CI: 0.41-1.84) (18).
    - Four cluster and outbreak investigations consistently reported fewer secondary cases when index cases and/or their contacts wore masks (19-22).

Table 1. Experimental and observational studies on the effectiveness of face masks to protect against COVID-19 in community settings (n=16)

STUDY	METHODS	KEY OUTCOMES
Randomized control trials (n=1)		
Bundgaard (2020) (3) Randomized control trial Denmark Apr-May 2020	This RCT assessed whether surgical mask use outside the home reduced the risk for SARS-CoV-2 infection. The study was conducted in a community where masks were uncommon and recommended by public health. 4862 participants were included (3030 were randomly assigned to wear masks and 2994 were assigned not wear a face mask). Study limitations: missing data, variable adherence to mask wearing, patient-reported findings on home tests, no blinding, and no assessment of whether masks could decrease disease transmission from mask wearers to others.	• Infection with SARS-CoV-2 occurred in 42 participants recommended to wear masks (1.8%) and 53 control participants (2.1%). • The between-group difference was 0.3 percentage point (95% CI: 1.2-0.4 percentage point, p=0.38) (OR 0.82, 95% CI: 0.54-1.23, p=0.33). • Adherence to mask wearing was self-reported. Based on the lowest adherence reported during follow-up, 46% of participants wore the mask as recommended, 47% predominantly as recommended, and 7% not as recommended.
Longitudinal studies (n=2)		
Aravindakshan (2020) *preprint* (12) Longitudinal study Global Feb-Jul 2020	A reduced form model econometric analysis was applied to measure associations between reported face mask use and SARS-CoV-2 spread in 24 countries. A longitudinal survey was conducted every 7 days to collect information on NPIs and adherence across 24 countries.	• Widespread mask-wearing by 100% of individuals in a country was associated with a 7% (95% CI: 3.94-9.99%) decline in the daily active cases of COVID-19. Over a 30 day period this accumulated to an 88.5% (95%CI: 68.7-89.2%) decline in active cases.
Rader (2020) *preprint* (23) Longitudinal study USA	Serial surveys were conducted Jun 3- Jul 27 across the USA (N=378,207) to gather data on community mask and social distancing behaviours in different communities. These data were	• There was a significant association between the proportion of people reporting wearing a mask and community transmission control (Rt<1): OR = 1.14 (95% CI: 1.07-1.20).

Jun-Jul 2020	combined with the local Rt, mobility data and information on implemented policies. The data was analysed using multivariate regression analyses to explore factors associated with community SARS-CoV-2 transmission control in the USA.	• The odds of transmission control (Rt<1) increased (OR 3.53, 95% CI: 2.03-6.43) for each 10% increase in community mask wearing reported in the survey. • Mask wearing was a robust protective factor towards community transmission control across all analyses. • Community transmission control was predicted to be highest with both high mask wearing and social distancing in place. Where social distancing was low despite high mask use community transmission control dropped to 35%. • The analysis did not find a significant increase in mask usage following mask mandate policy, possible reasons for this were not discussed. • Adherence to mask wearing was highest among women, elderly, non-white or Hispanic ethnic groups and lower income respondents. • Mask wearing was highest along the coast, southern border and in urban areas of the USA.
Cohort studies (n=2)		
Kwon (2020) *preprint* (15) Prospective cohort study USA Mar-Jul 2020	This prospective cohort "COVID symptom study" included participants in the USA using an app from March 29- July 16. Participants provided baseline and health information and were prompted to record health and COVID related information daily. 139,690 participants provided information for the association between self-reported use of a face mask and predicted risk of COVID-19.	• Individuals who reported using a mask in the community (sometimes, most of the time, or always) had an adjusted HR for predicted COVID-19 of 0.35 (95% CI: 0.30-0.42) compared to those that never wore a face mask. • Self-reported masking was associated with a 69%, 71%, and 63% reduced risk of predicted COVID-19 among individuals living in communities with excellent, fair, and poor social distancing, respectively. • The findings provide support for the efficacy of mask-wearing in reducing

	The study used predicted COVID-19 as a proxy for a positive COVID-19 test due to the small number of COVID-19 test positive app users during the study period. Survival analysis adjusted for age, sex, ethnicity, state, smoking, frontline workers and comorbidities.	COVID-19 transmission even in settings of poor social distancing.
Wang (2020) (17) Retrospective cohort study China Feb-Mar 2020	This retrospective cohort study consisted of 335 people in 124 families with at least one laboratory confirmed COVID-19 case in Beijing from Feb 28 - Mar 27, 2020.	• The secondary attack rate in families was 23.0% (77/335). • Face mask use by the primary case and family contacts before the primary case developed symptoms was 79% effective in reducing transmission (OR=0.21, 95% CI: 0.06 to 0.79). • However, wearing a mask after illness onset of the primary case was not significantly protective.
Case-control studies (n=1)		
Doung-ngern (2020) (18) Case-control study Thailand Mar 2020	This retrospective case-control study used contact tracing records in Thailand to establish their sample. 1,050 contacts of COVID-19 patients from Mar 1-31, 2020 were retrospectively interviewed. Cases (n=211) were defined as asymptomatic contacts of COVID-19 patients who later tested positive for SARS-CoV-2 infection and controls (n=839) were asymptomatic contacts who never tested positive.	• Wearing a mask at all times (aOR 0.23, 95% CI: 0.09-0.60) was independently associated with lower risk of COVID-19 infection compared to not wearing masks. However, wearing a mask sometimes (aOR 0.87, 95% CI: 0.41-1.84) was not. • Those that wore masks all the time were more likely to wash hands and practice social distancing.
Cross-sectional studies (n=5)		
Lopez (2020) *preprint* (14) Cross-sectional study	In this study, the SARS-CoV-2 seroprevalence of 753 public school staff was determined and correlations between seropositivity and self-reported histories (e.g.	• The seroprevalence was estimated to be 1.7% (90% CI: 0.27- 3.3). • After controlling for six confounders, the results of the multivariate analysis reveal that self-reported mask-wearing history

USA Jul 2020	mask wearing) and demographics were analyzed.	reduces the risk of being seropositive (RR 0.83, 95% CI: 0.18-3.8).
Rodríguez-Barranco (2020) (24) Cross-sectional study Spain Apr-May 2020	This study looked at possible routes of exposure to SARS-CoV-2, risk factors, and the effectiveness of the recommended hygiene measures. Self-reported information was collected from 2086 individuals via online survey.	• 73.4% of individuals wore a mask when they left confinement (34.9% FFP2/FFP3 face mask, 64.4% surgical, and 0.7% homemade mask). • The estimated prevalence of COVID-19 was 4.7% (49 confirmed and 50 suspected cases). • Not taking any other variable into consideration, there was no association between COVID-19 status and mask use (p=0.205): 3.9%, 5.7%, 0%, 3.1%, 5.8% reported having confirmed or suspected COVID-19 of individuals who self-reported wearing an FFP2/FFP3 mask, surgical mask, homemade mask, no mask, and reported not leaving the house respectively.
Payne (2020) (13) Cross-sectional study USA Mar-Apr 2020	A survey of US Navy service members (convenience sample, n=382) linked to a COVID-19 outbreak in an aircraft carrier was conducted to collect information on self-reported face mask use and other protective measures (e.g. avoiding common areas, social distancing). The results were analyzed to determine associations with infection risk. 284 individuals within the sample were found to be positive for SARS-CoV-2 priori to or at the time of serum testing.	• Participants that self-reported wearing a mask (55.8%) had a lower odds of COVID-19 (OR 0.3, 95% CI: 0.2–0.5) compared to those who reported not wearing a mask (80.8%).

Clipman (2020) (16) Cross-sectional study USA Jun 2020	Associations with self-reported SARS-CoV-2 positivity and adoption of NPIs was analyzed using an online survey of 1030 residents in Maryland. Logistic regression was used to identify variables associated with ever testing positive for SARS-CoV-2.	• Of the study sample, 5% (n=55) self reported ever testing positive for SARS-CoV-2. • 53% of participants reported always wearing a mask in indoor and outdoor settings. • A small association between mask wearing (always) and testing positive for SARS-CoV-2 was identified, aOR 0.63 (95% CI: 0.36-1.09).
van den Broek (2020) *preprint* (25) Cross-sectional study USA Apr-Jun 2020	In this study, community residents were surveyed and respondents (n=454) were offered RT-PCR and serological SARS-CoV-2 testing. Multivariate analysis using probit models was conducted to identify associations.	• 2.2% (95% CI: 0.8-3.6%) of the study sample were found to be SARS-CoV-2 positive by serology testing. • Mask wearing outside of work was not statistically different between those that tested positive (0.5%, SE 0.189) vs. negative (0.7%, SE 0.230) for COVID-19.
Cluster and outbreak investigations (n=4)		
Hendrix (2020) (19) Cluster investigation USA May 2020	This retrospective epidemiological investigation analyzed 139 clients that were exposed to 2 hair stylists in Missouri, USA who were infected with SARS-CoV-2. Both clients and hair stylists were wearing face masks.	• Of the 139 clients who were exposed, 67 were tested. • There were no symptomatic secondary cases reported, which was most likely due to the use of face masks.
Cheng (2020) (20) Cluster investigation Hong Kong Jan-Apr 2020	This study describes the findings of cluster investigations in Hong Kong during the first 100 days of the pandemic. The number of COVID-19 clusters involving wearing a mask and not wearing a mask were compared. Hong Kong had initiated a mandatory face mask use policy	• Up to day 100 of the epidemic, 961 cases of COVID-19 cases were confirmed in Hong Kong. Among these cases, 11 clusters of 113 persons were directly engaged in mask-off activities such as dining and drinking in a restaurant or bar, singing at karaoke, and exercise in fitness clubs compared to 3 clusters involving 11

	and adherence was estimated to be 96.6% (95% CI: 95.7 – 97.2%).	persons engaged in mask-on settings at the workplace (Chi square p=0.036).
Hong (2020) (22) Cluster investigation China Jan-Mar 2020	Clinical and epidemiological data were retrospectively retrieved from electronic medical records and valid individual questionnaires from Jan 23-Mar 1, 2020 of 127 patients with COVID-19 in Zhejiang, China.	• Before they were diagnosed, 41 COVID-19 pre-symptomatic patients had close contact with local residents. • 28/41 were wearing masks and had close contact with 123 residents, leading to 10 secondary SARS-CoV-2 infections. • The other 13 who did not wear masks had close contact with 74 residents, leading to 14 secondary SARS-CoV-2 infections. • The percentage of local residents infected with SARS-CoV-2 was significantly lower in the group who came into contact with infected individuals wearing a mask than those who came into contact with infected individuals not wearing a mask (8.1% vs. 19.0%; p < 0.001).
Liu (2020) (21) Outbreak investigation China 2020	This was a retrospective epidemiological investigation of SARS-CoV-2 exposure on public transportation. It described two bus trips in quick succession by an infected and symptomatic individual from Chongqing, the first without a face mask, and the second with a face mask.	• On the bus trip that the infected individual wore a mask, there were no others infected (14 passengers). • On the bus trip that the infected individual did not wear a mask, 5/39 people were infected.
Natural experiment (n=1)		
Pletz (2020) *preprint* (26) Natural experiment Germany Apr 2020	The effects of universal face masks in public settings was compared between two cities close together that had a similar size and community structure. In the implementation of NPIs the city of Jena implemented a face mask policy at the beginning of a 4 week lockdown and Erfurt issued the face	• No new cases of SARS-CoV-2 were observed in Jena 5 days after the implementation of a mandatory face cover policy. • In Erfurt, infections continued to spread within the community during the lockdown period, until community masking was imposed alongside lockdown phase lifting.

	mask policy at the end of lockdown. Note: both cloth masks and scarfs were acceptable if mouth and nose were covered.	• The observations may have been caused by other things so conclusions are limited, but it was a unique opportunity to look at the impact of a face mask policy between two similar communities.

CI = confidence interval, HR = hazard ratio, NPI = non-pharmaceutical intervention, OR = odds ratio, Rt = effective reproduction number

ECOLOGICAL STUDIES ASSESSING IMPACT OF POLICIES AND SOCIETAL NORMS

Twenty-seven ecological studies were identified on the impact of face mask recommendations and policies to prevent COVID-19 in community settings (Table 2). All of these studies analyzed aggregate population level data to estimate the impact of face mask polices on reducing COVID-19. A variety of approaches and sensitivity analyses were used across studies and are not detailed here; readers are encouraged to refer to the individual studies for more on their methodology.

- The majority (n=26) of these ecological studies demonstrated that face mask polices were protective against COVID-19, however the magnitude varied across studies.
    - Nine studies associated implementation of community face mask polices showed a range from 3.2-48% decrease in COVID-19 infections (4-7, 9, 27-30).
    - Five studies showed a 17-23% reduction in Rt after the implementation of mask policies. (11, 29, 31-33).
    - In an Ontario study, mask policies resulted in a 25-31% weekly reduction in COVID-19 cases two weeks after implementation (4).
    - Early and late mask policies were both effective in reducing COVID-19 infections as demonstrated in a study from the USA (8).
    - One study that compared mask effectiveness in countries with pre-existing norms compared to countries with no pre-existing mask norm found that in countries where all sick people normally wear masks, there was a lower daily growth rate of COVID-19 cases and deaths (10).
- The only study that did not show the mask policy had a significant impact was one during lock down conditions -1% (95% CI: -13 to 8%) (9).
- One study assessed effectiveness of a universal mask policy by age. Age related COVID-19 case reduction associated with a universal mask policy in New York demonstrated a 20.8% reduction in cases for both 65-74 year olds and 75+ year-olds in the first month, whereas 25-44 and 45-64 year-olds were associated with 4.5% and 8.1%, respectively (5).

- Employee face mask policies were associated with a decrease in COVID-19 infections and deaths across three studies (1, 6, 7). However, this association was not as strong or as consistent across analyses as universal mask policies (7).
- Recommendations for mask use in the community is not as effective as mask policies (1). Implementation of mask policies was shown in two studies to increase mask use by 30-54% (4, 11)
- Adherence to any of the NPIs is critical to success, one study suggested a 75% adherence rate was needed for community mask wearing to be effective and that if adherence was over 85%, social distancing policies had no additional effect on further mitigating the number of COVID-19 cases (34).

Table 2. Ecological studies on the effectiveness of face mask policies and/or societal norms to protect against COVID-19 in community settings (n=27)

STUDY	METHODS	KEY OUTCOMES
Global (n=8)		
Haug (2020) (32) Ecological study Global Mar-Aug 2020	This study aimed to assess the effectiveness of NPIs to mitigate the spread of SARS-CoV-2. Using a coded dataset of 6,068 NPIs implemented in Mar – Apr 2020 in 79 territories, the impact of government interventions on Rt was conducted using four different statistical approaches. Findings were validated using two external datasets recording 42,151 additional NPIs from 226 countries.	• Wearing a mask was associated with a significant impact on Rt by three different methods (ΔRt between −0.018 and –0.12). • Results indicate that a suitable combination of NPIs are necessary to curb the spread of the virus.
Miyazawa (2020) *preprint* (35) Ecological study 22 countries Mar-May 2020	The study aimed to identify the association between mask wearing rate and the cumulative number of deaths caused by COVID-19 across countries. Mask wearing rates were calculated from survey responses during March 9–18 and April 26 – May 1, 2020, respectively.	• In March, the face mask non-wearing rate was positively associated with the cumulative number of deaths (β 0.0048, SE 0.011, adjusted R2 0.680), but not in Apr–May (β 0.0020, SE 0.011, adjusted R2 0.466). • The regression models explained 69% of the variation in the cumulative number of deaths per million among 22 countries and identified the face mask wearing rate in March as an important predictor.
Brauner (2020) *preprint* (9)	In this study, the effectiveness of eight NPIs in 41 countries was	• Under lock down conditions some masking in public did not have a large

Ecological study Global Jan-May 2020	estimated with a Bayesian hierarchical model by linking NPI implementation dates to national case and death counts. They explored mandating mask policies, limiting gatherings <1000 or <100, or <10, closing high-risk businesses, closing non-essential businesses, closing schools and universities and stay at home orders.	impact. The mean proportion reduction with mandating mask-wearing in (some) public places was -1% (95% CI: -13 to 8%). • In this study, mandatory masking policies were implemented after all the other social distancing and school and business closures and the study ended before lifting of these restrictions.
Esra (2020) *preprint* (29) Ecological study Global Jan-May 2020	Using globally reported SARS-CoV-2 cases to fit a Bayesian model framework, this study aimed to estimate transmission associated with NPIs in 26 countries and 34 USA states. NPIs examined include stay home mandates, gathering limits, school closures, and mask policies.	• The mean reduction in Rt in SARS-CoV-2 infections was 17% (95% CI: 6-28%) with mask policies.
Zhang (2020) (36) Ecological study China, Italy, USA Jan-May 2020	This analysis of daily SARS-CoV-2 infection trends Jan 23- May 9 that specifically look at the linear trajectory of COVID-19 cases and changes that occurred after face mask policies were implemented in Italy and NYC.	• Face mask use was estimated to have avoided >75 000 in Italy (from Apr 6 – May 9) and >66 000 infections in NYC (from Apr 17 - May 9). • While other areas of the world show a linear increase, this study showed that the implementation of the mask policies in Italy and NYC reduced the spread of COVID-19.
Leffler (2020) (37) Ecological study 196 countries Jan-May 2020	The impact of masks on per-capita COVID-19 related mortality was investigated using mortality data from 196 countries up to May 9, 2020.	• Duration of mask-wearing by the public had a negative independent association with mortality (all p<0.001). • In countries with cultural norms or government policies supporting public mask-wearing, per-capita coronavirus mortality increased on average by just 16.2% each week, compared with 61.9% each week in remaining countries.

Abaluck (2020) *preprint* (10) Ecological study Global Feb-Mar 2020	This study analyzes the impact of face masks by considering the relationship between norms of face mask use and COVID-19 spread at the country level. Countries with pre-existing norms that all sick people wear masks were compared to countries that do not, but later required masks for infected individuals, and countries with no mask norm and no official mask recommendation. Countries with at least 5 million people with at least 8 days of data available after the first day with 100 reported cases were included.	• Countries with pre-existing norms that sick people should wear masks (South Korea, Japan, Hong Kong, and Taiwan) have been among the most effective countries in containing the spread of the epidemic. • The average daily growth rate of confirmed cases is 18% in countries with no pre-existing mask norms and 10% in countries with such pre-existing norms. • The average daily growth rate of deaths is 21% in countries with no pre-existing mask norms and 11% in countries with such pre-existing norms. • After adjusting for concurrent interventions, the impact of mask norms (β [SE]) was −0.076 [0.030], p<0.05 for cases, and −0.107 [0.024], p<0.01 for deaths.
Kenyon (2020) *preprint* (38) Ecological study 49 countries Jan-Mar 2020	The association between COVID-19 cases and the national promotion of face masks in public was analyzed, controlling for the age of the epidemic and testing intensity. Only countries with at least 500 cumulative cases and whose first case was reported before Mar 7, 2020 were included. 8/49 countries advocated wearing face masks in public (China, Czechia, Hong Kong, Japan, Singapore, South Korea, Thailand, and Malaysia).	• Results of multivariate analysis show face mask use in public had a negative association with the number of COVID-19 cases/inhabitant (β -326, 95% CI: -601 to -51, P=0.021).
North America (n=13)		
Karaivanov (2020) *preprint* (4)	The impact of NPIs was assessed using publically available data on mask policies in Ontario, other NPIs	• After a 2 week lag, mask policies resulted in a 25-31% weekly reduction in COVID-19 cases.

Ecological study Canada Jul-Aug 2020	in Canada, and the number of COVID-19 cases.	• Mask policies increased mask usage by 30%.
Spiegel (2020) *preprint* (1) Ecological study USA Mar-Oct 2020	This regression analysis looked at the fatality growth due to COVID-19 and the impact of mandatory mask policies across every county in the USA from March to October.	• Mandatory mask policies equate to a 1% lower 4 week and 6 week fatality growth rate compared to no mask policy, $p<0.01$. • Mask policies were effective in every specification of the model and are accompanied by relatively low economic and social costs. This result was both statistically significant and important in magnitude. • Employee mask policies were not consistently protective across all analyses. • Mask recommendations consistently did not have a protective effect on the fatality growth rate.
Shacham (2020) *preprint* (28) Ecological study USA Jun-Sep 2020	This study analyzed the impact of a mask policy implemented in 2 counties of a 5-county metropolitan region on COVID-19 cases over a 3-month period of time.	• County-level mask policies were associated with significantly lower COVID-19 case growth over time compared to neighboring counties that did not implement a mask policy. • Crude modeling with a difference-in-difference indicator showed that after three weeks of mask policy implementation, counties with a mask policy had a daily percent COVID-19 growth rate that was 1.32 times lower (32% decrease) compared to counties without a mask policy. • At 12 weeks post-mask policy implementation, the average daily COVID-19 case growth among counties without a mask policy was 2.42% (±1.92), and was significantly higher than the average daily

		COVID-19 case growth among counties with a mask policy (1.36% (±0.96%)) ($p<0.001$).
Yilmazuday (2020) *preprint* (34) Ecological study USA Feb-Aug 2020	Using a difference in-difference design, county-level data on changes in COVID-19 cases or deaths were analyzed using social interactions measured by Google mobility. Counties were categorized as mask-wearing vs. non-mask-wearing by using Mask-Wearing Survey Data. The impact of mask wearing on the causal relationship between COVID-19 cases and social interactions was subsequently analyzed.	• Adherence to wearing a face mask in the community needs to exceed 75% to reduce COVID-19 cases and deaths. The effects of social interaction on COVID-19 were statistically eliminated when more than 85% of people in a county "always" wore a face mask in public settings.
Matzinger (2020) *preprint* (8) Ecological study USA Mar-Jul 2020	A regression analysis was conducted to assess the impact of NPIs on COVID-19 cases, hospitalizations, and deaths. Mask policies were implemented between Mar-Jul, allowing for an opportunity to evaluate both early and late policies.	• Regression analysis showed that closing schools, closing bars, and wearing masks had major effects on infections, hospitalizations and death rates in the US during the COVID-19 pandemic. • For four states (IL, NJ, MA, MD), a drop in the rates of infections were observed after implementing a mask policy. Decreased rates were followed by a 2-fold drop in hospitalizations and deaths. • Across the dataset, the mask policies occurred at different times and the authors show the rate reductions followed in a predictable manner. Later policies correlated to later inflection points. This supports the evidence that these rate reductions were due to wearing masks as opposed to other potential changes in mobility or behavior. • The early and late mask policies were both effective in reducing COVID-19 infections.

		• The lag time between the implementation of mask policies to a reduction in COVID-19 infections was between 16-23 days. • One exception to the effect of early mask policies was shown in the data from NY which mandated masks after it had already turned its rapidly rising infection numbers into declining ones. The mask policy had no further suppressive effect on infections. However, when NY later opened its economy and infections began to rise, the increase was remarkably lower than those of states that opened without mask policies in place. This suggests continuing the mask policy had an effect when lifting other NPIs.
Kaufman (2020) (39) Ecological study USA Jan-Jul 2020	This study estimated the excess COVID-19 burden in USA states that had an evidence-based reopening strategy, defined as reopening indoor dining rooms after implementing a statewide masking policy, compared to states that lacked an evidence-based reopening strategy, defined as reopening indoor dining rooms before implementing a statewide masking policy.	• An estimated > 50,000 excess deaths were prevented within 6 weeks in 13 states that implemented mask policies prior to reopening. • In states reopening without mask policies, the number of excess cases per 100,000 residents is ten times the number in states with mask policies 8 weeks after reopening (643.1 cases; 95% CI: 406.9-879.2 vs. 62.9 cases; 95% CI: 12.6-113.1). • Excess cases after 6 weeks could have been reduced by 90% from 576,371 to 63,062 and excess deaths reduced by 80% from 22,851 to 4858 had states implemented mask policies prior to reopening.
Yang (2020) *preprint* (31) Ecological study	This study analyzed county level Rt values over time using a mechanistic meta-population model and associated these with county-level characteristics and NPIs such as school closures,	• The estimated impacts of individual interventions were measured during layered intervention strategies and do not estimate the potential impact if done alone.

USA Jan-Jul 2020	daycare closures, banning nursing home visits, stay home orders, and wearing a face mask. With the exception of the mask policy, the closures were confounded by workplace presence which also decreased at the same time as the closures.	• Face mask policies were associated with an 18% reduction in Rt (95% CI: 16-20%).
Chernozhukov (2020) (6) Ecological study USA Mar-Jun 2020	This study uses case data and information on changes to NPIs to assess the impact on the growth rates of confirmed COVID-19 cases and deaths. The face mask policy in this study is mandating face masks for employees. NPIs examined included stay at home orders, business closures, and school closures.	• The results attribute a 9% reduction in the weekly growth rate and a 15% reduction in the weekly death rate with a 14 day lag time to mandating employees wearing masks, $p<0.01$. This was stable across several types of analysis.
Maloney (2020) *preprint* (40) Ecological study USA Mar-Jun 2020	This study used a non-parametric machine learning algorithm to test the hypothesis that mask policies were associated with reductions in new COVID-19 cases. Data on new COVID-19 cases in 38 USA states was analysed in the month before and after the mask policy implementation date.	• All state analysis: The mean overall number of new COVID-19 cases before vs. after the mask policy was 654 (N=1138, SD=1357) vs. 639 (N=1177, SD=975), respectively. 13 states had higher mean case numbers pre vs. post mask policy. • State-wise analysis: With the exception of Georgia and Wyoming, the states with a greater mean pre vs post mask policy achieved statistical significance: strongly to moderately supporting a reduction in COVID-19 cases after implementation of the mask policy in eleven states. • Societal cohesion and close social ties was shown to best predict states where mask policies were successful. They suggest that this represents compliance across different states.
Li (2020) (30)	Analysis of the total infections and daily infections in the top 15	• The analysis finds that despite stay at home orders most states experienced an

Ecological study USA Mar-May 2020	infected USA states was conducted to investigate the impact of NPIs: such as social distancing, stay at home orders and face mask policies (6 states had no face mask orders, 9 states had face mask policies) March 1 to May 18, 2020. Changes in the regression slopes after the implementation of NPIs were measured and compared across states.	upward trend in daily new infections. Eight states experienced a reversed downward trend or slowing trend after face mask policies were introduced. • In contrast, in states where face masks were not mandated the upward trend in cases extended for up to two additional months. • The analysis estimates ~252,000 infections have been avoided across 7 states that introduced mandatory face mask policies with a projected proportion of cases prevented ranging from 3.2% to 48% up to May 18.
Lyu (2020) (7) Ecological study USA Mar-May 2020	This study measured the effects of state government policies for face mask use in the public issued by 15 states (and DC) from Apr 8-May 15, 2020. County-level case data was used from March 31 (seven days before the first state signed a face cover policy) through May 22. Between Apr 17-May 9, 2020, the impact of 20 states mandating that certain employees wear face masks was also assessed.	• There was a significant decline in daily COVID-19 growth rate after mandating face masks in public with the effect increasing over time. • There was a decline in the daily COVID-19 growth rate by 0.9, 1.1, 1.4, 1.7, and 2.0% in 1–5, 6–10, 11–15, 16–20, and 21+ days after implementation of mandatory face mask policies, respectively. • It was estimated that 230,000–450,000 cases may have been averted due to these policies by May 22. • The impact of employee-mandated face mask use was small and not statistically significant.
Yang (2020) *preprint* (5) Ecological study USA	This study used a linear regression accounting for mobility data in NYC to estimate the effectiveness of NPIs for the entire population and by age group.	• Face covering policies resulted in a 6.6% (95% CI: 0.8 - 12.4%) reduction in cases in the first month and a 3.4% reduction (95% CI: -1.9 - 8.6%) across the entire eight weeks of lockdown. • This effect varied by age: 20.8% (95% CI: -0.1-41.6%) for 65-74 year olds and 20.8% (95% CI: -0.9 – 42.5%) for 75+ year olds

Apr 2020		during the first month and remained at similar levels afterwards. For 25-44 and 45-64 year olds the effectiveness was 4.5% (95% CI: -0.6 – 9.7%) and 8.1% (95% CI: -0.1 – 16.1%) in the first month, respectively; however, it reduced substantially afterwards, likely due to reversed risk behavior.
Xu (2020) (41) Ecological study USA Mar-Apr 2020	In this study, the associations of stay-at-home order (SAHO) and face masking recommendation with COVID-19 epidemics were analyzed. The temporal trends in daily new cases and deaths COVID-19 cases and Rt were modeled. The CDC recommended the use of face masks on Apr 3, 2020.	• The overall slope change of daily new deaths face-masking were −0.13 (95% CI: −0.25 to −0.07). • The overall slope change of daily new cases attributable to face-masking were −0.10 (95% CI: −0.18 to −0.08).
Australia (n=1)		
Scott (2020) *preprint* (11) Ecological study Australia Jul-Aug 2020	Due to a resurgence of COVID-19 in Melbourne, a mandatory mask policy was implemented on Jul 22 creating a natural experiment to assess the impact of the policy on the epidemic growth rate as the policy introduction occurred in the absence of other changes to restrictions.	• The introduction of a mandatory mask policy was associated with an estimated 23% reduction in Rt, from 1.18 to 0.91. • The shift in epidemic growth was observed eight days after the policy was introduced which is consistent with the incubation time of COVID-19 plus the time needed to test and report new cases. • Analysis of images of people in public spaces showed mask usage rose from approximately 43% to 97% and survey data found that before policy introduction, 44% of participants reported "often" or "always" wearing a mask; and after, 100% reported "always" doing so.
Europe (n=4)		
Sruthi (2020) *preprint* (33) Ecological study	This study aimed to develop a systematic relation between the degrees of NPIs implemented by the 26 cantons in Switzerland and	• The mask wearing policy on public transport and in secondary schools contributed to a 0.025 (CI: 0.018-0.03)

Switzerland Mar-Sep 2020	their respective contributions to Rt. The mask wearing policy was only on public transportation and in secondary schools.	reduction in Rt compared to baseline with no policies. • When analyzed separately, a reduction of Rt 0.011 (CI: 0.008-0.0127) and 0.0139 (CI: 0.0132-0.0144) was estimated for the use of masks in secondary school and on public transport, respectively. • Some places added mandatory masks in shops, but no further reduction in Rt was detected.
Mergel (2020) *preprint* (42) Ecological study Germany Apr-Jul 2020	In this study, the impact of a face mask policy on the daily COVID-19 Rt and fatality rate was investigated. The study also looked at the implementation/lifting of NPIs (mass gathering prohibited, public life restricted, private contacts restricted, face masks in public spaces and easing of lockdown).	• In this study mask wearing was implemented April 27 after all the other restrictions. • It was not possible to separate the potential positive effect of spring and summer on the trajectory of the pandemic from the mask wearing policy that was implemented. • They did not detect an impact on Rt attributable to the mask policy. • During the time the mask policy was implemented, cases became less lethal from 7% on Apr 27 to 1% in July.
Pedersen (2020) *preprint* (43) Ecological study Italy Feb-Jul 2020	To determine which public health measures altered disease dynamics, change points in COVID-19 dynamics were estimated using regional and national data. A change point is an identified time point where there is a shift in the number of daily confirmed cases from the introduction of a public intervention 7–11 days prior.	• In Veneto, a change point was identified on Apr 21 (95% CI: 14 - 28), which corresponds to the policy of mandatory face mask use on Apr 14. • In Tuscany, a change point was identified on Apr 16 (95% CI: 8 – 24), which corresponds to face mask distribution on Apr 7. • The change points in regional COVID-19 cases correlate well with face mask policies.
Mitze (2020) *unpublished* (27)	Using epidemic data from Germany, a synthetic control method was used to assess the	• Ten days after masks became compulsory in Germany, the cumulative number of

Ecological study Germany Jan-May 2020	effect of face masks on the spread of COVID-19. The city of Jena implemented a mandatory face mask policy on Apr 6, 2020. Jena was compared to a synthetic control area that closely followed the COVID-19 trend before the introduction of mandatory masks in Jena.	registered COVID-19 cases were reduced between 2.3-13%. • After the face mask policy, the daily growth rate of reported infections decreased by 18.94%. After taking the treatment effect for larger cities into account, authors conclude there was a reduction in the growth rate of infections by around 40%.
Middle East (n=1)		
Saki (2020) *preprint* (44) Ecological study Iran Jun-Jul 2020	This study investigated the effects of implementing a social distancing policy, and the impact of its lifting, as well as the effects of face mask policies on the temporal trend of new COVID-19 cases. Data was collected both two weeks before and after the implementation of each policy.	• Prior to the implementation of the policy of wearing masks in the community, there were approximately 2491.97 new daily confirmed cases and an upward slope ($p<0.001$). • With the implementation of the face mask policy, the trend in the number of daily confirmed cases decreased that caused a change in the slope of the epidemic curve -25.84 ($p<0.001$).

CI = confidence interval, HR = hazard ratio, NPI = non-pharmaceutical intervention, NYC = New York City, OR = odds ratio, Rt = effective reproduction number, SE = standard error

SYNTHESIS RESEARCH ASSESSING EFFECTIVENESS

Six synthesis research reviews were identified on the protective effect of the use of face masks in community settings, including four systematic reviews and two rapid reviews (Table 3). The earliest review was conducted in April 2020. Two of the later reviews included studies published up to early October. A progression of evidence from April to October is discernable in these reviews. Many of the studies in the reviews are considered relevant to this rapid review and are also included in the evidence tables above.

Table 3. Synthesis research on the use of face masks to prevent COVID-19 in community settings (n=6)

STUDY	METHODS	KEY OUTCOMES
Systematic reviews (n=4)		
Li (2020) *preprint* (45) Systematic review and meta-analysis	The purpose of this review was to evaluate the effectiveness of using face masks to protect from SARS-CoV-2 infection. Six case-control studies were included, five on	• Overall, wearing a mask significantly reduced the risk of SARS-CoV-2 infection (MA OR 0.38, 95% CI: 0.21-0.69, I^2= 54.1%).

China, India, Thailand, USA Oct 2020	healthcare workers and one on the general population. Review contains literature up until Oct 2020. AMSTAR: high quality Note: Meta-analysis (MA) was conducted. Where I^2, a measure of between study heterogeneity, was > 50% a random effects model was used, otherwise a fixed-effect model was used.	• In a subgroup analysis, healthcare workers wearing a mask had a reduced risk of COVID-19 by ~70% (MA OR 0.29, 95% CI: 0.18-0.44, I^2=11%). • For the single study on the general population, wearing a mask reduced the risk of SARS-CoV-2 infection by ~28% (OR 0.72, 95% CI: 0.46-1.12) and after adjusting for confounders (aOR 0.23, 95% CI: 0.09-0.59) (18). • Studies in China showed a higher protective effect than other countries: China MA OR 0.21, 95% CI: 0.09-0.53, I^2 =26.1% vs. other countries MA OR 0.55, 95% CI: 0.32-0.95, I^2 = 39.3%.
Coclite (2020) (46) Systematic review and meta-analysis China, Hong Kong, Iran, Israel, Italy, Japan, Malaysia, Netherlands, Saudi Arabia, South Korea, Taiwan, UK, USA Apr 2020	This review aimed to summarize the evidence on the effectiveness of face mask use in the community to reduce the spread of disease. Thirty-five studies were included (3 RCTs, 13 predictive models, 10 observation studies, and 9 laboratory experiments). Seven predictive models and one laboratory study were specific to SARS-CoV-2. Review contains literature up until Apr 22, 2020. AMSTAR: high quality	• No observational studies on wearing face masks in the community for reducing the spread of COVID-19 were identified. • Mathematical models indicated a decrease in mortality when the population mask coverage was near-universal, regardless of mask efficacy. • All types of masks might reduce aerosol exposure. However, personal respirators were more efficient than surgical masks, which were more efficient than home-made masks. • RCTs showed a trend towards the protective effect of wearing face masks versus no mask (aOR 0.90, 95% CI: 0.78-1.05), however these results were not significant. Similar findings were reported in observational studies.
Chou (2020) (47) Chou (2020) (update 1) (48)	The effectiveness of N95, surgical, and cloth masks in community and health care settings for preventing respiratory virus infections was	• In the first version and second update of this review, no studies evaluating masks for preventions of SARS-CoV-2 infections in community settings were identified.

Chou (2020) (update 2) (49) Chou (2020) (update 3) (50) Living systematic review China, Thailand, USA Oct 2020	assessed in this living systematic review. Search dates: Original search: 2002 – Jun 2, 2020 Update 1: Jun 2 – July 2, 2020 Update 2: July 3 – Aug 2, 2020 Update 3: Aug 3 – Oct 2, 2020 AMSTAR: moderate-high quality (no *a priori* protocol, quality assessment was not conducted with a formal instrument, sub-optimal reporting e.g. unsure if double reviewers for quality assessment).	• The first update identified a cohort study of 124 households with an index SARS-CoV-2 case and 355 uninfected household contacts. In households where masks were used by at least one family member (including the index case) before the development of symptoms were associated with decreased risk for incident infections (aOR 0.21, 95% CI: 0.06-0.79). There was no association between mask use after illness onset in the index case and risk for SARS-CoV-2 infections in family members (17). • The third update identified a case control study in Thailand. Wearing a mask all of the time versus no use was associated with decreased risk for SARS-CoV-2 infection (aOR 0.23, 95% CI: 0.09-0.60), whereas inconsistent use was not associated with decreased risk (aOR 0.87, 95% CI: 0.41-1.84). Mask type (medical mask only, nonmedical mask only, or both) was not independently associated with risk for SARS-CoV-2 infection (p = 0.54) (18).
Chaabna (2020) (51) Systematic review and meta-analysis Australia, China, France, Germany, Hong Kong, Thailand, USA May 2020	The evidence on the effectiveness of cloth and medical face masks for preventing transmission of respiratory infections in community settings was assessed in this review. Twelve studies were included, only one on SARS-CoV-2. Review contains literature up until May 12, 2020. AMSTAR: low quality (missing an *a priori* protocol, double reviewers, only searched two databases, no formal quality assessment).	• No primary studies on cloth face mask effectiveness to prevent respiratory infection transmission were identified. • The meta-analysis identified that medical face mask use significantly reduced the risk of transmitting respiratory infections (pooled OR=0.66, 95% CI: 0.54-0.81). • One study specific to SARS-CoV-2 was identified. This retrospective cohort study demonstrated medical face masks are effective in reducing SARS-CoV-2 transmission when used before those infected develop symptoms (17).

Rapid reviews (n=2)		
Warkentin (2020) *unpublished* (52) Rapid Review Canada, China, Germany, Israel, Japan, South Africa, Thailand, Uganda, UK, USA Aug 2020	This rapid review aimed to assess the evidence on the impact of community mask use on the susceptibility to and transmission of COVID-19, and how mask use compliance affects mask effectiveness. Thirty-one studies were included (21 primary and 10 models on the effectiveness of masks and 5 on mask compliance). Of the 17 primary studies on the effectiveness of masks, there were 9 ecological studies, 1 cohort study, 1 case-control study, and 6 case report/epi investigations. Literature search included Dec 2019 – Aug 2020. AMSTAR: low quality (missing an *a priori* protocol, double reviewers, and quality assessment).	• There was insufficient evidence to quantify the effectiveness of face mask use. • Overall, mask use within the community reduced the number of COVID-19 cases within a population. • Case reports consistently reported fewer secondary cases when index cases and/or their contacts wore masks. • Modelling studies found that wearing a mask, in conjunction with other mitigation strategies, had the potential to reduce mortality due to COVID-19 and avert a resurgence of cases in places where lockdown measures had already reduced the number of cases. • There were no studies that investigated the impact of face mask use in schools.
The Royal Society (2020) *unpublished* (53) Rapid Review China Jun 2020	This rapid review aimed to evaluate the effectiveness of cloth masks and face coverings for the general public and in health-care settings. This included an international comparison of the timing and introduction of face mask policies in relation to COVID-19. Only one study on SARS-CoV-2 was included. Review contains literature up until Jun 26, 2020. AMSTAR rating: low quality (there are little details on the process of conducting the review: search, screening, assessment or extraction of data/analysis).	• Results revealed that no systematic review and meta-analysis has yet been conducted on the effectiveness of other types of cloth masks beyond surgical masks and N95 respirators. • Empirical and experimental evidence on community mask wearing and/or cloth masks is limited. • One study specific to SARS-CoV-2 was identified. This retrospective cohort study demonstrated medical face masks are effective in reducing SARS-CoV-2 transmission when used before those infected develop symptoms (17). • The meta-analysis was based on non-SARS-CoV-2 literature in the healthcare setting indicated protection afforded by

		gauze or cloth masks (RR=0.46; 95% CI: 0.22-0.97; N=746) and paper masks (RR=0.61; 95% CI: 0.41- 0.90; N=166) compared to no mask.

aOR = adjusted odds ratio, CI = confidence interval, MA = meta analysis, RCT = randomized control trial

Methods

A daily scan of the literature (published and pre-published) is conducted by the Knowledge Synthesis team in the Emerging Science Group, Public Health Agency of Canada. The scan has compiled COVID-19 literature since the beginning of the outbreak and is updated daily. Searches to retrieve relevant COVID-19 literature are conducted in Pubmed, Scopus, BioRxiv, MedRxiv, ArXiv, SSRN, Research Square, and COVID-19 information centers run by Lancet, BMJ, Elsevier, Nature and Wiley. The cumulative scan results are maintained in a Refworks database and an excel list that can be searched. Details on this search strategy are available upon request. From this database and excel list, article titles and summaries will be systematically searched for the following key words: mask* OR (face AND cover*). Each potentially relevant reference was analyzed to confirm its relevance and data was extracted into the review. This review contains research published up until November 19, 2020.

Prepared by: Tricia Corrin, Lisa Waddell, and Chatura Prematunge. Emerging Science Group, PHAC.

Preuve émergente sur la COVID-19

Revue rapide sur les effets physiologiques du port du couvre-visage

Introduction

Quelles sont les données probantes sur les changements physiologiques associés au port d'un couvre-visage? Y a-t-il des preuves que le port d'un couvre-visage peut avoir des effets néfastes sur les personnes ayant des problèmes médicaux?

De nombreux organismes de santé publique à l'échelle mondiale, comme l'Organisation mondiale de la Santé, recommandent le port d'un couvre-visage dans les espaces publics pour se protéger contre la COVID-19. Des préoccupations ont été soulevées au sujet du port du couvre-visage dans certains contextes ou par des personnes ayant certains problèmes de santé. La revue rapide porte donc sur les effets physiologiques du port d'un couvre-visage sur les systèmes respiratoire et cardiovasculaire, et inclut les différences statistiquement significatives signalées. Les réactions dermatologiques et psychologiques au port d'un couvre-visage ne sont pas incluses dans cette revue. Elles pourraient cependant être traitées comme un sujet distinct, puisqu'il s'agit d'effets liés au port d'un couvre-visage (1). Cette revue rapide résume la documentation disponible jusqu'au 2 décembre 2020 sur les changements physiologiques principalement liés aux systèmes respiratoires et cardiovasculaires découlant du port d'un couvre-visage, effets qui peuvent se produire tant dans les populations en santé que chez celles qui ont des problèmes médicaux.

Points clés

- Vingt articles ont été recensés, dont quinze études sur les réactions physiologiques associées au port du couvre-visage, une revue et quatre documents d'orientation. La majorité des études ont comparé les effets physiologiques associés au port d'un masque N95 ou d'un masque chirurgical. Seules deux études ont inclus des masques non médicaux (voir l'annexe pour obtenir des renseignements sur les types de masques). Ces sujets ont été étudiés dans différentes populations, soit des volontaires sains (n = 8), des travailleurs de la santé (n = 2), des femmes enceintes (n = 2) et des personnes ayant des problèmes de santé (n = 3).
- Huit études ont évalué le port d'un couvre-visage chez des volontaires en santé. Deux études portaient uniquement sur des activités sédentaires, cinq comprenaient une gamme d'activités allant des exercices légers (p. ex., marcher à un MET de 3 à 5) à intenses, alors qu'une autre a évalué les répercussions du port du couvre-visage pour des pilotes volant à une altitude de 1 524 m (5 000 pi).

  Limites :

  - Les huit études sur les volontaires sains comportaient des échantillons de petite taille, avec une moyenne de 12 participants (83 volontaires sains au total et 32 pilotes). Ces études comprenaient des

groupes de participants homogènes, p. ex., des étudiants de niveau collégial ou uniquement des hommes. Leur durée était souvent courte et ne reflétait donc pas l'incidence potentiellement associée au port d'un couvre-visage pendant une longue période. La plupart des études ont effectué des analyses pour établir la signification statistique de deux mesures ou plus, mesures qui sont indiquées dans le rapport comme des résultats significatifs. Comme les auteurs ont rarement discuté de la signification clinique des résultats présentés, les résultats des études inclus dans cette revue sont donc préliminaires. Il faudra effectuer plus de recherches avec de plus grands échantillons et des échantillons plus représentatifs pour évaluer la possibilité de généraliser ces résultats.

Masques N95 :

- Six études réalisées sur des volontaires sains indiquent que comparativement à l'absence de masque, les masques N95 ont grandement augmenté la résistance respiratoire, réduit le volume d'échange d'air, provoqué une augmentation de la fréquence cardiaque et une réduction du CO_2 en fin d'expiration et diminué la saturation en oxygène. Les symptômes associés à ces changements physiologiques incluaient une dyspnée (difficulté à respirer), des étourdissements et de la difficulté à se concentrer.
- Cinq études ont examiné l'effet du masque chez des volontaires sains qui effectuaient des exercices légers à intenses. Lorsque le port d'un masque N95 augmentait l'intensité de l'exercice, cela a eu de plus grandes répercussions sur certains paramètres physiologiques, notamment une augmentation du CO_2 en fin d'expiration, ainsi qu'une diminution du débit ventilatoire et du VO_{2max} global que lorsque les exercices étaient faits sans masque.
- Une étude a évalué les répercussions physiologiques globales des différents types de masques et classé ainsi les masques, des répercussions les plus fortes aux plus faibles : KN95 > masques chirurgicaux > masques médicaux, masques avec éponge et masques civils jetables > gaze et aucun masque.
- Quatre études ont comparé les répercussions des masques N95 et des masques chirurgicaux et déterminé que les répercussions physiologiques les plus importantes étaient associées aux masques N95. Une étude n'a pas jugé que ces différences étaient significatives, deux études les ont vues comme étant significatives pour certains paramètres, soit la fréquence cardiaque (n = une étude sur deux), le débit ventilatoire et le VO_{2max} (n = une étude sur deux), sans cependant les indiquer, alors que la quatrième présentait des données brutes et des résumés graphiques.

Masques chirurgicaux :

- Quatre études (n = 63 observations) ont examiné les effets des masques chirurgicaux comparativement à l'absence de masque et indiquent que ces masques entraînent différentes répercussions, soit une fréquence cardiaque élevée (n = 3) et une baisse de la saturation du sang en oxygène (n = 1) comparativement aux données obtenues en l'absence de masque, tant au repos que pendant l'exercice. Les masques chirurgicaux ont considérablement réduit le débit ventilatoire, mais pas le VO_{2max} À la fin d'une séance d'entraînement intense, le CO_2 de fin d'expiration avait

statistiquement augmenté avec un masque chirurgical comparativement au résultat obtenu sans masque. Le niveau d'effort perçu était également plus élevé chez les personnes qui portaient un masque chirurgical (n = 2). Les symptômes n'ont pas été mentionnés aussi fréquemment pour les masques chirurgicaux que pour les masques N95, mais incluaient tout de même de la dyspnée, des vertiges et des difficultés de concentration.

- Des pilotes qui portaient un masque en tissu chirurgical ou non médical et ont pris part à un exercice de simulation de 90 minutes à 1 524 m (5 000 pi) n'ont vu aucune différence dans leur rythme cardiaque, leur CO_2 de fin d'expiration, leur fréquence respiratoire ou leurs niveaux d'oxygène (2).

Masques non médicaux :

- Deux études ont porté sur des couvre-visages non médicaux en tissu, en éponge, en gaze ou décrits comme des masques civils jetables. Dans ces études, les répercussions physiologiques des différents matériaux composant les masques n'étaient pas significativement différentes de celles des masques chirurgicaux (2, 3).

- Des études sur les travailleurs de la santé (n = 2) ont été menées afin de comprendre l'incidence du port d'un masque N95 ou chirurgical lors de l'exécution de différentes tâches dans le cadre de leur profession.
  - Une enquête menée auprès de 250 travailleurs de la santé portant des masques chirurgicaux ou N95 plus de quatre heures par jour a révélé que 58,2 % d'entre eux ($P < 0,01$) avaient de la difficulté à respirer à l'effort. Parmi les autres symptômes, citons une transpiration excessive autour de la bouche (67,6 %), une irritation de la peau (39 %) et une douleur derrière l'oreille (45,2 %).
  - Les changements hémodynamiques cérébraux associés au port d'un masque N95 ont été évalués chez 154 travailleurs de la santé qui ont déclaré avoir des maux de tête découlant du port d'un masque N95. Cinq minutes après avoir mis le masque N95, on a remarqué une augmentation importante du débit moyen et du CO_2 en fin d'expiration. L'ajout d'un appareil de protection respiratoire à épuration d'air motorisé (APR) a cependant permis de ramener ces mesures à des niveaux normaux.
- Des femmes enceintes, saines, qui en étaient entre 13 et 35 semaines de gestation, ont également pris part à deux études (n = 2) afin de connaître l'incidence du port du masque N95.
  - Les masques N95 portés par 42 femmes enceintes effectuant un travail physique de routine (équivalent à un METS de 3) ont entraîné une diminution importante de l'air courant, du débit ventilatoire et de la consommation d'oxygène, une augmentation de la pression partielle transcutanée en raison du CO_2, ainsi que des résultats contradictoires pour la fréquence respiratoire. Aucune des deux études n'a cependant indiqué de changement dans la fréquence cardiaque maternelle, la fréquence cardiaque fœtale ou la saturation en oxygène comparativement à l'absence de masque.
  - Comparer les résultats des femmes enceintes et des femmes non enceintes n'a pas permis de voir de différences dans les répercussions physiologiques associées du port d'un masque N95 (4).

- Trois études ont évalué certains problèmes médicaux, y compris la maladie pulmonaire obstructive chronique (MPOC) (n = 2), l'asthme (n = 2) et la rhinite chronique (n = 1). Les informations portant sur d'autres conditions médicales n'ont pas été mentionnées.
    - Dans une étude sur 97 patients atteints de MPOC qui ont porté des masques N95, 7 % n'ont pas pu le garder en raison de dyspnée, de maux de tête et d'étourdissements. Il s'agissait en général de personnes atteintes d'un MPOC plus grave. Pour les patients qui ont pu terminer l'étude, les résultats indiquaient une augmentation de la fréquence respiratoire, du rythme cardiaque, de la pCO_2 en fin d'expiration et une diminution de la saturation en oxygène comparativement aux données obtenues au repos, sans masque. Les différences observées entre les résultats obtenus avec un masque N95 et sans masque se sont également accentuées pendant un exercice léger (marche). Une deuxième étude portant sur 14 patients atteints d'une MPOC légère a fait état d'une diminution du volume ventilatoire et d'un pourcentage de VEMS inférieur au volume prédit lorsque les patients portaient un masque N95 ou un demi-masque.
    - Les 42 personnes atteintes d'asthme ont, quant à elles, vu une diminution du volume respiratoire et un pourcentage de VEMS inférieur à celui qui avait été prédit avec un masque N95 ou un demi-masque, le demi-masque ayant eu une incidence légèrement moins importante. De même, la capacité respiratoire maximale a été considérablement réduite chez trois asthmatiques qui portaient un masque chirurgical.
    - Parmi les 17 personnes atteintes de rhinite chronique, les répercussions du port d'un masque N95 ou d'un demi-masque étaient similaires à celles observées chez les volontaires sains.
- Les personnes qui portent un masque doivent être conscientes de leur effort et de leur fréquence cardiaque, puisque les études montrent que le port d'un masque augmente la charge cardio-respiratoire et que les répercussions liées au masque augmentent avec l'exercice. Elles doivent s'assurer que leur fréquence cardiaque reste inférieure à 150 battements/min ou à 70 % de la fréquence cardiaque maximale selon leur âge.
- Les documents d'orientation établis par le Canada, les États-Unis et l'Organisation mondiale de la Santé (OMS) sur l'utilisation des masques non médicaux dans la collectivité recommandent que les personnes incapables de retirer leur masque sans aide n'en portent pas en raison du risque de suffocation. Cela inclut les enfants de moins de deux ans et toute personne inconsciente, handicapée ou qui a de la difficulté à respirer. Les lignes directrices de l'OMS précisent également que les masques ne doivent pas être portés à des fins de contrôle à la source pour empêcher la transmission des virus provenant d'un enfant de moins de 5 ans atteint de la COVID-19.
- La Société canadienne de thoracologie et Asthme Canada indiquent que les personnes atteintes d'un problème pulmonaire sous-jacent devraient être capables de porter un couvre-visage non médical, mais devraient consulter un professionnel de la santé si cela leur pose des problèmes.
- Les lignes directrices actuelles de l'OMS sur le port de couvre-visage dans la collectivité indiquent que ceux-ci devraient pouvoir être retirés par toute personne qui a de la difficulté à respirer.

Vue d'ensemble des éléments de preuve

Quinze articles portant sur les changements physiologiques respiratoires et cardiovasculaires associés au port d'un masque ont été recensés et inclus dans cette revue rapide. La plupart étaient des rapports d'études quasi expérimentales utilisant un modèle en chassé-croisé dans lequel les personnes exerçaient un autocontrôle. Bon nombre des études portaient sur des populations saines et comportaient de petits échantillons formés de populations homogènes (p. ex., des étudiants de niveau collégial ou uniquement des hommes), alors que d'autres incluaient des travailleurs de la santé (n = 1) et des femmes enceintes (n = 2). Il n'y a eu que trois études portant spécifiquement sur le port du masque par des personnes ayant des problèmes médicaux, soit la MPOC (n = 2) et l'asthme (n = 2). Bien que ces études aient été bien exécutées et qu'elles aient utilisé des mesures objectives pour établir leurs résultats, elles comportaient de petits échantillons et des échantillons homogènes. Il est donc probable qu'elles comportent un biais dans la sélection, mais cela n'a pas pu être évalué dans la plupart des études. Les résultats de ces études ne devraient donc pas être généralisés sans recherches supplémentaires. Une étude portant sur les travailleurs de la santé comportait une enquête transversale axée sur les répercussions autodéclarées des masques et des couvre-visage. Même si elle comprenait un échantillon de grande taille formé de travailleurs de la santé œuvrant dans un hôpital et a utilisé un questionnaire fondé sur des recherches formatives, la nature autodéclarée des résultats risque fort d'entraîner de nombreux biais.

Il faudrait donc que d'autres recherches soient effectuées avec de plus grands échantillons, qu'elles portent sur tous les types de masques et incluent également l'utilisation prolongée des masques ou des couvre-visages. De futures recherches pourraient changer notre compréhension des répercussions associées au port à court et à long terme du masque ou du couvre-visage et nous permettre de savoir précisément quelles personnes ne devraient pas en porter.

TABLE DES MATIÈRES

ÉLÉMENTS PROBANTS SUR LES EFFETS PHYSIOLOGIQUES DU PORT DU MASQUE

La réaction physiologique au port du masque a été évaluée dans 15 études portant sur différentes populations, soit des bénévoles sains, des travailleurs de la santé, des femmes enceintes, des pilotes instructeurs et des personnes atteintes de MPOC, d'asthme ou de rhinite chronique (tableau 1). Un seul

examen, jugé de très basse qualité selon AMSTAR, porte sur la réponse physiologique à l'obstruction du débit d'air causée par le port d'un masque et inclut une interprétation de ces répercussions (5). Les résultats physiologiques évalués pour chacune des études variaient d'une étude à l'autre et sont présentés dans le tableau lorsqu'ils ont été évalués. Il s'agit notamment des paramètres respiratoires (p. ex., volume total inhalé/expiré, fréquence respiratoire), de la fonction respiratoire (p. ex., niveaux d'oxygène et de CO_2), de la fréquence cardiaque, de la tension artérielle et des changements hémodynamiques cérébraux.

Parmi les huit études portant sur des volontaires sains, deux incluaient uniquement des activités sédentaires alors que cinq comprenaient une gamme d'activités allant des exercices légers (p. ex., marcher à un MET de 3 à 5) à des exercices intenses. Ces études ont donc examiné les résultats de 83 volontaires sains (taille moyenne de l'étude : 12). Une seule étude a évalué les répercussions du port du masque chez les pilotes (n = 32) lors d'une simulation de vol à 1 524 m (5 000 pi).

Six études réalisées sur des volontaires sains ont évalué le port des masques N95. Les résultats obtenus indiquaient notamment que comparativement à l'absence de masque, ce type de masque avait grandement augmenté la résistance respiratoire et réduit le volume d'échange d'air, en plus d'avoir provoqué une augmentation de la fréquence cardiaque et une réduction du CO_2 en fin d'expiration, ainsi qu'une diminution de la saturation en oxygène. Les symptômes associés aux changements physiologiques signalés comprenaient de la dyspnée (difficulté à respirer), des étourdissements et de la difficulté à se concentrer. Cinq études ont également examiné les répercussions lorsque les volontaires faisaient des exercices légers à intenses avec un masque. Les résultats ont démontré de plus grandes répercussions sur certains paramètres physiologiques, y compris une augmentation du CO_2 en fin d'expiration et une diminution du débit ventilatoire et du VO_{2max} global que lorsque ces exercices étaient faits sans masque.

Comparant les répercussions physiologiques globales de différents types de masques ou couvre-visage chez des volontaires sains, une étude a évalué les répercussions physiologiques globales de différents types de masques et classé ainsi les masques (des répercussions les plus fortes aux plus faibles) : KN95 > masques chirurgicaux > masques médicaux, masques avec éponge et masques civils jetables > gaze et aucun masque. Quatre autres études ont comparé les masques N95 aux masques chirurgicaux. L'une d'elles a notamment indiqué des répercussions moins fortes même si les différences physiologiques n'étaient pas statistiquement différentes, alors que deux autres ont mentionné que ces différences étaient significatives pour certains paramètres, soit la fréquence cardiaque (n = une étude sur deux), le débit ventilatoire et le VO_{2max} (n = une étude sur deux), mais sans les indiquer, alors que la quatrième présentait des données brutes et des résumés graphiques.

Comparativement à l'absence de masque, le port d'un masque chirurgical par des volontaires (n = 4) a révélé une fréquence cardiaque élevée (n = 3) et une baisse de la saturation en oxygène du sang (n = 1) au repos ou à l'effort. Les masques chirurgicaux ont considérablement réduit le débit ventilatoire, mais pas le VO_{2max} À la fin d'une séance d'entraînement intense, le CO_2 de fin d'expiration avait augmenté de manière importante avec un masque chirurgical comparativement au niveau observé sans masque. Le niveau d'effort perçu était également plus élevé avec un masque chirurgical (n = 2) que sans masque. Des symptômes comme de la

dyspnée, des étourdissements et de la difficulté à se concentrer ont cependant été signalés moins fréquemment avec les masques chirurgicaux qu'avec pour les masques N95.

Les masques non médicaux n'ont été examinés que dans deux études réalisées sur des volontaires sains. Ainsi, dans une étude, des pilotes qui portaient un masque en tissu chirurgical ou non médical et ont pris part à un exercice de simulation de 90 minutes à 1 524 m (5 000 pi) n'ont vu aucune différence dans leur rythme cardiaque, leur CO_2 de fin d'expiration, leur fréquence respiratoire ou leurs niveaux d'oxygène (2). La deuxième étude a, quant à elle, comparé des masques non médicaux faits d'éponge ou de gaze ou décrits comme des masques civils jetables. Les résultats sont présentés dans des graphiques et les répercussions du port de ces masques se trouvent entre les résultats associés au port du masque chirurgical et à ceux qui ont été obtenus sans masque (3).

Des études portant sur les travailleurs de la santé visaient à comprendre l'incidence du port d'un masque N95 ou chirurgical lors de l'exécution de différentes tâches dans le cadre de leur profession. Ainsi, une enquête menée auprès de 250 travailleurs de la santé portant des masques chirurgicaux ou N95 plus de quatre heures par jour a révélé que 58,2 % d'entre eux ($P < 0,01$) avaient de la difficulté à respirer à l'effort. Parmi les autres symptômes, citons une transpiration excessive autour de la bouche (67,6 %), une irritation de la peau (39 %) et une douleur derrière l'oreille (45,2 %). Une deuxième étude portait sur les changements hémodynamiques cérébraux associés au port d'un masque N95 chez les travailleurs de la santé qui ont signalé des maux de tête associés à l'utilisation d'un masque. On a remarqué une augmentation importante du débit moyen et du CO_2 en fin d'expiration cinq minutes après que les travailleurs aient mis leur masque N95. L'ajout d'un appareil de protection respiratoire à épuration d'air motorisé a cependant permis de ramener ces mesures à des niveaux normaux.

Des femmes enceintes, saines, entre 13 et 35 semaines de gestation ont également été évaluées afin de connaître l'incidence du port du masque N95. Les deux études qui ont porté sur cet échantillon ont évalué les répercussions du port du masque N95 lorsque ces femmes effectuaient un travail physique de routine (équivalent à un METS de 3). Les résultats obtenus ont indiqué une diminution importante de l'air courant, du débit ventilatoire et de la consommation d'oxygène, une augmentation de la pression partielle transcutanée en raison du CO2, ainsi que des résultats contradictoires pour la fréquence respiratoire. Aucune des études n'a cependant indiqué de changement dans la fréquence cardiaque maternelle, la fréquence cardiaque fœtale ou la saturation en oxygène. Une des études qui comparait les résultats des femmes enceintes à ceux des femmes non enceintes n'a pas trouvé de différences dans les répercussions physiologiques associées du port d'un masque N95 (4).

Trois études ont évalué certains problèmes médicaux, y compris la maladie pulmonaire obstructive chronique (MPOC) ($n = 2$), l'asthme ($n = 2$) et la rhinite chronique ($n = 1$). Les informations portant sur d'autres conditions médicales n'ont pas été mentionnées. Une étude a également évalué le port du masque N95 par 97 patients atteints de MPOC. Parmi les personnes évaluées, 7 % ont été incapables de le garder en raison de dyspnée, de maux de tête et d'étourdissements. Il s'agissait en général de personnes atteintes d'un MPOC plus grave. Les patients qui ont pu terminer l'étude ont, quant à eux, vu une augmentation de la fréquence respiratoire, du rythme cardiaque, de la pCO_2 en fin d'expiration et une diminution de la saturation en

oxygène. L'exercice léger (la marche) a également eu des répercussions sur ces différents paramètres. Une deuxième étude portant sur des patients atteints d'une MPOC légère a fait état d'une diminution du volume ventilatoire et d'un pourcentage de VEMS inférieur à celui obtenu sans masque et avec un masque N95 ou un demi-masque. Les personnes atteintes d'asthme ont, quant à elles, vu une diminution du volume respiratoire et un pourcentage de VEMS inférieur à celui qui avait été prédit avec un masque N95 ou un demi-masque, le demi-masque ayant eu des répercussions légèrement moins importantes. De même, la capacité respiratoire maximale a été considérablement réduite chez les asthmatiques qui portaient un masque chirurgical. Le port du masque N95 ou du demi-masque n'a eu, quant à lui, aucun effet significatif pour les personnes atteintes de rhinite chronique.

Les faiblesses globales en ce qui concerne les preuves présentées incluent la petite taille des échantillons, la diversité limitée des échantillons et le fait que les évaluations physiologiques aient uniquement été effectuées après une courte période de temps avec le masque. Ces différents éléments limitent la généralisabilité des conclusions et empêchent de les extrapoler aux situations dans lesquelles le masque doit être porté pendant plus de quatre heures. Puisque les auteurs ont rarement discuté de l'importance clinique des résultats déclarés, même si ces résultats ont permis d'obtenir une certaine importance statistique, l'importance clinique qui en découle pourrait différer.

Tableau 1. Preuves des effets physiologiques associées au port de masques N95, de masques chirurgicaux ou de couvre-visage non médicaux (n = 15)

RÉFÉRENCE	DESCRIPTION DE L'ÉTUDE	RÉSULTATS PERTINENTS
Volontaires sains (n = 8)		
Liu 2020 (3) Étude quasi-expérimentale Chine Mai 2020	Douze étudiants sains ont reçu un masque chirurgical, un masque médical KN95, un masque avec éponge, un masque en gaze ou un masque civil jetable qu'ils devaient porter pendant une centaine de minutes alors qu'ils étaient assis et lisaient. Ils ont ensuite rempli un questionnaire et différentes mesures physiologiques ont été prises.	• Deux éléments ont ensuite été utilisés et ont permis d'obtenir différents résultats, y compris des votes de sensation thermique et des symptômes comme des étourdissements, de la difficulté à se concentrer ou à réfléchir, l'évanouissement et la difficulté à respirer, ainsi que la peau et la bouche sèches. Les effets ressentis qu'ont ressentis les étudiants qui portaient un masque N95 étaient plus prononcés que chez ceux qui avaient un masque chirurgical ou non chirurgical, mais tous ont obtenu des résultats plus élevés ($p < 0,05$) que s'ils n'avaient pas porté de masque. • Le port du masque a également eu différentes répercussions, y compris une augmentation de la fréquence cardiaque

		(p = 0,04), une diminution de la saturation en oxygène du sang (p = 0,048) et une augmentation de la température cutanée moyenne (p < 0,01). • Comparativement aux résultats obtenus sans masque, les masques KN95 sont ceux qui ont provoqué les changements les plus importants dans ces paramètres, suivi des masques chirurgicaux, des masques médicaux, des masques avec éponge et des masques civils jetables et de la gaze. Les résultats de ces analyses sont présentés dans des graphiques. • Il n'y a pas eu de changement significatif de la tension artérielle (changement systolique < 4 %, p = 0,915, changement diastolique < 3 %, p = 0,529). • Cette étude ne peut donc pas être généralisée en raison de la petite taille et de l'homogénéité de l'échantillon.
Epstein 2020 (6) Étude quasi-expérimentale Israël Septembre 2020	Dans cette étude, 16 volontaires sains de sexe masculin ont effectué de multiples essais autocontrôlés en chassé-croisé sur des bicyclettes ergométriques dans le cadre d'un protocole d'épreuve d'effort. Ces essais d'effort maximal ont été effectués sans masque, avec un masque chirurgical et avec un masque N95. Les paramètres physiologiques et le temps de performance jusqu'à l'épuisement ont ensuite été comparés. Les éléments mesurés incluaient la fréquence cardiaque (FC), la saturation en oxygène (SO_2), la fréquence respiratoire (FR), le dioxyde de carbone en fin	• La fréquence cardiaque, la fréquence respiratoire, la tension artérielle, la saturation en oxygène et le temps de performance jusqu'à l'épuisement ne différaient pas de façon significative entre les différents types de masques. Cependant, lorsqu'on compare les données obtenues sans masque au repos, les résultats de chacune des étapes de l'essai d'effort, on peut voir que le masque N95 a chaque fois été associé à une augmentation importante du CO_2 en fin d'expiration. La différence était plus prononcée lorsque la charge augmentait (intensité de l'exercice). En ce qui concerne les masques chirurgicaux, les résultats n'ont indiqué de différence significative dans le

	d'expiration ($EtCO_2$) et la pression artérielle.	CO_2 de fin d'expiration calculé que dans la dernière phase de l'entraînement. • Cette étude ne peut donc pas être généralisée en raison de la petite taille et de l'homogénéité de l'échantillon.
Fikenzer 2020 (7) Étude quasi-expérimentale Allemagne Juillet 2020	Cette étude en chassé-croisé qui a porté sur 12 hommes sains visait à mesurer les résultats de trois tests d'effort incrémentiels effectués sans masque, avec un masque chirurgical ou avec un masque N95 (FFP2). Les essais d'effort ont été effectués sur un ergomètre semi-couché à une vitesse constante de 60 à 70 tours par minute. La charge de travail a augmenté jusqu'à l'épuisement volontaire, puis a été suivie d'une période de récupération de 10 minutes. Le débit cardiaque (DC), le volume d'éjection systolique (ES), la fréquence cardiaque (FC), la consommation maximale d'oxygène (VO_{2max}) et le débit ventilatoire (DV) ont été surveillés en continu lorsque les participants étaient au repos, pendant le test d'effort et pendant la récupération.	• Le volume d'éjection systolique, le débit cardiaque et le bilan cardiaque ne différaient pas de manière significative, que les participants portent ou non un masque ou qu'ils aient porté un masque chirurgical ou un masque N95 ($p > 0,05$). • On a cependant pu observer un effet marqué sur les paramètres pulmonaires puisque, comparativement aux mesures obtenues sans masque, le débit ventilatoire a été réduit de -12,0 ± 12,6 % avec un masque chirurgical et de -23,1 ± 13,6 % avec un masque N95. • Le VO_{2max} était considérablement plus bas avec le masque N95 comparativement aux données obtenues avec un masque chirurgical ou sans masque. La différence entre les données obtenues avec le masque chirurgical et l'absence de masque était cependant limite. • Cette étude ne peut donc pas être généralisée en raison de la petite taille et de l'homogénéité de l'échantillon.
Li 2005 (8) Étude quasi-expérimentale Hong Kong Mai 2005	Cet essai en chassé-croisé comprenait 10 participants sains qui ont fait des exercices intermittents (à trois niveaux, de faible à modéré) sur un tapis roulant dans une chambre climatique avec un masque N95 ou un masque chirurgical avec et sans traitement nanofonctionnel	• Les différences entre les masques N95 avec ou sans nanotraitement et les masques chirurgicaux n'étaient pas significatives. • La fréquence cardiaque moyenne était beaucoup plus élevée chez ceux qui portaient un masque N95 que chez ceux qui portaient un masque chirurgical.

	(traitement utilisé pour repousser l'eau et inactiver les bactéries). La température, la fréquence cardiaque et la tension artérielle ont été mesurées.	• Plus les exercices étaient intenses, plus on voyait de différence dans la fréquence cardiaque avec les différents types de masques. • L'humidité et la température à l'intérieur des masques chirurgicaux avec ou sans nanotraitement étaient inférieures à celles observées dans les masques N95 (P = 0,000). • Les symptômes de fatigue, de dyspnée et d'inconfort général étaient beaucoup plus importants avec les masques N95. • Cette étude ne peut donc pas être généralisée en raison de la petite taille et de l'homogénéité de l'échantillon.
Wong 2020 (9) Étude quasi-expérimentale Hong Kong Octobre 2020	Vingt-trois bénévoles sains provenant de différents milieux sportifs ont participé à un essai en chassé-croisé dans lequel ils ont marché à une vitesse de 4 km/h pendant six minutes avec et sans masque chirurgical sur un tapis roulant dont l'inclinaison augmentait graduellement pour étudier l'effet physiologique (fréquence cardiaque et effort perçu mesurés sur une échelle de 6 à 20) du port du masque pendant un exercice modéré.	• Par rapport aux résultats obtenus sans masque, les masques chirurgicaux ont entraîné une accélération de la fréquence cardiaque (128,4 ± 13,2 contre 124,4 ± 12,8 battements par minute) et les participants ont déclaré un niveau d'effort perçu plus élevé après 3 minutes d'exercice (12,7 ± 2,1 contre 10,8 ± 2,2). Les résultats présentés ont été établis après six minutes d'exercice. • L'auteur laisse entendre que faire de l'exercice avec un masque à un niveau sous-maximal induirait des réponses physiologiques plus fortes. Cette différence peut cependant être due à une ventilation limitée, à une respiration plus lourde et à différentes réactions sympathiques. • Puisque l'augmentation de la charge cardio-respiratoire est directement liée au fait d'avoir effectué un exercice avec un masque, les auteurs suggèrent que les personnes qui portent des masques

		doivent être conscientes des efforts qu'elles font et de leur fréquence cardiaque pour s'assurer de ne pas dépasser les 150 battements/minute ou 70 % de leur fréquence cardiaque maximale prévue selon leur âge. • Cette étude ne peut donc pas être généralisée en raison de la petite taille de l'échantillon.
Morris (2020) (10) Étude quasi-expérimentale Danemark* 2020*	Un essai en chassé-croisé comprenant 8 participants masculins a été effectué pour évaluer les répercussions du fait d'effectuer un exercice léger (5 METS) pendant 45 minutes avec un masque KN95 à une température de 40 °C avec 20 % d'humidité. Les performances cognitives et motrices fines ont été évaluées à l'aide de tests qui ont déjà démontré leur fiabilité et leur grande sensibilité pour détecter les diminutions dans la performance cognitive associée à la chaleur, y compris la déshydratation et le rayonnement. La dyspnée a, quant à elle, été mesurée à l'aide de l'échelle de dyspnée de Borg.	• Il n'y avait pas de différence significative au repos en ce qui concerne la dyspnée, mais pendant l'exercice, on a pu observer beaucoup plus de dyspnée dans le groupe dont les membres portaient un KN95 (51,3 % [27,6]) que dans le groupe sans masque (21,4 % [14,5], < 0,001). • Les résultats en ce qui concerne la mesure de la température corporelle n'étaient pas significativement différents, que le participant ait ou non porté un masque KN95. • Les autres résultats cognitifs et moteurs fins n'étaient pas non plus significativement différents, que le participant ait ou non porté un masque KN95. • Cette étude ne peut donc pas être généralisée en raison de la petite taille et de l'homogénéité de l'échantillon.
Dattel 2020 (2) Étude quasi-expérimentale États-Unis Juillet 2020	Cette étude a exploré les effets des masques en tissu (sans détails sur la composition) ou des masques chirurgicaux. On a étudié les répercussions des masques en tissu ou des masques chirurgicaux sur 32 pilotes	• Les pilotes instructeurs ont signalé des problèmes de confort et de fatigue, ainsi qu'en raison des restrictions de mouvement associées au port du masque. • Aucune différence dans le CO_2, la fréquence cardiaque, la fréquence respiratoire ou le niveau d'oxygène n'a été

	instructeurs qui se trouvaient dans une chambre de pilotage à pression normale. Des mesures du CO_2, de la fréquence cardiaque, de la fréquence respiratoire et de la saturation en oxygène ont été prises pendant 90 minutes.	constatée entre les pilotes qui portaient un masque en tissu et ceux qui portaient un masque chirurgical après un vol simulé de 90 minutes à une altitude de 1 524 m (5 000 pi). • Cette étude ne peut donc pas être généralisée en raison de la petite taille de l'échantillon.
Lee 2011 (11) Étude quasi-expérimentale Singapour 2010*	Cette étude portait sur la résistance respiratoire causée par les masques N95 (3M 8210) portés par 14 adultes sains. La résistance respiratoire a été mesurée pour l'inspiration et l'expiration, et le volume total (l en 30 s) a été mesuré avec et sans masque N95.	• Avec un masque N95, la résistance respiratoire atteignait en moyenne 126 % du débit inspiratoire et 122 % du débit expiratoire. • Il y a donc eu une réduction moyenne de 37 % du volume d'échanges gazeux lorsque les participants portaient un masque N95. • Cette étude ne peut donc pas être généralisée en raison de la petite taille de l'échantillon.
Travailleurs de la santé (n = 2)		
Purushothaman 2020 (12) Étude transversale Inde Juillet 2020	Un sondage a été effectué auprès de 250 travailleurs de la santé sans comorbidité dans un hôpital tertiaire. Ces travailleurs portaient chaque jour des masques chirurgicaux ou des masques N95 pendant au moins quatre heures. Les données ont été recueillies dans un questionnaire d'auto-évaluation élaboré à l'aide de recherches formatives, mais n'ayant pas été prétesté.	Cette étude ne fait pas de distinction entre les résultats associés aux masques chirurgicaux ou aux masques N95. • 58,2 % des travailleurs de la santé ont indiqué avoir de la difficulté à respirer à l'effort ($p < 0,001$). Aucun renseignement supplémentaire sur ce qu'on entend par « effort » n'a été fourni. • Les participants ont indiqué un vaste éventail d'éléments d'inconfort, dont les plus fréquents incluaient une sudation excessive autour de la bouche (67,6 %), de l'acné (56,0 %), une irritation de la peau (39 %) et une douleur derrière l'oreille (45,2 %).

Bharatendu 2020 (13) Étude quasi-expérimentale Singapour Février à avril 2020	Cette étude a porté sur 154 travailleurs de la santé qui ont demandé des soins médicaux en raison de maux de tête liés à l'utilisation d'ÉPI. De ce nombre, 25 % avaient des migraines et 80 % ont dit avoir eu de nouveaux maux de tête après avoir porté un masque N95. La surveillance par Doppler transcrânien de l'artère cérébrale moyenne a été effectuée à l'aide de deux mesures validées de la vitesse moyenne d'écoulement, de l'index de pulsatilité et de la pression associée au dioxyde de carbone ($ETCO_2$) en fin d'expiration, qui ont été enregistrées avant le port du masque N95 et cinq minutes après l'avoir enlevé. L'évaluation a été effectuée pour un masque N95 (masque 3M® N95) avec et sans appareil de protection respiratoire à épuration d'air motorisé (APR, 3M® Versaflo® série TR-300).	• Comparativement aux mesures obtenues sans masque, le fait de porter un masque N95 a entraîné une augmentation importante du volume de débit moyen, une variation relative de 12,3 % (ET 29,8, $p < 0,001$), une diminution de la variation relative de l'index de pulsatilité de 13,3 % (ET 11,3, $p < 0,001$) et des niveaux très élevés de dioxyde de carbone en fin d'expiration soit une augmentation de 3,1 mmHg (ET 1,2). • Quant aux vingt-quatre participants qui ont utilisé un APR, les résultats n'ont montré aucune différence dans le volume de débit moyen, l'index de pulsatilité ou les niveaux de dioxyde de carbone en fin d'expiration dans les cinq minutes qui ont suivi l'utilisation du masque avec les mesures obtenues sans masque. Le respirateur à adduction d'air rétablit donc les changements hémodynamiques cérébraux causés par le masque N95. • Étant donné que les mesures ont été prises après cinq minutes, il est impossible de savoir si ces changements se sont maintenus ou ont été corrigés par autorégulation.
Femmes enceintes (n = 2)		
Tong 2015 (14) Étude quasi-expérimentale Singapour Septembre 2011	La phase I a permis d'évaluer le volume d'absorption d'O_2 (VO_2) de huit travailleuses enceintes qui exécutaient des tâches d'infirmières lors d'une simulation. La phase 2 a comparé les données associées à l'utilisation ou non d'un masque N95 chez 20 femmes enceintes (27 à 32 semaines de	Le fait de respirer à travers un masque N95 comparativement à l'absence de masque a entraîné ce qui suit : • Un volume d'air courant significativement plus bas de -0,15 L (IC à 95 %, -0,23 à -0,08 L) au repos et de -0,21 L (-0,32 à -0,10 L) pendant l'exercice, soit une diminution globale d'environ 23 %.

	gestation) pendant deux cycles d'exercices d'une durée de 15 minutes sur un tapis roulant à 3 METS (ce qui équivaut au travail modéré normal qu'effectue un travailleur de la santé [données provenant de la phase 1]). Dans ces deux phases, les femmes portaient un masque respiratoire Hans Rudolph bien ajusté avec valve anti-asphyxie ouverte ou recouverte par le matériel utilisé pour fabriquer les masques N95. Les mesures effectuées incluaient notamment le volume d'oxygène (VO_2) et de dioxyde de carbone (VCO_2), le débit ventilatoire (DV), l'expiration forcée d'O_2 (FeO_2) et les concentrations de CO_2.	• Un débit ventilatoire (DV) fortement réduit (5,55 L [IC à 95 %, 7,58 % à 3,51 %], soit environ 25,8 %. • Aucun changement significatif dans la fréquence respiratoire avec le masque N95. • Une réduction importante de la concentration d'O_2 à l'expiration forcée (FeO_2) pendant l'exercice (-0,54 % [-0,70 à -0,38]). • Des augmentations importantes de la concentration de CO_2 expirée ($FeCO_2$) tant pendant l'exercice que dans les périodes qui ont précédé et suivi l'exercice (0,30 % [0,18 à 0,42]). • Une baisse significative de VO_2 de 13,8 % et de VCO_2 de 17,7 % a été déclarée en ce qui concerne les échanges gazeux pulmonaires. • Aucune différence n'a été observée pour le rythme cardiaque, la saturation en oxygène ou le taux d'effort perçu pour la mère ou le fœtus avec le masque N95. • Cette étude ne peut donc pas être généralisée en raison de la petite taille et de la courte durée de l'exercice.
Roberge 2014 (4) Essai contrôlé États-Unis Octobre 2014	Étude contrôlée réalisée avec 22 femmes saines enceintes (de 13 à 35 semaines de gestation) et 22 femmes saines non enceintes afin de déterminer s'il y a une différence entre les effets physiologiques et subjectifs du port d'un masque N95 (appareil respiratoire filtrant pour le visage, APR). Les éléments qui ont été évalués incluaient la fréquence respiratoire,	• Dans l'ensemble, l'utilisation du masque N95 a réduit considérablement la fréquence respiratoire, a entraîné une différence mineure comparativement à la moyenne de 0,94 (IC à 95 %, de 0,1 à 2,2) de respirations par minute, alors que la pression partielle transcutanée du dioxyde de carbone ($PtcCO_2$) a augmenté pendant l'exercice pour toutes les femmes en raison de la réinspiration des niveaux de CO_2 plus élevés générés pendant l'exercice.

	la température cutanée sur la paroi de la cage thoracique, la fréquence cardiaque maternelle et fœtale, ainsi que la saturation en oxygène déduite du pouls (SpO_2). L'échelle Borg de perception de l'effort 6 à 20 a aussi été utilisée. Des mesures ont été prises avec et sans masque N95 pendant des exercices et des activités sédentaires posturales sur une période d'une heure.	• Il n'y a cependant pas eu de différences significatives dans les réponses physiologiques et subjectives mesurées chez les femmes enceintes comparativement aux femmes non enceintes lorsque celles-ci ont porté un masque N95 pendant une heure, tant pendant les exercices que lorsqu'elles étaient sédentaires. • Il n'y a pas eu d'effet significatif sur la fréquence cardiaque fœtale. • Cette étude ne peut donc pas être généralisée en raison de la petite taille de l'échantillon.
Personnes atteintes de maladies chroniques (n = 3)		
Kyung 2020 (15) Étude quasi-expérimentale Corée du Sud Mars à mai 2015	Dans cette étude, 97 patients atteints de MPOC de gravité variable ont fait l'objet d'un suivi afin d'évaluer leurs symptômes et différentes variables physiologiques lorsqu'ils portaient un masque N95. Ces mesures ont été prises pendant une période de repos de 10 minutes et pendant un test de marche de 6 minutes. Les patients étaient âgés entre 19 à 80 ans, pouvaient marcher sans aide, n'étaient pas sous oxygénothérapie à long terme et n'avaient pas d'antécédents d'hospitalisation récente. Les mesures utilisées incluaient la fréquence respiratoire, la dyspnée, la fréquence cardiaque, la SpO_2, la tension artérielle et un questionnaire sur les symptômes avec une échelle modifiée sur la	• 7 sujets sur 97 n'ont pas pu porter le masque N95 pendant tout le test. Un score de ≥ 3 sur l'échelle de dyspnée modifié par le Conseil de recherches médicales (RC 167, IC à 95 %, de 8,4 à > 999,9; $P = 0,008$) ou un VEMS < 30 % (RC 163, IC à 95 %, de 7,4 à > 999,9; $P = 0,001$) était associé à une incapacité de continuer à porter le masque N95. Les symptômes dans ce groupe étaient plus prononcés et incluaient la dyspnée, des étourdissements et des maux de tête. Chez les membres du groupe qui ont terminé le test : • Même lorsqu'ils étaient au repos, leur fréquence respiratoire a augmenté avec un masque N95 (20,7 respirations/min) alors qu'elle était de 19,7 lorsqu'ils ne portaient pas de masque. • Le PCO_2 en fin d'expiration a atteint 25,7 mm Hg lorsqu'ils portaient un

	dyspnée établie par le Conseil de recherches médicales. La gravité de l'obstruction du débit d'air associé à la MPOC a été mesurée en utilisant le VEMS post-bronchodilatateur. Parmi tous les sujets, 31 avaient un VEMS supérieur à 50 % comme niveau de référence.	masque N95 alors qu'il était de 24,8 lorsqu'ils ne portaient pas de masque. • Les niveaux de SpO_2 étaient plus faibles avec un masque N95 (96,0 %) que lorsqu'ils ne portaient pas de masque (96,4 %). • Après 6 minutes de marche, on a constaté des différences significatives dans la fréquence cardiaque (92,4 comparativement à 87,7), la fréquence respiratoire (25,7 comparativement à 23,3 respirations/min), le PCO_2 de fin d'expiration était plus élevé (35,5 au lieu de 34,0 mm Hg) alors que les niveaux de SpO_2 (93,0 comparativement à 93,8 %) étaient plus bas chez les personnes qui portaient un masque N95 que chez celles qui n'en avaient pas. • Les auteurs ont déclaré qu'il faut avertir les patients atteints de MPOC de retirer immédiatement le masque N95 en cas de dyspnée, de maux de tête ou d'étourdissements.
Harber 2010 (16) Essai contrôlé États-Unis 2010	Cet essai visait à évaluer les effets respiratoires des demi-masques à double cartouche ou des masques N95 lorsque 97 personnes, 42 asthmatiques, 14 personnes atteintes de MPOC légère, 17 personnes atteintes de rhinite chronique et 24 personnes saines effectuaient certaines tâches. Les résultats respiratoires comprenaient le volume courant, le débit ventilatoire, le temps d'inspiration/expiration, le cycle inspiratoire et expiratoire et le débit d'écoulement de l'air.	• Comparativement aux données obtenues en portant un masque N95, le volume courant, le débit ventilatoire et la fréquence respiratoire étaient légèrement inférieurs avec un demi-masque, mais l'on ne sait pas quelle importance ces données pourraient avoir au niveau clinique. Aucun effet cohérent n'a été observé pour les volumes dans les cas de MPOC ou d'asthme. • Les personnes atteintes de MPOC ont mis plus de temps pour atteindre leur débit expiratoire maximal.

		• Les personnes atteintes de rhinite ont obtenu un meilleur rendement que celles qui étaient atteintes de MPOC et d'asthme. • L'âge n'était pas un facteur. • Les personnes atteintes d'asthme ou d'une MPOC légère présentaient un pourcentage de VEMS inférieur aux prévisions, associé au volume du masque. • Cette étude ne peut donc pas être généralisée en raison de la petite taille de l'échantillon.
Ciocan 2020 (17) Étude quasi-expérimentale Italie Octobre 2020	Dix travailleurs de la santé, dont trois souffrant d'asthme et trois fumeurs, ont été inclus dans cet essai croisé. Ils ont porté un masque chirurgical à quatre couches (AFLUID) pendant quatre heures lorsqu'ils effectuaient des activités normales, de niveau calme à modéré, dans le cadre de leur travail. Leur fonction respiratoire a été surveillée pendant ce temps. Un test de fonction respiratoire a été effectué à trois moments distincts et des échantillons de sanguin artériel ont été prélevés pour effectuer une gazométrie avant les premiers et troisièmes tests de fonction respiratoire.	• Comparativement à ceux qui ne portaient pas de masque, la ventilation volontaire maximale (VVM) était réduite avec un masque chirurgical à quatre couches ($p = 0,002$) et est demeurée basse même pendant l'activité ($p = 0,041$). • Aucune variation significative des paramètres RFT et ABG observés n'a été signalée, bien que l'étude n'ait pas permis de détecter les différences. • Cette étude ne peut donc pas être généralisée en raison de la petite taille de l'échantillon.

CONSEILS SUR L'UTILISATION DES COUVRE-VISAGES DANS LA POPULATION EN GÉNÉRAL

Des directives clés émises par le Canada, les États-Unis et l'OMS ont été déterminées et examinées afin de formuler des recommandations sur le port du couvre-visage pour les personnes qui ont des problèmes médicaux chroniques, ainsi que sur le port générique du couvre-visage dans la collectivité (tableau 2).

- La Société canadienne de thoracologie et Asthme Canada indiquent que les personnes atteintes d'un problème pulmonaire sous-jacent devraient être capables de porter un couvre-visage non médical. Cependant, pour celles qui ont de la difficulté à porter un couvre-visage, il est suggéré de travailler en collaboration avec un prestataire de soins de santé pour trouver une solution ou éviter, dans la mesure du possible, les situations dans lesquelles elles doivent porter un couvre-visage pour minimiser le risque (18).
- Les plus récentes lignes directrices de l'OMS précisent que les masques ne doivent pas être portés à des fins de contrôle à la source pour empêcher la transmission des virus provenant d'un enfant de moins de 5 ans atteint de la COVID-19 (19). Elles ne précisent pas si les enfants de 2 à 5 ans doivent porter un masque pour se protéger, mais indiquent cependant toutes que les enfants de moins de 2 ans ne doivent pas porter de couvre-visage.

Les lignes directrices diffusées par le Canada (20), les États-Unis (21) et l'OMS (19) mentionnent que les couvre-visages ne devraient pas être requis pour toute personne incapable d'enlever son couvre-visage sans aide, ce qui inclut les enfants de moins de deux ans, et pour toute personne qui a de la difficulté à respirer, est inconsciente ou est frappée d'incapacité en raison du risque de suffocation.

- Il est également suggéré que les personnes ayant certains handicaps ou de jeunes enfants pourraient être incapables de porter leur couvre-visage correctement et ne devraient donc pas en avoir (20, 21).

Tableau 2. Conseils sur le port du couvre-visage pour les personnes atteintes de maladies et pour le grand public (n = 5)

RÉFÉRENCE	DESCRIPTION DE L'ÉTUDE	RÉSULTATS PERTINENTS
Organisation mondiale de la Santé (19) Document d'orientation Suisse Décembre 2020	Il s'agit d'une mise à jour du guide de l'OMS en date du 5 juin axé sur le port des masques et des couvre-visages : • gestion des masques; • transmission du SRAS-CoV-2; • port du couvre-visage dans les zones des établissements de santé où l'on retrouve des	• Le port du couvre-visage devrait s'inscrire dans le cadre d'une approche à plusieurs niveaux faisant partie des interventions de santé publique. • Les couvre-visages peuvent être destinés à la protection ou au contrôle des sources. (Portez un masque médical si vous pensez avoir la COVID-19).

	grappes de personnes et une transmission sporadique; • port de couvre-visage par le public dans les zones de transmission communautaire et les grappes; • solutions de rechange aux couvre-visages non médicaux pour le public; • soupape d'expiration sur les masques médicaux et couvre-visages non médicaux; • port d'un couvre-visage pendant une activité physique dont l'intensité est élevée; • paramètres essentiels dont il faut tenir compte lors de la fabrication de couvre-visages non médicaux (Annexe).	• Des lignes directrices sur l'utilisation, le rangement et le nettoyage appropriés sont présentées. • Les enfants de moins de 5 ans ne doivent pas porter de couvre-visage à des fins de contrôle à la source. L'utilisation de couvre-visage chez les enfants plus âgés varie selon des facteurs locaux et les enfants de plus de 12 ans doivent suivre les directives pour les adultes. • La fabrication de couvre-visages non médicaux doit respecter les principes suivants : trois couches avec une couche interne hydrophile, une couche externe hydrophobe et une couche intermédiaire hydrophobe qui améliore la filtration. • Les soupapes d'expiration sont déconseillées.
Canada.ca (20) Document d'orientation Canada Novembre 2020	Conseils sur l'utilisation des masques non médicaux pour prévenir la propagation de COVID-19 dans la communauté. • Ordonnances en ce qui concerne le port des masques et des couvre-visages. • Composition des masques non médicaux. • Utilisation des filtres dans les couvre-visage. • Mise en place, nettoyage et rangement. • Enfants. • Sécurité.	• Les couvre-visages non médicaux protègent la personne qui les porte et les autres contre la propagation de la COVID-19. • Des politiques sur le port obligatoire des masques et des couvre-visage sont mises en place en fonction de la transmission locale de la COVID-19. • Les masques non médicaux doivent être faits d'au moins trois couches, soit deux couches de tissu serré et une troisième couche (centrale) en tissu filtrant, comme un tissu de polypropylène non tissé. Ils doivent être bien ajustés au visage et recouvrir le nez et la bouche, mais être encore perméables à l'air.

	• Personnes malentendantes. • Écrans faciaux, cache-cou (réchauffeurs du cou), soupapes d'expiration.	• Du tissu en polypropylène non tissé (p. ex., tissu utilisé pour l'artisanat, pour les sacs à provisions réutilisables) peut être utilisé comme filtre, tout comme des filtres jetables. • Les enfants de moins de deux ans ne doivent pas porter de couvre-visage et il faut s'assurer de bien surveiller tout enfant de 2 à 5 ans qui porte un masque ou un couvre-visage. • Il faut éviter la stigmatisation des personnes qui ne peuvent porter de couvre-visage en raison d'une maladie ou d'un handicap.
Centers for Disease Control and Prevention 2020 (21) Document d'orientation États-Unis Novembre 2020	Des considérations relatives au port du masque, sans préciser de type, sont fournies pour aider à ralentir la propagation de la COVID-19. Sujets abordés : 1) Preuves de l'efficacité des masques 2) Qui doit et ne doit pas porter de masque ou de couvre-visage 3) Différence entre les types de masques ou de couvre-visages 4) Autres types de protection faciale	• Les masques ou couvre-visages ne doivent pas être portés par des enfants de moins de deux ans, par des personnes qui ont de la difficulté à respirer et par des personnes inconscientes, frappées d'incapacité ou incapables de retirer leur masque sans aide. • Les personnes ayant certains handicaps ou les enfants qui ne peuvent pas porter de masque ou de couvre-visage correctement ne devraient pas en porter. • La plupart des personnes atteintes de troubles médicaux sous-jacents peuvent et doivent porter un masque ou un couvre-visage. Si elles ont des préoccupations à cet égard, elles doivent en discuter avec leur fournisseur de soins de santé. • Le port d'un masque en tissu n'augmente pas le niveau de dioxyde de carbone (CO_2) dans l'air respiré.

		• Les masques médicaux et les masques N-95 ne doivent pas être utilisés, car ils doivent être réservés aux travailleurs de la santé. • Les écrans faciaux ou les lunettes de protection ne remplacent pas les masque ou couvre-visage. • Les masques ou les couvre-visages en tissu les plus efficaces sont perméables à l'air, comportent deux ou trois couches et sont faits de tissus serrés comme du coton et des mélanges de coton. • Les personnes qui se fient à la lecture des lèvres pour communiquer (personnes sourdes, malentendantes ou qui prennent soin de personnes ayant une déficience auditive) pourraient être incapables de porter des masques ou de couvre-visages en tissu. Le CDC recommande un masque ou couvre-visage transparent, une communication écrite ou une réduction du bruit de fond pendant la communication.
Bhoutani (2020) (18) Document d'orientation Canada Juillet 2020	Il s'agit d'une directive et d'un énoncé de position de la Société canadienne de thoracologie sur l'utilisation des masques par le public pendant la pandémie de SRAS-CoV-2.	• La Société canadienne de thoracologie appuie la recommandation de l'Agence de la santé publique du Canada de porter un masque ou couvre-visage non médical dans la collectivité lorsqu'il n'est pas possible de maintenir la distanciation physique de deux mètres. • Rien n'indique que le port d'un masque ou d'un couvre-visage non médical aggravera un problème pulmonaire sous-jacent. • Le port d'un masque ou d'un couvre-visage ne préviendra pas la propagation

		de la COVID-19 et devrait s'ajouter à d'autres mesures de santé publique recommandées, comme l'amélioration de l'hygiène des mains et la distanciation physique. • L'on recommande aux personnes qui éprouvent de la difficulté à porter un masque ou couvre-visage à parler à leur prestataire de soins de santé afin d'élaborer des stratégies pour pouvoir en porter un. Si, malgré tous les efforts, le port d'un masque ou d'un couvre-visage n'est pas possible, les personnes doivent éviter ou minimiser les circonstances dans lesquelles le respect de la distanciation physique n'est pas possible.
Asthme Canada (22) Document d'orientation Canada 2020	Asthma Canada a publié ces conseils destinés aux personnes asthmatiques afin de répondre aux préoccupations liées au port de masque ou couvre-visage et à la COVID-19.	Recommandations pour les personnes atteintes d'asthme : • Les masques sont offerts en différents styles et matériaux; choisissez le masque ou couvre-visage qui vous convient le mieux. • Testez le masque à la maison pour vous habituer à la façon dont vous vous sentez quand vous le portez. • Si vous ne pouvez pas porter de masque ou de couvre-visage puisque cela entraîne des problèmes respiratoires, n'en portez pas. Respectez plutôt la distanciation de deux mètres et réduisez au minimum le temps passé autour des personnes à l'extérieur de votre ménage. • Consultez votre professionnel de la santé pour revoir votre plan d'action contre l'asthme et explorer d'autres options pour vous protéger.

Méthodologie

Une analyse documentaire quotidienne (ouvrages publiés et en prépublication) est effectuée par le Groupe des sciences émergentes de l'ASPC. L'analyse a compilé les ouvrages sur la COVID-19 depuis le début de l'éclosion et est mise à jour quotidiennement. Les recherches visant à extraire les ouvrages pertinents sur la COVID-19 sont menées dans Pubmed, Scopus, BioRxiv, MedRxiv, ArXiv, SSRN, Research Square et dans les centres d'information de la COVID-19 gérés par Lancet, BMJ, Elsevier et Wiley. Les résultats cumulatifs de l'analyse sont conservés dans une base de données Refworks et une liste Excel consultable. Des détails sur cette stratégie de recherche sont disponibles sur demande. Une recherche ciblée par mot-clé dans les titres et les résumés des articles a été effectuée dans ces bases de données et dans la liste en Excel. Les termes de recherche utilisés comprenaient : mask* OU (face ET cover*). Une recherche supplémentaire de documents d'orientation et de preuves à l'appui sur les personnes qui ne devraient pas porter de masque ou couvre-visage a été effectuée en se concentrant sur le Canada et les principaux organismes de santé, en utilisant une technique de boule de neige et en ciblant les sites web des pays. Chaque référence potentiellement pertinente a été examinée pour confirmer qu'elle comportait des données pertinentes, qui ont été extraites dans la revue. La présente revue contient des recherches publiées jusqu'au 2 décembre 2020.

ANNEXE : TYPES DE COUVRE-VISAGE

Le blogue du NCCEH a publié un article sur le port du couvre-visage pendant la pandémie de COVID-19 (27 octobre 2020) qui décrit les différents types de couvre-visages et comprend le tableau suivant, sur les types de couvre-visages.

	Respirator	Surgical or procedure mask	Non-medical cloth mask
			Types	N95, 99, 100 (US, Canada), FFP2 or FFP3 (EU). Various styles including cup, flat-fold and duckbill. May also include an exhalation valve.	Typically a 3-layer laminate structure that can include a combination of non-woven air-laid paper and polypropylene.[3]	Wide variability in fabric, number of layers and design with 2-layer cotton being a common design.
Use	For use in environments where exposure to aerosols is likely. Protect against most particles (e.g., N95 block 95% of particles and provide some splash and spray protection). Medical grade N95s are tested for resistance to fluids including blood, but commercial grade are not.	For use in routine care to reduce inward and outward transfer of respiratory droplets. Filter particles > 20 µm diameter and some finer droplet nuclei.[4] Block blood and infectious materials from contact with oral, nasal and skin area. Effective against splash and sprays.	For use by the public in non-healthcare settings as source control to reduce respiratory emissions from the wearer and to reduce exposure to respiratory emissions of others.[3,5]
Approval	U.S. National Institute for Occupational Safety and Health (NIOSH) for N95 or similar and EU standards for FFP equivalents.[6] The Government of Canada lists other approved alternatives to N95s.	FDA with grading based on the level of resistance to splashing (e.g., ASTM 1 – venous pressure; ASTM 2 – arterial pressure; ASTM 3 – high velocity splash).	Not approved for use in any healthcare setting; not tested to any standard of effectiveness. **Note:** Many procedure-type masks found in retail outlets may not be assessed to any approval standards, and would also be considered non-medical masks.
Advantages	Medical grade respirators can be effective against aerosol penetration. Can be reused and disinfected with precautions.	Some protection against contact transmission, are disposable and inexpensive. Fit testing is not required.	Inexpensive and can be made from household materials. Can act as a reminder to not touch face.[5] Can be reused and laundered.[7]
Disadvantages	Filtration efficiency for aerosols is only effective if properly fit tested. Some users may experience some reduction in comfort/breathability. Expensive and may be in short supply.	Less effective against smaller particles (e.g., 0.4-1.3 µm), looser fit than N95 respirators, and therefore more penetration via leaks.[8] Not recommended for reuse or disinfection for use in healthcare environments.	Variable performance for respiratory protection and breathability depending on the material and design.[9] They do not replace other protective measures (e.g., hand hygiene and distancing).[5,10]

Emerging Evidence on COVID-19

Rapid Review on the Physiological Effects of Wearing Face Masks

Introduction

What is the evidence on the physiological changes from mask use? Is there evidence that mask use may adversely affect those with medical conditions?

Many public health organizations globally such as the World Health Organization recommend the use of face masks in public spaces to protect against COVID-19. Concerns about wearing a face mask in some settings or among people with certain medical conditions have been raised. The review focuses on the physiological effects of wearing a mask on the respiratory and cardiovascular systems and highlights were statistically significant differences were reported. The dermatological and psychological reactions to mask use are not included in this review; they may be covered as a separate topic given these are also impacts of wearing a mask (1). This rapid review summarizes literature until December 2, 2020 on the physiological changes mainly related to respiratory and cardiovascular systems from mask use that may occur in healthy populations and those with medical conditions.

Key Points

- Twenty articles were identified, which included fifteen studies investigating physiological responses arising from wearing masks, one review and four guidance documents. The majority of the studies compared the physiological effects of an N95 respirator and/or a surgical mask; only two studies included non-medical masks, see appendix for information on mask types. These were studied in different populations: healthy volunteers (n=8), health care workers (HCW) (n=2), pregnant women (n=2) and people with medical conditions (n=3).
- Healthy volunteer face mask use was assessed in eight studies. Two studies included sedentary activities only, five had a range of activity from light exercise (e.g. walking at MET 3-5) to strenuous exercise and one study evaluated the impact of wearing masks among pilots flying at 5000ft.

  Limitations:

  - The eight studies on healthy volunteers were small, a median study size of 12 (83 total healthy volunteers and 32 pilots). Studies included homogeneous groups of participants e.g. college students and/or all male. The period of study was often short and as such would not reflect the potential impact of wearing a mask for prolonged periods of time. Most studies conducted analyses to establish statistical significance between two or more measurements, these are highlighted throughout the report as significant results. The clinical significance of the reported results were rarely discussed by

the authors. The findings of studies in this review are preliminary. More research is needed with larger and more representative samples to assess the generalizability of these findings.

N95 masks:

- Across six studies of healthy volunteers, N95 masks significantly increased breathing resistance and reduced air exchange volume, they caused increased heart rate and end tidal CO_2 and decreased oxygen saturation compared to no mask. Symptoms associated with these physiological changes included dyspnea (difficulty breathing), dizziness, and trouble concentrating.
- Five studies examined light to strenuous exercise in healthy volunteers. When wearing an N95 mask increased exercise intensity resulted in a more pronounced impact on some physiological parameters including increased end-tidal CO_2, and decreased minute ventilation and overall VO_{2max} compared to wearing no mask.
- One study looked at several different masks and indicated the overall physiological impact was highest for the KN95 > surgical masks > medical masks, sponge and civilian disposable masks> gauze and wearing no mask.
- In four studies, comparing the effects of N95 vs. surgical masks there was a greater physiological impact associated with N95 masks. These differences were not significant in one study, were significant for some parameters in two studies: heart rate (n=1/2 studies), minute ventilation and VO_{2max} (n=1/2) and were not reported although raw data and graphical summaries were available in the fourth study.

Surgical masks:

- Four studies (n= 63 observations) looked at surgical masks compared to no mask and they report elevated heart rate (n=3) and decreased blood oxygen saturation (n=1) compared to no mask when at rest or exercising. Surgical masks significantly reduced minute ventilation, but not VO_{2max}. At the end of the strenuous workout, end-tidal CO_2 was statistically increased with surgical mask use compared to no mask. Perceived level of exertion was higher in those who wore a surgical mask (n=2). Symptoms were not as frequently reported for surgical masks compared to N95 masks, but included dyspnea, dizziness and difficulty concentrating.
- Pilots, wearing either a surgical or non-medical cloth mask, who underwent a 90 minute 5000ft simulation exercise were found to have no difference in heart rate, end tidal CO_2, respiration rate or oxygen levels (2).

Non-medical face masks

- Two studies included non-medical face masks made of cloth, sponge, gauze or described as a civilian disposable masks. The physiological impact of different mask composition was not significantly different than surgical masks in these studies (2, 3).

- HCW studies (n=2) were conducted to understand the impact of wearing an N95 or surgical mask when executing duties related to their occupation.
    - A survey of 250 HCWs who wore surgical or N95 masks >4 hours/day reported 58.2% ($P<0.01$) had trouble breathing on exertion. Other symptoms included excessive sweating around the mouth (67.6%), skin irritation (39%) and pain behind the ear (45.2%).
    - The cerebral hemodynamic changes of donning an N95 mask were evaluated among 154 HCWs who reported headaches in association with N95 mask use. Five minutes after donning the N95 mask a significant increase in mean flow volume and end-tidal CO_2 were reported. Adding a powered air-purifying respirator (PAPR) restored these measures to normal levels.
- Pregnant women, healthy and between 13-35 weeks in gestation were studied (n=2) for the impact of N95 mask use.
    - N95 masks worn by 42 pregnant women during routine physical work (equivalent to 3 MET) showed significantly decreased tidal volume, minute ventilation and oxygen consumption, an increase in transcutaneous partial pressure CO_2, conflicting results for respiratory rate and no change in maternal heart rate, fetal heart rate or oxygen saturation compared to no mask in both studies.
    - Comparing pregnant and not pregnant women, there were no differences in the physiological impact of wearing an N95 mask (4).
- Medical conditions were assessed in three studies and included chronic obstructive pulmonary disease (COPD) (n=2), asthma (n=2) and chronic rhinitis (n=1). Information on other medical conditions was not identified.
    - In a study of 97 COPD patients using N95 masks, 7% were unable to wear the mask due to dyspnea, headache and dizziness; these tended to be individuals with more severe COPD. Those who completed the study were studied at rest and experienced increased respiratory rate, heart rate, end-tidal pCO_2 and decreased oxygen saturation compared to no mask. These differences between N95 and no mask became greater with light exercise (walking). A second study of 14 mild COPD patients reported decreased ventilatory volumes and lower FEV_1 percentage of predicted with N95 or half face mask use.
    - Among 42 people with asthma there was decreased ventilatory volumes and lower FEV_1 percentage of predicted with N95 or half face mask, the half face mask had a slightly lower impact. Similarly, the maximal voluntary ventilation was significantly reduced in three asthmatics when using a surgical mask.
    - Among 17 people with chronic rhinitis, the impact of N95 or half face mask was similar to healthy volunteers.
- Mask wearers should be cognisant of their exertion and heart rate given the studies show an increased cardio-respiratory burden of wearing any face mask and the impact increases with exercise. Heart rate should be maintained below 150 beats/min or 70% of their age max heart rate.

- Guidance Documents from Canada, United States (USA) and World Health Organization (WHO) on non-medical mask use in the community recommend that masks should not be worn by anyone who is unable to remove their mask without assistance due to risk of suffocation. This includes children under 2 years of age, and anyone who is unconscious, incapacitated, or who has trouble breathing. WHO guidelines also note masks should not be worn for source control to prevent transmission from a child under 5 with COVID-19.
- The Canadian Thoracic Society and Asthma Canada both indicate people with an underlying lung condition should be able to wear a non-medical face mask and to consult with a health care professional if this poses difficulties
- Current WHO guidelines for mask use in the community identify that masks should be removed by those who are having trouble breathing.

Overview of the Evidence

Fifteen articles pertaining to respiratory and cardiovascular physiological changes from mask use were identified and included in this review. Most were reports of quasi-experimental studies using a cross-over design where individuals acted as their own control. Most studies were in healthy populations, had small sample sizes and included homogenous populations (e.g. college students and/or male only); others included HCWs (n=1) and pregnant women (n=2). There were only three studies that specifically investigated face mask use among individuals with medical conditions: COPD (n=2), asthma (n=2). Although these studies were well-executed and had objective outcome measurements, they had low sample sizes and homogenous samples, selection bias is likely present, but could not be assessed in most studies and the findings should not be generalized without additional research. One study of HCWs was a cross-sectional survey of the self-reported impact of mask usage, the study represented HCW staff in a hospital, had a large sample size and used a questionnaire informed by formative research, however the self reported nature of results is at risk of many biases.

More research with larger sample sizes is needed for all mask types, research on the prolonged use of face masks is also needed. Thus, future research could change our understanding of the short and long term impact of wearing a face mask and who should not wear a face mask.

CONTENTS

EVIDENCE ON THE PHYSIOLOGICAL EFFECTS OF WEARING FACE MASKS

The physiological response to wearing face masks was assessed in fifteen studies on various populations: healthy volunteers, HCWs, pregnant women, instructor pilots, and persons with COPD, asthma or chronic rhinitis (Table 1). A single review, assessed to be of very low quality by AMSTAR, covers the physiological response to impeded airflow caused by face mask use and interprets this impact (5). Physiological outcomes assessed for each study were variable from study to study and are presented in the table if they were assessed. These include breathing parameters (e.g. total volume inhaled/ exhaled, breathing rate), respiratory function (e.g. oxygen and CO_2 levels), heart rate, blood pressure, and cerebral hemodynamic changes.

Eight studies using healthy volunteers included two studies on mask wearing when sedentary only, five on a range of activity from light exercise (e.g. walking at MET3-5) to strenuous exercise and included a total of 83 healthy volunteers (median study size was 12). A single study evaluated the impact of wearing masks among pilots (n=32) in a simulated flying exercise at 5000ft.

N95 masks were assessed in six studies on healthy volunteers, the masks significantly increased breathing resistance, reduced air exchange volume, heart rate and end tidal CO_2 and decreased oxygen saturation compared to no mask. Symptoms associated with the physiological changes included dyspnea (difficulty breathing), dizziness, and trouble concentrating. Five studies examined light to strenuous exercise and showed higher exercise intensity resulted in a more pronounced impact on some physiological parameters including increased end-tidal CO_2, and decreased minute ventilation and overall VO_{2max} compared to no mask.

Comparing the overall physiological impact of different masks in healthy volunteers, one study showed the impact was highest for the KN95 followed by surgical masks > medical masks, sponge and civilian disposable masks> gauze and wearing no mask. Four additional studies compared N95 to surgical masks and reported a smaller magnitude of impact where physiological outcomes were not significantly different in one study; were significant for some parameters in two studies: heart rate (1/2 studies), minute ventilation and VO_{2max} (1/2 studies) and were not reported although raw data and graphical summaries were available in the forth study.

Surgical mask use in healthy volunteers compared to no mask (n=4) report elevated heart rate (n=3) and decreased blood oxygen saturation (n=1) when at rest or exercising. Surgical masks significantly reduced minute ventilation, but not VO_{2max}. At the end of a strenuous workout end-tidal CO_2 was significantly increased with surgical masks compared to no mask. Perceived level of exertion was higher with a surgical mask (n=2) compared to no mask. Symptoms such as dyspnea, dizziness and difficulty concentrating were less frequently reported for surgical masks than N95 masks.

Non-medical face masks were only used in two studies on healthy volunteers. Pilots, wearing either a surgical or non-medical cloth mask, who underwent a 90 minute 5000ft simulation exercise were found to have no difference in heart rate, end tidal CO_2, respiration rate or oxygen levels (2). The second study compared non-

medical masks made of sponge, gauze or described as a civilian disposable masks, results are only in graphs and the impact of these masks are between surgical mask and wearing no mask (3).

Healthcare workers studies aimed to understand the impact of wearing an N95 or surgical mask when executing duties related to their occupation. A survey of 250 HCWs that wore surgical or N95 masks >4 hours/day reported 58.2% ($P<0.01$), had trouble breathing on exertion. Other symptoms included excessive sweating around the mouth (67.6%), skin irritation (39%) and pain behind the ear (45.2%). The second study examined cerebral hemodynamic changes of donning an N95 mask among HCWs who reported headaches in association with mask use. Five minutes after donning the N95 mask a significant increase in mean flow volume and end-tidal CO_2 was reported. Adding a powered air-purifying respirator (PAPR) restored normal levels.

Healthy pregnant women between 13-35 weeks in gestation were evaluated for the physiological impact of N95 mask use. Two studies assessed the N95 during routine physical work (equivalent to 3 MET) and showed significantly decreased tidal volume, minute ventilation and oxygen consumption, an increase in transcutaneous partial pressure CO2, conflicting results for respiratory rate and no change in maternal heart rate, fetal heart rate or oxygen saturation across two studies. One of the studies also compared pregnant and not pregnant women and found no differences in the physiological impact of wearing an N95 mask (4).

Medical conditions in three studies included COPD (n=2), asthma (n=2) and chronic rhinitis (n=1). Information on other medical conditions was not identified. A study of N95 mask use in 97 COPD patients 7% were unable to wear the mask due to dyspnea, headache and dizziness, these tended to be individuals with more severe COPD. Those that completed the study had an increased respiratory rate, heart rate, end-tidal pCO_2 and decreased oxygen saturation compared to no mask. These levels were further impacted by light exercise (walking). A second study of mild COPD reported decreased ventilatory volumes and lower FEV_1 percentage of predicted with N95 or half face mask use compared to no mask. People with asthma had decreased ventilatory volumes and lower FEV_1 percentage of predicted with N95 or half face mask, the half face mask had a slightly lower impact. Similarly, the maximal voluntary ventilation was significantly reduced when using a surgical mask. No impact of the N95 or half face mask was significant for people with chronic rhinitis.

Overall weaknesses of the current evidence include small sample sizes, limited sample diversity, and physiologic assessments after only a short duration of mask wearing. This limits the generalizability of the findings and prevents extrapolation to situations when masks are worn for more than 4 hours. The clinical significance of the reported results were rarely discussed by the authors, thus while the results reported reached statistical significance, the clinical significance may be different.

Table 1. Evidence on the physiological effects of wearing N95 respirators, surgical masks or non-medical face masks (n=15)

STUDY	METHODS	KEY OUTCOMES
Healthy volunteers (n=8)		

Liu 2020 (3) Quasi-Experimental study China May 2020	12 healthy college males were given either a surgical mask, KN95 medical mask, a sponge mask, a gauze mask, or a disposable civilian mask which they wore while seated and reading for about 100 minutes. A questionnaire was then filled out and physiological measurements were taken.	• Self-reported thermal sensation vote (TSV) and symptoms such as dizziness, difficulty concentrating or thinking, listlessness and difficulty breathing, as well as dry skin and dry mouth were more pronounced with a KN95 mask than with a surgical or non-medical mask and were elevated compared to wearing no mask $p<0.05$. • Heart rate increased with wearing a mask ($p=0.04$), blood oxygen saturation decreased with wearing a mask ($p=0.048$) and mean skin temperature increased with wearing a mask ($p<0.01$). • The KN95 caused the largest change in these parameters followed by surgical masks > medical masks, sponge and civilian disposable masks> gauze and wearing no mask. Results in graphs. • There was no significant change in blood pressure (systolic < 4% change, $p=0.915$, diastolic <3% change, $p=0.529$). • This study is not generalizable due to small sample size and homogenous sample population.
Epstein 2020 (6) Quasi-Experimental study Israel Sep 2020	16 healthy male volunteers, participated in this multiple cross-over, self-control trial, using a standard cycle ergometry ramp protocol. Maximal exercise tests without a mask, with a surgical mask, and with an N95 respirator were conducted. Physiological parameters and time to exhaustion were compared. Heart rate (HR), oxygen saturation (SO_2), respiratory rate (RR), and	• Heart rate, respiratory rate, blood pressure, oxygen saturation, and time to exhaustion did not differ significantly among the different types of masks Compared to no mask at rest and at all stages of exercising the N95 mask was associated with a significant increase in end-tidal CO_2. The difference was more pronounced with increased load (more intense exercise). For surgical masks there was only a significant difference in the end tidal CO_2 in the last phase of the workout.

	end-tidal carbon dioxide ($EtCO_2$) and blood pressure were measured.	• This study is not generalizable due to small sample size and homogenous sample population.
Fikenzer 2020 (7) Quasi-Experimental study Germany Jul 2020	12 healthy males enrolled in the cross-over study which measured three incremental exertion tests, with either no mask, a surgical mask or an N95 mask (FFP2). The exertion tests were conducted on a semi-recumbent ergometer at a constant speed of 60–70 revolutions per minute. Workload increased until voluntary exhaustion occurred followed by a 10-min recovery period. Cardiac output (CO), stroke volume (SV), heart rate (HR), maximum oxygen consumption (VO_{2max}) and minute ventilation (VE) were monitored continuously at rest, during the exertion test and during recovery.	• Stroke volume and cardiac output and cardiac work did not differ significantly when wearing no mask a surgical mask or an N95 mask ($p>0.05$). • There was a marked effect on pulmonary parameters: Compared to no mask, minute ventilation was reduced with a surgical mask by −12.0±12.6% and with an N95 mask by −23.1±13.6%. • The VO_{2max} was significantly decreased with the N95 mask compared to both the surgical mask and no mask. The difference between the surgical mask and no mask was borderline. • This study is not generalizable due to small sample size and homogenous sample population.
Li 2005 (8) Quasi-Experimental study Hong Kong May 2005	10 healthy participants were enrolled in this cross-over trial. They performed intermittent exercise (at three low to moderate workloads) on a treadmill in a climate chamber wearing an N95 or surgical mask with and without nano-functional treatments (a treatment that repels water and has been shown to inactivate bacteria). Temperature, heart rate and blood pressure were measured.	• Differences between nano-treated and untreated N95 and surgical masks were not significant. • Average heart rate was significantly higher for those wearing an N95 mask compared to a surgical mask. • Increased intensity of exercise equated to a more pronounced difference in heart rate between mask types. • The humidity and temperature inside the nano-treated and untreated surgical masks were lower than for both N95 mask ($P=0.000$).

		• Symptoms of fatigue, dyspnea and overall discomfort were significantly worse for N95 masks. • This study is not generalizable due to small sample size and homogenous sample population.
Wong 2020 (9) Quasi-Experimental study Hong Kong Oct 2020	23 healthy volunteers of various sporting backgrounds participated in a case-crossover study where they underwent graded treadmill walking at 4km/hr for 6 minutes with and without a surgical mask on to investigate the physiological effect (heart rate and perceived exertion measured on a scale from 6 to 20) during moderate exercise.	• Surgical masks elevated heart rate when wearing the face mask during exercise compared to without (128.4 +/- 13.2 vs. 124.4 +/- 12.8 beats per minute) and participants reported a higher perceived level of exertion starting after 3 minutes of exercise (12.7 +/- 2.1 vs. 10.8 +/- 2.2). Results extracted for 6 minutes of exercise. • The author suggests that exercising with face masks at a submaximal level induces higher physiological responses. This may be due to restricted ventilation, heavier breathing, and sympathetic responses. • Due to increased cardio-respiratory burden from masked exercise the authors suggest that mask wearers be cognisant of their exertion and heart rate taking care not to exceed 150 beats/min or 70% of their age-predicted max heart rate. • This study is not generalizable due to small sample size.
Morris (2020) (10) Quasi-experimental study Denmark* 2020*	A cross-over trial with 8 male participants was conducted to evaluate the impact of a KN95 respirator when worn in 40°C and 20% humidity during light exercise of 5 MET for 45 minutes. Cognitive and fine-motor performances were assessed using tests previously demonstrated to	• Dyspnea was not significantly different at rest, but with exercise there was significantly more dyspnea in the KN95 group 51.3% (27.6) vs the no mask group 21.4% (14.5), < 0.001. • Results for no mask – KN95 mask body temperature measurements were not significantly different.

	be highly sensitive and reliable at detecting heat-related decrements in cognitive performance, including dehydration, and radiation. Dyspnea was measured using the Borg breathlessness scale.	• Other cognitive and fine motor outcomes were not significantly different for no mask vs. KN95 mask. • This study is not generalizable due to small sample size and homogenous sample population.
Dattel 2020 (2) Quasi-Experimental study USA Jul 2020	This study explored the effects of cloth face masks (composition not described) or surgical face masks. 32 instructor pilots were studied in a normobaric flight chamber wearing either a cloth mask or a surgical face mask. Measurements on CO_2, heart rate, respiration rate, and oxygen saturation were taken over a 90 minutes period.	• Instructor pilots reported comfort issues, fatigue, and restriction of movement from wearing face masks. • No differences in CO_2, heart rate, respiration rate, or oxygen level were found between the cloth mask and surgical mask after a 90 minute simulated flight at 5000ft. • This study is not generalizable due to small sample size.
Lee 2011 (11) Quasi-experimental study Singapore* 2010*	14 healthy adults participated in a study of breathing resistance caused by N95 respirators (3M 8210). Breathing resistance was measured for inspiration and expiration and total volume (l per 30s) were measured with and without an N95 respirator.	• Breathing resistance was a mean of 126% inspiratory and 122% expiratory flow resistance with the use of N95 respirators. • There was an average reduction of 37% in air exchange volume with the use of N95 respirators. • This study is not generalizable due to small sample size.
Healthcare Workers (n=2)		
Purushothaman 2020 (12) Cross-sectional study India Jul 2020	A survey was completed by 250 HCWs without comorbidities at a tertiary hospital who consistently wore either surgical masks or N95 respirators for a minimum of 4h/day. Data was collected in a self-reported questionnaire that was developed with formative research, but not pretested.	This study does not distinguish outcomes by surgical mask or N95 respirator. • 58.2% of HCWs indicated they experienced trouble breathing on exertion ($p<0.001$). No additional information on what is meant by exertion was provided. • Participants self-reported a range of discomfort, some common complaints were; excessive sweating around the mouth

		(67.6%), acne (56.0%) skin irritation (39%), and pain behind ear 45.2%.
Bharatendu 2020 (13) Quasi-Experimental study Singapore Feb-Apr 2020	154 HCWs seeking medical attention for headaches related to PPE use were studied; 25% had migraines and 80% indicated the headaches were *de novo* after using the N95 mask. Transcranial Doppler (TCD) monitoring of middle cerebral artery was performed using two validated measurements mean flow velocity (MFV), pulsatility index (PI) and end-tidal carbon-dioxide (ET-CO_2) pressure, which were recorded prior to donning the N95 respirator and five minutes after. N95 (3M® N95 respirator mask) was evaluated with and without a powered air-purifying respirator (PAPR, 3M® Versaflo® TR-300 series).	• Donning of a N95 respirator resulted in significant increase in mean flow volume, relative change 12.3% (SD 29.8, p<0.001), decrease in pulsatility index relative change 13.3% (SD 11.3, p<0.001) and end-tidal carbon dioxide levels were significantly elevated, an increase of, 3.1 mmHg (SD 1.2) in the N95 mask compared to no mask. • 24 participants used a PAPR and results indicate no difference in the mean flow volume, pulsatility index or end-tidal carbon dioxide levels within 5 minutes of donning the respirator compared to wearing no mask. Thus, powered air-purifying respirator restores N95 mask induced cerebral hemodynamic changes. • Given measurements were taken at 5 minutes, it is unknown if the changes are sustained or corrected by autoregulation.
Pregnant women (n=2)		
Tong 2015 (14) Quasi-Experimental study Singapore Sep 2011	Phase I assessed volume of O_2 uptake (VO_2) in 8 pregnant health care workers while performing simulated nursing tasks. Phase 2 compared the use of N95 masks to no masks in 20 pregnant women (27-32 weeks gestation) during two 15-minute exercise cycles on a treadmill at 3 METS (which was equivalent to the normal moderate work of a HCW recorded in phase 1).	Breathing through a N95 mask compared with no mask resulted in: • A significantly lower tidal volume (TV) at rest -0.15L (95%CI: -0/23- -0.08L) and during exercise -0.21L (-0.32- -0.10L), overall a ~23% decrease. • A significantly lowered minute ventilation (VE) by 5.55L (95%CI −7.58 % - −3.51) which is ~ 25.8% lower. • No significant change in breathing frequency with the N95 mask.

	In both Phases the women wore a tight fitting Hans Rudolph respirator mask that had an outlet that was either open to air or covered by N95 mask materials. And measurements included volumes of oxygen (VO_2) and carbon dioxide (VCO_2) tidal volume (TV), minute ventilation (VE), forced expired O_2 (FeO_2), and CO_2 concentrations.	• Significant reductions of forced expired O_2 concentration (FeO_2) -0.54% (-0.70 - -0.38) during exercise. • Significant elevations forced expired CO_2 concentration ($FeCO_2$) during exercise 0.30% (0.18, 0.42) and in the pre-exercise and post-exercise periods. • Pulmonary gas exchange: Significantly lower VO_2 by 13.8 % and VCO_2 by 17.7 % were reported. • There were no differences in the maternal or fetal heart rate, oxygen saturation or rating of perceived exertion with the N95 mask. • This study is not generalizable due to small sample size and short duration of exercise.
Roberge 2014 (4) Controlled Experiment USA Oct 2014	Controlled study of 22 pregnant (13-35 weeks) and 22 non-pregnant healthy women to determine if there is a difference in the physiological and subjective effects of wearing an N95 mask (filtering face piece respirator, FFR). Respiratory rate, chest wall skin temperature, maternal and fetal heart rate, pulse-derived oxygen saturation (SpO_2). Borg rating of perceived exertion scale 6-20. Measurements were taken with and without wearing an N95 mask during exercise and postural sedentary activities over a 1 hour period.	• Overall N95 use significantly decreased respiratory rate, a minor difference, mean 0.94 (95%CI: 0.1-2.2) breaths/min and transcutaneous partial pressure of carbon dioxide ($PtcCO_2$) increased over time during exercise for all women due to re-breathing of higher CO_2 levels generated during exercise. • There were no significant differences in measured physiological and subjective responses in pregnant women compared with non-pregnant women wearing N95 masks for 1 hour during exercise and sedentary activities. • There was no significant effect on fetal heart rate. • This study is not generalizable due to small sample size.
People with chronic conditions (n=3)		

Kyung 2020 (15) Quasi-Experimental study South Korea Mar-May 2015	97 patients with varying severity of COPD were monitored for symptoms and physiologic variables during a 10-min rest period and 6-min walking test while wearing an N95 face mask. Patients were 19-80 yrs, could walk unassisted, were not on long term oxygen therapy and did not have a history of recent hospitalization. Measurements included breathing frequency, dyspnea, heart rate, S_{pO2}, blood pressure and a symptom questionnaire that included modified Medical Research Council dyspnea scale score. Severity of air-flow obstruction in COPD was measured by using post bronchodilator FEV_1, 31 subjects had a FEV_1 < 50% at baseline.	• 7/97 subjects failed to wear the N95 mask for the entire test. A modified Medical Research Council dyspnea scale score ≥ 3 (odds ratio 167, 95% CI 8.4 to >999.9; *P* = .008) or a FEV_1 < 30% (odds ratio 163, 95% CI 7.4 to >999.9; *P* = .001) was associated with an inability to continue wearing an N95 mask. Symptoms in this group were more pronounced and included dyspnea, dizziness and headache. Among the group that completed the test: • At rest breathing frequency was increased wearing an N95 mask (20.7 breaths /min) vs. no mask (19.7). • End tidal PCO_2 (25.7 mm Hg) wearing an N95 mask vs. no mask (24.8). • S_{pO2} levels were lower with an N95 mask (96.0%) vs. no mask (96.4%). • After 6 minutes of walking, significant differences were found with heart rate (92.4 vs. 87.7), breathing frequency (25.7 vs. 23.3 breaths/min), end tidal PCO_2 (35.5 vs. 34.0 mm Hg) was higher and S_{pO2} levels were (93.0 vs. 93.8 %) lower in those with an N95 mask vs. no mask. • The authors stated that COPD patients should be warned to remove the N95 mask immediately with the onset of dyspnea, headache, or dizziness.
Harber 2010 (16) Controlled experiment USA 2010	97 individuals, 42 with asthma, 14 mild COPD, 17 chronic rhinitis and 24 healthy individuals' respiratory effects of using a dual cartridge half face mask or a N95 respirator while doing work tasks.	• Compared with an N95, tidal volume, minute ventilation and respiratory rate were slightly lower with half mask, but this may not be of clinical significance. No consistent effect was noted for volumes for COPD or asthma.

	Respiratory outcomes included tidal volume, minute ventilation, inspiratory/ expiratory time, duty cycle and flow rates.	• COPD had prolonged time to reach peak expiratory flow rate. • Those with rhinitis performed better than COPD and asthma. • Age was not a factor. • Those with asthma or mild COPD had a lower FEV_1 percentage of predicted, which was associated with ventilator volume. • This study is not generalizable due to small sample size.
Ciocan 2020 (17) Quasi-Experimental study Italy Oct 2020	10 HCWs including 3 with asthma and 3 current smokers were included in this cross-over trial. They wore a 4 layer surgical mask (AFLUID) during 4 hours of mild-moderate usual working activities and their respiratory function was monitored. A Respiratory Functional Test (RFT) was performed at three time periods and Arterial Blood Gas (ABG) samples were taken before the first and third RFT.	• Compared to no mask, Maximal Voluntary Ventilation (MVV) was reduced with a 4-layer mask (p=0.002) and remained low even during activity (p=0.041). • No significant variations in observed RFT and ABG parameters were reported although the study did not have sufficient power to detect differences. • This study is not generalizable due to small sample size.

* Location or date of study was estimated based on author affiliations and / or publication date. HCW= healthcare worker

GUIDANCE ON FACE MASK USE IN THE GENERAL POPULATION

Key guidance from Canada, the USA and WHO were identified and examined for recommendations on mask use for those with chronic medical conditions and general use in the community (Table 2).

- The Canadian Thoracic Society and Asthma Canada both indicate people with an underlying lung condition should be able to wear a non-medical face mask. However, for those that have trouble wearing a mask it is suggested to work with a healthcare provider to find a solution or avoid situations where you need a mask as much as possible to minimise your risk (18).

- The WHO's newest guidance recommends that face masks should not be worn for source control to prevent transmission from a child under 5 with COVID-19 (19). They do not specifically address if children 2-5 years old should wear a mask for protection. All guidance states children under 2 years old should not wear a mask.

Guidance from Canada (20), the USA (21) and WHO (19) state that masks should not be required for anyone who is unable to remove their mask without assistance, including children under two years old, and anyone who has trouble breathing, is unconscious, or is incapacitated due to the risk of suffocation.

- It is also suggested that people with certain disabilities or small children may be unable to wear their mask properly and thus should not wear a mask (20, 21).

Table 2. Guidance on face mask use for those with medical conditions and the general public (n=5)

STUDY	METHODS	KEY OUTCOMES
World Health Organization (19) Guidance document Switzerland Dec 2020	This is an update to WHO June 5 guidance on mask use and covers: • mask management; • SARS-CoV-2 transmission; • masking in health facilities in areas with community clusters and sporadic transmission; • mask use by the public in areas with community and cluster transmission; • alternatives to non-medical masks for the public; • exhalation valves on respirators and non-medical masks; • mask use during vigorous intensity physical activity; • Essential parameters to be considered when manufacturing non-medical masks (Annex).	• Face mask use should be part of a layered approach to public health interventions. • Masks can be for protection or source control. (Wear a medical mask if you suspect you have COVID-19). • Appropriate use, storage and cleaning guidelines are presented. • Children under 5 should not wear a mask for source control. Use of masks in older children are based on local factors and those over 12 years old should follow guidelines for adults. • Manufacturing non-medical masks: 3 layers with a hydrophilic inner layer, a hydrophobic outer layer and a hydrophobic middle layer that enhances filtration. • Exhalation valves are discouraged.
Canada.ca (20) Guidance document	Guidance on the use of non-medical masks to prevent the	• Non-medical masks protect the person wearing it and others from the spread of COVID-19.

Canada Nov 2020	spread of COVID-19 in the community. • Mask mandates • Composition of non-medical masks • Use of mask filters • Application, cleaning and storage • Children • Safety • Hearing impaired • Face shields, neck gaiters, exhalation valves	• Mandatory mask policies are put in place depending on the local spread of COVID-19. • Non-medical masks should be 3 layers, two layers of tightly woven fabric and a middle layer with filtration properties e.g. non-woven polypropylene fabric. Masks should fit snugly to the face covering the nose and mouth, but still be breathable. • Non-woven polypropylene fabric is readily available (e.g. craft fabric, interfacing or reusable shopping bags). Disposable mask filters may also be used. • Children under 2 should not wear a mask. Between 2-5 yrs mask wearing should be supervised. • Avoid stigmatization of people who cannot wear a mask due to illness or disability.
Centers for Disease Control and Prevention 2020 (21) Guidance document USA Nov 2020	Considerations for wearing masks, type not specified, to help slow the spread of COVID-19 are provided. Topics include: 1) Evidence for effectiveness of masks 2) Who should and shouldn't wear a mask 3) Difference between types of masks 4) Other types of face protection	• Face masks should not be worn by children under the age of 2 years old, anyone who has trouble breathing, and anyone who is unconscious, incapacitated, or unable to remove their mask without assistance. • Individuals with certain disabilities or children who cannot wear a mask properly should not wear one. • Most people with underlying medical conditions can and should wear a mask. Discuss with your healthcare provider if you have concerns. • Wearing a cloth mask does not raise the carbon dioxide (CO_2) level in the air you breathe.

		• Medical masks and N-95 respirators should not be used as they should be conserved for healthcare workers. • Face shields or goggles are not a substitute for masks. • The most effective cloth masks are breathable, have two-three layers, and are made of tightly woven fabrics such as cotton and cotton blends. • Those who rely on lip-reading to communicate (those that are deaf, hard of hearing, or who care for those who are hearing impaired) may be unable to wear cloth face coverings. CDC recommends a clear face covering, relying on written communication, or decreasing background noise while communicating.
Bhutani (2020) (18) Guidance document Canada July 2020	This is a guidance and position statement from the Canadian Thoracic Society on the use of face masks by the public during the SARS-CoV-2 pandemic.	• The Canadian Thoracic Society supports the recommendation from the Public Health Agency of Canada to wear a non-medical face mask in the community when it is not possible to consistently maintain a 2-meter physical distance from others. • There is no evidence that wearing a non-medical face mask will exacerbate an underlying lung condition. • Wearing a face mask alone will not prevent the spread of COVID-19 and should be complemented with other recommended public health measures such as increased hand hygiene and physical distancing. • For those experiencing challenges with wearing a mask, it is recommended they speak with their health care provider to

		develop strategies to be able to wear a face mask. If despite best efforts, wearing a mask is not possible then individuals should avoid or minimize circumstances where physical distancing is not possible.
Asthma Canada (22) Guidance document Canada 2020	Asthma Canada issued this guidance to people with asthma to address concerns related to mask use and COVID-19.	Recommendations given for people with asthma: • Masks come in different styles and material; select a mask that is most comfortable for you. • Test the mask at home to get used to how it feels. • If you cannot wear a mask without experiencing breathing issues, do not wear a mask. Instead practice 2 meter distancing and minimize time spent around people from outside your household. • Consult with your healthcare professional to go over your asthma action plan and explore other options to protect yourself.

Methods

A daily scan of the literature (published and pre-published) is conducted by the Knowledge Synthesis team in the Emerging Science Group, Public Health Agency of Canada. The scan has compiled COVID-19 literature since the beginning of the outbreak and is updated daily. Searches to retrieve relevant COVID-19 literature are conducted in Pubmed, Scopus, BioRxiv, MedRxiv, ArXiv, SSRN, Research Square, and COVID-19 information centers run by Lancet, BMJ, Elsevier, Nature and Wiley. The cumulative scan results are maintained in a Refworks database and an excel list that can be searched. Details on this search strategy are available upon request. From this database and excel list, article titles and summaries will be systematically searched for the following key words: mask* OR (face AND cover*). An additional search for guidance documents and supporting evidence on persons who should not wear a mask focused on Canada and key health organizations was conducted using a snowball technique and targeting country websites. Each potentially relevant reference was analyzed to confirm its relevance and data was extracted into the review. This review contains research published up until December 2, 2020.

APPENDIX: TYPES OF FACE MASKS

The NCCEH blog post on masking during the COVID-19 pandemic (October 27, 2020) describes the different mask types and includes the following figure on types of masks.

	Respirator	Surgical or procedure mask	Non-medical cloth mask
			Types	N95, 99, 100 (US, Canada), FFP2 or FFP3 (EU). Various styles including cup, flat-fold and duckbill. May also include an exhalation valve.	Typically a 3-layer laminate structure that can include a combination of non-woven air-laid paper and polypropylene.[3]	Wide variability in fabric, number of layers and design with 2-layer cotton being a common design.
Use	For use in environments where exposure to aerosols is likely. Protect against most particles (e.g., N95 block 95% of particles and provide some splash and spray protection). Medical grade N95s are tested for resistance to fluids including blood, but commercial grade are not.	For use in routine care to reduce inward and outward transfer of respiratory droplets. Filter particles > 20 µm diameter and some finer droplet nuclei.[4] Block blood and infectious materials from contact with oral, nasal and skin area. Effective against splash and sprays.	For use by the public in non-healthcare settings as source control to reduce respiratory emissions from the wearer and to reduce exposure to respiratory emissions of others.[3,5]
Approval	U.S. National Institute for Occupational Safety and Health (NIOSH) for N95 or similar and EU standards for FFP equivalents.[6] The Government of Canada lists other approved alternatives to N95s.	FDA with grading based on the level of resistance to splashing (e.g., ASTM 1 – venous pressure; ASTM 2 – arterial pressure; ASTM 3 – high velocity splash).	Not approved for use in any healthcare setting; not tested to any standard of effectiveness. **Note**: Many procedure-type masks found in retail outlets may not be assessed to any approval standards, and would also be considered non-medical masks.
Advantages	Medical grade respirators can be effective against aerosol penetration. Can be reused and disinfected with precautions.	Some protection against contact transmission, are disposable and inexpensive. Fit testing is not required.	Inexpensive and can be made from household materials. Can act as a reminder to not touch face.[6] Can be reused and laundered.[7]
Disadvantages	Filtration efficiency for aerosols is only effective if properly fit tested. Some users may experience some reduction in comfort/breathability. Expensive and may be in short supply.	Less effective against smaller particles (e.g., 0.4-1.3 µm), looser fit than N95 respirators, and therefore more penetration via leaks.[8] Not recommended for reuse or disinfection for use in healthcare environments.	Variable performance for respiratory protection and breathability depending on the material and design.[9] They do not replace other protective measures (e.g., hand hygiene and distancing).[5,10]

Emerging Evidence on COVID-19

Evergreen Rapid Review on COVID-19 Vaccine Attitudes and Uptake – Update 8

Introduction

What is the global evidence on COVID-19 vaccine uptake and the COVID-19 vaccine attitudes evidence for Canadians and specific populations?

The purpose of this evergreen rapid review is to identify and summarize literature on COVID-19 vaccination uptake and attitudes to better understand the factors associated with vaccine uptake in Canada. This report focuses on Canadian evidence on uptake and attitudes, and evidence from five eye countries related to specific populations up to July 1, 2021. Evidence on pre-defined priority populations from Australia, New Zealand, USA, and UK were included to complement areas where there was little Canadian research. Priority populations include healthcare workers, LGBTQ+, faith groups, newcomers, parents, women who are pregnant or breastfeeding, people living in rural communities, older adults, people with comorbidities, and people experiencing multiple barriers to health (e.g., homelessness, mental health and/or substance use disorder). Previous versions of this report (updates 1-7) included evidence up to June 1, 2021 on vaccine knowledge, attitudes, and behaviours and can be requested through phac.ocsoevidence-bcscdonneesprobantes.aspc@canada.ca. The What's New and Key Points sections below focus on highlighting important findings from the most recently conducted studies (within the last five months).

What's New

- This update identified 40 new studies or updates to existing studies on COVID-19 vaccination uptake and attitudes including six specific to Canada. New studies are indicated throughout the tables as *new* and all tables have been moved to appendices to assist readers in navigating the document.

Vaccine Uptake

- Vaccine uptake and refusal trends continue to mirror vaccine intention trends. Across all populations, vaccine uptake was positively associated with increasing age, male gender, and prior history of receiving a flu vaccine. Those with a history of SARS-CoV-2 infection were less likely to vaccinate and Black and minority ethnic groups had the lowest uptake rates.
- To date there has been one study on vaccine uptake in Canadian healthcare workers (HCWs) completed in Dec 2020. In Montreal, 80.9% of HCWs offered a vaccine accepted and 19.1% refused. 74.1% of those that declined a vaccine reported they will accept a vaccine in the future with 53.2% wanting to delay a few months and 31.9% wanting to wait a year (1). The most common reasons for refusal were the newness of the vaccine, a preference for others to get vaccinated first, a lack of information about the vaccine, and not having enough time to make a decision (1).

- In a group of 266 liver transplant recipients in Italy, 96.6% accepted a vaccine when offered. Despite receiving adequate information, five patients (1.8%) refused vaccination due to concerns over the potential for serious adverse events. The barriers in place for the remaining four patients (1.6%) could be lifted either by providing further details regarding the vaccination or following resolution of medical and logistical issues (4).
- In a group of 85 hospitalized psychiatric patients in the UK who had the capacity to decide if they wanted a COVID-19 vaccine, 80% accepted and 20% refused. White British patients were less likely to refuse compared to Black, Asian, minority ethnic (BAME) patients (16.9% vs 30%). The reasons for refusal included concerns about the safety and side effects of the vaccine, a belief there is a low risk to their personal health from contracting COVID-19, broader distrust of healthcare services, and concerns about animal testing (5).

Vaccine Uptake Intervention Strategies

- The implementation of two text-message reminders (either on the personal or social benefits of vaccination) increased vaccine uptake rates in Israel. The aggregate effect over eight days post intervention revealed the personal benefit reminder led to a 9% relative increase compared to the social benefit reminder (23.8% vs 21.7%, P<0.0001) (2).
- Israel implemented a policy where entry to certain public places required the presentation of a "green pass" which could be acquired from either receiving a vaccine or a recent negative COVID-19 test. The implementation of this policy in February was associated with a relative increase of 22.2% in vaccine uptake after three days (2).
- In February, a community based vaccine site (Unidos en Salud UeS) was deployed to overcome barriers to COVID-19 vaccination faced by Latinx individuals in San Francisco. 56.1% reported they got vaccinated earlier because of the site and 65.3% reached out to three or more individuals to recommend the vaccine after their positive experience (3).

Adherence to Public Health Measures Post-Vaccine

- Using a Global Positioning System (GPS) in the UK, the median daily increase in average daily travel distance from a participant's registered address was 45.0m (95% CI: 25-65m, P = <0.001) between the vaccination date and 99 days after vaccination (6).
- At the beginning of the vaccination campaign (January) in Israel, those who were infected with COVID-19 were less careful about social distancing (29.7%) and mask-wearing (18.8%) compared to those who received the first dose of vaccine (12.8% and 8.2%), or those who were neither vaccinated nor infected (19.2% and 11.6%) (7).

Canada

- Two surveys conducted in June show that 84-88% of Canadians have either received a vaccine or wish to get a vaccine as soon as possible, an increase from April and May surveys (8, 9).
- In June, 89% of Canadians who had one dose reported they intend to receive a second dose, 9% have already had their second dose, 1% probably will not, and 1% were unsure (10).

- In a group of 70 parents or guardians of children aged 12-17 from Manitoba, 15% and 13% were not sure or would not vaccinate their children, respectively (11). Those who were hesitant to vaccinate their children were in households making less than $40,000/year, would not get the vaccine themselves, and didn't believe adults should get all the regular vaccines (11).
- 48% of Canadians were uncomfortable about receiving a different brand of vaccine as their second dose, whereas 46% were comfortable and 6% were unsure. Of those who received AstraZeneca as their first dose, 50% preferred to receive AZ as their second dose, 32% preferred another brand as their second dose, and 18% were unsure (10).
- Financial incentives (monetary, vouchers, complimentary items, draws for prizes, discounts) were not reported to increase the likelihood of accepting a vaccine in a study conducted in Manitoba (between 7-84% of respondents stating the incentive would not make them more likely to vaccinate). However, 70% would be concerned if only vaccine hesitant individuals received large ($50-100) incentives (11).
- Vaccine passports have high support in Quebec with 72% of residents in favour (12).

Parents

- Parental and child vaccine intentions continue to be highly correlated with each other (13-16). Among a group of American parents or caregivers surveyed in April, 61.9% intended to vaccinate their youngest child (mean age 4.7 years), 23.3% were unsure, and 14.8% did not. Having a child attend daycare more than once a week was associated with increased intentions (aPR 1.23, 95% CI: 1.05-1.45) (16).
- Similar to the general population, parents from lower-income households, who are younger, less educated, have a history of not accepting other vaccines, who are female, and ethnic minorities were more likely to reject a vaccine for their children (14, 16-19).

Other Populations of Interest

- In a UK study, those reporting Christian faith were significantly more likely to get a vaccine if vaccine passports were introduced for domestic (aOR 1.23, 95% CI: 1.08-1.41) and international (aOR 1.22 95% CI: 1.07-1.39) travel compared to atheists and agnostics (20).
- A quasi-experimental study of 709 unvaccinated registered voters in South Dakota, USA demonstrated that messaging from a religious leader had a statistically significant positive effect on intention to vaccinate, while messages from a political or medical leader did not (21).

Key Points

- There have now been 205 studies on COVID-19 vaccine uptake and attitudes conducted in Canada on the general public and in Canada, Australia, New Zealand, USA, and the UK on healthcare workers (HCWs), high-risk populations, and other populations of interest (Tables 1-7). The majority have focused on intention to vaccinate. Since vaccine rollout began in December 2020, 29 studies have evaluated vaccine uptake and 7 evaluated continued adherence to public health measures post-vaccination.

Vaccine Uptake

- Vaccine uptake and factors associated with uptake in HCWs were evaluated in 14 studies from the USA, UK, Canada, and Israel, and in two studies of adults over 70 in the UK and Poland (Table 1). The proportion of HCWs who accepted and received one dose of the vaccine ranged between 52-94% across studies. Doctors were more likely to get vaccinated compared to nurses and non-clinical HCWs.
- Vaccine uptake and factors associated with uptake were studied in the general population of the UK, USA, Israel, and New Zealand (n=6 studies) and in several specific populations: one study in people experiencing homelessness in the USA, one in disabled adults in the UK, one in stroke and transient ischaemic attack (TIA) survivors in the UK, one in older adults and high risk populations in the USA, one on dialysis patients in the USA, one in liver transplant recipients in Italy, one in patients with irritable bowel syndrome in Italy, one in a psychiatric hospital population in the UK, two in prisons in the USA and two in military units in Israel (Table 1).
- Across all populations, vaccine uptake was positively associated with increasing age and male gender. Those with a history of SARS-CoV-2 infection were less likely to vaccinate and Black, Asian, and minority ethnic groups had the lowest uptake rates.

Vaccine Intention in Canada

- Forty-nine studies on vaccine intention were from Canada: four on HCWs, 36 on the general public, three on HCWs and the general public, two on parents, one on individuals living with obesity, one on youth (aged 16-21), and two engaging expert opinion on who to vaccinate initially. The most recent studies from Mar-May report intention to vaccinate is increasing and currently varies between 66-86% in the general public and 57-82% in HCWs across the Canada. The Atlantic provinces, British Columbia, and Quebec have the highest intentions to vaccinate.

Facilitators and Barriers to Vaccine Intention

- The most common factors positively associated with intention to vaccinate in Canada and globally were male gender, older age, higher education, adequate knowledge or health literacy, trust in experts and government, history of a prior influenza vaccine, higher socioeconomic status, and heightened worry or concern about COVID-19.
- Compared to nurses and other healthcare professionals, doctors were significantly more likely to accept a COVID-19 vaccine.
- Three studies demonstrated that LGBTQ2+ were 6-25% more willing to accept a vaccine compared to non-LGBTQ2+.
- Partisanship was associated with intention to vaccinate. Those who voted liberal/democrat expressed intention to vaccinate at higher rates than other parties.
- A recommendation to get the vaccine by a healthcare provider (e.g., doctor) had a positive impact on vaccine intention.

- Intention to vaccinate varied widely by race/ethnicity, with White ethnic groups more likely to vaccinate compared to other ethnic groups such as Black, Asian, and Hispanic in studies from Canada, USA, and UK.
- Parents had lower intentions to vaccinate their children compared to themselves. Parental and child vaccine intentions were highly correlated with each other, with parents who were intending to take a vaccine being more likely to intend to vaccinate their children. Those with younger children (aged 0-4) were more hesitant compared to those with children over the age of 5.
- Religion and belief in conspiracy theories were associated with vaccine hesitancy.
- Concerns about vaccine safety and effectiveness were the two most cited reasons for vaccine refusal. Other commonly cited reasons include newness of the vaccine, and the belief that a COVID-19 vaccine is unnecessary.
- Compared to the general population, intention to vaccinate is lower in some high-risk populations such as pregnant women, people experiencing homelessness, those with substance use disorders, and vulnerable populations.
- Rural participants were slightly less likely to accept a vaccine compared to urban and suburban participants.

Overview of the Evidence

Two-hundred and five articles pertaining to COVID-19 vaccine uptake and attitudes were identified and included in this review. Of these, 99 are preprints or reports and have not completed the peer-review process. This report focuses on the global evidence on COVID-19 vaccine uptake and Canadian evidence on attitudes. To complement the Canadian literature, evidence on pre-defined priority populations from Australia, New Zealand, USA, and UK was also included. This includes healthcare workers, LGBTQ+, faith groups, newcomers, parents, women who are pregnant or breastfeeding, people living in rural communities, older adults, people with comorbidities, and people experiencing multiple barriers to health (e.g., homelessness, mental health and/or substance use disorder).

The publications reporting on COVID-19 vaccine uptake and attitudes are mainly observational studies with a few randomized controlled trials, controlled before and after studies, and quasi-experimental studies exploring factors associated with intention to vaccinate and the impact of messaging on these intentions. The outcomes in the experimental studies did not assess prevalence, but rather were designed to inform what may be most effective across a range of options. Randomized controlled trials have the added advantage of balancing the intervention groups to avoid the influence of non-comparable groups (e.g., confounding).

A formal risk of bias evaluation was not conducted. Across observational studies the reliability of the outcome is based on obtaining a representative sample of the target population that is sufficiently large to obtain a representative spectrum of results. Studies frequently did not demonstrate the representativeness of their samples to the target population in both unpublished and published studies. Longitudinal studies where a target population was sampled more than one time to monitor changes in vaccine attitudes and uptake over

time were the strongest observational study design identified. Most observational studies were cross-sectional online surveys of a target population at a single point in time. These study designs are at moderate/high risk of bias and thus, are considered medium-low quality depending on the sample size and whether the sample represents the target population as well as how well the survey tool can measure the outcome(s) of interest (e.g., was it informed by formative research, validated and pretested prior to implementation). For most of the included studies the outcomes are self-reported, which can be biased by response and social desirability biases. Other biases considered in these studies include response rate and missing data. Most studies captured in this rapid review did not report and/or account for one or more of the criteria listed above either due to conduct or reporting of the study. While there are many studies that show similar trends, the conclusions could change with additional research, larger sample size, different sampling strategies, data collection tools, and progression through the pandemic.

A key knowledge gap in this research are studies that address vaccine intentions and reasons for hesitancy in high-risk and unserved populations. The majority of studies used online surveys, and to a lesser extent telephone surveys, which may limit segments of population due to lack of access. Although the vaccine rollout has been underway for a few months, there have been minimal studies released on vaccine refusal and the knowledge and attitudes associated with actually rejecting or accepting a vaccine. This information is crucial to determine why people are accepting or refusing vaccinations to continue developing strategies to encourage vaccine uptake in those who are hesitant.

CONTENTS

COVID-19 VACCINE UPTAKE & ADHERENCE TO PUBLIC HEALTH MEASURES POST-VACCINE

Vaccine uptake and factors associated with uptake in health-care workers (HCWs) was evaluated in 14 studies from the USA, UK, Canada, and Israel (1, 22-34), two studies of adults over 70 in the UK and Poland (35, 36), two in prisons in the USA (37, 38), two in military units in Israel (39, 40), one study in people experiencing homelessness in the USA (41), one in stroke and transient ischaemic attack (TIA) survivors in the UK (42), one in disabled adults and parents in the UK (43), one study in older adults and high risk populations in the USA (44), one in patients on hemodialysis in the USA (45), one in liver transplant recipients in Italy (4), one in patients with irritable bowel syndrome in Italy (46), one in a psychiatric hospital population in the UK (5), and six studies in the general population of the UK, USA, Israel, and New Zealand (2, 15, 44, 47-49). Only studies where it is has been established or can be inferred that the entire group was offered a vaccine prior to measuring uptake were included. This includes studies from the beginning of the vaccine rollout (December 2020 onwards). Seven studies assessed adherence to public health measures post-vaccine in the UK and Israel (6, 7, 35, 50-53). High level points are listed below and detailed outcomes for each study are located in the Appendix (Table 1). These studies should be interpreted with caution as vaccine uptake and refusal were reported as secondary outcomes to other primary outcomes such as vaccine efficacy in a few studies and in other studies measurement of vaccine refusal was unclear due to reporting or the preliminary nature of the results.

Overall Trends

- Vaccine uptake was positively associated with increasing age (1, 15, 25, 26, 29, 30, 34, 38, 45, 50, 54) and male gender (1, 15, 22, 25, 26, 29, 30, 36, 45, 47).
- Those with a history of SARS-CoV-2 infection were less likely to vaccinate in four studies (25-27, 45). Other reasons for declining a vaccine included concerns over the vaccine being new, potential side effects, safety, belief there is a low risk to their personal health from contracting COVID-19, broader distrust of healthcare services, concerns about animal testing, and being experimented on (1, 4, 5, 27, 28, 30, 32, 36, 46).
- Those who did not receive the flu vaccine were less likely to get the vaccine compared to those who did in three studies in the USA (30, 32, 45).
- Ten studies evaluated vaccine uptake across different ethnic/race groups. Black and minority ethnic groups had the lowest uptake rates (5, 22, 25-27, 29, 30, 32, 34, 38, 49).
- These trends mirror the trends seen in intention to vaccinate.

Healthcare Workers

- In six studies of HCWs in hospitals across the USA, 70-94% of HCWs chose to receive the vaccine when offered (22, 27, 30-33).
- In a December survey conducted in Montreal, Canada, 80.9% of HCWs offered a vaccine accepted and 19.1% refused. 74.1% of those that declined a vaccine reported they will accept a vaccine in the future with 53.2% wanting to delay a few months and 31.9% wanting to wait a year (1).

- High rates of vaccination among HCWs in Israel were reported in two studies where all HCWs had been offered vaccine. As of Jan 21 and Jan 24, 90% (n=1500) and 79% (n=9109) of HCWs had received at least one vaccine dose (23, 24).
- Across three studies of HCWs who were offered a vaccine in hospitals in the UK, 63-89% chose to receive the vaccine (25, 26, 29).
- Across 87 care homes in the UK where all staff were offered a vaccine, 52.6% (n=1119) had received their first vaccination with a mean vaccination rate per care home of 51.4% (95% CI: 43.9-58.8%). A common reason for not receiving the vaccine was staff being off-site during vaccination sessions (36.5%). If logistical issues such as this were resolved, the mean vaccination rate per care home could have increased to 69.8% (95% CI: 63.2-76.3%) (28).
- Physicians were more likely to have accepted the vaccine compared to nurses and non-clinical HCWs (22, 27, 29, 30).

Older Adults (70+)

- In a UK study of older adults (80+) where 99.8% reported that they had been offered a vaccine, 99% had taken at least one dose, 15% had two doses, and 1% refused (35, 54).
- In a study of 1427 older adults (70+) living among the general public in Poland, 62.7% had been given the vaccine and 37.3% said they were unwilling to get vaccinated. Independent predictors of vaccine uptake were receiving an explanation by a medical professional as to why they should be vaccinated (OR 4.23, 95% CI: 2.90-5.75), living with others (OR 3.13, 95% CI: 2.03-4.26), being able to travel independently to their general practitioner (OR 1.92, 95% CI: 1.45-2.76), having chronic illnesses (OR 2.98, 95% CI: 2.05-4.01), and higher socio-economic status (OR 1.79, 95% CI: 1.33-2.15) (36).

People Experiencing Homelessness

- In a group of 90 people experiencing homelessness in Los Angeles, 17 were offered a vaccine of which 10 accepted and 7 refused. Reasons for refusal were not explored (41).

Prisons

- Across correctional facilities in Rhode Island and California, 66.5-76.4% of incarcerated individuals accepted a vaccine. Reasons for refusal were not explored (37, 38).

General Population

- A longitudinal study of the general population of the UK demonstrated vaccine refusal rates are between 1-2%. Of those who have been offered a vaccine, vaccine refusal rates were 2% in those aged 16-29, 1% in those aged 30-49, and 2% in those aged 50-69 (50, 54).
- In a North West London vaccination program where 413,919 individuals were offered a vaccine, 5.88% of people refused the vaccine and 0.7% were hesitant. Deprivation was negatively associated with declining vaccination ($r=-0.94$, $P<0.01$). For those living in the deprived areas, the highest rates of refusal were in those aged 70+ (70-74 = 17.5%; 75-80 = 19.0%; 80+ = 25.9%), the clinically extremely vulnerable (19.2%) and Black and Black British (20.0%) communities (49).
- In a longitudinal survey of adults from New Zealand, vaccine refusal rates dropped from 2% in April to 1% in May (15).

- In the UK, 5% of those identifying as other religion and 4% of Buddhists who had been offered a vaccine had declined compared to 1% reporting no religion (47).
- Two studies were conducted to measure the impact of text-message reminders on booked vaccination rates in the USA and Israel. In the USA study, an initial text reminder sent one day after an individual was notified of vaccine eligibility boosted appointment and vaccination rates by 86% and 26%, respectively (44). A second text reminder sent to those who had not scheduled an appointment eight days after the first boosted appointment and vaccination rates by 52% and 16%, respectively (44). In the Israel study, individuals received one of two text-message reminders about either the social or personal benefits to vaccination (2). The aggregate effect over eight days post intervention revealed the personal benefit reminder led to a 9% relative increase compared to the social benefit reminder (23.8% vs 21.7%, P<0.0001) (2).
- Israel implemented a Green Pass policy where entry to certain public places required the presentation of a "green pass" which could be acquired from either receiving a vaccine or a recent negative COVID-19 pass. The implementation of this policy in February was associated with a relative increase of 22.2% in vaccinate uptake after three days (2).

Military Units

- Vaccine uptake was high (84.8-89.8%) in military units across two studies in Israel (39, 55). In a group of 28 soldiers who were not intending to vaccinate, 47.4% proceeded to vaccinate after attending an on-site physician consultation to discuss their concerns (P = 0.004) (39).

Other Populations

- In the UK, 1% of those with disabilities and 1% of clinically extremely vulnerable respondents had been offered a vaccine but declined, which was slightly higher than the general population (2%) (56). 3% of parents with children aged 0-4 had been offered a vaccine and declined compared to 2% of those with children over 5 years or 1% among non-parents and those not living with dependent children (43).
- 14.2% of dialysis patients in a USA study refused a vaccine when offered. Those on dialysis for more than 5 years were more likely to refuse a vaccine (OR 1.7, 95% CI: 1.08-2.70, P=0.023) (45).
- In 377 stroke and transient ischaemic attack (TIA) survivors in the UK, 2% of respondents declined the vaccine when offered (42).
- In a group of 266 liver transplant recipients in Italy, 96.6% accepted a vaccine when offered. Despite receiving adequate information, five patients (1.8%) refused vaccination due to concerns over the potential for serious adverse events. The barriers in place for the remaining four patients (1.6%) could be lifted either by providing further details regarding the vaccination or following resolution of medical and logistical issues (4).
- In a group of 85 hospitalized psychiatric patients in the UK who had the capacity to decide if they wanted a COVID-19 vaccine, 80% accepted and 20% refused. White British patients were less likely to refuse compared to Black, Asian, minority ethnic (BAME) patients (16.9% vs 30%). The reasons for refusal included concerns about the safety and side effects of the vaccine, a belief there is a low risk to

their personal health from contracting COVID-19, broader distrust of healthcare services, and concerns about animal testing (5).

- Of 56 patients with irritable bowel syndrome in Italy, 96.4% accepted a vaccine when offered. Refusal was due to concerns over potential adverse reactions (46).

Adherence to Public Health Measures Post-Vaccine

- In a UK study of older adults (80+) who had received at least one dose within the last three weeks, 43% had met someone outside of their bubble, household, or care staff indoors, 49% met someone who they do not live with outdoors, 54% had gone shopping, and 45% had left home to participate in outdoor leisure activities (35).
- A longitudinal study in the UK demonstrated that vaccinated adults (at least one dose received) were more likely than unvaccinated adults to wash their hands when returning home (90% vs 82%), maintain social distancing when meeting up with others outside of their household/bubble (90% vs 72%), and avoiding physical contact outside their homes (86% vs 74%) (50).
- After the second-dose, 21.1% and 47.3% of respondents in the UK reported wearing a mask less and social distancing less post-vaccination and 75.7% and 48.4% did not change their behavior, respectively. Those aged 50+ were less likely to change their behaviors compared to those <50. Similar trends were seen in HCWs for social distancing, but the majority (95.7%) reported no changes in mask wearing post-vaccination (51).
- Preventative behaviors did not change in 73.2% of USA adults after receiving at least one dose of a COVID-19 vaccine. Preventative behaviors increased and decreased in 4.3% and 21.9% of the study population, respectively (53).
- At the beginning of the vaccination campaign in Israel, those who were infected with COVID-19 were less careful about social distancing (29.7%) and mask-wearing (18.8%) compared to those who received the first dose of vaccine (12.8% and 8.2%), or those who were neither vaccinated nor infected (19.2% and 11.6%) (7).
- Using a Global Positioning System (GPS) in the UK, the median daily increase in average daily travel distance from a participant's registered address was 45.0m (95% CI: 25-65m, P = <0.001) between the vaccination date and 99 days after vaccination (6).

COVID-19 VACCINE ATTITUDES IN THE GLOBAL POPULATION

The comparison of COVID-19 vaccine attitudes in the general population across different countries around the world was reported in six articles. Only studies that included Canada and reported outcomes by country were included. High level points from the most recent studies (January 2021 onwards) are listed below and detailed outcomes for all other studies are located in the Appendix (Table 2).

- As of January, countries with the highest intentions to vaccinate (63-77%) included the UK, Denmark, and the Netherlands. Intention to vaccinate in Canada was 55% (57).

- Increases in intention to vaccinate between November and January were seen in Spain (24.1%), UK (23.2%), Sweden (22.7%), Finland (20.4%), Netherlands (18.5%), Italy (15.4%), Norway (14.6%), France (14.2%), Denmark (13.3%), Germany (13.0%), Canada (11%), and Japan (0.8%) (57).
- In 11/15 countries there was a significant decrease in the proportion of individuals who reported concern about the side-effects of a vaccine. In Canada, this worry decreased from 53.3% in November to 47.9% in January (57).

COVID-19 VACCINE ATTITUDES OF THE CANADIAN GENERAL PUBLIC

The majority of research on COVID-19 vaccine attitudes has been conducted on the general public. Forty-two studies were specific to the Canadian population, of which 27 were unpublished and seven were preprints. High level points from January 2021 onwards are listed below and detailed outcomes for each study are located in the Appendix (Table 3).

Intentions to Vaccinate

- According to the most recent Canadian studies from June 2021, intention to vaccinate is between 84-88% (8, 10). The Atlantic provinces, British Columbia, and Quebec have the highest intentions to vaccinate (58-73).
- Three longitudinal studies demonstrate that intention to vaccinate continues to rise in Canada from baselines measured between September-December 2020 (10, 74, 75).
- In June, 89% of Canadians who had one dose reported they intend to receive a second dose, 9% have already had their second dose, 1% probably will not, and 1% were unsure (10).
- In a group of 70 parents or guardians of children aged 12-17 from Manitoba, 15% and 13% were not sure or would not vaccinate their children, respectively (11). Those who were hesitant to vaccinate their children were in households making less than $40,000/year, would not get the vaccine themselves, and didn't believe adults should get all the regular vaccines (11).
- 48% of Canadians were uncomfortable about receiving a different brand of vaccine as their second dose, whereas 46% were comfortable and 6% were unsure. Of those who received AstraZeneca as their first dose, 50% preferred to receive AZ as their second dose, 32% preferred another brand as their second dose, and 18% were unsure (10).
- Financial incentives (monetary, vouchers, complimentary items, draws for prizes, discounts) were not reported to increase the likelihood of accepting a vaccine in a study conducted in Manitoba (between 7-84% of respondents stating the incentive would not make them more likely to vaccinate). However, 70% would be concerned if only vaccine hesitant individuals received large ($50-100) incentives (11).
- Vaccine hesitancy dropped dramatically in Alberta from 45% in January to 25% in April to 17% in May (76).

- In Southern Ontario, 82.8% were willing to receive a vaccine and 17.2% were unwilling in a study conducted in January-February 2021 (77).
- A study in May 2021 demonstrated that most felt comfortable with the Pfizer (93%) and Moderna (89%) vaccines while less were comfortable with Johnson and Johnson (49%) and AstraZeneca (35%) vaccines. Women and those aged 55+ were more uncomfortable with the AstraZeneca (AZ) and Johnson and Johnson (J&J) vaccines compared to men and those <55. Of those who were uncomfortable with the AZ and J&J vaccines, 40% of women and 31% of men reported they would still accept these vaccine if offered (76).
- Three studies demonstrated that LGBTQ2+ were more willing to accept a vaccine compared to non-LGBTQ2+ (87.6% vs 76.4% in one study, OR=3.04, 95% CI: 1.08-8.55, p=0.04 in another, and 83.3% vs 77% in a third) (78-80).
- 71% of youth aged 12-17 intended to receive a vaccine in a survey conducted in January-February 2021 (81).
- Immigrants living in Canada for less than 10 years (80.3%) and more than 10 years (70.7%) had comparable intentions to vaccinate compared to non-immigrants (75.9%) (78). Another study showed that immigrants were slightly less likely to vaccinate (74.6%) than the general public (77%) but this varied greatly between older and younger immigrants (73.2% for 12-64 and 81.1% for those 65+) (80).
- Within visible minority groups in Canada, intention to vaccinate from lowest to highest was Black (57.0%), Latin American (58.5%), Filipino (64.2%), South East Asian (75.8%), other visible minorities (77.6%), Chinese (85.5%), and Arab (88.3%). 69.3% of those reporting an Aboriginal identity are accepting of a vaccine compared to 77.6% not reporting an Aboriginal identity (78).
- The highest intentions among visible minorities were Japanese (86.5%), Korean (85.6%), South Asian (82.5%), Chinese (79.3%), visible minority not indicated/multiple (79.1%), Southeast Asian (78.3%), West Asian (78.3%), Filipino (75.1%), Arab (68.1%), Latin American (66.0%), and Black (56.6%). Non-visible minority's intention to vaccinate was 77.6% (82).
- Intention to vaccinate among Indigenous respondents was 71.8% overall, which was significantly less than non-Indigenous respondents (77.1%). 74.2% of First Nations living off reserve were willing to vaccinate compared to 67.8% of Métis and 72.5% of Inuit. Older Indigenous people (65+) were more likely to want a vaccine compared to younger individuals (74.9% vs 71.3%) (82).
- In a survey of Indigenous residents of British Columbia, 68% stated they would like to be vaccinated as soon as possible or had been vaccinated compared to 58% of Asian and 66% of South Asian respondents (83).
- In British Columbia, intention to vaccinate was highest in East (61%) and South Asian (70%) continuing care workers. Latino and Black respondents were the most likely to refuse a vaccine (30%) and those with an Indigenous background were most likely to be unsure about their decision to vaccinate (40%). Indigenous respondents had the least amount of trust in all sources of information including healthcare providers (84).

- In Canada, those who voted Liberal or NDP in the 2019 election were more likely to indicate the intention to vaccinate compared to those who voted for other parties (58-60, 85).
- Rural participants were less likely to accept a vaccine compared to urban and suburban participants in three studies (10, 86, 87).
- Men were more likely to intend to vaccinate than women across 11 studies (58, 61, 77-79, 81, 88-92).
- The most common factors positively associated with intention to vaccinate were older age, higher education, adequate knowledge or health literacy, trust in experts and government, higher socioeconomic status, history of receiving an influenza vaccine, and heightened worry or concern about COVID-19.
- Concerns about vaccine safety and effectiveness were the two most cited reasons for vaccine refusal. Other commonly cited reasons include newness of the vaccine, and the belief that a COVID-19 vaccine is unnecessary.
- A recommendation to get the vaccine by a healthcare provider (e.g., doctor) had a positive impact on vaccine intention in five studies (74, 79, 83, 93, 94).
- Conspiracy beliefs were associated with decreased intentions to vaccinate (59, 90, 95).

Attitudes Toward Vaccine Rollout and Vaccine Passports

- Vaccine passports have high support in Quebec with 72% of residents in favour (12).
- 61% of respondents now agree that Canada should have vaccine passport, an increase from 54% in April (73).
- Two studies demonstrated high support for showing proof of vaccination when traveling by plane (79-82%), events with large crowds (69-75%), attending in-person university (71%) and lower support for showing proof of vaccination to stay in a hotel (68%), go to work (55-68%), or go to public places such as restaurants, bars, and movie theatres (55-64%) (73, 96).
- Of those who were vaccine hesitant, 7-18% of respondents across two surveys reported they could be swayed by the ability to travel, attend sporting or cultural events, or visit loved ones (11%) (96, 97).
- Of those who received an AstraZeneca vaccine, 2% fully regret getting it and 66% have serious second thoughts or doubts (76).
- 51-55% believed that Canada has done a good job procuring vaccine doses (75, 86).
- When asked about the vaccine rollout plan for British Columbia, 5% of residents rated the rollout as excellent, 30% good, 51% fair, 14% poor, and 7% very poor. Similar trends were seen for perceptions on clarity of the rollout and prioritization levels (98).
- 71% of respondents are comfortable with how the Manitoba government is determining priority groups for early vaccination (99).

- Approval of the overall vaccine rollout in Alberta was split, 48% were satisfied and 43% were dissatisfied. For the order of priority groups established by the government, 64% were satisfied and 28% were dissatisfied (100).
- In terms of vaccine distribution, 42% of Canadians believe their provincial government is doing a good job and 39% believe they are doing a bad job. Dissatisfaction was highest in AB, MB, and ON. Those in BC and QC were more approving (68).
- Two studies analyzed the perspective of experts on vaccination strategies for COVID-19. Public health experts agree that those who are the most vulnerable to severe illness and death from COVID-19 (e.g., long-term care residents, healthcare workers, those with chronic conditions, etc.) should be prioritized for vaccination (101, 102).

COVID-19 VACCINE ATTITUDES OF HEALTHCARE WORKERS

Evidence on COVID-19 vaccine attitudes of healthcare workers (HCWs) in Canada, Australia, New Zealand, UK, and the USA includes 42 studies. All studies targeted HCWs including nurses, doctors, and personal support workers. High level points from January 2021 onwards are listed below and detailed outcomes for each study are located in the Appendix (Table 4).

- The most recent studies show that intention to vaccinate in Canadian HCWs ranged between 57-82% (103-105). In the USA intention to vaccinate is between 55-93% (106-117).
- A participants' acceptance or rejection of a COVID-19 vaccine was not different between those employed within the healthcare sector compared to those not in the healthcare sector in one study from Canada (88). In the USA, two studies showed that HCWs were less likely to intend to vaccinate compared to the general population (115, 118) and two showed the opposite with HCWs having higher intentions to vaccinate compared to the general population (112, 119).
- Pregnant HCWs were 7.12 times more likely to be hesitant compared to non-pregnant HCWs (aOR 7.12, 95% CI: 4.74-10.70) (114).
- Doctors were significantly more likely to intend to vaccinate compared to nurses and other HCWs (37, 107, 110, 116, 117, 120).
- Seventeen studies demonstrated that male HCWs are more likely to intend to vaccinate than female HCWs (37, 84, 88, 105, 106, 109, 110, 114, 116, 117, 120-126).
- The proportion of those likely to get the COVID-19 vaccine was directly related to older age (37, 84, 88, 103, 105, 109, 110, 114, 116, 121, 123, 124), the likelihood of receiving an influenza vaccine (37, 84, 105, 109, 114, 126, 127) and an individuals' perceived risk of COVID-19 infection (105, 117, 123, 126).
- The main concerns about vaccination include safety, efficacy, insufficient knowledge about the vaccine, side-effects, speed of vaccination development, and believing that vaccination was not necessary (37, 84, 88, 103, 105, 106, 108-110, 112-114, 116, 119-121, 124, 126-130).
- A study of social service employees supporting individuals with intellectual disabilities in Ontario found that Indigenous, First Nations, and Metis (aOR 1.73, 95% CI: 0.67- 4.43), Latin (aOR 1.22, 95% CI:

0.21-7.24), and mixed ethnicities (aOR 1.11, 95% CI: 0.27-4.55) were more likely to refuse a vaccine compared to European ethnicity (105).

- In a Canadian study of personal support workers, 64.2% of respondents intend to vaccinate when it is available, 16.2% refuse to vaccinate, 10.7% are unsure, and 8.9% will only take the vaccine if it's mandatory. The majority (71.7%) do not believe there is enough clear education on the vaccine (131).
- In a study of 8634 non-physician HCWs in Ontario, 80.4% stated they intend to vaccinate. HCWs were more likely to intend to vaccinate if direct financial supports such as paid sick days were provided (103). Non-physician HCWs in Ontario, Canada who identified as Filipino (OR 1.07, 95% CI: 0.41-2.76, P<0.001), Caribbean (OR 3.20, 95% CI: 1.52-6.75, P<0.001), or other (OR 1.44, 95% CI: 0.93-2.22, P<0.001) ethnicity were more likely to refuse a vaccine compared to those who identified as European (103).
- In Quebec, Canada, 79.6% of nurses would definitely or probably recommend their patients vaccinate, 3.1% would not, and 17.2% were unsure. For themselves, 70.4% would definitely or probably be willing to receive the vaccine, 11.8% would refuse, and 17.8% were unsure (127).
- Two studies in the USA demonstrated that urban nurses were more willing to receive a vaccine than rural nurses when available (109, 132).
- Eleven studies evaluated intention to vaccinate in HCWs in the USA. Black HCWs were 12-84% less willing to accept the vaccine compared to White and Asian HCWs (106, 109, 112, 116, 118, 119, 121, 123, 125, 126, 133).
- Those who believed the vaccine would reduce their social isolation had higher odds of advising their patients to receive the vaccine (aOR 2.95, 95% CI: 1.32-6.59, P < 0.008) (113).
- In a UK survey of 220 general practitioners, over 50% had low confidence in counselling patients about COVID-19 vaccines (134).

COVID-19 VACCINE ATTITUDES OF HIGH-RISK POPULATIONS

It is important to develop evidence-based strategies to target high-risk populations for vaccination. Twenty-four were identified on COVID-19 vaccine attitudes in high-risk populations in Canada, Australia, UK, USA, and one global study including 16 countries. This includes older individuals, those with substance use disorders, those who are pregnant or breastfeeding, people experiencing homelessness, and vulnerable communities. High level points from January 2021 onwards are listed below and detailed outcomes for each study are located in the Appendix (Table 5).

- Pregnant women exhibited a low intention to vaccinate (41-62.1%) across three studies (19, 135, 136). Pregnant HCWs were 7.12 times more likely to be hesitant compared to non-pregnant HCWs (aOR 7.12, 95% CI: 4.74-10.70) (114). The most common reasons for hesitancy were potential side effects for their baby and the lack of safety and effectiveness data among pregnant women (19, 135, 136). Similar to the general population, women from lower-income households, aged < 25 years, history of

not accepting other vaccines, and ethnic minorities were more likely to reject a vaccine while pregnant (19, 135, 136).

- Intention to vaccinate and reasons for hesitancy were assessed in two studies in people experiencing homelessness in the USA (41, 137). One study showed that 51% would take a vaccine if offered, 32% would refuse, and 17% refused to answer (41). Common reasons for hesitancy included fear of side effects, wanting more information, concerns the vaccine makes people sick, and mistrust of the government (41, 137). Despite social exclusion and lack of access to technology, participants followed news reports about the vaccine and desired information about vaccine efficacy and safety (41).
- Intention to vaccinate was high (>79%) in six studies looking at older adults (65+) (15, 92, 138-141).
- In February, a community based vaccine site (Unidos en Salud UeS) was deployed to overcome barriers to COVID-19 vaccination faced by Latinx individuals in San Francisco. 56.1% reported they got vaccinated earlier because of the site and 65.3% reached out to 3 or more individuals to recommend the vaccine after their positive experience (3).
- In a survey of 391 Amish families from Ohio, 75.7% did not plan to vaccinate their children against COVID-19 and Swartzentruber Amish were significantly less likely to intend to vaccinate compared to other Amish affiliations (142).
- A qualitative study of vulnerable communities (e.g., homeless, mental health issues, and Gypsy, Roma, and Travellers) reveals general apprehension, skepticism, and low levels of trust pertaining to COVID-19 vaccine trials. Unique barriers were shown in each group such as a reluctance to go to the hospital, loss of confidentiality, concerns about animal products in vaccines, and belief of hidden agendas of vaccine developers and the government that should be taken into consideration when developing vaccine confidence plans (143).
- Of 87 individuals with substance use disorders in the USA, 48% were either unsure or unwilling to receive a vaccine if it were available. Reasons for hesitancy included the rush of vaccine development, potential side-effects, not believing themselves to be high risk, and worry about interactions with pre-existing conditions (144).
- Compared to former smokers and those who have never smoked, current smokers were both the most undecided (27.6 (95% CI: 26.1-29.1)) and unwilling (21.5% (95% CI: 20.2-22.9%)) to intend to vaccinate (145). In another study, willingness to receive a vaccine did not significantly differ between cannabis users and controls ($t88$ = 0.33, P = 0.74; BF_{01} = 4.3) (146). A study conducted in the USA found that the use of cigarettes, e-cigarettes, marijuana, and heavy drinking was not associated with vaccine hesitancy (147).
- Willingness to receive a COVID-19 vaccination was positively associated with the belief that the COVID-19 outbreak is going to continue for a long time, perceived severity of the disease, personal health consequences, and health consequences to others (138, 139, 148, 149).
- Similar to the general population, intention to vaccinate was positively associated with male gender (139, 150), higher education (135, 136, 139), higher income (135, 139, 150), White ethnicity (136, 139), past acceptance of flu vaccination (136), and older age (135).

- A recommendation to get the vaccine by a healthcare provider (e.g., a doctor) had a positive impact on vaccine intention in two studies on older adults (139, 141) but made little difference in pregnant women (135).

COVID-19 VACCINE ATTITUDES OF INDIVIDUALS WITH COMORBIDITIES

Twenty-three studies with evidence on COVID-19 vaccine attitudes in individuals with comorbidities in Canada, Australia, UK, and the USA were identified. There was a range of comorbidities including obesity, hypertension, chronic respiratory or autoimmune diseases, HIV, and intellectual and developmental disabilities. High level points from January 2021 are listed below and detailed outcomes for each study are located in the Appendix (Table 6).

- The majority (15/23) of studies were conducted in the USA followed by Canada (1/23), Australia (2/23), the UK (4/23), and a combination of the US/UK (1/23).
- In a study from Canada, 64.6% of those who are overweight or obese were comfortable receiving a vaccine and 35.4% were hesitant (151). Comfort levels in receiving the vaccine were positively associated with male gender, having more comorbidities, having lower depression scores, not practicing social distancing, and past acceptance of influenza vaccinations (151).
- One study demonstrated there were no significant differences in willingness to vaccinate for COVID-19 between people with hypertension compared to healthy matched controls (152). Another indicated that those who reported chronic respiratory diseases were 5.7% more willing to be vaccinated (95% CI: 0.05-0.09) compared to healthy controls (153).
- In a group of 97 cancer patients and their caregivers from the USA, intention to vaccinate increased from 71% to 82.5% after attending an educational webinar on COVID-19 vaccines specific for cancer patients and caregivers (154).
- In a study conducted at an urban dialysis center which serves a predominately Black patient population in the USA, 49% of respondents indicated they would be willing to receive a COVID-19 vaccine, 34% were unwilling, and 17% were unsure (155).
- If a vaccine was offered at a dialysis facility, vaccine hesitancy in patients on hemodialysis in the USA would decrease from 20% to 18% (156).
- Three studies analyzed intention to vaccinate in disabled adults. Two demonstrated that disabled adults had slightly less vaccine hesitancy compared adults who were not disabled in the UK (43, 140) and Australia (141). The other indicated that 62% would definitely or probably get a COVID-19 vaccine in the USA (157).
- A study of 101 Black people living with HIV in the USA demonstrated low intentions to vaccinate (32%). Low education and COVID-19 related mistrust were both associated with an increase in vaccine hesitancy (158).

- In a group of patients who received care for chronic gastrointestinal and liver conditions in the USA, they were more likely to follow their specialists' recommendation about receiving a vaccine (91%) compared to the government or their doctor (75%) or their employer (56%) (159).
- The most common reasons for hesitancy included concern about side effects, concerns about existing health conditions, lack of adequate information, mistrust in the government, and worries about long-term effects (140, 141, 155, 156, 158-163).
- Similar to the general population, intention to vaccinate was positively associated with male gender (156, 159-161, 164, 165), having more comorbidities (164, 166), higher education (148, 149, 156, 160, 165), higher income (149, 159, 165), White ethnicity (149, 156, 160), past acceptance of flu vaccination (155, 156, 159, 160, 162, 164, 165), and older age (149, 156, 157, 159-161).

COVID-19 VACCINE ATTITUDES OF OTHER POPULATIONS OF INTEREST

Sixty-one studies were identified on COVID-19 vaccine attitudes in other populations of interest in Canada, Australia, New Zealand, UK, and the USA. These populations include the LGBTQ+ community, parents, those with religious affiliations, immigrants, youth (aged 14-24), those with past SARS-CoV-2 infection, and urban and rural communities. High level points from January 2021 are listed below and detailed outcomes for each study are located in the Appendix (Table 7).

LGBTQ+

- Seven studies assessed intention to vaccinate in LGBTQ+ individuals in Canada (78-80) and the USA (167-170). Three studies demonstrated that LGBTQ2+ were 6-25% more willing to accept a vaccine compared to non-LGBTQ2+ (78, 80, 168). Two studies indicated that non-binary, pansexual, gender queer, agender, two-spirit or other were significantly more 1.6-4.38 times more likely to receive a vaccine (79, 169). Compared to gay men, participants grouped in the "Other" sexual identity (e.g., bisexual, queer, multiple identities, same-gender loving) were less likely to intend to vaccinate ($\beta = -1.102$, $P = 0.047$) (167).

Rural vs Urban Communities

- Differences in intention to vaccinate were analyzed in urban and rural residents in twelve studies. Eleven demonstrated that urban residents were marginally more likely to intend to vaccinate compared to rural residents (10, 86, 87, 109, 115, 166, 171-175), and one indicated the opposite (176).

Religious Affiliations

- Twelve studies evaluated the impact of religion on intention to vaccinate in the USA and UK, all of which associated some religions with vaccine hesitancy (126, 171, 174, 176-183). One study demonstrated that those who reported Hinduism or Judaism as their religion were more likely than atheists or agnostics to accept a vaccine (OR 1.66, 95% HPDI: 1.11-2.43) and those who reported their

religion as Muslim (OR 0.75, 95% HPDI: 0.57-0.96) or other (OR 0.72, 95% HPDI: 0.62-0.82) were less likely to intend to vaccinate (178).

- In a UK study, those reporting Christian faith were significantly more likely to get a vaccine if vaccine passports were introduced for domestic (aOR 1.23, 95% CI: 1.08-1.41) and international (aOR 1.22 95% CI: 1.07-1.39) travel compared to atheists and agnostics (20).
- A quasi-experimental study of 709 unvaccinated registered voters in South Dakota, USA demonstrated that messaging from a religious leader had statistically significant positive effect intention to vaccinate, while messages from a political or medical leader did not (21).
- Strong vaccine hesitancy was reported in a study of 102 Haredi-Orthodox Jewish adults in New York from Dec 2020-Jan 2021 with 12% of respondents willing to accept a vaccine for themselves and their family, 47% strongly hesitant, and 41% undecided. Independent predictors of vaccine hesitancy were the belief that natural infection was better than a vaccine for developing immunity, agreement that prior SARS-CoV-2 infection with antibodies precludes need to mask or practice social distancing, and loss of trust in physicians resulting from the pandemic (183).
- In a Quebec study, 28% of respondents who did not intend to receive a vaccine believe vaccination is incompatible with their religious beliefs or personal principles (90).

Parents

- Ten studies reported participants were more willing to accept a COVID-19 vaccine for themselves than for their children (16, 19, 94, 135, 151, 164, 184-187). One study showed parents were more likely to vaccinate their children compared to themselves (188). Those with younger children (aged 0-4) were more hesitant compared to those with children over the age of 5 (14, 16, 43).
- Parental and child vaccine intentions are highly correlated with each other, with parents who were intending to take a vaccine more likely to intend to vaccinate their children (11, 13-16, 151). Similar to the general population, parents from lower-income households (11, 14, 16, 19, 188), who are younger (17, 19, 188, 189), less educated (14, 16, 17, 184, 188), have a history of not accepting other vaccines (17, 19, 189), who are female (14, 16, 17, 188) and ethnic minorities (16-19, 185) were more likely to reject a vaccine for their children.
- A study of 380 parents with children aged 2-17 in Montreal revealed that parents were 61% very likely, 25% somewhat likely, 9.2% somewhat unlikely, and 4.5% very unlikely to have their child vaccinated. Visible minority parents were more likely to reject a vaccine for their children compared to non-visible minority parents (32.9% vs. 9.5%) (18).

Youth

- In a text message poll of 911 youth aged 14-24 across the United States, 80.7% reported willingness to vaccinate if proven safe and recommended. Black youth (OR = 3.31) were more likely to refuse vaccination and Asian youth (OR = 0.46) were less likely to refuse vaccination compared to White youth ($P < 0.001$) (190).
- 71% of Canadian youth aged 12-17 intended to receive a vaccine in a survey conducted in Jan-Feb 2021 (81).

Immigrants

- In a sample of 32 immigrants in the UK, 28% report they will definitely get a vaccine, 59% were unsure, and 6% would decline (191). Two UK studies demonstrate multiple barriers to vaccination for migrants such as access to technology, not having a doctor, access to vaccine information in their own language, not having vaccines at frequently used places such as walk-in clinics and charities, and clear communication that the vaccine would be provided at no cost (191, 192).
- In an Australian study, those born overseas were more likely to report intention to vaccinate compared to those born in Australia (70.7% vs 67.2%). This was more apparent for those who arrived within the last ten years (74.6%) compared to those arriving more than 10 years ago (69.1%) (141).

Past SARS-CoV-2 Infection

- Two studies from the USA demonstrate that those with a previous SARS-CoV2- infection were less likely to intend to vaccinate that those with no previous infection (115, 193).

Methods

Prior to the initiation of this rapid review, a pre-defined rapid review protocol was developed to ensure the methods were reproducible, transparent, and consistent. The protocol is available upon request. This rapid review will be kept evergreen and updates will contain key research articles published up to the latest search date.

Publications and Pre-prints

A daily scan of the literature (published and pre-published) is conducted by the Knowledge Synthesis team in the Emerging Science Group, Public Health Agency of Canada. The scan has compiled COVID-19 literature since the beginning of the outbreak and is updated daily. Searches to retrieve relevant COVID-19 literature are conducted in Pubmed, Scopus, BioRxiv, MedRxiv, ArXiv, SSRN, Research Square, and COVID-19 information centers run by Lancet, BMJ, Elsevier, Nature and Wiley. The cumulative scan results are maintained in a Refworks database and an excel list that can be searched. Details on this search strategy are available upon request. From this database and excel list, article titles and summaries will be systematically searched for the following key words: ("vaccin*" OR "immuni*") AND ("accept*" OR "hesitan*" OR "preference" OR "confidence" OR "intent*" OR "willing*" OR "readiness" OR "behavio*" OR "knowledge" OR "attitude*" OR "belief*" OR "believe*" OR "perception" OR "influence*" OR "reject*" OR "refus*" OR "oppos*" OR "consent*" OR "fear" OR "motiv*" OR "anti vax*" OR "antivax*" OR "trust*" OR "mistrust*" OR "anti vaccin*" OR "pro vaccine*" OR "provax*" OR "pro vax" OR "decision*" OR "decid*" OR "uptake"). The original search was conducted on October 16, 2020. The first update was conducted on November 30, 2020, the second update on January 5, 2021, the third on February 3, 2021, the fourth on March 2, 2021, the fifth on April 2, 2021, the sixth on May 3, 2021, the seventh on June 3, 2021, and the eighth on July 2, 2021.

Grey Literature

A grey literature search was conducted to compliment the database search. The grey literature search focused on Canadian research only. Where time permits, the grey literature search will be extended to include research from Australia, New Zealand, the United States, and the United Kingdom. A detailed list of websites

searched is available in the protocol. The original grey literature search was conducted on November 5-6, 2020. The first updated grey literature search was conducted on December 9-10, 2020, the second on January 4, 2021, the third on February 1-2, 2021, the fourth on March 7, 2021, the fifth on April 13-22, 2021, the sixth on May 3-7, 2021, the seventh on June 9-11, 2021, and the eight on June 28-30, 2021.

Quality of Survey Instrument

Three criteria which determine the quality of the survey instrument were reported. These include the availability of the survey tool in the report, the use of formative research to design the survey, and evidence of pre-testing the survey. A yes or no was provided for each criteria. If the information was not reported, the answer no was selected. These criteria evaluate the degree to which the survey items evaluate the theoretical concepts the survey is focused on, are comparable to other surveys and whether the instrument was comprehensive, clear and valid when applied to the target population. There is an increased risk of bias when these features are missing (194).

Peer-review

This document underwent peer-review by a subject matter expert, and editorial and science to policy review by the Office of the Chief Science Officer.

Prepared by: Tricia Corrin and Austyn Baumeister, NML, Emerging Science Group, PHAC.

APPENDIX: EVIDENCE TABLES

VACCINE UPTAKE & ADHERENCE TO PUBLIC HEALTH MEASURES POST-VACCINE

Table 1. Evidence of vaccine uptake and adherence to public health measures post-vaccination (n=37)

STUDY	METHODS & SURVEY TOOLS	KEY KAB OUTCOMES
VACCINE UPTAKE		
HEALTHCARE WORKERS		
CANADA		
Dzieciolowska (2021) (1) *new* Cross-sectional study Canada Dec 2020	Vaccine uptake was evaluated through an online survey in 2,761 nurses, physicians, orderlies, hospital administration working in 17 health institutions in Montreal to determine factors that are predictive on uptake. All HCWs were offered a vaccine. Question Topics: 1) Vaccine uptake 2) Vaccine hesitancy Survey tools available? Yes Formative research conducted? No Survey pre-tested? No	• 80.9% of those offered a vaccine accepted and 19.1% refused. • Multivariate analysis revealed that men (aOR 1.62, 95% CI: 1.16-2.26), those aged 50-59 (aOR 1.62, 95% CI: 1.07-2.44) or 60+ (aOR 3.28, 95% CI: 1.74-6.18), had occupational contact with COVID-19 patients (aOR 3.88, 95% CI: 2.29-6.58), or worked in rehabilitation centers (aOR 1.76, 95% CI: 1.17-2.66) were more likely take a vaccine when offered. • The most common concerns or reasons for refusal among those who did not accept a vaccine were the newness of the vaccine (82%), preferred that others get vaccinated first (77%), felt they lacked information about the vaccine (74%), and that they did not have enough time to make a decision (60%). • 74.1% of those that declined a vaccine reported they will accept a vaccine in the future with 53.2% wanting to delay a few months and 31.9% wanting to wait a year. • Those who never plan on accepting a vaccine were more likely to cite not trusting experts or pharmaceutical companies, preferring natural immunity, belief that the risk of vaccination outweighed risk of COVID, or that they had a past poor vaccine reaction.
USA		

Fossen (2021) (34) Cross-sectional study USA Jan-Mar 2021	This study aimed to assess vaccine uptake among 3,401 employees at a 437-bed hospital in Arlington, Virginia who were eligible to receive a COVID-19 vaccine starting in Jan 2021. Question Topics: 1) Vaccine uptake	• As of Mar 10, 2021, 71% had accepted a first dose of a COVID-19 vaccine. • Vaccine uptake was positively associated with being aged 50+ (OR 1.85, 95% CI: 1.53–2.24, P<0.01), working in a clinical department (OR 1.19, 95% CI: 1.01-1.42, P=0.02), and White race (OR 4.55, 95% CI: 3.74–5.52, P<0.01).
Jameson (2021) (31) Cohort study USA Dec 2020-Mar 2021	During a vaccination program in a medium-sized urban hospital in the Midwest region of the USA starting in Dec 2020, the BNT162b2 vaccine was offered to all 4,318 HCWs. The study aimed to determine vaccine uptake and the effectiveness of the vaccine in those who were vaccinated.	• As of Mar 24, 2021, 70% had accepted a vaccine and 30% had refused.
Oliver (2021) *preprint* (30) Cross-sectional study USA Dec 2020-Feb 2021	All staff in two large integrated healthcare systems (one private and one public) in New York City were eligible to receive a COVID-19 vaccine starting on Dec 14, 2020. An online survey of 1,933 HCWs who were offered the vaccine was conducted to assess vaccine uptake and reasons for acceptance and refusal. Question Topics: 1) Vaccine uptake Survey tools available? No Formative research conducted? Yes Survey pre-tested? Yes	• Of those offered the vaccine, 81% reported they had received it, 11% plan to get it but had not scheduled their appointment, and 8% chose not to receive the vaccine. • In the bivariate analysis, vaccine uptake was higher in males compared to females (88% vs 80%, p<0.001). Those who were under 40 (86%) and older than 60 (85%) had higher uptake rates compared to those 40-49 (79%) and 50-59 (74%), P<0.001. Also, non-Hispanic or undisclosed ethnicity (84%) were more likely to get a vaccine compared to Hispanic HCWs (69%), P<0.001. • In the multivariate analysis, Black HCWs were less significantly likely to get a vaccine compared to White HCWs (OR 0.38, 95% CI: 0.24-0.59, P<0.001). Compared to physicians, nurses (OR 0.37, 95% CI: 0.21-0.65, P=0.001), administrative, logistics, and management positions (OR 0.46, 95% CI: 0.36-0.78, P=0.006), and allied health

		professionals (OR 0.48, 95% CI: 0.27-0.81, P=0.007) were less likely to get the vaccine. • Those who did not receive the flu vaccine were less likely to get the vaccine compared to those who did (OR 0.28, 95% CI: 0.18-0.44, P<0.001). • Those who expressed concern about vaccine safety (OR 0.39, 95% CI: 0.28-0.55, P<0.001), concern about being experimented on (OR 0.44, 95% CI: 0.31-0.60, P<0.001), and who did not agree with statements about the vaccine's importance in protecting others (OR 0.37, 95% CI: 0.27-0.52, P<0.001) were less likely to get the vaccine.
Amin (2021) (27) Cross-sectional study USA Jan 2021	All HCWs in an emergency department at a large urban public hospital in Chicago, IL were eligible to receive the vaccine starting on Dec 17, 2020. Associations with vaccine uptake was assessed using an online survey of 240 HCWs. Question Topics: 1) Vaccine uptake Survey tools available? No Formative research conducted? No Survey pre-tested? No	• 92% reported they received the vaccine or are scheduled to and 8% reported they will not be getting the vaccine. • Vaccine acceptance rates varied by profession with physicians having higher uptake rates compared to nurses and radiology technicians. • Of the 8% who declined vaccination, the majority identified as Black (65%) and were 51–60 years old with varying job categories. • Reasons for declining a vaccine included having previous COVID-19 infection, and concerns over the vaccine being new, and worry about side effects.
Schrading (2021) (22) Cross-sectional study USA Jan 2021	Three weeks after COVID-19 vaccination was offered to emergency department healthcare professionals (ED HCPs) across 20 high-volume urban academic medical centers, an online survey was conducted in 1321 of these individuals who were offered the vaccine. The goal was to describe differences in vaccination rates	• 86% of those who were offered the vaccine chose to receive it and 14% declined. • Among physicians and advanced practice providers, 37/674 (5.5%) declined the vaccine compared to 77/345 (22.3%) of nurses and 71/302 (23.5%) of non-clinical HCPs. Of those who declined a vaccine, the most common reasons were safety concerns (45.4%), health conditions (13.5%), and previous COVID-19 diagnosis (13.5%).

	among various types ED HCPs and reasons for declining vaccination. Question Topics: 1) Vaccine uptake Survey tools available? No Formative research conducted? No Survey pre-tested? No	• Non-Hispanic Black HCPs had the lowest uptake rates (65.4%) followed by Hispanic or Latinx (76.7%). The highest uptake rates were in Non-Hispanic Other (88.9%), Non-Hispanic White (88.5%), and Non-Hispanic Asian (87.3%) HCPs. • Men had higher uptake rates (93.5%) compared to women (88.5%). • After vaccination, recipients stated they felt safer (86.7%) and those in their households felt safer (87.1%). Vaccinated recipients planned to use the same amount of PPE at work (89.8%) and in public (91.8%).
Pamplona (2021) (33) Cross-sectional study USA Jan 2021	Vaccine uptake and hesitancy during a vaccine program implemented between January 13-21, 2021 was recorded in 157 staff members from four Renal Research Institute clinics and one home dialysis program in New York. Question Topics: 1) Vaccine uptake 2) Vaccine hesitancy Survey tools available? No Formative research conducted? No Survey pre-tested? No	• 73.2% were vaccinated and 26.8% were unvaccinated. • 3.8% of staff reported vaccine hesitancy and did not receive a vaccine. Reasons were not reported. • The remainder of the staff who were not vaccinated included: those on a leave of absence (2.5%), pregnant or breastfeeding (5.1%), and those with past SARS-CoV-2 infection (15.3%). • Staff with a history of confirmed SARS-CoV-2 infection > 90 days ago or at some unknown time in the past were offered vaccination, but wished to receive the vaccine later.
UK		
Bell (2021) *preprint* (32) Cross-sectional and qualitative study UK	1658 healthcare workers and 261 social care workers completed an online survey and 20 participants were interviewed to gain insights into the beliefs, attitudes, and behaviours with regard to vaccination. Question topics:	• 1762 (91.9%) participants had been offered vaccination. Of those, 6.6% had declined or will decline the vaccine. • Compared to their counterparts, higher levels of declining the vaccine were seen in Black or Black Caribbean (22%), those aged 25-35 (8.4%), and Christian (6.7%) religion. • Odds of declining a vaccine were significantly increased if respondents were Black/Black British/Black mixed (aOR 5.5, 95% CI: 2.2-13.4),

Jan-Mar 2021	1) Vaccine uptake 2) Vaccine perceptions Survey tools available? Yes Formative research conducted? Yes Survey pre-tested? Yes	felt that they were under pressure from their employer to get the vaccine (aOR 1.75, 95% CI: 1.2-2.4), or were worried about side effects (aOR 1.68, 95% CI: 1.1-2.4). • Odds of accepting a vaccine were significantly increased if a flu vaccine was taken in the past two years (aOR 0.27, 95% CI: 0.1-0.47) and the combined belief that vaccines are safe, important, and effective (aOR 0.51, 95% CI: 0.3-0.8). • Reasons for declining or planning to decline a vaccine included worry about side effects (51%), concern over lack of research (50%), and concerns about effectiveness (21%). • The most common reasons for vaccinating were to protect friends/families (64%), to protect themselves (57%), and protect patients (28%). • Black or mixed Caribbean respondents were less likely to perceive the vaccine as safe, as important to protect themselves or families, believe that vaccination is required to get back to normal, believe that their friends and family do not expect them to get a vaccine, and are more concerned about side effects. • For the interview portion, all participants had been offered vaccination, 13 had been vaccinated, and 7 had declined. • Interviews revealed issues of access (lack of clarity for those not in the National Health Service to get vaccinated), perceptions of risk and severity (low perceived risk associated with not requiring a vaccine), low trust (in the vaccine, policymakers, and in pharmaceutical/health industry), vaccine effectiveness, vaccine importance to protecting other or to return to normal, pressure to vaccinate, concerns about allergies, impact on childbearing, wanting more vaccine information, and wanting assurances the vaccine was halal.

Martin (2021) *preprint* (25) Cross-sectional study UK Dec 2020-Feb 2021	Associations with vaccine uptake was assessed in 19,044 HCWs from one of the largest acute hospital trusts in the UK. All staff were eligible to receive the BNT162b2 mRNA ChAdOx1 nCoV-19 vaccines starting on Dec 12, 2020. Question Topics: 1) Vaccine uptake	• As of Feb 3, 2021 the proportion of HCWs who received one-dose of the vaccine was 64.5%. • The number of vaccinations per week peaked the week of Jan 11-17 and has been declining since. • Vaccine uptake was positively associated with increasing age (≤30 years: aOR 0.48, 95% CI: 0.44-0.53; 51-60 years: aOR 1.19, 95% CI: 1.07-1.31 compared to age 41-50) and male gender (aOR 1.24, 95% CI: 1.15-1.35). • Compared to White HCWs, vaccine uptake was lower in those of Black (aOR 0.30, 95% CI: 0.26-0.34) and South Asian ethnicity (aOR 0.67, 95%CI: 0.62-0.72). • Those with a history of SARS-CoV-2 infection were less likely to vaccinate (aOR 0.71, 95% CI: 0.60-0.85). • Those living in the most deprived areas were less likely to vaccinate (P<0.001).
Hall (2021) *preprint* (26) Cohort study UK Dec 2020-Feb 2021	The SARS-CoV-2 Immunity and Reinfection Evaluation (SIREN) study is a prospective cohort study of 23,324 staff working across 36 publicly funded hospitals. Starting in Aug 2020, baseline risk factors, vaccination status, symptoms, and results from PCR and antibody testing were recorded at bi-weekly intervals. The study aimed to determine factors associated with vaccine uptake and the effectiveness of the BNT162b2 mRNA vaccine in those who were vaccinated. Question Topics: 1) Vaccine uptake	• As of Feb 5, 2021 the proportion of staff who received one and two doses of the vaccine were 89% and 8%, respectively. • Vaccine uptake was significantly lower in those with prior SARS-CoV-2 infection (aOR 0.59, 95% CI: 0.54-0.64), females (aOR 0.72, 95% CI: 0.63-0.82), under 35 years old (aOR 0.78, 95% CI: 0.64-0.96), from Black, Asian, or minority ethnic groups (aOR 0.26, 95% CI: 0.21-0.32), who lived in neighbourhoods of higher deprivation (aOR 0.75 , 95% CI: 0.65-0.87), and who worked as a porter/security/estates (aOR 0.61, 95% CI: 0.42-0.90) or midwife (aOR 0.74, 95% CI: 0.57-0.97).

Tulloch (2021) *preprint* (28) Cross-sectional study UK Jan 2021	All staff and residents in 87 care homes within the Liverpool City Council area were eligible to receive a COVID-19 vaccine starting on Dec 23, 2020. An online survey of 46 staff managers was conducted to determine associations with vaccine uptake and reasons for hesitancy. This survey was self-reported and the views of staff were compiled by one senior member of the care home. Therefore it is possible that this may not reflect the views of all staff members. Question Topics: 1) Vaccine uptake	• 52.6% (n=1119) had received their first vaccination with a mean vaccination rate per care home of 51.4% (95% CI: 43.9-58.8%). • The most common reasons for not receiving the vaccine were concerns about lack of vaccine research (37.0%), staff being off-site during vaccination sessions (36.5%), pregnancy and fertility concerns (5.6%), and concerns about allergic reactions (3.2%). • If logistical issues were resolved (e.g., staff member not on site the day vaccines were being administered), the mean vaccination rate per care home could have increased to 69.8% (95% CI: 63.2-76.3%). • Staff reported methods that would help address vaccine hesitancy included one-on-one meetings to discuss concerns (34.8% of care homes), staff meetings (15.2%), educational material (15.2%), individual discussions with general practitioners or the vaccination team (10.9%), and managers leading by example and encouragement (6.5%).
Azamgarhi (2021) (29) Cohort study UK Jan 2021	This study aimed to assess vaccine uptake and efficacy of the Pfizer BioNTech vaccine among 2260 healthcare workers at a tertiary hospital. All staff were offered their first dose of the vaccine over an 8-day period up to Jan 14, 2021. Question Topics: 1) Vaccine uptake	• 62.3% of staff received one-dose of the vaccine. Uptake increased to 72.9% after specific measures were implemented by a vaccine hesitancy working group. • Vaccine uptake was higher in men compared to women (67.3% vs 61%, P=0.004). • White (72.6%) and Asian (68.1%) HCWs were the most likely ethnic groups to vaccinate. Black/Afro-Caribbean (28.5%) and mixed-race (45%) were the least likely (P = 0.001). • By occupation, the highest vaccine uptake rates were seen in surgeons and medics (79.2%), allied health professionals (78.3%), and administration and clerical staff (73.3%). The lowest rates were in nursing (55.5%), clinical support staff (50.4%), and porters, domestic and catering staff (31.6%) (P = 0.001).

		• Vaccine uptake increased with age. 70.7% of those 55 or older received the vaccine, followed by 65.7% of those aged 35-54 and 51.9% of those aged 16-34.
ISRAEL		
Jabal (2021) (23) Cohort study Israel Dec 2020-Jan 2021	This study had two purposes: 1) to report on vaccine uptake in ~1500 HCWs located in a single medical center, and 2) to describe immunogenicity 21 days post-dose 1 BNT162b2 mRNA COVID-19 vaccine among 514 HCWs. Starting in Dec 2020, the vaccine was offered to all staff. Question Topics: 1) Vaccine uptake	• As of Jan 21, 2021 the proportion of HCWs who received one-dose of the vaccine was ~90%.
Amit (2021) (24) Cohort study Israel Dec 2020-Jan 2021	This study had two purposes: 1) to report on vaccine uptake in 9109 HCWs located in a single medical center, and 2) to evaluate reductions in SARS-CoV-2 infection and COVID-19 rates in BNT162b2 COVID-19 vaccinated HCWs. Starting in Dec 2020, the vaccine was offered to all staff. Question Topics: 1) Vaccine uptake	• As of Jan 24, 2021, the proportions of HCWs who received one and two doses of the vaccine were 79% and 66%, respectively.
PEOPLE EXPERIENCING HOMELESSNESS		
Kuhn (2021) *preprint* (41) Cross-sectional study USA	The level of vaccine uptake and hesitancy among 90 individuals experiencing homelessness in Los Angeles (18+) was evaluated using a mobile phone survey. Question Topics:	• Of the 90 participants, 17 were offered a vaccine of which 10 accepted and 7 refused. • Among the 73 who were not offered the vaccine, 51% said they would take it if offered, 32% would refuse, and 17% refused to answer. • Together, 48% refused a vaccine when offered, would refuse when offered, or refused to answer and were deemed "vaccine hesitant".

Dec 2020-Feb 2021	1) Vaccine uptake 2) Vaccine hesitancy 3) Vaccine intentions Survey tools available? No Formative research conducted? No Survey pre-tested? No	• Of those who were vaccine hesitant, the most common reasons were fear of side effects (37%), wanting to have more information (30%), and they don't get any vaccines (27%). • A multivariate analysis, those with a high COVID-19 threat perception (OR 0.25, P=0.02), and those who trusted official sources (OR 0.37, P=.08) were significantly less likely to be vaccine hesitant. Those who engaged in highly protective behavior (OR 3.63, P=0.02) and who trusted personal contacts (OR 2.70, P=0.07) were more likely to be hesitant.
PRISONS		
Chin (2021) (38) Cross-sectional study USA Dec 2020 – Mar 2021	The California Department of Corrections and Rehabilitation (CDCR) launched a vaccination program for residents of its 35 prison facilities on Dec 22, 2020. Of the 97,779 incarcerated residents, 64,633 were offered a vaccine. Question Topics: 1) Vaccine uptake	• 66.5% accepted at least one vaccine dose, and 33.5% refused. Among those who had initially declined and were subsequently reoffered vaccination (n=1,962), 45.9% accepted at least one dose. • Vaccine uptake was highest among Hispanic residents (72.6%, 99.6% CI: 72.1-73.1) and White residents (72.1%, 99.6% CI: 71.3-72.9), followed by American Indian or Alaska Native residents (67.7%, 99.6% CI: 64.4-71.0), Asian or Pacific Islander residents (67.7%, 99.6% CI: 64.8-70.6), and Black residents (54.9%, 99.6% CI: 54.3-55.5). • Those who were older and medically vulnerable were more likely to accept a vaccine compared to younger and healthier residents.
Berk (2021) *preprint* (37) Cross-sectional study USA Dec 2020 – Feb 2021	Vaccine uptake was assessed among 1,474 staff and 1,447 incarcerated individuals at the Rhode Island Department of Corrections who were offered a vaccine. The vaccine program started on Dec 22, 2020 and all first doses were administered by Feb 5 and second doses by Mar 5, 2021.	• Of the correctional staff, 68.4% accepted a vaccine and 31.6% refused. Reasons for refusal were not reported. • Of all of the incarcerated individuals, 76.4% accepted a vaccine and 23.6% refused. Reasons for refusal were not reported • In round 1 of the highest-risk incarcerated individuals (n=143), 90.9% accepted and 9.1% refused a vaccine.

	The vaccine was offered in 4 rounds: 1) highest-risk individuals (aged 65+ or 55+ with specific comorbidities), 2) smaller facilities in attempt to achieve herd immunity, 3) the largest remaining security facility: Medium Security, and 4) all individuals who had previously tested positive for COVID-19 within 90 days and individuals who had initially declined but subsequently accepted. Question Topics: 1) Vaccine uptake	• 64.5% accepted the vaccine and 34.6% refused during round 2 of the smallest facilities (n=222). • Of those in the largest security facility (n=730) during round 3, 82.9% accepted and 17.1% refused a vaccine. • In the last round of the remaining incarcerated individuals (n=352), 64.8% accepted a vaccine and 35.2% refused.
MILITARY UNITS		
Segal (2021) (55) Cross-sectional study Israel Dec 2020 – Feb 2021	Vaccination uptake rates between frontline battalions and highly essential military units (group A, n=12,642) and rear administration and support military units (group B, n=6,077) were compared. This included 70 military units comprised of 18,719 individuals of both sexes, mostly free of significant comorbidities. The vaccine program started at the end of Dec, 2020. Question Topics: 1) Vaccine uptake	• As of Feb 18, 2021, 84.8% of the entire study population had received their first dose of a COVID-19 vaccine, 3.88% had a previous SARS-CoV-2 infection, and 11.34% refused a vaccine. • Vaccine uptake was higher in Group A compared to Group B (86.4% vs 81.4%, P<0.001). Group A had a slightly lower mean age and a higher number of men (P <0.001), but similar cumulative SARS-CoV-2 cases rates (P = 0.677).
Talmy (2021) (39) Cross-sectional study Israel	This study aimed to assess real-world vaccine uptake joined with primary care communication efforts including group lectures, on-site consultations, and primary care office visits. Vaccine intentions were capture by telephone survey	• Prior to the vaccine campaign, 77.7% of soldiers intended to vaccinate, 17.6% intended to refuse, and 4.7% were unsure. • 70.3% attended a group lecture, 6.5% arrived for on-site physician consultation, and 3.7% attended primary care clinic visits.

Dec 2020 - Feb 2021	prior to the vaccine campaign. During the campaign, 511 soldiers in a military unit were offered a vaccine. The vaccination site operated during two different sessions. Those who refused vaccination following the initial session were contacted to set voluntary appointments for clinic visits to discuss their specific concerns. Question Topics: 1) Vaccine uptake 2) Vaccine intentions	• Of the 90 soldiers who stated they did not intend to receive a vaccine, 60.0% attended the group lectures, 31.1% arrived for on-site consultation, and 16.7% attended primary care visits to discuss their motives and concerns. • Between Jan 3 and Feb 18, 2021, 89.8% of soldiers received at least one dose of the vaccine. • Of the 90 soldiers who did not intend to receive a vaccine, 42.2% decided to receive a vaccine. • 47.4% of the 28 soldiers not intending to vaccinate and arriving for on-site physician consultation proceeded to vaccinate (P = 0.004).
OLDER ADULTS (70+)		
Office for National Statistics (2021) *unpublished* (35) Cross-sectional survey UK Feb 2021	Responses of 2070 adults over 80 years old were collected through an online survey to determine vaccine coverage, attitudes, and vaccinations effect on protective behaviors. Question Topics: 1) Vaccine uptake 2) Vaccine attitudes Survey tools available? No Formative research conducted? No Survey pre-tested? No	• 99.8% reported that they had been offered a vaccine, 99% of which had taken at least one dose and 15% had two doses. • 41% reported common side effects including tenderness in the arms where they received an injection (26%). • 63% report that the side effects experienced would not affect their decision to get the second dose and 35% said side effects made them more likely to get a second dose. • 96% would encourage others to get vaccinated. • 86% would likely get a COVID-19 test if they developed COVID-19 symptoms. • Almost half (49%) perceived COVID-19 to be a major risk to themselves before receiving a vaccine. This decreased to 19% after receiving one dose.
Malesza (2021) *preprint* (36)	Associations with vaccine uptake were assessed in 1427 older adults (70+) living among the general public using structured interviews.	• 62.7% had been given the vaccine and 37.3% said they were unwilling to get vaccinated. • The two most significant independent predictors of vaccine uptake was receiving an explanation

Cross-sectional study Poland Jan-Feb 2021	A mass vaccination program began in the last weeks of 2020. The Minister of Health recommended that every individual aged 70+ should be encouraged to receive the COVID-19 vaccination. It is assumed that at the time of these interviews, all individuals aged 70+ were encouraged and able to receive the vaccine. Question Topics: 1) Vaccine uptake Survey tools available? No Formative research conducted? No Survey pre-tested? No	by a medical professional as to why they should be vaccinated (OR 4.23, 95% CI: 2.90-5.75) and living with others (OR 3.13, 95% CI: 2.03-4.26). Other predictors included being able to travel independently to their general practitioner (OR 1.92, 95% CI: 1.45-2.76), having chronic illnesses (OR 2.98, 95% CI: 2.05-4.01), higher socio-economic status (OR 1.79, 95% CI: 1.33-2.15), and male gender (OR 1.22, 95% CI: 0.67-1.98). • The top reasons people accepted the vaccine were self-protection (90.6%), to protect close relatives (69.3%), receiving a reminder from a doctor (67.7%), and receiving advice from a medical professional (65.0%) or from a friend (49.9%). • Reasons for not receiving the vaccine included concerns about safety (91.4%), fear of side effects (89.7%), belief that COVID-19 is not a severe disease (75.4%), did not want to be used as the subject of an experiment (69.5%), belief that vaccines are ineffective (66.7%), having medical conditions that contraindicated the vaccine (53%), having family/friends that had a bad experience from the vaccine (57.1%), disliking shots (35.3%), and believing it was inconvenient (30.8%).
GENERAL POPULATION		
Horizon Research (2021) *unpublished* (15, 195) Longitudinal study New Zealand	An online survey of adults (16+) was conducted to measure vaccine uptake. Mar-Apr, n=1,350 Apr-May, n=1387 Question Topics: 1) Vaccine uptake Survey tools available? Yes	**Apr-May** • 1% of respondents reported that they had been offered a vaccine but declined (1% drop since month prior). • Those who were unlikely to accept an offered vaccine were female, younger than the average age, had lower incomes, lower education qualifications, and had children in their households. **Mar-Apr** • 2% of respondents reported that they had been offered a vaccine but declined.

Mar-May 2021	Formative research conducted? No Survey pre-tested? No	
Office for National Statistics (2021) *unpublished* (43, 47) Longitudinal study UK Mar-May 2021	Responses from four waves of results collected from the online Opinions and Lifestyle Survey (196) were pooled to focus on demographic specific associations with vaccine hesitancy. The number of disabled, clinically extremely vulnerable, and parents was not reported. Feb-Mar: 17,201 responses pooled Mar-Apr: 16,362 responses pooled Apr-May: 15,170 responses pooled Questions Topics: 1) Vaccine uptake Survey tools available? Yes Formative research conducted? Yes Survey pre-tested? Yes	**Apr-May** • 2% of adults who had been offered a vaccine and declined. • Refusal rates were 1% in those aged 16-29, 2% in those aged 30-49, and 1% in those 50+. • 2% of women declined a vaccine compared to 1% of men. • 5% of those identifying as other religion and 4% of Buddhists had been offered a vaccine and declined compared to 1% reporting no religion. • 63% of those who reported Muslim faith who were unlikely to be vaccinated or declined were worried about side effects. • Those in more deprived quintiles declined vaccines more frequently than those at higher deprivation quintiles (3% at the lowest quintile and 1% are the least deprived). • By occupation those in sales and customers services and elementary occupation declined vaccines at a rate of 3% compared to the average 2%. **Mar-Apr** • 3% of parents with children aged 0-4 had been offered a vaccine and declined compared to 2% of those with children over 5 years or 1% among non-parents and those not living with dependent children.
Office for National Statistics (2021) *unpublished* (48, 50, 54, 197) Longitudinal study	A weekly online survey of vaccine intentions was conducted in a nationally representative sample of UK adults. Apr 7-11: n= 6,030 April 28-May 3: n=3,830 May 19-23: n= 3,070 June 2-6: n=4,010	**June 9-13** • 2% of those aged 50 to 69 have been offered a vaccine and declined compared to 1% of those 70+ and the overall average of 3%. **May 19-23** • 18% of those aged 50-69 have received one vaccine dose and 80% (up from 25%) have received two doses. 1% have been offered a

UK Dec 2020- May 2021	June 9-13: n=3,600 *new* Question Topics: 1) Vaccine uptake Survey tools available? Yes Formative research conducted? Yes Survey pre-tested? Yes	vaccine and declined to be vaccinated. 58% in this age group are concerned for side effects • <1% of those 70 or older have received one vaccine dose and 99% have received two doses. <1% have been offered a vaccine and declined to be vaccinated. **Apr 28-May 3** • 69% of those aged 50-69 have received one vaccine dose and 25% have received two doses. 2% have been offered a vaccine and declined to be vaccinated and 1% have not been offered a vaccine. **Apr 7-11** • 39% of those aged 30 to 49 years of age have had at least one dose and 1% have been offered a vaccine and are waiting to be vaccinated. 1% have been offered a vaccine and declined. • 19% of those aged 16 to 29 have had at least one dose and 1% have been offered a vaccine and are waiting to be vaccinated. 2% have been offered a vaccine and declined. • 98% of those the 50 to 69 years of age have received a vaccine or intend to accept a vaccine. 1% have been offered a vaccine and are waiting to be vaccinated and 1% have been offered a vaccine and declined. • 99% of those 70 years or older have either received a vaccine or are likely to accept a vaccine. 1% have been offered a vaccine and declined.
Dai (2021) *preprint* (44) Randomized control trial USA	A randomized controlled trial was conducted to measure the impact of interventions (text message reminder) in increasing the uptake in vaccine eligible populations (those aged 65+, patients with any transplant, and high-risk patients	• Receiving a basic text message significantly raised booked appointment rates within 6 days by 5.14 percentage points ($p<0.001$), and vaccination rates within 4 weeks by 2.89 percentage points ($p<0.001$) compared to the control group. This amounts to a relative increase of 85.5% and 26.3%, respectively.

Jan-Mar 2021	with qualifying pre-existing conditions) in California. RCT 1: Text message reminder including a link to schedule the appointment and either a plain text, ownership message, plain text with video, or ownership message with video one day after they receive notice of vaccine eligibility (n=132,337). RCT 2: A second text reminder was sent eight days after the initial reminder to participants that had not scheduled their first-dose appointment (n=102,675). Messages fell into 6 categories: (1) simple text (2) prosocial (3) exclusivity of early access (4) early access and prosocial (5) fresh start (6) fresh start and prosocial. Question Topics: 1) Vaccine uptake	• Receiving a text message also increased the speed of actual vaccinations with the control group taking 27 days to reach the vaccination rate of the text group at day 17. • Including a video did not significantly increase appointments or vaccinations when compared to messages without an education video likely due to low view rate (21%). • The highest impact of text messages were among those received at least one flu vaccine in the previous two years. • 12% of those who booked their appointment after the first message cancelled without rescheduling and 0.1% did not go to their appointment. • A second text reminder significantly increased scheduling the first dose appointment by 1.26% percentage points (a 52.3% increase, P <0.001) within 6 days and getting the first dose within 4 weeks by 0.68 percentage points (15.9% increase, P <0.001) compared to the control group. • All message types boosted appointment and vaccinate rates.
Senderey (2021) *preprint* (2) *new* Before and after study Israel Feb 2021	Vaccination uptake rates were compared before and after the implementation of text message reminder. Eligible unvaccinated individuals (16+) were randomly assigned to receive one of two reminders (following their receipt of the baseline reminder). There were two types of reminders, one highlighting the social benefit of vaccinating and the other the personal benefit of vaccinating.	• Vaccine uptake increased from 2.3% two days prior to intervention to 3.6% two days post intervention (P<0.001). • The personal benefit message was more effective than the social benefit message. • The aggregate effect over 8 days post intervention demonstrates that the personal benefit reminder led to a 9% relative increase compared to the social benefit reminder (23.8% vs. 21.7%, P < 0.0001). • When comparing three days before and after the implementation of the Green Pass policy, a

	Vaccines were available to all individuals aged 16+. Vaccine uptake rates were also compared before and after the implementation of the Green Pass policy where the entry to certain public places required the presentation of the "green pass" which could be acquired from receiving a vaccine or a recent negative COVID-19 test. Question Topics: 1) Vaccine uptake	relative increase of 22.2% (from 3.6% to 4.4%) was demonstrated.
Glampson (2021) *preprint* (49) Cohort study UK Dec 2020-Feb 2021	This study aimed to assess vaccine uptake and effectiveness of efficacy over a ten-week follow-up period across an integrated care system of eight Collaboration of Clinical Commissioning Groups (CCGs) leveraging a unique population-level care dataset in North West London. During the vaccine program time period, 413,919 adults (16+) were offered a vaccine. Individuals were counted as declining a vaccine if they indicated to their GP they did not want a vaccine when offered, and then did not receive a vaccine. Question Topics: 1) Vaccine uptake	• Of those offered a vaccine, 24,332 (5.88%) people declined and did not receive a vaccination. • In the vaccinated group, 2,957 individuals had initially declined but subsequently went on to receive a vaccination, indicating a hesitancy rate of 0.71%. • The Black or Black British group had the highest vaccine refusal rates (16.1%) followed by mixed ethnicity group (10.4%), other ethnic group (9.95%), and ethnicity unrecorded group (8.5%). The lowest rates of refusal was seen in the White (4.9%) and Asian and Asian British groups (3.2%). • In the Black or Black British group, those who were aged 80+ (27.9%) or were clinically extremely vulnerable (24.0%) had the highest refusal rates. • No overall difference in refusal rates was seen between men and women (5.9% vs 5.8%), younger men (aged <65) were more likely to decline than younger women (3.2% vs 2.2%), and older women (aged 65+) were more likely to decline than older men (7.9% vs 7.1%).

		• Deprivation was negatively associated with declining vaccination (r=-0.94, P <0.01). In the most deprived areas, 13.5% of individuals refused vaccination compared to 1.0% in the least deprived areas. • For those living in the deprived areas, the highest rates of refusal were in those aged 70+ (70-74 = 17.5%; 75-80 = 19.0%; 80+ = 25.9%), the clinically extremely vulnerable (19.2%) and Black and Black British (20.0%) communities.
OTHER POPULATIONS		
Office for National Statistics (2021) *unpublished* (43, 47) Longitudinal study UK Mar-May 2021	Responses from four waves of results collected from the online Opinions and Lifestyle Survey (196) were pooled to focus on demographic specific associations with vaccine hesitancy. The number of disabled, clinically extremely vulnerable, and parents was not reported. Feb-Mar: 17,201 responses pooled Mar-Apr: 16,362 responses pooled Apr-May: 15,170 responses pooled Questions Topics: 1) Vaccine uptake Survey tools available? Yes Formative research conducted? Yes Survey pre-tested? Yes	**Apr-May** • Declining a vaccine was slightly lower among disabled respondents (1%) and clinically extremely vulnerable (CEV) (1%) compared to the average (2%). • 58% of disabled respondents had general concerns about vaccine safety and CEV respondents most were worried about fertility concerns (28%). • The largest anticipated difficulty for obtaining a vaccine was long waits and taking time off work (8%). **Mar-Apr** • 2% of those with disabilities had been offered a vaccine but declined, this was 1% higher than those without disabilities. • 3% of clinically extremely vulnerable (CEV) respondents had been offered a vaccine and declined compared to 1% of non-CEV. • 3% of parents with children aged 0-4 had been offered a vaccine and declined compared to 2% of those with children over 5 years or 1% among non-parents and those not living with dependent children.
Turner (2021) *preprint* (42) *new*	Using an online survey, the factors that influence uptake and perceptions of the COVID-19 vaccine were measured in 377	• 87% of respondents had received at least their first dose or were booked for an appointment and 8% had not been offered a vaccine yet.

Cross-sectional study UK Feb-Apr 2021	stroke and transient ischaemic attack (TIA) survivors during an early period of vaccine rollout in the UK. Question Topics: 1) Vaccine uptake 2) Vaccine hesitancy Survey tools available? Yes Formative research conducted? Yes Survey pre-tested? Yes	• 2% of respondents had declined the vaccine and 3% had been offered but not taken up the offer yet. • Concerns with high agreement included worry about side effects (36%), that vaccine increased stroke risk (34%), the safety of the vaccine (32%), how new the vaccine is (29%), and vaccine affecting blood thinner medication (28%). • Most respondents felt that getting the vaccine was the right thing to do (92%), they knew other people who have had the vaccine (98%), believed that it will reduce spread of COVID-19 (85%), and that the vaccine will protect them (87%). • Good understanding of how to get a vaccine appointment was demonstrated (91%). Many disagreed that that they needed to consult their doctor (61%), that they will have difficulty accessing an appointment (64%) or that they will not have time to get an appointment (74%). • Open text responses found concern over the relationship between AstraZeneca and blood clots, side effects, mistrust of the government, vaccine efficacy, uncertainty about the relationship between stroke/TIA and COVID-19, accessing vaccine appointments, and difficulties getting information specific to them.
Bowman (2021) *preprint* (45) Cross-sectional study USA Jan – Mar 2021	A dialysis program-wide vaccination program was implemented over a series of 4 visits to 12 dialysis clinics in Virginia where all 859 dialysis patients aged 18+ were offered a vaccine. Question Topics: 1) Vaccine uptake	• As of Mar 16, 79.6% of dialysis patients who were offered a vaccine accepted, and 14.2% refused. The 6.2% who did not accept or refuse a vaccine were due to either hospitalization or no-shows to treatment on the vaccine clinic day. • The likelihood of vaccine refusal decreased by 13% for every 5-year increment in age (OR 0.87, 95% CI: 0.80-0.95, P=0.002). • Women were more likely to refuse a vaccine compared to men (OR 2.40, 95% CI: 1.64-3.50, P<0.0001). • An increased likelihood of vaccine refusal was seen in those who did not receive a flu shot in

		2020 (OR 5.44, 95% CI: 3.15-9.39, P<0.0001), those on dialysis for more than 5 years (OR 1.7, 95% CI: 1.08-2.70, P=0.023), and those with a positive PCR test for COVID-19 (OR 1.56, 95% CI: 0.97-2.52, P=0.067).
Giannini (2021) (4) *new* Cross-sectional study Italy NR 2021	Acceptance and refusal rates of a COVID-19 vaccine was assessed in a group of 266 individuals who underwent liver transplantation. Question Topics: 1) Vaccine uptake	• 96.6% of patients accepted and received a COVID-19 vaccine and 3.4% did not receive a vaccine. • 5 patients refused vaccination due to concerns about severe adverse events. These patients had received adequate information about the vaccine and received the vaccinations recommended in liver transplant recipients prior to refusing. • 2 patients requested more time to decide whether or not to receive the vaccine due to concerns over potential harms. • 1 patient required further work-up for previous allergic reactions to vaccination, and 1 patient was temporarily abroad while vaccines were offered.
Gibbon (2021) (5) *new* Cross-sectional study UK NR 2021	COVID-19 vaccine uptake, and reasons for refusal was evaluated in 92 current psychiatric in-patients in a medium secure hospital in the UK. Question Topics: 1) Vaccine uptake	• 85 patients had capacity to decide if they wanted a COVID-19 vaccine. • 80% consented to accept a vaccine and 20% refused. • White British patients were less likely to refuse a vaccine compared to Black, Asian, minority ethnic (BAME) patients (16.9% vs 30%). • Of the 17 patients who refused vaccination, the reasons for refusal included: concern about the safety and side-effects of the vaccine (n=5), belief that there is a low risk to their personal health from contracting COVID-19 (n = 4), broader distrust of healthcare services (n=2), and concerns about animal testing (n=1). Five individuals were unwilling to explain their reasons for refusal.
Giannini (2021) (46) *new*	Vaccine uptake rates were assessed in 56 patients with irritable bowel	• 92.6% accepted a vaccine and 7.4% refused.

Cross-sectional study Italy NR 2021	syndrome who were followed at an irritable bowel centre. Question Topics: 1) Vaccine uptake	• The two patients who refused did so due to concerns about potential adverse reactions.
ADHERENCE TO PUBLIC HEALTH MEASURES POST-VACCINE		
United Status Census Bureaus (2021) *unpublished* (53) Longitudinal study USA May 2021	Estimates of preventative behaviours of those who have received at least one vaccine dose were collected in the biweekly online Phase 3.1 Household Pulse Survey. Week 30 May 12-24, n=192,277,515 Question Topics: 1) Vaccine uptake Survey tools available? Yes Formative research conducted? Yes Survey pre-tested? Yes	• 73.2% of those that had received at least one dose of the vaccine did not change preventative behaviours post-vaccine, 21.9% decreased preventative behaviours, and 4.3% increased preventative behaviours. • Decreasing preventative behaviours was reported more among those aged 18-39 (24-25%), males (23%), White non-Hispanic (27%), those who were married (24%), had a bachelors degree or higher (30%), in household with 2 (25%) and 4 people (23%), were employed (24%), and had household incomes above $75,000 (23-37% for $200,000 and above) compared to their counterparts.
Office for National Statistics (2021) *unpublished* (50, 54, 197, 198) Longitudinal study UK	A weekly online survey of vaccine intentions was conducted in a nationally representative sample of UK adults. Apr 7-11: n= 6,030 April 28-May 3: n=3,830 June 2-6: n= 4,153 June 9-13: n=3,600 *new* Question Topics:	**June 9-13** • Social distancing with people outside their household continued to fall from 74% in May survey to 66% in June survey (88% early April). • Physical contact outside the home dropped by 1% in the latest survey to 71%. • 46% (down from 50%) of adults were meeting up indoors with people outside their households, childcare, or support bubble. **June 2-6**

Dec 2020- May 2021	1) Post-vaccine behaviors Survey tools available? Yes Formative research conducted? Yes Survey pre-tested? Yes	• Social distancing with people outside their household continued to fall from 74% in May survey to 68% in June survey. • Physical contact outside the home dropped by 1% in the latest survey to 72%. • 50% of adults were meeting up indoors with people outside their households, childcare, or support bubble. • Meeting outdoors amongst adults has increased from 53% to 65% in since the last survey. **Apr 28-May 3** • 90% of vaccinated individuals (at least one dose) always or often wash their hands when returning home compared to 82% of unvaccinated. • 90% of vaccinated individuals (at least one dose) have been always/often maintaining social distancing when meeting up with people outside their household, support or childcare bubble compared to 72% of unvaccinated. • Those having received at least one dose have avoided physical contact outside their homes compared to those unvaccinated (86% vs 74%). • 25% of vaccinated adults (at least one dose) have stayed home or left only for work, exercise, essential shopping or medical needs compared to 15% of unvaccinated adults. • Fewer vaccinated adults work from home than unvaccinated (33% vs 43%).
Rahamin-Cohen (2021) *preprint* (51) Cross-sectional study Israel Mar-Apr 2021	To assess behavior changes in the vaccinated population, an online survey sent via text message was answered by 185 individuals from the general population (18+) and 23 HCWs (18+). HCW outcomes in the HCW section. Question Topics: 1) Post-vaccine behaviors	• After the second dose, 21.1% of respondents reported wearing a mask less than before receiving the vaccination and 75.7% did not change their behavior. More individuals <50 years old decreased their mask wearing (28.1%) compared to those aged 50+ (17.2%). Only 1/23 (4.3%) HCWs reported wearing a mask less post-vaccination. • When comparing social distancing behavior before and after vaccination, 48.4% reported no change and 47.3% reported a decrease in social

	Survey tools available? No Formative research conducted? No Survey pre-tested? No	distancing. This differed by age with 41.8% of the 50+ group reporting a decrease in social distancing and 53.3% reporting no change compared to 56.1% and 40.4% in the <50 group, respectively. In HCWs, 43.5% reported a decrease in social distancing and 52.2% reported no change post-vaccination.
Wright (2021) *preprint* (52) Longitudinal study UK Oct 2020 – Mar 2021	Results from an ongoing online monthly survey on 70,000 adults (18+) was used to explore changes in compliance following vaccination. Question Topics: 1) Post-vaccine behaviors Survey tools available? No Formative research conducted? No Survey pre-tested? No	• There was no evidence showing that receiving a COVID-19 vaccine reduced compliance behaviors. • Increased compliance from the beginning of the second wave of COVID-19 was shown in both vaccinated and unvaccinated individuals.
Office for National Statistics (2021) *unpublished* (35) Cross-sectional survey UK Feb 2021	Responses of 2070 adults over 80 years old were collected through an online survey to determine vaccine coverage, attitudes, and vaccinations effect on protective behaviors. Question Topics: 1) Post-vaccine behaviors Survey tools available? No Formative research conducted? No Survey pre-tested? No	• Of those that had received at least one dose, 43% had met someone outside of their bubble, household, or care staff indoors. • Most respondents who received at least one dose ventured outside their homes to do an activity (49% met someone who they do not live with outdoors, 54% had went shopping, and 45% had left home to participate in outdoor leisure activities). Only 20% reported that they had not left home for any reason. • 25% of those received their first dose and 33% with both doses were willing to go the hospital for a medical reason.
Nguyen (2021) *preprint* (6) *new*	The rate of change in average daily travel distance from a participant's	• The median daily travel distance travelled was 8.9km (IQR: 3.50km, 24.17km) between 157 days

Cohort study UK Sep 2020-Feb 2021	registered address before and after SARS-CoV-2 vaccination was measured using Virus Watch. Virus Watch used Global Positioning System (GPS) to collect data on the movement of 228 vaccinated individuals.	prior to vaccination until the day before vaccination. • Between the day of vaccination and 100 days after vaccination, the median daily travel distance travelled was 10.30km (IQR: 4.11, 27.53km). • After removing outlier data, there was a median daily increase in movement of 45.0m (95%CI: 25m, 65m, P = <0.001) between the vaccination date and 99 days after vaccination. • After restricting the analysis to the 3rd national lockdown (Jan 4 - Apr 5, 2021), there was a median daily movement increase of 9m (95%CI: -25m, 45m, P = 0.57) in the 30 days prior to vaccination and the vaccination date, and a median daily movement increase of 10m (95%CI: -60m, 94m, p-value = 0.69) in the 30 days after vaccination.
Kaim (2021) (7) *new* Cross-sectional study Israel Jan 2021	Protective behavioral adjustments (i.e., mask wearing and social distancing) during the initial phase of the vaccination campaign was evaluated in a group of 1120 adults using an online survey. Of these individuals 64 were infected with COVID-19, 453 were vaccinated, and 603 were not vaccinated. Question Topics: 1) Post-vaccine behaviors Survey tools available? No Formative research conducted? No Survey pre-tested? No	• At the beginning of the vaccination campaign, those who were infected were less careful about social distancing (29.7%) compared to those who received the first dose of vaccine (12.8%), or those who were neither vaccinated nor infected (19.2%) (χ^2 = 19.32, P = 0.001). • Similarly, those who were infected were less careful about mask wearing (18.8%) compared to those who received the first dose of the vaccine (8.2%) and those who neither were vaccinated nor infected (11.6%) (χ^2 = 13.02, P = 0.011). • A higher level of social distancing was maintained among Non-Jewish individuals compared to Jewish individuals: those who were vaccinated (41.7% among non-Jewish vs 14.3% among Jewish; χ^2 = 22.9, P < 0.001), those who were infected (33.1% among non-Jewish vs 8.3% among Jewish; χ^2= 7.29, P = 0.026), and those who were neither vaccinated nor infected (24.3% among non-Jewish and 8.8% among Jewish; χ^2 =

		28.81, P < 0.001). Similar trends were observed for mask wearing.

GLOBAL POPULATION

Table 2. Evidence of vaccine attitudes of the global population (n=6)

STUDY	METHODS & SURVEY TOOLS	KEY KAB OUTCOMES
Quasi-experimental studies (n=1)		
Duch (2021) *preprint* (199) Quasi-experimental study 13 countries (Australia, Brazil, Canada, Chile, China, Colombia, France, India, Italy, Spain, Uganda, UK, USA) Nov-Dec 2020	To understand public opinions on key aspects of vaccine allocation, an online experiment of 15,536 adults (18+) across 13 countries was conducted. Participants were require to make eight binary choices about hypothetical vaccine recipients that randomly varied on five attributes including occupation, age, transmission status, risk of death from COVID-19, and income. Question Topics: 1) Vaccine perceptions Survey tools available? Yes Formative research conducted? Yes Survey pre-tested? No	• Overall there was global consensus on which population segments should have priority for a COVID-19 vaccine. • In almost all countries and across participants of different education levels, incomes, and political ideologies, results show that the public favors prioritizing the vaccine to healthcare workers, those at high risk, those in lower income brackets, and older populations. • At least two thirds of participants in each of the countries (80% in Canada) believed that the government should assume the lead role in the distribution of COVID-19 vaccines. However, there is evidence that a large proportion of individuals would be willing to pay for a vaccine if it were available privately. This ranged from 18% of participants in France to 79% in India and Uganda. 35% of Canadians would be willing to pay for a vaccine. • There was no consensus on support for mandatory vaccination either globally or within national borders. In the global sample, 24% were strongly opposed and 38% were strongly in favor. In France 60% of participants opposed mandatory vaccination whereas in China, India, and Uganda very few people were strongly opposed.
Cross-sectional studies (n=5)		
Crespo (2021) *preprint* (57)	Change in intention to vaccinate over time was assessed using two online surveys, one in Nov 2020	• In Canada, intention to vaccinate increased from 44.2% in Nov to 55.2% in Jan.

Cross-sectional studies 15 countries: Australia, Canada, Denmark, Finland, France, Germany, Italy, Japan, Netherlands, Norway, Singapore, South Korea, Spain, Sweden, UK Nov-Jan 2021	and the other in Jan 2021 across fifteen countries. It is unclear if and how many individuals completed both surveys. Question Topics: 1) Vaccine intentions Survey tools available? No Formative research conducted? No Survey pre-tested? No	• In the Jan survey, the countries with the highest intentions to vaccinate included the UK (77.5%), Denmark (67%), and the Netherlands (63.1%). The countries with the lowest intentions included South Korea (43.7%), France (39.2%), and Singapore (34.8%). • Increase in intention to vaccinate between Nov and Jan was seen in Spain (24.1%), UK (23.2%), Sweden (22.7%), Finland (20.4%), Netherlands (18.5%), Italy (15.4%), Norway (14.6%), France (14.2%), Denmark (13.3%), Germany (13.0%), Canada (11%), and Japan (0.8%). • Countries with a decrease in intentions between Nov and Jan included Australia (-6.6%), South Korea (-5.0%), and Singapore (-1.3%). • In 11/15 countries there was a significant decrease in the proportion of individuals who reported concern about the side-effects of a vaccine. In Canada, this concern decreased from 53.3% in Nov to 47.9% in Jan.
Clarke (2021) (200) Cross-sectional study Australia, Canada, France, Italy, Spain, UK and USA Nov-Dec 2020	An international online survey of 8209 adults from high income countries was conducted with the goal of evaluating perceptions of prioritization of global vaccine allocation on a scale 0 ('very much disagree') to 100 ('very much agree'). Question topics: 1) Vaccine perceptions Survey tools available? No Formative research conducted? No Survey pre-tested? No	• All countries favoured in order of most support: allocating based on need, by affordability, and by which country developed the vaccine. • The UK had the largest percentage of respondents who do not favor donating purchased vaccines to other countries (26%) and Italy and Spain had the lowest (15%). • Between 48% and 56% of respondents would donate their country's vaccines at some level. The highest was Canada (56%) and lowest France (48%).
World Economic Forum (2020)	An online survey of 18526 individuals globally analyzed intention to vaccinate and	• 73% stated they would get a vaccine for COVID-19 if it were available. Compared to three months earlier (Aug), this is a 4% drop.

unpublished (201) Cross-sectional study 15 countries (Australia, Brazil, Canada, China, France, Germany, India, Italy, Japan, Mexico, South Africa, South Korea, Spain, UK, and USA) Oct 2020	perceptions on the vaccine. Of these, 1000 participants were Canadian. Question Topics: 1) Vaccine intentions 2) Vaccine perceptions 3) Vaccine hesitancy Survey tools available? Yes Formative research conducted? Yes Survey pre-tested? Yes	• Intention has declined between Aug and Oct in 10/15 countries, most of all China, Australia, Spain, and Brazil. • Countries with the highest intent include India (87%), China (85%), South Korea (83%), and Brazil (81%). • France has the lowest intention to vaccinate (54%), followed by the USA (64%), and Spain (64%). • 52% indicated that they would become vaccinated within three months after vaccine becomes available to all. • 55% believe that a vaccine will not be available on the market until the third quarter of 2021. • Globally, the most common reasons for hesitancy include concerns about side-effects (34%), and concerns that clinical trials are moving too quickly (33%).
Mannan (2021) *preprint* (202) Cross-sectional study 60 countries: (Afghanistan, Algeria, Argentina, Australia, Bangladesh, Belgium, Bolivia, Botswana, Brazil, Canada, Chile, China, Columbia, Cuba, Dominican Republic, Ecuador, Egypt,	Sixty national representative online and telephone surveys were conducted capturing 26,852 responses from adults (19+) regarding vaccine acceptance and attitudes. Question Topics: 1) Vaccine intentions 2) Vaccine hesitancy 3) Vaccine attitudes Survey tools available? Yes Formative research conducted? Yes Survey pre-tested? No	• 62.6% of Canadians strongly accepted a COVID-19 vaccine which was the lowest acceptance recorded among countries in North America. • 65.5% strongly agreed that it was important to get a vaccine to protect others, 57.6% agreed that pharmaceutical companies will develop a safe vaccine, and 31.7% believed that vaccines were safer if they made in America or Europe rather than other countries. • Hesitancy was demonstrated with 48.7% worried about side effects, 44.7% worried about unforeseen impacts, 43.7% had concerns over commercial profiteering, 42.6% had general mistrust of vaccine benefits, and 34.6% had a preference for natural immunity. • Vaccine acceptance for each country: **Africa** Algeria (66.3%), Egypt (43.6%), Botswana (71.2%), Kenya (61.3%), Libya (49.6%), Mali (62.4%), Mauritius (82.8%), Morocco (48.4%), Nigeria (61.5%), South Africa (79.3%)

El Salvador, England, Fiji, France, Germany, Guatemala, India. Italy, Jamaica, Japan, Kenya, Kiribati, Libya, Mali, Malaysia, Mauritius, Mexico, Morocco, Nauru, New Zealand, Nicaragua, Nigeria, Palau, Panama, Papua New Guinea, Paraguay, Peru, Poland, Russia, South Africa, Saudi Arabia, Singapore, Solomon Islands, Spain, South Korea, Sweden, Switzerland, Turkey, Tonga, Tuvalu, United States of America, Uruguay, Venezuela) Jun-Sep 2020		**Asia** Afghanistan (47.2%), Bangladesh (49.8%), China (87.4%), India (73.9%), Japan (71.4%), Malaysia (52.7%), Saudi Arabia (51.1%), Singapore (66.8%), South Korea (76.2%), Turkey (59.2%) **Oceania** Australia (89.9%), Fiji (87.2%), New Zealand (88.4%), Kiribati (89.8%), Nauru (88.3%), Palau (89.2%), Papua New Guinea (91.9%), Solomon Islands (92.6%), Tonga (92.9%), Tuvalu (90.5%) **North America** Canada (62.6%), Cuba (77.9%), Dominican Republic (79.5%), El Salvador (71.8%), Guatemala (75.0%), Jamaica (71.0%), Mexico (73.3%), Nicaragua (81.2%), Panama (87.4%), United States (74.8%) **South America** Argentina (81.3%), Brazil (86.2%), Bolivia (82.8%), Chile (79.2%), Columbia (81.8%), Ecuador (70.2%), Paraguay (67.7%), Peru (77.8%), Uruguay (75.6%), Venezuela (74.8%) **Europe** England (69.3%), Belgium (60.4%), Germany (65.2%), Italy (68.4%), France (51.9%), Poland (52.3%), Spain (72.5%), Sweden (62.7%), Switzerland (60.2%), Russia (51.3%)
Lazarus (2020) (203) Lazarus (2021) (204)	Vaccine acceptance rates and factors influencing acceptance of a COVID-19 vaccine was analyzed using an online survey of 13,426	• 71.5% of participants reported that they would be “very likely” or “somewhat likely” to take a COVID-19 vaccine

Cross-sectional study 19 countries: (Brazil, Canada, China, Ecuador, France, Germany, India, Italy, Mexico, Nigeria, Poland, Russia, Singapore, South Africa, South Korea, Sweden, UK, USA) Jun 2020	adults. The data from this survey was analyzed differently in two publications. Question Topics: 1) Vaccine intentions Survey tools available? Yes Formative research conducted? Yes Survey pre-tested? Yes	• 48.1% reported that they would accept their employer's recommendation to take the vaccine. • China (88.6%), Brazil (85.4%), and South Africa (81.6%) had the highest acceptance rates and Nigeria (58.9%), Poland (56.3%), and Russia (54.9%) had the lowest. • The acceptance rate in Canada was 68.7%. • Individuals aged 25+ were more likely to accept the vaccine than those aged 18-24. The strongest difference was seen (OR 1.73, 95% CI: 1.48-2.02) when responses from the oldest age cohort (65+) were compared to the youngest cohort (18-24). • People with higher education, women, those who earned more income, those who reported COVID-19 illness in the family, and those who trusted their government were more likely to accept the vaccine. • Having a high/very high education may be linked to lower vaccine acceptance in Canada, Spain, and the UK.

CANADIAN GENERAL POPULATION

Table 3. Evidence of vaccine attitudes of the general public (n=42)

STUDY	METHODS & SURVEY TOOLS	KEY KAB OUTCOMES
Longitudinal studies (n=8)		
Leger (2021) *unpublished* (10, 69-73, 205, 206) Longitudinal study Canada & USA Nov 2020 & Jan-June 2021	An online survey of Canadian and American adults (18+) was conducted to evaluate vaccine perceptions and intentions to vaccinate. Wave 1: Nov 2020, 1516 Canadians and 1002 Americans Wave 2: Jan 2021, 1516 Canadians and 1003 Americans Wave 3: Feb 2021, 1535 Canadians and 1002 Americans	**Wave 12** • Canadians intention to be vaccinated or who have been vaccinated increased to 88% from May. • The percentage of those who did not intend to vaccinate was highest in MB and SK (18%) followed by AB (16%), among those aged 18-34 (14%, decreased from 18% at last polling), and among rural residents (16%, decreased from 22% at last polling). • Belief that vaccines are dangerous stayed at 7% since May (81% believe vaccines are safe and 12% do not know).

	Wave 4: Feb 2021, 1,532 Canadians and 1002 Americans Wave 5: Apr 2021, 1,504 Canadians and 1,002 Americans Wave 6: Apr 2021, 1,548 Canadians and 1,003 Americans Wave 7: May 2021, 1,529 Canadians, 1,003 Americans Wave 8: May 2021, 1,529 Canadians, 1,003 Americans Wave 9: May 2021, 1,624 Canadians and 1,002 Americans. Wave 10: May 2021, 1,624 Canadians and 1,002 Americans. Wave 11: June 2021, 1,539 Canadians, 1,004 Americans *new* Wave 12: June 2021, 1,542 Canadians and 1,001 Americans *new* Question Topics: 1) Vaccine intentions 2) Vaccine perceptions Survey tools available? No Formative research conducted? No Survey pre-tested? No	**Wave 11** • Canadians intention to be vaccinated or who have been vaccinated held steady at 86% (no change from May). • The percentage of those who did not intend to vaccinate was highest in AB (20%) followed by Atlantic Provinces (19%), among those aged 18-34 (18%), and among rural residents (22%). • 89% certainly or probably will receive a second dose, 1% probably will not, 9% already have received a second dose, and 1% were unsure. • 3% of those who reside in QC and 3% of those aged 18-24 indicated they either probably will not or certainly will not get a second dose. • 48% of Canadians were uncomfortable about receiving a different brand of vaccine as their second dose whereas 46% were comfortable and 6% were unsure. • Those in MB/SK (34%), those aged 35 to 55 (25%), and rural residents (26%) had the highest levels of not being comfortable with a different vaccine as a second dose. • 50% of those who had a first dose of Astra-Zeneca would prefer getting a second dose of Astra-Zeneca compared to 32% who would like a second dose of another brand, and 18% who did not know. • Belief that vaccines are dangerous increased 1% to 7% since May (82% believed vaccines are safe and 11% did not know). **Wave 10** • Canadians were split 50-50 on whether they were comfortable if some of their colleagues were not vaccinated. • Discomfort with unvaccinated coworkers was highest in BC (62%) and 60% of Atlantic Canada and MB/SK were comfortable. • Older (55+) Canadians were less comfortable with unvaccinated coworkers (52% uncomfortable)

		along with urban residents (53% uncomfortable) compared to rural residents (44% uncomfortable). **Wave 9** • 51% of respondents felt the vaccine campaign in their province was proceeding about the same as other provinces. QC residents felt they were doing better than other provinces whereas ON and AB felt vaccinations were slower. • Canadians had high support for showing proof of vaccination when traveling by plane (82%), attending events with large crowds (75%), attending in-person university (71%) and had lower support for going to their place of work (68%), staying in a hotel (68%), and dining in a restaurant (64%). Support for showing vaccination was consistently higher among those aged 55+. • Since earlier polling in May there was a 4% increase (to 86%) of those who had been vaccinated or intended to get a vaccine. • Provinces with the highest combined level of vaccination or intention to get a vaccine was in QC (90%), followed by AB (87%), Atlantic provinces (86%), BC (85%), and MB/SK (84%). • Belief that vaccines are safe and should be given has stayed steady at 81% but those who did not know increased 1% to 12%. • Waves 1-8 summarized in previous versions of this report.
Angus Reid (2021) *unpublished* (8, 60, 61, 66, 68, 76, 82, 83, 85) Longitudinal study Canada	Vaccine intentions and perceptions were analyzed in Canadian adults (18+) using an online survey. Wave 1: Jul 2020, n=1519 Wave 2: Sep 2020, n=1660 Wave 3: Dec 2020, n=1603 Wave 4: Jan 2021, n=1580 Wave 5: Feb 2021, n=1201 Wave 6: Mar 2021, n=1748	**Wave 10** • 84% have received at least one shot or will get vaccinated as soon as possible (an increase of 2% from May), 4% will get a vaccine but wish to wait (down from 6%), 9% will not get a vaccine (no change), and 3% were unsure (no change). • Vaccine hesitancy remains highest in AB and SK (18%). This has increased 1% in AB and decreased 6% in SK since May. • 57% of respondents would like equal emphasis on distributing first and second doses, 26% would

Jul, Sept, Dec 2020 & Jan-Feb and May-Jun 2021	Wave 7: Apr 2021, n=NR Wave 8: Apr 2021, n=1594 Wave 9: May 2011, n= 1,319 Wave 10: June 2021, n=4,948 *new* Question Topics: 1) Vaccine intentions 2) Vaccine perceptions 3) Vaccine hesitancy Survey tools available? Yes Formative research conducted? No Survey pre-tested? No	prefer priority of getting all eligible first doses administered, and 16% would like the focus to be on second doses and circling back to first doses. Support for focusing on administering first doses was higher among those waiting for vaccination (39%) and among those aged 18-24 (40%). • Canadians are supportive of continuing vaccinations until everyone in Canada has been vaccinated (72%) with 18% wanting to shift focus to at risk populations globally and 10% were unsure. • Respondents felt the second dose vaccinations were progressing as well as could be expected (49%) with nearly equal split between feeling it was taking too long (27%) and that it was going at great pace (24%). 55% of QC residents felt that things were going great whereas 40% of ON residents felt things were moving too slowly. • 51% felt Canada has done a good job of securing vaccine doses and 41% felt it had been a poor job. However, 60% and 69% still had confidence that the federal and provincial government can manage vaccine distribution, respectively. **Wave 9** • 82% of respondents have either received a vaccine or wish to get a vaccine as soon as possible, up from 71% in April. • Fewer respondents report being unsure about vaccinations (3% down from 13%), wanting to wait before receiving a vaccination (6% down from 13%), or report not wanting a vaccine (9% down from 13%) compared to April responses. • 53% of respondents have received at least one dose, an increase of 36% since April. • Vaccine hesitancy is highest in SK (24%) with the level remaining stable (22% in April and 26% in January. • Vaccine hesitancy dropped dramatically in AB from 45% in January to 25% in April to 17% in May.

		• Hesitancy in BC, MB, ON, QC, and the Atlantic provinces varied between 10-12% in May. • Vaccine hesitancy was highest in males aged 35-54 (18%) followed in by females aged 18-34 (15%). • Of those that received an AstraZeneca, 2% fully regret getting it and 66% have serious second thoughts or doubts. • Canadians remain very comfortable with Pfizer and Moderna (93% and 89%, respectively) but became less confident in AstraZeneca (52% in April to 35% in May) and Janssen (54% to 49%). • Unvaccinated men are more comfortable than women to receive AstraZeneca (29% vs 36% extremely uncomfortable) however 40% women would take a vaccine they are uncomfortable with compared to 31% of men. • Wave 1-8 summarized in previous versions of this report.
Engage Manitoba (2021) *unpublished* (97, 207) Longitudinal study Canada Jan-Jun 2021	A series of online surveys in Manitoba were implemented to assess vaccine intentions within the Safely Restoring Services in Manitoba Survey. Survey 1: Jan 10-15, n=73,351 Survey 2: Feb 4-9, n= 33,687 Survey 3: Feb 25-Mar 2, n=26,909 Survey 4: Mar 18-23, n=31,776 Survey 5: Jun 4-8, n= 33,904 Question Topics: 1) Vaccine intentions 2) Vaccine perceptions	**Survey 5** • 86% have received at least one dose of a vaccine (up from 9% in survey 4). • 2% have booked their first dose appointment, 2% will get the vaccine but are in no rush (down from 13%), 4% are unsure if they will get a vaccine (down from 12%), and 5% will not get a vaccine (down from 10%). • Of those who were not sure or do not intend to be vaccinated, very few would be swayed by the ability to travel within Canada (9%), attend sporting events or cultural events (7-9%), visit facilities or events (10%), or visit loved ones (11%). **Survey 4** • 9.0% of respondents have already received a vaccination (up 4% since survey 3). • 56% intend to sign up for a vaccination as soon as they are eligible (up 1.9%).

	Survey tools available? Yes Formative research conducted? No Survey pre-tested? No	• 13% report that they want a vaccine but are not in a rush (down from 16.2%). • 12% are unsure if they will get a vaccine when it's available (down from 14.2%). • 10% would refuse a vaccine (down from 10.5%). • Approval of the Manitoba governments approach to vaccinations is high in the latest survey with 33% strongly approving, 47% somewhat approving, 13% somewhat disapproving, 7% strongly disapproving.
Government of Manitoba (2021) *unpublished* (11) *new* Longitudinal study Canada May 2021	An online research panel of 600 Manitobans were surveyed to understand attitudes towards vaccination and possible incentives to increase uptake. Question Topics: 1) Vaccine intentions 2) Vaccine perceptions Survey tools available? No Formative research conducted? No Survey pre-tested? No	• 87% have received a vaccine or intend to be vaccinated (74% received and 13% intend), and increase of 11% from April. • 5% will get a vaccine but were not in a rush (down from 12%), 5% were unsure if they will get a vaccine (down from 7%), and 4% will not get a vaccine (down from 5%). • From April to June there was an 18% drop in the number of people strongly approving of Manitoba's vaccine distribution (42% to 24%), 49% somewhat approve (up from 43%), 17% somewhat disapprove (up from 11%), and 10% strongly disapprove (up from 4%). • In a group of 70 parents or guardians of children aged 12-17, 15% were not sure if they will vaccinate their children, and 13% will not vaccinate their children. • Those who did not intend to vaccinate their children were in households making less than $40,000, would not get the vaccine themselves, and didn't believe adults should get all the regular vaccines. • 31% of respondents felt much more positive about COVID-19 vaccine now then when first introduced, 19% felt slightly more positive, 45% felt the same, 3% felt slightly more negative, and 2% felt much more negative.

		• 55% felt that whether they got the vaccine or not should be a choice, 42% felt that it should not be a choice, and 3% were unsure. • Those who would promote vaccination tended to be younger than 30 or over 65 and believed that adults should have all their regular vaccines. • The types of information that were the most likely to influence decision to vaccinate included information about possible side effects (42%), being able to choose the vaccine (42%), information about testing (41%), and information about how the vaccine works (36%). • The least persuasive type of information was hearing stories from celebrities who got their vaccine (90% unlikely to impact). • Women would be the most influenced by being able to choose the vaccine. • Residents of Winnipeg were more influenced than those in rural areas by getting a vaccine from a family doctor/pharmacist, speaking to their family doctor/pharmacist, having someone come to their home, and hearing stories from celebrities. • Manitobans were largely not swayed by community incentives such as being able to travel without having to isolate (50% no more likely to vaccinate), being able to visit long term care homes without restrictions (52% no more likely), entry into provinces or countries (48% no more likely), being able to attend large events (60% no more likely), attend larger gathering (54% no more likely), certain businesses/facilities to those that are vaccinated (61% no more likely). • Those aged 30 to 44 were more likely to be influenced by being able to attend larger gatherings (community, faith, or personal). • Financial incentives (monetary, vouchers, complimentary items, draws for prizes, discounts) were not reported to increase the likelihood of accepting a vaccine (between 75% and 84% stating they are not more likely by any financial incentive).

		• 70% of respondents were concerned if only hesitant individuals received large ($50-$100) incentives.
Statistics Canada (2020) & Statistics Canada (2021) *unpublished* (65, 80, 81) Longitudinal study Canada Sep 2020 – Feb 2021	An online survey conducted by Statistics Canada as part of the Canadian Community Health Survey (CCHS) assessed Canadians behaviors to safeguard their own health as well as the health of others. In the September survey, a question about vaccine intentions was added. The most recent report captures 25,321,400 responses from individuals aged 12+. Question Topics: 1) Vaccine intentions Survey tools available? Yes Formative research conducted? Yes Survey pre-tested? Yes	**Jan-Feb 2021** • 82.3% of respondents were very or likely to get a COVID-19 vaccine. • Vaccine intention was highest in those over 65 years (88.1%) with a decreasing level of intention in those aged 12-17 (71.0%). • Vaccine intention was similar between males and females (82.8% vs 81.9%, respectively). **Sept-Dec 2020** • Over the sampling period 77% were willing to receive a vaccine. This represents an increase from Sept (75.5%) to Oct (74.8%), and Nov/Dec (80.3%). • Vaccine intentions were highest in Prince Edward Island (89.1%), Nova Scotia (81.5%), and British Columbia (81.4%). Vaccine intention was lowest in Prairie provinces (75.2%) • Men were more likely to vaccinate then women (77.9% vs 75.8%). • Immigrants were slightly less likely to vaccinate (74.6%) but this varied greatly between older and younger immigrants (73.2% for 12-64 and 81.1% for those 65+). • LGBTQ2+ were more likely to get a vaccine (83.3%). • The highest intentions among visible minorities were Japanese (86.5%), Korean (85.6%), South Asian (82.5%), Chinese (79.3%), visible minority not indicated/multiple (79.1%), Southeast Asian (78.3%), West Asian (78.3%), Filipino (75.1%), Arab (68.1%), Latin American (66.0%), and Black (56.6%). Non-visible minority's intention to vaccinate was 77.6%. • Older visible minorities were more likely to vaccinate than those 12-64 (77.4% vs 74.6%). • Intention to vaccinate among Indigenous respondents was 71.8% which was significantly less than Non-Indigenous respondents (77.1%). 74.2%

		of First Nations living off reserve were willing to vaccinate compared to 67.8% of Métis and 72.5% of Inuit*. • Older Indigenous people (65+) were more likely to want a vaccine compared to younger (74.9% vs 71.3%). *Use with caution. Coefficient of variation (CV) from 15.1% to 35.0%.
Impact Canada (2020) *unpublished* (74) Longitudinal study Canada Apr 2020 – Feb 2021	Vaccine confidence and hesitancy in the Canadian context was explored through the implementation of the World Health Organization (WHO) Behavioural Insights (BI) Tool on COVID-19 in eight waves of adults (18+) using the same participants where possible. Wave 1: n=2023, Wave 2: n=2,098, Wave 3: n=2,000, Wave 4: n=2,152, Wave 5: n=2,169, Wave 6: n=2,141 , Wave 7: n=2,129, Wave 8: n=2,117, Wave 9: n=2,055, Wave 10: n=2,125, Wave 11: n= 2,037 Question Topics: 1) Vaccine intentions 2) Vaccine perceptions 3) Vaccine hesitancy Survey tools available? Yes Formative research conducted? Yes Survey pre-tested? No	**Wave 11** • Intention to get vaccinated right away has increased to 58% (up from 49% in wave 10). 24% intend to vaccinate but would like to wait, 9% would not vaccinate, and 8% were unsure. • Those who plan to wait are mostly like to want to wait 1 to 2 months (33%). • 68% have made up their mind if they will or will not get a vaccine and 25% need more information before deciding. • The two most common reasons for vaccine hesitancy included a lack of testing or research (26%) and belief that the vaccine was not safe (15%). • 47% report that getting the most effective vaccine is the most important criteria for selecting a vaccine, followed by the vaccine that is available first (15%), and fewest side effects (12%). • 56% and 22% would like more information regarding the safety and effectiveness of the vaccine, respectively. • A vaccine recommendation from a healthcare provider would likely influence 45% of respondents. **Wave 10** • Vaccine acceptance rose slightly from wave 9 (61%) to wave 10 (65%). • Intention to get vaccinated right away has increased to 49% (up from 43% in wave 9). 31%

		intend to vaccinate but would like to wait, 11% would not vaccinate, and 8% were unsure. • Of those wanting to wait for a vaccine, 42% wanted to wait several months (up from 27% in wave 9). • The top reasons for wanting to wait were to ensure safety (80%) and efficacy (64%). • Those who would decline a vaccine were asked about hypothetical incentives. 58% would like assurances that the vaccine would not be a risk for exposure to COVID-19, 56% wanted a convenient booking system, and 52% wanted a convenient location. • 56% of participants stated they would vaccinate to be able to return to work, travel, or attend large gatherings. • 63% reported that their mind was made up whether to vaccine or not and 32% would like more information before they decide.
INSPQ (2020), INSPQ (2021), INSPQ (2021), INSPQ (2021), INSPQ (2021) *unpublished* (12, 86, 88, 90, 91, 95) Longitudinal study Canada Apr 2020 – Jun 2021	Analysis of the acceptability of vaccination against COVID-19 was evaluated using an online survey of adults and healthcare workers in Quebec. Number of participants was not clearly stated (~3300 each collection period). There were multiple collection periods, one in Apr-May 2020, Sep and Dec 2020, Apr-Jun 2021 *new*. Articles in French. Question Topics: 1) Vaccine intentions 2) Vaccine hesitancy Survey tools available? No Formative research conducted? No Survey pre-tested? No	**June** • 49% agreed that vaccinated adults should be able to gather without masks in private, 44% disagreed, and 6% were unsure. • Almost half of respondents felt that vaccinated people should be able to gather without masks in private (49%) but also agree that masks should be worn outside with people they don't live with (56%). • Vaccine passports have high support with 72% in favour (23% disagreed and 4% were unsure). • 73% of respondents disagreed that it is important to follow protective measures based on the rate of vaccination and the decrease in COVID-19 cases. **May** • 74% of respondents who have not been vaccinated yet intend to get a vaccine, a 3% drop since late April. 18% do not intend to get a vaccine

		(a 4% increase), and 8% do not know (1% decrease). • Intention to vaccinate was lowest in those aged 25-34, women, those without secondary education, who were unemployed, more deprived, were not worried about getting COVID-19, those with conspiratorial views, and those who check social media once a week or less. • Households with minors had lower intentions to vaccinate compared to single person households, and households without minors. • Immigrants were more hesitant and unsure about receiving a vaccine compared to non-immigrants. • The top three reasons among those who were not intending to vaccinate included worry about side effects, lack of confidence in vaccines in general, and the newness of the vaccine. • 28% of those who do not intend to vaccinate believe that it is incompatible with their religious beliefs or personal principles. **Earlier** • 77% of respondents who have not been vaccinated yet intend to get a vaccine, a 1% drop since early April. 14% do not intend to get a vaccine (no change), and 9% do not know (1% increase). Intention has increased 7% since December. • Intention to get a vaccine was higher among men compared to women (78% vs 76%), older respondents (79% for those 60+ vs 75% for those 18-25), and among those with university degree (85% of those with university, 78% with college). • Intention to vaccinate generally increased as communities increased in size, from living in small villages less than 10,000 (71%), towns 10,000 to 100k (73%), greater Montreal area (81%) and Montreal (79%). • 68% disagree with the statement "people vaccinated against COVID-19 should have the right

		to have private gatherings and no longer wear a mask in public" whereas 25% agreed and 7% were unsure. • In December those with low intentions to vaccinate were concerned about side effects (27%), the newness of the vaccine (24%), and not trusting vaccines in general (24%). • Those holding conspiratorial world views were less likely to accept a vaccine (51% vs. 76%). • Agreement with compulsory vaccination continues to trend downwards with 54% agreeing in December.
Saskatchewan Population Health and Evaluation Research Unit (2020) *unpublished* (208) Longitudinal study Canada May-Sep 2020	An online survey was used to evaluate intention to vaccinate in residents of Saskatchewan over time. Surveys were conducted from May-Sep. The number of individuals is not stated and it is unclear if they are the same participants over time. Question Topics: 1) Vaccine intentions Survey tools available? No Formative research conducted? No Survey pre-tested? No	• From May to Sep, intention to vaccinate dropped from 84.9% to 56.5%. • Intention to vaccinate is highest in those 65-74 years of age and lowest in those under 48 years of age.
Cross-sectional studies (n=29)		
Angus Reid (2021) *unpublished* (96) Cross-sectional study Canada	1601 Canadian adults were surveyed about their thoughts on vaccination policies (proof of and vaccine passports) online. Question Topics: 1) Vaccine intentions 2) Vaccine perceptions 3) Vaccine hesitancy	• 79% Canadians were supportive of showing proof of vaccination for international travel (excluding the US), 78% support it for commercial flights, and 76% were supportive for traveling to the USA. • Less support was shown for having proof of vaccination for attending large public events (69%), public places such as restaurants, bars, and movie theatres (55%), and at places of work (55%).

May 2021	Survey tools available? Yes Formative research conducted? No Survey pre-tested? No	• Those who were vaccine hesitant had much lower support for proof of vaccination across all presented scenarios. • 18% of those not willing to get a vaccine would be swayed to get vaccinated if proof of vaccination was required in many scenarios.
Leger (2021) *unpublished* (209) Cross-sectional study Canada Apr 2021	An online survey of 1004 participants in British Columbia was conducted to assess views on vaccines, vaccine passports, and vaccine rollout. Question Topics: 1) Vaccine intentions 2) Vaccine perceptions Survey tools available? No Formative research conducted? No Survey pre-tested? No	• 16% reported they had received a vaccine. • 49% intend to tell everyone they know when they receive a vaccine, especially for respondents in urban areas (53%) compared to rural (40%). Fewer respondents would only tell immediate family and friends (42%). • 24% intend to share when they get a vaccine on social media. • Most don't feel they should be vaccinated before others (27%), or are jealous (25%), or anxious (25%) of others being vaccinated. • Vaccine passports had high support in international travellers coming to BC (77%) and BC travellers going abroad (75%). Support for passports for Canadians traveling within Canada (68%) and within BC (56%) was slightly lower. • Vaccine passports for any situation had higher support among those 55+. • 70% are happy with the order of vaccination prioritization in BC and 44% are satisfied with the rollout. • Support for health figures or leaders has decreased since Dec 2020 (Dr. Bonnie Henry: 65%, Adrian Dix: 58%, Dr. Theresa Tam: 53%, Justin Trudeau: 45%).
Statistics Canada (2021) *unpublished* (210) Cross-sectional study	Vaccine intentions and perceptions were analyzed in 1025 Canadian adults (18+) residing in the capital cities of the territories using mail invites and computer assisted telephone interview for non-responses.	• The majority of respondents had already received one dose (80%) with 16% likely to get vaccinated and few unlikely to get vaccinated (4%). • Respondents were more likely to have received a vaccine or were likely to be vaccinated if they has a post-secondary degree or higher (85% vs 68% for having received a vaccine and 13% vs 23% for likely to get vaccinated respectively).

Canada Mar-Apr 2021	Question Topics: 1) Vaccine intentions 2) Vaccine perceptions 3) Vaccine hesitancy Survey tools available? Yes Formative research conducted? Yes Survey pre-tested? Yes	• 10% of those unlikely to be vaccinated had household income of less than $60,000 compared to 2% among those with incomes between $60,000 to more than $120,000. • Most felt vaccines were safe (95%) and effective (97%) compared to the COVID-19 vaccine which garnered lower support for safety (86%) and efficacy (88%). • 94% of respondents felt confident that Canada's process only approved safe and effective vaccines (94%). • Top sources for COVID-19 vaccination information were Public Health Agency of Canada and Health Canada (89%) and provincial, territorial or regional health authorities (85%).
Centre for Addiction and Mental Health (2021) *unpublished* (211) Cross-sectional study Canada Mar 2021	An online survey of 1000 Canadians as part of Asking Canadians web panel was conducted to measure mental health and vaccine intentions. Question Topics: 1) Vaccine intentions Survey tools available? No Formative research conducted? No Survey pre-tested? No	• 66.4% of respondents who haven't received a vaccine yet definitely intend to get one, 21.8% will probably get a vaccine, and 11.8% definitely or probably will not get a vaccine.
Tang (2021) *preprint* (212) Cross-sectional study Canada Jan-Mar 2021	To assess vaccination hesitancy in population subgroups in Canada, an online survey of 14,621 panel members from the nationally representative Angus Reid Forum was conducted. Question Topics: 1) Vaccine intentions 2) Vaccine hesitancy	• Overall, 9.3% do not intend on receiving a vaccine. This was highest in AB (16.4%), MB & SK (13.8%) and lowest in QC (8.3%), the Atlantic provinces (8%), ON (7.8%), and BC (7.2%). • Vaccine hesitancy was significantly associated with those aged 40-59 years (OR 0.87, 95% CI: 0.78-0.97), being a visible minority (OR 0.56, 95% CI: 0.37-0.84), lower education, and belonging to a household of five or more people (OR 0.82, 95% CI: 0.76-0.88).

	Survey tools available? No Formative research conducted? No Survey pre-tested? No	
Syan (2021) *preprint* (77) Cross-sectional study Canada Jan – Feb 2021	Factors associated with intention to receive a COVID-19 vaccine was assessed in 1,367 adults (18+) living in Southern Ontario using an online survey. Question Topics: 1) Vaccine intentions 2) Vaccine hesitancy 3) Vaccine attitudes Survey tools available? No Formative research conducted? No Survey pre-tested? No	• 82.8% were willing to receive a vaccine and 17.2% were unwilling. • The most common reasons for vaccine hesitancy were concern over long-term (65.5%) and immediate (60.5%) side effects, and a lack of trust in the vaccine (55.2%). • Higher intention to vaccinate was significantly associated with male gender (P=0.002) and higher education levels (P<0.001). • The perception of COVID-19 vaccine safety was significantly lower (-10.7%) than vaccines in general. Females, older adults, and those with less education reported lower perceived COVID-19 vaccine safety.
Leger (2021) *unpublished* (99) Cross-sectional study Canada Jan 2021	An online survey of 800 participants from Manitoba (18+) was conducted to investigate vaccine perceptions and intentions to vaccinate. Question Topics: 1) Vaccine intentions 2) Vaccine perceptions 3) Vaccine rollout perceptions Survey tools available? No Formative research conducted? No Survey pre-tested? No	• 72% reported the intention to vaccinate when a vaccine is available. • Intention to vaccinate increases with age. 82% of those aged 55+ reported they would definitely or probably intend to vaccinate compared to 65% of those aged 18-51. • Higher education and higher incomes are associated with an increased intention to vaccinate. • Vaccine safety is still a concern as 57% don't want to be in the first wave of people getting vaccinated and want to wait until safety has been established. 49% have concerns about safety but have generally pro-vaccine opinions. • >66% agree that the vaccine should be mandatory for all healthcare workers. • 71% of respondents are comfortable with how the Manitoba government is determining priority groups for early vaccination.

Leger (2021) *unpublished* (100) Cross-sectional study Canada Jan 2021	1000 residents of Alberta (18+) were surveyed online regarding their perceptions of the vaccine rollout. Question Topics: 1) Vaccine rollout perceptions Survey tools available? No Formative research conducted? No Survey pre-tested? No	• Approval of the overall vaccine rollout in Alberta was split, 48% were satisfied and 43% were dissatisfied. • For the order of priority groups established by the government, 64% were satisfied and 28% were dissatisfied. • 44% were satisfied with the government's communication of the rollout plan and 48% were not. • More individuals were dissatisfied (56%) with the pace of the rollout compared to satisfied (35%). • 53% believe they will have the opportunity to receive a vaccine after September.
Insights West (2021) *unpublished* (67) Cross-sectional study Canada Jan 2021	Intention to vaccinate was analyzed using an online survey of 824 residents of British Columbia. Question Topics: 1) Vaccine intentions 2) Vaccine rollout perceptions Survey tools available? Yes Formative research conducted? No Survey pre-tested? No	• 58% of respondents were definitely willing to be vaccinated, 22% were probably willing, 5% probably will not get vaccinated, and 7% definitely will not. • 67% of older respondents (55+) were more likely to get vaccinated compared to those in younger age groups (52% among 18-34 year olds). • 69% felt that those with underlying conditions were should have been put ahead of others on the list. • When asked about the vaccine rollout plan, 5% rated the rollout as excellent, 30% good, 51% fair, 14% poor, and 7% very poor. Similar trends were seen for perceptions on clarity of the rollout and prioritization levels.
Afifi (2021) (213) *new* Cross-sectional study Canada Nov-Dec 2020	Using survey respondents from the longitudinal Well-Being and Experiences study (2017-2020) vaccine intentions were recorded for Winnipeg adolescents aged 16-21 and their caregivers/parents using an online survey. Question Topics: 1) Vaccine intentions 2) Vaccine hesitancy	• 65.4% of respondents intend to receive a vaccine, 26.1% were not sure, and 8.5% were not willing. • Parents with trade school, community college or less, with incomes of less than $49,999, experienced quite a bit COVID-19 financial strain, self-reported low knowledge of COVID-19 were associated with lower intentions to get a vaccine. • Having a self-reported health condition was associated with higher intentions to accept a vaccine. • After adjusting for sex, age and household income, children who had no experience with spanking

	Survey tools available? No Formative research conducted? No Survey pre-tested? No	(aRR 0.33, 95% CI: 0.17–0.62), no peer victimization (aRR 0.49, 95% CI: 0.25–0.96), no household substance abuse (aRR 0.41, 95% CI: 0.20–0.83), no contact with foster care/child protective office (aRR 0.34, 95% CI: 0.16–0.72), and no risk of their household running out of money (aRR 0.45 95% CI: 0.21–0.97) were more willing to get vaccinated. • Reporting no to any household challenge adverse childhood experience (ACE) was associated with willingness to vaccinate (aRR 0.45, 95% CI: 0.20–0.99). • The top concerns for being unwilling to accept a vaccine were for vaccine safety (64.5%), not knowing enough about the vaccine (60.6%), and not thinking the vaccine would be effective (23.4%).
Province of Manitoba (2020) *unpublished* (214) Cross-sectional study Canada Nov 2020	An online survey of 9872 adults in Manitoba was conducted to assess COVID-19 vaccine perceptions and intention to vaccinate. Question Topics: 1) Vaccine intentions 2) Vaccine perceptions Survey tools available? Yes Formative research conducted? No Survey pre-tested? No	• 55% and 19% of participants reported they definitely or probably will receive the COVID-19 vaccine when available, respectively. The other participants stated they were undecided (8%), probably would not (7%) or definitely would not (12%) take the vaccine. • 61% of participants agreed with the statement "Vaccines are safe and I have no doubts about vaccinating myself or my family, as recommended by my doctor".
Independent Polling System of Society (IPSOS)/Radio Canada (2020) *unpublished* (215) Cross-sectional study	Intention to vaccinate and perceptions on the vaccine were analyzed using an online survey of 3001 adults (18+). Question Topics: 1) Vaccine intentions 2) Vaccine perceptions	• 64% of participants would probably or certainly get vaccinated, 16% definitely would not, and 21% were unsure. • Of those who would be vaccinated, 36% would get vaccinated as soon as possible, 38% would wait one or two months to see what happens, 15% would wait several months, and 11% were undecided.

Canada Nov 2020	Survey tools available? No Formative research conducted? No Survey pre-tested? No	• The majority of respondents were worried about possible side-effects and risks associated with the vaccine.
Independent Polling System of Society (2020) *unpublished* (93) Cross-sectional study Canada Nov 2020	An online survey of 1001 adults (18+) analyzed intention to vaccinate and perceptions on the vaccine. Question Topics: 1) Vaccine intentions 2) Vaccine perceptions 3) Vaccine hesitancy Survey tools available? No Formative research conducted? No Survey pre-tested? No	• 52% of respondents would take a COVID-19 vaccine as possible without hesitation. However, when other options, 36% would take the vaccine waiting to see if there were adverse side-effects and 28% would after waiting to see if it's effective. • 13% of participants would refuse vaccination under any circumstance. • 71% of participants say that taking a vaccine that was created and approved so quickly makes them nervous and 69% are concerned about long-term effects. • 59% of participants support mandatory COVID-19 vaccination, a drop from 61% in Sept, and 72% in July. • Some participants stated that a recommendation by a family doctor (21%), or seeing friends and family receive the vaccine (10%) would make them willing to take a vaccine. • Most agree that frontline healthcare workers (62%) and first-responders (52%) should be first in line to receive the vaccine. However, outside of these target groups, Canadians are divided on who should be a priority. • Three in ten (30%) believe that we can beat COVID-19 without a vaccine, down from 40% in Oct.
Independent Polling System of Society (2020) *unpublished* (62) Cross-sectional study	An online survey of 1000 adults analyzed intention to vaccinate and perceptions on the vaccine. Of these, 1000 participants were Canadian. Question Topics: 1) Vaccine intentions 2) Vaccine perceptions	• 54% of Canadians would be willing to take a vaccine as soon as it is available. Atlantic Canada have the highest intentions (75%), followed by SK/MB (65%), QC (63%), BC (60%), AB (58%), and ON (57%). • 61% of participants support mandatory COVID-19 vaccination, a drop from 72% in July. • 82% indicate that they would wait for reports about the effectiveness or any side-effects of a COVID-19 vaccine before taking it.

Canada Oct 2020	3) Vaccine hesitancy Survey tools available? No Formative research conducted? No Survey pre-tested? No	• The majority (88%) of participants agree that seniors and other vulnerable communities should be the first priority to receive the vaccine. • Four in ten (40%) believe that we can beat COVID-19 without a vaccine.
Toronto Public Health (2020) *unpublished* (216) Cross-sectional study Canada Oct 2020	Intention to receive a COVID-19 vaccine was evaluated using an online survey of 1201 residents of Toronto, Ontario. Question Topics: 1) Vaccine intentions Survey tools available? No Formative research conducted? No Survey pre-tested? No	• 73% of participants report that when a COVID-19 vaccine is available they will "definitely" or "probably" get it. 20% will "definitely" or "probably" not receive it and 11% are undecided.
Statistic Canada (2020) *unpublished* (78) Cross-sectional study Canada Sept-Oct 2020	A telephone survey of 120,000 (18+) was conducted to assess intention to vaccinate. Question Topics: 1) Vaccine intentions Survey tools available? Yes Formative research conducted? Yes Survey pre-tested? Yes	• Immigrants living in Canada for less than 10 years (80.3%) and more than 10 years (70.7%) had comparable intentions to vaccinate compared to non-immigrants (75.9%). • Women who were non-immigrants or who immigrated less than 10 years ago had lower intentions than men (74.7% vs 77.2% for non immigrants and 78.1% vs 82.9% for less than 10 years). • When comparing all visible minorities against Whites race, vaccine intentions were nearly identical (77.3% vs 77.0%). • Within visible minority groups intention to vaccinate from lowest to highest was Black (57.0%), Latin American (58.5%), Filipino (64.2%), South East Asian (75.8%), other visible minorities (77.6%), Chinese (85.5%), and Arab (88.3%). • 69.3% reporting an Aboriginal identity were accepting of a vaccine compared to 77.6% not reporting an Aboriginal identity.

		• 87.6% of LGBTQ2+ were willing to accept a vaccine compared to 76.4% non-LGBTQ2+. • Higher levels of education and having an underlying medical condition were associated with higher acceptance.
Ogilvie (2021) (79) Cross-sectional study Canada Aug-Sep 2020	Intention to vaccinate was assessed in 4058 adults and healthcare workers from British Columbia (25-69 years old). Question Topics: 1) Vaccine intentions 2) Vaccine perceptions 3) Vaccine hesitancy Survey tools available? Yes Formative research conducted? Yes Survey pre-tested? Yes	• 79.8% of respondents were somewhat or very likely if available to them and was recommended for them. • 81.8% of healthcare workers report that they intend to receive a vaccine. • Non-binary, gender queer, agender, two-spirit or other were more likely to be receive a vaccine (OR 3.04, 95% CI: 1.08-8.55). • Households with two adults (OR 1.2, 95% CI: 1.00-1.43) were more likely to vaccinate but there were no significant changes in intention with number of children. • Multivariate analysis demonstrated that younger respondents (30-40 years old aOR 0.64, 95% CI: 0.49-0.83, 40-50 years old aOR 0.78, 95% CI: 0.62-0.97, 50-60 years old aOR 0.67, 95% CI: 0.55-0.82), females (aOR 0.7, 95% CI: 0.55-0.89), lower education level (aOR 0.62, 95% CI: 0.51-0.77), South Asian (aOR 0.65, 95% CI: 0.39-1.07), non-White (aOR 0.76, 95% CI: 0.61-0.95), identified as Indigenous (aOR 0.58, 95% CI 0.38-0.87), other essential non-health care workers (aOR 0.72, 95% CI: 0.6-0.87), and those who suspected they had COVID-19 (aOR 0.76, 95% CI: 0.61-0.96) had significantly lower odds of intending to receive a vaccine. • Lack of confidence in vaccines (aOR 0.66, 95% CI: 0.57-0.75) and belief in vaccine risks (aOR 0.72, 95% CI: 0.66-0.80) were associated with decreased intention to vaccinate. • Intention to vaccinate was positively associated with higher attitudinal scores towards the vaccine (aOR 1.06, 95% CI: 1.04-1.08), influenced by direct social norms (aOR 1.06, 95% CI: 1.03-1.08), indirect social family doctor/primary care physician

		opinions (aOR 1.04, 95% CI: 1.00-1.08), indirect norms from the provincial health officer (aOR 1.04, 95% CI: 1.01-1.08), and indirect family norms (aOR 1.09, 95% CI: 1.06-1.13).
Lang (2021) (87) Cross-sectional study Canada Aug 2020	An online survey of 60 adults (18+) in Alberta was conducted to assess their intention to vaccinate. Question Topics: 1) Vaccine intentions Survey tools available? Yes Formative research conducted? No Survey pre-tested? No	• 68% of respondents would accept a vaccine if it were available, 20% would not, and 12% were unsure. • White respondents were less likely to accept a vaccine (63%) compared to other ethnicities (100%). • Those with higher education (college or university) were less likely to accept a vaccine (63%) compared to those who had attended post-secondary technical school (100%) or had a high school diploma (70%). • Intention to vaccinate was positively associated with concerns about getting COVID-19 (P <0.001) and spreading the virus (P = 0.006), and complying with public health measures such as staying home when sick (P = 0.033), masking in public (P < 0.001) and physical distancing (P = 0.005). • Respondents who received their COVID-19 health information from the Chief Medical Officer of Health media briefings (P = 0.030) and Alberta Health or Alberta Health Services websites (P = 0.040) were significantly more likely to accept a COVID-19 vaccine. • Intention to vaccinate was lower in other urban centers (29%) and rural Alberta (50%) compared to Calgary (75%) and Edmonton (80%), (*P* = 0.030).
Carleton University (2020) *unpublished* (217) Cross-sectional study	An online opinion survey regarding vaccine intentions and perceptions was conducted online in 2000 individuals. Question Topics: 1) Vaccine intentions 2) Vaccine hesitancy	• 62% will definitely get the vaccine, 24% will probably get the vaccine, 5% will not likely get the vaccine, and 9% will definitely not get the vaccine. • Resistance to a vaccine is highest in MB and SK where only 37% will definitely get vaccinated across both provinces.

Canada Jul 2020	3) Vaccine perceptions Survey tools available? No Formative research conducted? No Survey pre-tested? No	• In terms of views on mandatory vaccination, 36% strongly agree, 26% somewhat agree, 14% strongly disagree, and 7% somewhat disagree. • The most common reason (40%) for hesitancy was potential for harmful side-effects. • The 9% of respondents who expressed strong anti-vaccine views, suspicion about the influence of the pharmaceutical industry over public health care (41%) and concern about vaccine safety and the potential for harmful side-effects (29%) were the most common reasons for refusal.
Frank (2020) *unpublished* (63) Cross-sectional study Canada Jun 2020	Factors associated with willingness to vaccinate was investigated using an online survey of ~4000 adults. Question Topics: 1) Vaccine intentions 2) Vaccine hesitancy Survey tools available? No Formative research conducted? Yes Survey pre-tested? No	• 57.5% and 19% of respondents indicated they are very likely or somewhat likely to get a COVID-19 vaccine when it becomes available, respectively. • Older Canadians (65+) reported they were more likely to vaccinate (70.3%) compared to those aged 15-64 (52-58%). • Those that were born in Canada were more likely to vaccinate compared to immigrants (59.4% vs 52.0%). • Residents in the Atlantic Provinces are more likely to vaccinate (67.7%) followed by Ontario (58.8%), Prairies region (56.2%), BC (55.5%), and QC (54.3%). • Other factors associated with a higher intention to vaccinate include higher education and not having children under the age of 18. • The top two reasons for not intending to vaccinate were a lack of confidence in the safety of the vaccine (54.2%) and concerns about its risks and side-effects (51.7%).
Hetherington (2021) (218) Cross-sectional study Canada	Participants from the longitudinal cohort study All Our Families (n=1321) in Alberta were invited to participate in an online COVID-19 impact survey to understand factors associated with COVID-19 vaccine intentions among parents of 9-12 year old children.	• 60.4% of parents intended to vaccinate their children, 8.6% said they did not intend to vaccinate, and 31% were unsure. • Participants with less education were more likely to not want to vaccinate (OR 2.80, 95% CI: 1.78-4.40) or be unsure (OR 1.98, 95% CI: 1.47-2.71). A similar pattern was seen for income.

May-Jun 2020	Question Topics: 1) Vaccine intentions 2) Vaccine hesitancy Survey tools available? No Formative research conducted? No Survey pre-tested? No	• History of partial or non-vaccination was associated with intent to not vaccinate (OR 2.81, 95% CI: 1.78-4.40). There was no association between vaccination history and uncertainty regarding a COVID-19 vaccine (OR 1.29, 95% CI: 0.92-1.80). • Concerns over vaccine safety and efficacy, long-term effects, and a rushed vaccination process were reported.
Frank (2020) *unpublished* (219) Cross-sectional study Canada May-Jun 2020	An online survey of ~36,000 adults was conducted to investigate factors associated with willingness to vaccinate. Question Topics: 1) Vaccine intentions Survey tools available? No Formative research conducted? Yes Survey pre-tested? No	• 68.2% and 15.2% of participants reported that they were very likely or somewhat likely to accept a COVID-19 vaccine, respectively. 12% were unlikely or very unlikely to vaccinate. • Those who had a high level of trust in the federal government were more likely to be willing to vaccinate compared to those with a low level of trust (77.3% vs 53.8%). • Similar trends were also seen with trust in others, and trust in federal public health authorities.
Lackner (2021) (189) Cross-sectional study Canada May-Jun 2020	The demographic, experiential, and psychological factors associated with the anticipated likelihood and speed of having children receive a COVID-19 vaccine was investigated in 455 families (857 children). Question Topics: 1) Vaccine intentions Survey tools available? No Formative research conducted? Yes Survey pre-tested? No	• Factors associated with a higher likelihood of having their children vaccinated include older parental age, living in the Prairies (relative to Central Canada), more complete child and parental vaccination history, positive attitudes towards vaccines in general, higher psychological avoidance of the pandemic, and a greater tendency to prioritize the risks of the disease relative to the risks of side-effects. • In some models, perceived COVID-19 risk and higher levels of state anxiety were associated with increased likelihood of having children vaccinated. • The above factors were also predictors of faster speed of intended vaccination. However, higher SES was a trend-level predictor.
Taylor (2021) (220)	An online survey of 2078 adults (18+) was used to explore the potential relationship between	• The network of anti-masks attitudes is linked to other variables such as disregard for social distancing and anti-vaccination attitudes.

Cross-sectional study Canada & USA Jun-Jul 2020	attitudes on wearing a face mask and COVID-19 vaccination. The sample consisted of 1036 participants from the USA and 1042 from Canada. Question Topics: 1) Vaccine attitudes Survey tools available? No Formative research conducted? Yes Survey pre-tested? No	
Waite (2021) (92) Cross-sectional study Canada May 2020	An online survey of 1001 Canadians aged 50–64 years and 3,500 aged 65+ was conducted to evaluate intention to vaccinate against COVID-19. Question Topics: 1) Vaccine intentions 2) Vaccine attitudes Survey tools available? No Formative research conducted? Yes Survey pre-tested? No	• Among those aged 50-64 years, 69.1% intend to vaccinate when available, 11.3% would not vaccinate, and 19.6% were unsure. • 79.5% of those 65+ intend to receive a vaccine when available, 5.6% would not vaccinate, and 14.9% were unsure. • In both age groups, those who would accept a vaccine were significantly more likely to be male and more likely to have at least one chronic condition (P< 0.05). • The preferred location to receive a vaccine in both groups was family physician office, followed by pharmacy, workplace (for those 50–64 years), and public health clinics.
Taylor (2020) (89) Cross-sectional study Canada & USA May 2020	Intentions to vaccinate and attitudes towards vaccines were measured using an online survey of 3674 adults (Canada = 1902, USA = 1772). Question Topics: 1) Vaccine intentions 2) Vaccine hesitancy 3) Vaccine attitudes	• Significantly more Americans (25%) than Canadians (20%) responded that they would not get vaccinated if a vaccine was available, χ^2 (df = 1) = 12.41, p < 0.001. • Negative attitudes toward a COVID-19 vaccination, and vaccinations in general, were significantly correlated (p < 0.001) with the intention not to vaccinate. Mistrust of the benefit of a COVID-19 vaccine was the largest factor with respect to attitude on the decision not to get the vaccine. • Vaccination refusal was significantly associated with female gender, age, completed full or partial

	Survey tools available? No Formative research conducted? Yes Survey pre-tested? No	college education (vs. did not complete), being unemployed, and minority status (vs. Caucasian). • Of those who indicated they would not get vaccinated (n=812), 38% would vaccinate if they were convinced the vaccine had been rigorously tested and 36% would vaccinate if they saw that enough people were vaccinated without any serious side-effects. • Compared to White ethnicity, minority status (Asian, African American/Black, Latino/Hispanic, or other) was significantly associated with vaccine refusal ($r = -0.04$, $P < 0.05$).
Carleton University (2020) *unpublished* (59) Cross-sectional study Canada May 2020	An online opinion survey regarding vaccine intentions and perceptions was conducted online in 2000 individuals. Question Topics: 1) Vaccine intentions 2) Vaccine perceptions Survey tools available? No Formative research conducted? No Survey pre-tested? No	• 49% and 24% of the participants would "definitely" or "probably" get the vaccine when available, respectively. • 17% expressed uncertainty and 10% were unwilling. • 65% believe that the vaccine should be mandatory. • Age and political affiliation were significantly associated with intention to vaccinate. Older individuals were more willing to vaccinate than younger. Those who voted Liberal or NDP in the 2019 election were more likely to vaccinate compared to those who voted for other parties. • Respondents living in Atlantic Canada showed the strongest levels of intention to vaccinate compared to those in other provinces. • Those who believed one of the four health myths or conspiracy theories regarding COVID-19, were less likely to intend to vaccinate than those who did not believe the scientifically inaccurate claims about COVID-19.
Parsons Leigh (2020) (64) Cross-sectional study	COVID-19 perceptions, knowledge, attitudes, and behaviors were analyzed using an online survey of 1996 participants (18+). Question Topics:	• 75.8% (n = 1,436) of respondents reported that they would get vaccinated when a vaccine became available. • Participants responded they "strongly agree" or "agree" that they will get vaccinated in BC (72.1%),

Canada Apr-May 2020	1) Vaccine intentions 2) Vaccine knowledge Survey tools available? Yes Formative research conducted? Yes Survey pre-tested? Yes	AB (69.9%), MB/SK (69.9%), ON (66.1%), Atlantic (63.1%), and QC (41.9%). • Participants responded they "strongly agree" or "agree" that they will not get vaccinated in AB (12.4%), QC (12.1%), ON (8.1%), Atlantic (6.6%), MB/SK (6%), and BC (4.8%). • Information about vaccines and treatments were most frequently (n = 933, 48.9%, 95% CI: 46.7-51.2%) cited as topics of misinformation, however only half (n = 937, 47.4%, 95% CI: 45.2%-49.6%) of respondents felt moderately or extremely confident that they could identify incorrect or misleading information about COVID-19.
Underschultz (2021) (221) Cross-sectional study Canada Apr 2020	COVID-19 knowledge, attitudes, and practices were analyzed using an online survey of 1593 participants (16+). The survey was primarily targeted to residents of Alberta and Ontario. Question Topics: 1) Vaccine perceptions Survey tools available? No Formative research conducted? Yes Survey pre-tested? No	• 93% of respondents believe that a vaccine is needed in Canada and 81% endorsed a wide-spread vaccination strategy (having everyone vaccinated). • Vaccine acceptance was significantly associated with higher knowledge scores ($p<0.001$), being worried about COVID-19 (OR 20.4; 95% CI: 8.4-49.5, $p<0.001$), optimism in controlling the pandemic (OR 8.1; 95% CI: 3.4-19.7, $p<0.001$), and feeling informed about COVID-19 (OR 3.9; 95% CI: 1.7-9.3, $p=0.0049$).
Research Co (2020) *unpublished* (58) Cross-sectional study Canada Apr 2020	Intention to vaccinate was assessed using an online survey. Question Topics: 1) Vaccine intentions Survey tools available? No Formative research conducted? No Survey pre-tested? No	• If a vaccine becomes available, 42% and 31% would "definitely" or "probably" get the vaccine, respectively. • Men were more likely to vaccinate than women (78% vs 68%). • The Atlantic (79%) and Alberta (78%) had the highest intentions to vaccinate and Saskatchewan/Manitoba (65%) had the lowest. • Intention to vaccinate was highest in those who voted liberal (79%) in the 2019 election, followed by NDP (76%), and conservative (69%).

Qualitative studies (n=1)		
Benham (2021) (222) Qualitative study Canada Aug-Sep 2020	Nine focus groups were conducted with 50 adults (18+) from Alberta to evaluate attitudes towards public health measures including vaccination. Question Topics: 1) Vaccine intentions 2) Vaccine perceptions	• Intention to vaccinate responses were mixed. Some stated they would vaccinate right away, while others would not vaccinate as they believed COVID-19 would not impact their health or the health of their family members. • Some participants reported that they would be willing to take a vaccine but not right away. This was more prominent in the older age groups. • Participants who regularly received the annual flu vaccine were more likely to state they would take a COVID-19 vaccine when available. However, a few experienced side effects with the annual flu shot (e.g., getting sick) which would make them less likely to get a COVID-19 vaccine. • Barriers for vaccine uptake included a lack confidence that a vaccine will work, and that it may do harm.
Quasi-experimental studies (n=1)		
Poder (2021) *unpublished* (223) Quasi-experimental study Canada Oct-Nov 2020	An online survey of vaccine intentions of 1,695 Quebec adults was conducted which included an assessment of preferences through a series 12 binary choice scenarios (20,350 choice responses in total). Question Topics: 1) Vaccine intentions Survey tools available? Yes Formative research conducted? Yes Survey pre-tested? No	• At least 7.2% always chose not to be vaccinated in any given scenario. • Depending on the scenario, 69-93% of participants would opt for the vaccine when available. • 24% of participants would make the choice to refuse the vaccine if certain conditions were not met which were determined to be in order of priority: 1) vaccine efficacy 2) possible side effects of the vaccine 3) duration of effectiveness (minimum of 9 months for acceptability) 4) the organization recommending the vaccine (Public health organizations of Québec, WHO) 5) geographic origin of vaccine (European Union or United States)

		6) waiting period to be vaccinated once the vaccine is available in Quebec (4 months maximum) 7) high priority populations (no preferences)
Expert Stakeholders		
Cross-sectional studies (n=2)		
MacDonald (2020) *preprint* (101) Cross-sectional study Canada Aug-Oct 2020	Eighteen teleconference interviews with 25 public health leaders from 10 of 13 provinces and territories were conducted to evaluate perspectives on priority groups for early vaccination. Participants were asked to rank, in order of importance, their top five priority groups for vaccination. Question Topics: 1) Vaccine strategy perceptions Survey tools available? No Formative research conducted? No Survey pre-tested? No	• All ten province and territories ranked long-term residents and health-care workers in their top five priority groups to receive vaccination. • Those with chronic medical conditions and seniors were also ranked in the top five priority groups by nine and eight provinces and territories, respectively. • To a lesser extent, those with Indigenous ancestry (n=4), with socioeconomic disadvantage (n=3), with infants or children (n=2), living in remote communities (n=2), and new immigrants and refugees (n=1) were ranked in the top five priority groups.
Zhao (2020) *preprint* (102) Cross-sectional study Canada Jul-Aug 2020	Among 74 expert stakeholders, an online survey was conducted to establish perspective on the relative importance of pandemic immunization strategies for different COVID-19 pandemic scenarios at the time of initial COVID-19 vaccine availability. Questions asked the respondent to rank, in order of importance, four pre-defined COVID-19 pandemic immunization strategies.	• For all pandemic scenarios, stakeholders generally ranked the strategies in the following order from most to least important: ○ Protect those who are most vulnerable to severe illness and death from COVID-19 ○ Protect healthcare capacity ○ Minimize transmission of COVID-19 • Protect critical infrastructure

	Question Topics: 1) Vaccine strategy perceptions Survey tools available? No Formative research conducted? No Survey pre-tested? No	

aOR = adjusted odds ratio, CI = confidence interval, HCWs = healthcare workers, NR = not reported, RR = risk ratio

NORTH AMERICA		
CANADA		
Lunsky (2021) (105) Cross-sectional study Canada Jan-Feb 2021	To evaluate vaccination intent and predictors of intent, an online survey of 3371 social service employees supporting individuals with intellectual disabilities in Ontario was conducted. Question Topics: 1) Vaccine intentions 2) Vaccine hesitancy Survey tools available? No Formative research conducted? Yes Survey pre-tested? No	• 62% and 20% reported that they were very likely, or somewhat likely to accept a vaccine, and 7% and 11% somewhat unlikely or very unlikely to get the vaccine, respectively. • Compared to individuals aged 50 +, younger individuals aged 18-29 (aOR 2.74, 95% CI: 1.70–4.43) and 30-39 (aOR 1.75, 95% CI: 1.16–2.64) were more likely to refuse a vaccine when available. • Women were more likely to refuse a vaccine compared to men (aOR 1.58, 95% CI: 0.97-2.59). • Compared to European respondents, Asian (aOR 0.88, 95% CI: 0.33-2.36), African and Caribbean (aOR 0.81, 95% CI: 0.35-1.86), and unknown ethnicities (aOR 0.88, 95% CI: 0.36-2.17) were less likely to refuse a vaccine and Indigenous, First Nations, and Metis (aOR 1.73, 95% CI: 0.67- 4.43), Latin (aOR 1.22, 95% CI: 0.21-7.24), and mixed ethnicities (aOR 1.11, 95% CI: 0.27-4.55) were more likely to refuse. • Reasons to refuse a vaccine included lack of trust in the vaccine (OR 5.72, 95% CI: 3.84–8.53), fear of vaccine side effects (OR 2.30, 95% CI: 1.56–3.39),

		and belief that there was no need for the vaccine due to good health (OR 4.22, 95% CI: 2.66–6.68). • Individuals who would refuse a vaccine were less likely to believe that vaccination would protect clients (OR 0.36, 95% CI: 0.24-0.54) or family (OR 0.19, 95% CI: 0.13-0.28),be concerned about clients (OR 0.57, 95% CI: 0.34-0.97) or themselves (OR 0.51, 95% CI: 0.34-0.76) becoming ill with COVID-19, get the flu shot in a normal year (OR 0.61, 95% CI: 0.43-0.88), and get the vaccine if their co-workers did (OR 0.16, 95% CI: 0.08-0.29).
Desveaux 2021 *preprint* (103) Cross-sectional study Canada Jan 2021	Factors associated with intention to vaccinate was evaluated in 8634 non-physician HCWs (18+) in Ontario using an online survey. Question Topics: 1) Vaccine intentions 2) Vaccine hesitancy Survey tools available? No Formative research conducted? No Survey pre-tested? No	• 80.4% of participants reported that they intend to get a COVID-19 vaccine. • Compared to their counterparts, those who were younger (<40 years old) and who had less education (less than a high school diploma) were more likely to be unwilling to intend to vaccinate (P<0.001). • HCWs who identified as Filipino (OR 1.07, 95% CI: 0.41-2.76, P<0.001), Caribbean (OR 3.20, 95% CI: 1.52-6.75, P<0.001), or Other (OR 1.44, 95% CI: 0.93-2.22, P<0.001) ethnicity were more likely to be unwilling to vaccinate compared those who identified as European. • Vaccine hesitancy was strongly associated with mistrust about how fast the vaccines were developed and vaccine safety concerns. It was also associated with various beliefs such as not requiring a vaccine due to one's own good health, low confidence that the vaccine would protect their family and patients, and that getting vaccinated was not a professional responsibility. • HCWs were more likely to intend to vaccinate if direct financial supports such as paid sick days were provided (74% vs 25%, P<0.001).
SafeCare BC (2021) *unpublished* (104)	An online survey of 1,500 continuing care workers in British Columbia was conducted to	• 57% of respondents intend to get a vaccination, 28% were not sure, and 15% did not intend to get vaccinated.

Cross-sectional study Canada Dec 2020	evaluate attitudes on COVID-19 vaccination. Question Topics: 1) Vaccine intentions 2) Vaccine hesitancy Survey tools available? No Formative research conducted? No Survey pre-tested? No	• Male (72% vs 56%), higher age (65+) and flu shot acceptance were predictors of intention to vaccinate. • Managers and senior leaders had the highest intentions to vaccinate (71%). Healthcare assistants were the most unsure (30%), and nurses were most likely to say no to a vaccine (20%). • Reason for hesitancy were side effects (84.6%), the newness of the vaccine (64.6%), mistrust of authorities (23.5%), belief that the vaccine will not work (16%), preferred natural remedies (10.5%), and personal or religious beliefs (8%). • Intention to vaccinate was highest in East (61%) and South Asian (70%). Latino and Black respondents were the most likely to refuse a vaccine (30%) and Indigenous respondents were most likely to be unsure about their decision to vaccinate (40%). • East/South Asian respondents were more concerned about side effects (93%) whereas White or Indigenous respondents were more concerned about newness (72% and 62%, respectively). • 33% said more support for vaccinations is needed e.g. more information to understand the development process, efficacy, and transparency of reporting adverse events. • The biggest perceived barrier to administering the vaccine was storage and handling constraints (66%). • Indigenous respondents had the least amount of trust in all sources of information including healthcare providers.
INSPQ (2020) & INSPQ (2021) *unpublished* (88, 95) Longitudinal study	Analysis of the acceptability of vaccination against COVID-19 was evaluated using an online survey of adults and healthcare workers in Quebec. Number of participants was not clearly stated (~3300 each collection period). There were multiple collection periods, one in	• In May, 73% of HCWs responded with the intention to vaccinate. In Dec this decreased to 65% and increased to 71% in Dec. • Intention to vaccinate did not differ between the general public and healthcare workers and factors associated with intention to vaccinate were not differentiated between the two groups.

Canada Apr-Dec 2020	Apr-May and one in Sep and Dec. Article in French. Question Topics: 1) Vaccine intentions 2) Vaccine hesitancy Survey tools available? No Formative research conducted? No Survey pre-tested? No	• Those that were older (70+) were more likely to vaccinate compared to those 25-44 years old (83% vs 57%). • Men, those with a university education, and those with one or more chronic diseases are more likely to intend to vaccinate. • The most common reasons to not intend to vaccinate include fears related to taking a new vaccine, and concern regarding the effectiveness and side-effects.
Verger (2021) (127) Cross-sectional study Belgium, France & Canada Oct-Nov 2020	Intention to vaccinate and intention to recommend vaccination to patients was evaluated using an online and telephone survey in general practitioners (GPs) in France (n=1209) and French-speaking parts of Belgium (n=414) , and nurses in Quebec, Canada (n=1055). Belgium and France results can be found in the Europe section. Question Topics: 1) Vaccine intentions 2) Vaccine hesitancy Survey tools available? Yes Formative research conducted? No Survey pre-tested? Yes	• In Canada, 79.6% of nurses would definitely or probably recommend their patients vaccinate, 3.1% would not, and 17.2% were unsure. For themselves, 70.4% would definitely or probably be willing to receive the vaccine, 11.8% would refuse, and 17.8% were unsure. • 40.9% of participants reported that the safety of vaccines developed in an emergency during an epidemic cannot be guaranteed. • Opinion about the safety of vaccines developed in an emergency and distrust in the ministry of health to ensure vaccine safety were the two most important factors independently associated with vaccine hesitancy and reluctance. • Intention to vaccinate was positively associated with a history of personal vaccination against the flu.
Ogilvie (2021) (79) Cross-sectional study Canada	Intention to vaccinate was assessed in 4058 adults and healthcare workers from British Columbia (25-69 years old). Unclear how many healthcare workers in the survey. Question Topics:	• 81.8% of healthcare workers report that they intend to receive a vaccine. • Other results found in general population. • Multivariate analysis demonstrated that South Asian (aOR 0.65, 95% CI: 0.39-1.07), non-White (aOR 0.76, 95% CI: 0.61-0.95), and those who identified as Indigenous (aOR 0.58, 95% CI 0.38-

Aug-Sep 2020	1) Vaccine intentions 2) Vaccine perceptions 3) Vaccine hesitancy Survey tools available? Yes Formative research conducted? Yes Survey pre-tested? Yes	0.87) had significantly lower odds of intending to receive a vaccine.
The Canadian PSW Network (2020) *unpublished* (131) Cross-sectional study Canada NR 2020	Intention to vaccinate in 562 personal support workers (PSWs), nurses, and healthcare workers using an online survey. 84% of the sample were PSWs. Question Topics: 1) Vaccine intentions 2) Vaccine perceptions Survey tools available? No Formative research conducted? No Survey pre-tested? No	• 64.2% of respondents intend to vaccinate when it is available, 16.2% refuse to vaccinate, 10.7% are unsure, and 8.9% will only take the vaccine if it's mandatory. • 71.7% do not believe there is enough clear education on the vaccine.
UNITED STATES & UNITED KINGDOM		
Abohelwa (2021) (224) *new* Cross-sectional study USA Mar 2021	Uptake and intention towards vaccination were gathered online from 81 residents and fellows from Lubbock campus of Texas Tech University Health Sciences Center. Question Topics: 1) Vaccine intentions 2) Vaccine attitudes Survey tools available? No Formative research conducted? No Survey pre-tested? No	• 95.1% had already received the vaccine and 96.3% reported that they supported vaccination. • 3.7% did not want the vaccine. Reasons were not explored.

King (2021) *preprint* (181) Longitudinal study USA Jan-Mar 2021	As part of a monthly ongoing national COVID-19 survey, questions to measure vaccine acceptance and related factors of acceptance were collected in samples of adults (age 18-64). The number of HCWs was not reported. Jan survey: n= 791,716 Feb survey: n= 710,529 Mar survey: n= 732,308 Question Topics: 1) Vaccine hesitancy Survey tools available? Yes Formative research conducted? No Survey pre-tested? No	• Vaccine hesitancy overall decreased from 27.5% in January to 22.1% in March. • 78.3% of healthcare workers were vaccinated with 14.1% who responded in a way that indicated that they were vaccine hesitant. • The level of hesitancy varied by healthcare profession (lowest to highest): 8.5% in pharmacists, 11.7% nurses/nurse practitioners, 12.2% in physicians, 14.1% in practitioners/technicians, 15.1% in support, 19.0% in practical/vocational nurses, and home health aids/medical assistants/paramedics/nursing assistants/psychiatric aides 20.5% to 23.1%).
Pacella-LaBarbara (2021) (117) *new* Cross-sectional study USA Jan-Feb 2021	An online survey of 475 emergency department and emergency medical service workers from Ohio, Maryland, West Virginia, and New York was conducted to determine vaccine intentions and factors associated with intention. Question Topics: 1) Vaccine intentions 2) Vaccine hesitancy Survey tools available? No Formative research conducted? No Survey pre-tested? No	• 79% of HCWs had received or had plans to receive the COVID-19 vaccine and 21% had no plans to receive it. • Intention to vaccinate was lower among females (OR 0.34, 95% CI: 0.34-0.91, P =0.02) and those with a history of COVID-19 infection (OR 0.55, 95% CI: 0.31-0.98, P=0.04), and higher among those with higher education (OR 3.53, 95% CI: 1.16, 10.77, P = 0.03) and high perceived COVID-19 vulnerability (OR 1.99, 95% CI: 1.37, 2.90). • All physicians were either vaccinated or intended to vaccinate (100%) compared to 27% of nurses, 21% of EMS, and 27% of other clinicians and staff.
Woolf (2021) *preprint* (114)	To assess COVID-19 vaccine hesitancy and its predictors, an online survey was conducted with 11,584 HCWs (16+). Qualitative	• 23.3% of HCWs were vaccine hesitant. • Older HCWs (aOR 0.74, 95% CI: 0.70-0.78 for each decade increase) and those with prior receipt of

Cross-sectional study and qualitative study UK Dec 2020-Mar 2021	data was collected through interviews (n=24), focus groups (n=17), and open-ended survey responses (n=58). Question Topics: 1) Vaccine hesitancy Survey tools available? Yes Formative research conducted? Yes Survey pre-tested? No	the flu vaccine (aOR 0.51, 95% CI: 0.46-0.57) were less hesitant. • Compared to White British HCWs, those from Black Caribbean (aOR 3.37, 95% CI: 2.11-5.37), Black African (aOR 2.05, 95% CI: 1.49-2.82), and White Other (aOR 1.48, 95% CI: 1.19-1.84) ethnic groups were more likely to be hesitant. • Female HCWs (aOR 1.42, 95% CI: 1.24-1.62), pregnant HCWs (aOR 7.12, 95% CI: 4.74-10.70), and those who had tested positive for SARS-CoV-2 (aOR 1.30, 95% CI: 1.14-1.47) were more likely to be hesitant. • HCWs with higher scores on a COVID-19 conspiracy beliefs scale were more likely to be hesitant (aOR 1.12, 95% CI: 1.08-1.16 for each 1 point increase on the scale). • During interviews and focus groups HCWs suggested inclusive health communication (e.g., in multiple languages) and involving HCWs with diverse backgrounds from minority communities in the vaccine rollout to improve vaccine uptake in ethnic minority communities.
Manby (2021) *preprint* (128) Qualitative study UK Dec 2020-Mar 2021	Telephone interviews were conducted with 24 healthcare workers to assess factors influencing their attitudes towards the UK's COVID-19 vaccine program. Question Topics: 1) Vaccine attitudes	• Lack of available evidence was a key driver of vaccine hesitancy. • Belief that government decisions on vaccine rollout were not supported by evidence-based science and mixed and changing government messaging negatively impacted HCWs level of trust and confidence in the vaccine program. • Although the majority reported there was sufficient evidence to show the short-term safety of COVID-19 vaccines, there were concerns raised about the impact of mutant strains on vaccine effectiveness and long-term unknown side effects, such as the impact on fertility. • Online misinformation negatively affected vaccine attitudes, especially among more junior level and Black, Asian and Minority Ethnic (BAME) HCWs,

		with reports of online conspiracy theories targeted specifically to BAME groups. • Most felt motivated to promote vaccination to their patients and many felt it was their moral obligation.
Moniz (2021) *preprint* (116) Cross-sectional study USA Feb 2021	Factors associated with intention to receive a COVID-19 vaccine was assessed in 11,387 adults (18+) at an academic healthcare centre in the Midwest USA using an online survey. Question Topics: 1) Vaccine intentions 2) Vaccine hesitancy Survey tools available? Yes Formative research conducted? Yes Survey pre-tested? Yes	• 79.8% had received the vaccine, 4.8% planned to receive it as soon as possible, 8.4% were not intending to receive it soon but might in the future, and 3.2% had no intentions of ever receiving the vaccine. • Physicians (aOR 22.2, 95% CI: 9.1- 54.3), trainees (aOR 5.9, 95% CI: 3.0-11.4), and nurse practitioners/nurse midwives/physician assistants (aOR 1.9, 95% CI: 1.2-3.0) were significantly more likely to accept a vaccine compared to nurses and other clinical staff (aOR 0.8, 0.6-0.9) and all other employees (aOR 0.8, 0.6-1.0) were less likely. • Those with prior COVID-19 infection were less likely to accept a vaccine (aOR 0.4, 95% CI: 0.3-0.4). • Male HCWs were almost twice as likely to accept vaccines compared to female HCWs (aOR 1.9, 95% CI: 1.6-2.4). • Compared to non-Hispanic White respondents, non-Hispanic Asian respondents were more likely to accept a vaccine (aOR 2.3, 95% CI: 1.5-3.4) and non-Hispanic Black/Mixed/Other respondents were less likely (aOR 0.4, 95% CI: 0.4-0.5). • Mistrust of the vaccine due to how quickly it was developed and safety concerns were the two most common reasons for vaccine hesitancy.
McCabe (2021) *preprint* (166) Cross-sectional study USA	A national app distributed survey was conducted in 34,470 healthcare workers and adults from the general population to measure intent to receive a vaccine and factors associated with acceptance and refusal. Number of healthcare workers was not reported.	• 19% of healthcare workers are undecided, unlikely, or very unlikely to receive a vaccine. • Essential healthcare workers were 1.18 times more likely than non essential workers to be vaccine hesitant (aOR=1.18 95% CI: 1.06-1.32).

Dec 2020-Feb 2021	Question Topics: 1) Vaccine intentions 2) Vaccine hesitancy Survey tools available? Yes Formative research conducted? No Survey pre-tested? Yes	
Nguyen (2021) *preprint* (118) Cross-sectional study USA & UK Jan 2021	To assess intention to vaccinate and reasons for hesitancy, an online survey was conducted in 73,650 and 1,154,988 general population adults and HCWs in the USA and UK, respectively. The number of general population versus HCWs was unclear. Question Topics: 1) Vaccine intentions Survey tools available? Yes Formative research conducted? No Survey pre-tested? No	• In the USA, frontline HCWs were less likely to intend to vaccinate (6% unwilling and 11% unsure) compared to the general population (2% unwilling and 7% unsure). • Compared to the USA, HCWs the UK reported greater vaccine willingness. • Compared to White ethnicity, Black (aOR 3.00, 95% CI: 2.86-3.16), Hispanic (aOR 1.59, 95% CI: 1.51-1.67), Asian (aOR 1.83, 95% CI: 1.70-1.97), and those reporting more than one race (aOR 1.43, 95% CI: 1.36-1.52) were more likely to be vaccine hesitant in the age-adjusted analysis. • Across all race and ethnicities, the most frequently stated reasons for vaccine hesitancy included concern about long-term side effects (50-57%) and adverse reactions (45-54%). Black and Hispanic individuals cited a lack of knowledge about the vaccine (45-51%) at a higher rate than White individuals (37-42%).
Kociolek (2021) (106) Cross-sectional study USA Jan 2021	An online survey was used to assess the frequency of vaccine hesitancy, reasons for hesitancy, and characteristics of those who reported hesitance in 4448 HCWs at a children's hospital in Chicago, IL. Question Topics: 1) Vaccine intentions	• Of 4277 participants, 59.8% reported they intended to vaccinate, 8.6% had already received the vaccine, 8.8% would not vaccinate, and 10.1% were unsure. • Compared to their counterparts, the proportion of those who were vaccine hesitant were female, had confirmed or suspected COVID-19 history, had high-risk medical conditions, and were not concerned about the severity of COVID-19.

	2) Vaccine hesitancy Survey tools available? No Formative research conducted? No Survey pre-tested? No	• Black participants were more likely to be vaccine hesitant compared to non-Black (50.4% vs 15.6%) and Hispanic/Latinx more hesitant than non-Hispanic/Latinx (29.9% vs 17.1%). • Those who were in non-clinical roles were more hesitant than those in clinical roles (28.7% vs 11.9%) and hourly employees were more hesitant than salaried employees (27.6% vs 11.4%). • The most common reasons cited for vaccine hesitancy were long-term side effects (76.3%), safety (50.7%), and the mRNA method is too new (47.8%). • Among those reporting vaccine hesitancy, the most important resources for COVID-19 vaccine information were self-guided research (46.5%), primary care providers (33%), and federal and government agencies (28.8%). The most preferred communication method for vaccine information from hospital leaders was websites for self-learning (46.9%), email updates (36.7%), and Video updates from hospital leaders and vaccine experts (34.7%).
Ciardi (2021) (125) *new* Cross-sectional study USA Dec 2020-Jan 2021	428 healthcare workers were surveyed online regarding intentions, knowledge, and attitudes towards the COVID-19 vaccine. Question Topics: 1) Vaccine intentions 2) Vaccine attitudes Survey tools available? Yes Formative research conducted? No Survey pre-tested? No	• 64% planned on getting vaccinated within 30 days with 73% planning on getting a vaccine in the next 6 months. • Respondents who were over 65 (95%), who are Asian (79%), male (79%), and those living in Manhattan (81%) were significantly more likely to accept a vaccine within 30 days. • Those that were least willing to vaccinate in the next 30 days included those aged 36–45 (57%), African Americans (40%), women (60%), and those living in the Bronx (51%). • Intention to vaccinate was highly correlated to trust in PPE and public health measures ($r = 0.222$), public heath actions (r=0.208), confidence in PPE at work (r=0.0988), and those that expect that PPE and practices will need to be continued even after vaccination (r=-0.158).

		• Higher COVID-19 infection knowledge scores and following the news closely were correlated to a positive intent to receive a vaccine (r = 0.18 and r = 0.183, respectively). • Personal experience with COVID-19 was associated with higher intent to vaccinate. • Positive general vaccine attitudes and personal risk were positively and significantly associated with COVID-19 vaccine attitudes and concern about speed of testing was negatively associated.
Enwezor (2021) *preprint* (115) Cross-sectional study USA Dec 2020 – Jan 2021	Intention to vaccinate was assessed in 20,232 adults (15,062 non-HCWs and 5,170 HCWs) using an online survey. 476 of participants had a previous COVID-19 diagnosis. Question Topics: 1) Vaccine intentions Survey tools available? No Formative research conducted? No Survey pre-tested? No	• Intention to vaccinate was significantly different between HCWs (74%) and non-HCWs (77%), P=0.0014.
Dugani (2021) (113) Cross-sectional study USA Dec 2020-Jan 2021	An online survey was conducted with 128 hospitalists, comprised of 75 physicians and 53 advanced practice providers (APPs) including nurse practitioners and physician assistants in Arizona, Florida, Minnesota, and Wisconsin. This study aimed to assess potential differences between physicians and APPs in their attitudes toward COVID-19 vaccines. Question Topics: 1) Vaccine intentions 2) Vaccine attitudes	• 93.7% of hospitalists reported receiving or planning to receive the COVID-19 vaccine (88.7% APPs and 97.3% physicians). • Hospitalists were less likely to advise 100% of patients to receive the COVID-19 vaccine (66% APPs, 74.7% physicians) compared to the influenza vaccine (83% APPs, 80% physicians). Similar trends were seen for advising patients, family, and friend. • Reported barriers for recommending the vaccine to patients included health restrictions for patients (17% APPs, 10.7% physicians) and unknown vaccine safety profile (11.3% APPs, 6.7% physicians). • Hospitalists reported that patients and coworkers receiving the vaccine would reduce their anxiety levels (83% APPs, 75.3% physicians), reduce social

	Survey tools available? Yes Formative research conducted? No Survey pre-tested? No	isolation (60.4% APPs, 60.3% physicians), and increase emotional support (35.8% APPs, 41.1% physicians). • Those who believed the vaccine would reduce their social isolation had higher odds of advising their patients to receive the vaccine (aOR 2.95, 95% CI: 1.32-6.59, P < 0.008).
Armitage (2021) (134) Cross-sectional study UK Dec 2020 – Jan 2021	An online survey of 220 general practitioners (GPs) was conducted to assess their confidence in counselling patients about COVID-19 vaccines. Question Topics: 1) Vaccine attitudes Survey tools available? No Formative research conducted? No Survey pre-tested? No	• Over 50% of general practitioners had low confidence in counselling patients about COVID-19 vaccines. • Many GPs reported no or slight confidence in counselling patients on inclusion of clinically vulnerable patients in vaccine trials (58.2%), vaccine safety in specific groups (67.3%), potential of adverse reactions not yet seen in clinical trials (74.5%), whether individuals participating in trials will be eligible to receive an approved vaccine (78.2%), and the meaning of vaccine efficacies (81.%). • 52.7% and 54.5% of GPs reported no or slight confidence in accessing credible vaccine information for themselves and directing patients towards similar information, respectively.
Berry (2021) (225) Qualitative study USA Dec-Jan 2021	Concerns raised by 193 healthcare workers and staff from skilled nursing facilities in town hall meetings were reported. Location in the USA was not reported. Question Topics: 1) Vaccine hesitancy	• Early concerns that were raised consistently included belief the vaccine was developed too quickly, short and long-term side effects, infertility and safety in pregnancy, and wanting to wait to see how well the vaccine works for others. • After early concerns were addressed, other consistent concerns involved belief that the vaccine causes COVID-19, causes Bell's palsy, requirement for a booster shot, ineffective against new variants, and previously testing positive. • Some concerns that were raised later in the discussion included uncertainty whether receiving the vaccine will change precautions (wearing a mask, social distancing etc.), fear of microchips, and safety in individuals with chronic disease. •

Grumbach (2021) (112) Cross-sectional study USA Nov 2020 – Jan 2021	An online survey of 3161 adults in the community and 1803 HCWs across 3 medical centers in the San Francisco Bay Area was conducted to assess intentions to vaccinate and reasons for acceptance and hesitancy. Question Topics: 1) Vaccine intentions 2) Vaccine hesitancy Survey tools available? No Formative research conducted? Yes Survey pre-tested? No	• HCWs had higher intentions to vaccinate compared to the general population (83.6% vs 65.5%, P <0.001). • In HCWs, Black (aOR 0.24, 95% CI: 0.10-0.60), Latinx (aOR 0.50, 95% CI: 0.31-0.79), Asian (aOR 0.37, 95% CI: 0.27-0.51), multiracial (aOR 0.49, 95% CI: 0.29-0.82) and individuals of other races (aOR 0.28, 95% CI: 0.15-0.53) had lower intentions to vaccinate compared to White HCWs. • Reasons for intending not to vaccinate among Black, Latinx, and Asian respondents included lack of confidence in the vaccine's ability to prevent COVID-19 (aOR 2.39, 95% CI: 1.58-3.61; aOR 2.04, 95% CI: 1.58-2.64; aOR 1.85, 95% CI: 1.51-2.27, respectively), lack of trust in vaccine manufacturers (aOR 3.08, 95% CI: 2.00-4.73; aOR 1.85, 95% CI: 1.38-2.48; aOR 1.34, 95% CI: 1.04-1.72, respectively), and concerns about the rushed approval of the vaccine (aOR 2.10, 95% CI: 1.44-3.05; aOR 1.68, 95% CI: 1.34-2.10, aOR 1.81, 95% CI: 1.53-2.15, respectively).
Weng (2021) *preprint* (119) Cross-sectional study USA Nov 2020 – Jan 2021	Racial-ethnic differences in COVID-19 vaccination intentions were explored using an online survey of 3,161 adults from the general population and 1,803 HCWs in California. Question Topics: 1) Vaccine intentions 2) Vaccine hesitancy Survey tools available? No Formative research conducted? Yes Survey pre-tested? No	• HCWs were more likely than the general public to intend to vaccinate (83.6% vs 65.5%). • In HCWs, intention to vaccinate was highest in those who were White (89%) followed by multiple races (79%), Latinx/Hispanic (78%), Asian (75%), other race (66%), and Black/African American (65%). • Latinx and Asian respondents were significantly more likely than White respondents to report a doctor's recommendation as an important reason to get vaccinated. • Compared with Whites respondents, about 15% more of the Black, Latinx, and Asian respondents identified potential for a bad reaction to the vaccine and government rushing the approval process as major reasons to not get vaccinated. They were also much more likely to report concerns about the vaccine giving them COVID-19.

Woodhead (2021) (226) *new* Qualitative study UK Oct-Jan 2021	Semi-structured online interviews were conducted with 17 HCWs and 8 senior managers to investigate how decisions are made about taking the COVID-19 vaccine and if racism and discrimination factor into the decision. Question Topics: 1) Vaccine intentions 2) Vaccine hesitancy 3) Vaccine attitudes	• Respondents fell on a continuum of those who would accept a vaccine right away (slightly more than half) to a minority who were more certain they would decline, with a third expressing hesitant views. • Respondents tended to weigh benefits and risks actively with those that are hesitant seeing benefits and risks equally and decliners focusing on risks for themselves. • Acceptors were more likely to report that they viewed getting back to normality as a positive in decision making. • Risks were characterized by worries about side effects in relation with pre-existing vulnerabilities. • Past experiences with vaccines was related to normalization views (comparing to flu vaccine) for vaccine acceptors whereas the hesitant and decliners associating it with large harmful events like the Thalidomide tragedy. • Those expressing hesitant or oppositional views cited an absence of trustworthy information which could allow of manipulation and misinformation. • All groups suspected that they would get direct and indirect messages to get vaccinated but deniers and hesitant respondents were more concerned that they may be forced to vaccinate from their institutions.
Harrison (2021) (130) *new* Qualitative study USA Dec 2020	Five focus groups completed using video-conferencing (Zoom) with 54 participants were conducted with staff from skilled nursing facilities to better understand hesitancy. Location in the USA was not reported. Question Topics: 1) Vaccine hesitancy 2) Vaccine attitudes	• Among the vaccine hesitant were four themes; (1) general concerns and personal concerns about vaccine safety and effectiveness, (2) lack of trust in the vaccine effort, (3) misinformation about the vaccine, and (4) increasing vaccine uptake. • General concerns reflected the short development and testing period, newness, long term effects, how it would impact underlying conditions, or that COVID-19 wouldn't be serious if they did get sick. • Some respondents were mistaken that the vaccine would contain live or attenuated virus.

		Misinformation rumours covered microchips, live virus, and infertility. • Lack of trust was felt both for political affiliation or historical skepticism for people of colour. • When asked about how to increase uptake respondents wanted to see easy to understand information and bringing in representation to discuss (religious groups) or be seen getting the vaccine.
Abuown (2021) (227) Cross-sectional study UK Dec 2020	Intention to vaccinate was evaluated using an online survey of 514 HCWs in London. Question Topics: 1) Vaccine intentions 2) Vaccine hesitancy Survey tools available? No Formative research conducted? No Survey pre-tested? Yes	• 59% were willing to take a COVID-19 vaccine, 24% were not willing, and 17% were undecided. • Doctors were more likely to accept a vaccine compare to nurses ($P < 0.001$), healthcare assistants ($P < 0.001$), pharmacists ($P < 0.001$), allied health professionals ($P < 0.01$), and administrative staff ($P < 0.01$). Hospital management staff were more likely to accept compared to nurses, healthcare assistants, and pharmacists ($P < 0.01$). • Those who accepted an influenza vaccine were less likely to reject a COVID-19 vaccine (OR 0.45, 95% CI: 0.031–0.96) and those who rejected an influenza vaccine were more likely to reject a COVID-19 vaccine (OR 8.32, 95% CI: 5.36–12.91, $P < 0.001$). • Older HCWs (61+) were significantly more likely to intend to vaccinate ($P < 0.01$). • The odds ratio of vaccine rejection was 0.51 for men (95% CI: 0.34–0.77) and 1.26 for women (95% CI: 1.12–1.42, $P < 0.001$). • Intention to vaccinate was significantly lower amongst Black HCWs compared to White ($P < 0.01$), Indian ($P < 0.001$), or other Asian backgrounds ($P < 0.01$). • Safety concerns were the most common reason for hesitancy.

Meyer (2021) (228) Cross-sectional study USA Dec 2020	An online survey to assess vaccine intentions and reasons for hesitancy in 16,292 HCWs was conducted in Pennsylvania. Question Topics: 1) Vaccine intentions 2) Vaccine hesitancy Survey tools available? No Formative research conducted? No Survey pre-tested? No	• 55.3% of respondents intend to get vaccinated when available, 16.3% would not accept a vaccine, and 28.4% were undecided. • Patient facing HCWs reported higher vaccine intentions than non-patient facing (57.3% vs 51.4%, P < 0.001). • Within hospital areas those working in the ER had the lowest intention to get the vaccine (51.9%), whereas those working in the ICU (63.1%) and inpatient care (60.9%) had the highest intentions. • The top reasons for hesitancy were concerns about unknown risks of the vaccine (90.3%), concerns about known side-effects (57.4%), and wanting to wait to see the impact of the vaccine on others (44.3%). • Other reasons for hesitancy include a lack of trust of the FDA process or results (21.1%), concerns of state or hospital network tracking (13.9%), concerns about the mRNA technology (11.4%), and belief they are not at high risk for severe disease (10.4%). • Splitting responses received before the vote to approve the Pfizer vaccine (92.8% of responses) and after (7.2% of responses) finds that 79% reported they would receive the vaccine compared to 53.2% intending to vaccinate before the vote.
Piltch-Loeb (2021) (229) Cross-sectional study USA Dec 2020	The effect of media channels on vaccine acceptance was evaluated using an online survey of 2,650 adults in vaccine priority groups including healthcare workers. 61.4% of the participants worked in the healthcare sector. Question Topics: 1) Vaccine intentions 2) Vaccine hesitancy 3) Vaccine perceptions	• 39.9% reported they were likely to take the vaccine in two months, 47.3% had some level of hesitancy, and 12.8% were unlikely to take the vaccine. • 61% obtained COVID-19 vaccine information from local TV and 37.8% from Facebook. • Respondents indicated that the vaccine news reported was positive (53.6%), neutral (25.3%), mostly negative (16.3%), or that they did not report seeing vaccine information (4.8%). • Overall trust in vaccine information sources was moderate to low, with 23% reporting high trust, 40.5% moderate trust, and 36.3% low trust.

	Survey tools available? No Formative research conducted? No Survey pre-tested? Yes	• In the multivariable analysis, positive predictors of intention to vaccinate included knowing someone who died of COVID-19 (RR = 1.47, 95% CI: 1.08-1.99), having some trust in vaccine information (RR = 2.01, 95% CI 1.61-2.51), having high trust in vaccine information (RR =15.6, 95% CI: 11.69-20.81), and obtaining vaccine information from national TV (RR = 1.75, 95% CI: 1.02-1.53), local TV (RR = 1.75, 95%, CI: 1.40-2.19), or national newspapers (RR =1.81, 95% CI: 1.45-2.24). • Low intention to vaccinate was associated with respondents that only used social media (RR = 0.45, 95% CI: CI 0.32-0.64) or used both social media and traditional media channels (RR = 0.81, 95% CI: CI 0.66-1.00) compared to those who only used traditional media to obtain vaccine information.
Kuter (2021) (109) Cross-sectional study USA Nov-Dec 2020	To evaluate intentions to vaccinate, an online survey was conducted at two large, academic hospitals in Philadelphia in 12,034 hospital employees. Question Topics: 1) Vaccine intentions 2) Vaccine hesitancy Survey tools available? No Formative research conducted? Yes Survey pre-tested? Yes	• 63.7% reported intention to receive a COVID-19 vaccine when available, 26.3% were unsure, and 10.0% were unwilling. • Of those intending to vaccinate, 79.1% would receive the vaccine as soon as possible, 19.1% would like to wait 3–6 months after it had been administered to others, and 1.8% would after it had been administered to others for 12 months. • The two most important vaccine characteristics to respondents were safety (94.4%) and efficacy (82.8%). • If a vaccine were to include side effects such as high fever, muscle aches, chills, and headache resulting in loss of 2 days at work, only 28.3% of respondents said they would be willing to receive a vaccine. 33.2% said they were unsure. • Intention to vaccinate increased as vaccine effectiveness increased (35.8% willing to receive a vaccine with 50% effectiveness, 61.1% with 70% effectiveness, and 85.6% with 90% effectiveness). • Factors significantly associated with an intention to vaccinate were male gender (OR 2.41, 95% CI:

		2.12-2.75), older age (>65: OR 3.50, 95% CI: 2.50-4.90; 40-64: OR 1.41, 95% CI: 1.26-1.56), and higher education (post-graduate degree: OR 4.59, 95% CI: 3.83-5.50, Bachelor or Masters degree: OR 1.84, 95% CI: 1.59-2.13). • Compared to White ethnicity, intention to vaccinate was significantly lower among Blacks (OR 0.23, 95% CI: 0.19-0.27), Hispanics (OR 0.51, 95% CI: 0.39-0.67), and those reporting multiple/other races (OR 0.58, 95% CI: 0.47-0.73). • Those residing in urban areas were significantly more likely to intend to vaccinate compared to suburban (OR 0.71, 95% CI: 0.65-0.79) and rural (OR 0.41, 95% CI: 0.30-0.54) residents. • Intention to vaccinate was lower among those with poor or fair health (OR 0.73, 95% CI: 0.56-0.95) and among those who were not up-to-date on their vaccinations (OR 0.36, 95% CI: 0.18-0.71) compared to their counterparts. • The most common reasons to receive a vaccine were protection of one's family (86.7%), protecting themselves (82.9%), protecting one's community (68.8%), and getting life back to normal (59.4%). • The most frequent reasons for vaccine hesitancy or refusal were concern about side effects (89.1%), the vaccine being too new (84.0%), and lack of knowledge about the vaccine (77.9%).
Shaw (2021) (110) Cross-sectional study USA Nov-Dec 2020	Willingness to vaccinate was evaluated in 5287 HCWs from a large academic medical center in New York using an online survey. Question Topics: 1) Vaccine intentions 2) Vaccine hesitancy Survey tools available? No Formative research conducted? Yes	• 57.5% of respondents were willing to take a free vaccine, 26.4% were unsure, and 15.9% would refuse. • Men were more likely to intend to vaccinate (72.5%) compared to women (52.4%) or non-binary or non-disclosed individuals (41.0%), P<0.001. • Those that identified as Asian (73.8%) or White (58.4%) were more willing to take a vaccine compared to Other (47.6%), American Indian or Alaska Native (39.3%), or Black (30.8%) respondents, P<0.001.

	Survey pre-tested? No	• Scientists and Physicians (80.4%) and Public Safety and Spiritual Care employees (77.8%) were most likely to intend to vaccinate. Registered Nurses (41.2%), in Ancillary Services (46.4%), or as Allied Health Professionals (51.4%) were less likely, P<0.001. • Those that were older and those that were not providing direct patient care were more likely to intend to vaccinate. • White respondents agreed that a COVID-19 vaccine would be safe when approved (45.9%) more frequently than Black respondents (26.2%), P<0.001). • The most common concerns about the vaccine include safety, side-effects, efficacy, and speed of vaccine development.
Jain (2021) *preprint* (111) Cross-sectional study USA Nov-Dec 2020	Motivations, concerns, and intentions regarding COVID-19 vaccines were evaluated using an online survey in 2135 HCWs (18+) from 3 medical centers in California. Question Topics: 1) Vaccine intentions 2) Vaccine hesitancy 3) Vaccine knowledge Survey tools available? No Formative research conducted? No Survey pre-tested? No	• 69% of HCWS would receive the vaccine if formally FDA approved, 22% were unsure, and 10% would refuse. In contrast, only 35% would receive if approved via emergency use authorization only. • 25% wanted to be among the earliest to receive a vaccine, 36% preferred vaccination after the first round, and 18% want to wait for 2+ months. • The top motivating factors for vaccination included perceived risk from COVID-19 to self (65%), and family/friends (63%). • Top vaccine concerns were side effects (28%), political involvement in the FDA's approval process (21%), distrust of pharmaceutical companies (16%), and efficacy (12%). • 19% of respondents reported being highly informed or well informed about COVID-19 vaccine candidates whereas 66% reported they were somewhat informed, and 16% were not informed at all.
O'Brien (2021) *preprint* (107)	An online survey of 2070 HCWs across the USA was conducted in Oct to determine intention to vaccinate under emergency use	• Intention to vaccinate increased from 54.2% in Oct to 76.2% in Dec. Over this time period, vaccine intention increased from 64.0% to 90.5% in

Longitudinal study USA Oct-Dec 2020	authorization. This survey was repeated in 1541 HCWs in Dec. 998 participants responded to both surveys. Question Topics: 1) Vaccine intentions Survey tools available? No Formative research conducted? No Survey pre-tested? No	doctors, from 68.9% to 75% in paramedics, and from 46.6% to 66.9% in nurses. • For the 998 individuals who participated in both surveys, 69% were willing to vaccinate at both time points, 15% were hesitant at both time points, 13% were hesitant in Oct but were willing in Dec, and 2.9% were willing in Oct but hesitant in Dec.
Keleker (2021) (129) *new* Cross-sectional study USA Sep-Dec 2020	248 dental (DS) and 167 medical students (MS) from three dental schools and one medical school were surveyed online regarding past vaccination behaviour and current COVID-19 vaccine hesitancy. Question Topics: 1) Vaccine intentions 2) Vaccine hesitancy 3) Vaccine attitudes Survey tools available? No Formative research conducted? Yes Survey pre-tested? No	• 23% of medical students and 45% dental students reported that they were hesitant about getting the COVID-19 vaccine indicating that medical students were 2.7 times more likely to get a vaccine. • General vaccine attitudes were positive among MS with 99.4% agreeing that vaccines are important to stay healthy as a HCW and 99.4% believing there is a role for them to learn about vaccines for their patients. • MS students were significantly more likely to support mandatory vaccination for the general public (OR= 3.12, 95% CI: 2.06-4.76) and for HCWs (OR= 5.18, 95% CI: 3.15-8.76). • MS students were significantly more likely to trust information received about COVID-19 vaccines compared to DS students (OR= 3.51, 95% CI: 2.09-6.08) but were also more likely have concerns about vaccine effectiveness (OR= 2.78, 95% CI: 1.80-4.36). • MS were more unlikely than DS to say they would only get vaccinated if mandated by school or health systems (OR= 0.38, 95% CI: 0.22-0.62) as well as to report that as an adult they refused a vaccination for a reason other than illness or allergy (OR= 0.41, 95% CI: 0.23- 0.73). • In logistic analysis, being an under represented minority, believing COVID-19 vaccination should

		be mandatory for the public, believing COVID-19 vaccination is important to themselves as a HCW, trusting information about the COVID-19 vaccine was significantly associated with willingness to receive a vaccine whereas concern for adverse event and only getting a vaccine if required was associated with not being willing to accept a vaccine.
Unroe (2020) (121) Cross-sectional study USA Nov 2020	Willingness to vaccinate was evaluated in 8,243 nursing home and assisted living staff in Indiana using an online survey. Question Topics: 1) Vaccine intentions 2) Vaccine hesitancy Survey tools available? No Formative research conducted? No Survey pre-tested? No	• 45% of respondents would be willing to take an FDA-approved vaccine as soon as it was available. • Of those who would not be willing to take the vaccine immediately, 44% would be willing to receive the vaccine at a later date. • The most common reasons for vaccine hesitancy include potential side-effects (70%), heath concerns (34%), efficacy concerns (20%), and religious reasons (12%). • Compared to their counterparts, those over the age of 60, men, and those who identify as White ethnicity were more willing to take the vaccine (P < 0.0001). • Black HCWs were 12% (95% CI: 8.6-15.7%) less willing to accept the vaccine compared to White HCWs. • Dietary, housekeeping, and administrative staff were more likely to intend to vaccinate compared to clinical care staff including nurse aids and nurses (P < 0.0001).
Shekhar (2021) (123) Cross-sectional study USA Oct-Nov 2020	Intention to vaccinate was assessed in 3479 HCWs (18+) using an online survey. Question Topics: 1) Vaccine intentions 2) Vaccine perceptions Survey tools available? No Formative research conducted? No	• 36% of respondents were willing to take the vaccine as soon as it becomes available, 56% were not sure and would wait to review safety data before getting a vaccine, and 8% would refuse. • Intention to vaccinate increased with age (34% in the 18-30 group vs 47% in the >70 age group). • Male gender, higher education, higher income levels, living in the South, living in an urban area, and identifying as Liberal or Democrat were associated with higher intention to vaccinate as

	Survey pre-tested? No	soon as it becomes available compared to their counterparts. • Black (19%) and Native Americans/Alaska Native (10%) HCWs were less likely to intend to vaccinate as soon as it becomes available compared to White (37%) and Asian (44%) HCWs (p<0.001). The majority of Black (65%), Native American HCWs (80%), and all Native Hawaiian/Other Pacific Islander HCWs (100%) chose to wait to review data before receiving a vaccine. • Intention to vaccinate as soon as it become available was lower among those identifying as Hispanic or Latino (30%) compared to those who did not identify with this ethnicity (37%). • Those who believe themselves to be immune to COVID-19 (22%), who feel confident they won't get infected (27%), and those who had not taken care of COVID-19 patients (9.2%) had the highest rates of intending to refuse a vaccine. • The most prominent concerns expressed regarding vaccinating include safety/adverse effects (69%), effectiveness (69%), and rapidity of development/approval (74%). • The majority of HCWs trust their doctors and healthcare professionals recommending the vaccine (73%), but 46% do not trust information provided by the government about the vaccine and its severity and 34% do not trust regulatory authorities (e.g. CDC or FDA) overseeing the vaccine development and safety.
Caban-Martinez (2021) (133) Cross-sectional study USA	Across the USA, an online survey of 3,169 emergency medical service (EMS) workers and firefighters was conducted to evaluate intention to vaccinate. Question Topics: 1) Vaccine intentions	• 48.2% were willing to accept a vaccine when available, 27.6% were not willing, and 24.2% were unsure. • Those who were more likely to not accept a vaccine were aged 30-39 years (aOR 3.62, 95% CI: 2.00-6.55), Black race (aOR 3.60, 95% CI: 1.12-11.53]), multi-race (aOR 2.98, 95% CI: 1.61–5.51), Hispanic/Latinx ethnicity (aOR 2.39, 95% CI: 1.45-3.92), lower education (aOR 2.06, 95% CI: 1.29-

Oct 2020	Survey tools available? No Formative research conducted? Yes Survey pre-tested? No	3.27), married or unmarried couple (aOR 1.65, 95% CI: 1.03-2.65), and of current rank firefighter/EMS (aOR 2.21, 95% CI: 1.60-3.08).
Gadoth (2021) (120) Cross-sectional study USA Sep-Oct 2020	To understand HCWs intention to vaccinate and attitudes about vaccine safety, efficacy, and acceptability in the context of the COVID-19 pandemic, an online survey of 609 HCWs was conducted. Question Topics: 1) Vaccine intentions 2) Vaccine perceptions 3) Vaccine hesitancy Survey tools available? No Formative research conducted? Yes Survey pre-tested? No	• 47.8% of participants stated they would not participate in a COVID-19 vaccine trial. • 65.5% intend to delay vaccination, of which 49.4% would prefer to wait and see how the vaccine affects others first. Compared to doctors, the adjusted proportion reporting intent to delay vaccination or refusal was 0.52, 0.54, and 0.59 among nurses, other personnel with patient contact roles, and those without patient contact, respectively. • Respondents agreed on the utility of vaccines for protecting themselves from disease (mean Likert score 4.69 95% CI: 4.64-4.73) and for protecting community health (mean Likert score 4.69 95% CI: 4.65-4.74). However, doctors held these attitudes more strongly than nurses. • Opinion was split regarding the statement that new vaccines carry more risks than older (mean Likert score 3.23 95% CI: 3.14-3.32). • Less than half the respondents (46.9%) felt a vaccine would protect them against COVID-19 and 34.8% were confident about the scientific vetting process. • Women and racial or ethnic minorities expressed more hesitant attitudes towards vaccines than their counterparts. • The major variables impacting those who planned to delay or refuse vaccination were concerns about the fast-tracked nature of vaccine development and a lack of transparency and/or publicly available information on the vaccine.
Robbins (2021) (230)	An online survey was conducted in 593 HCWs from a major tertiary	• If a vaccine became available that was freely distributed through their employer, with

Cross-sectional study UK Sep 2020	referral hospital to assess intention to vaccinate. Question Topics: 1) Vaccine intentions 2) Vaccine perceptions Survey tools available? No Formative research conducted? No Survey pre-tested? No	appropriate safety and efficacy data, 83.4% would be likely or very likely to get a vaccine. • 58.9% would be willing to get their vaccine outside of their normal working hours (e.g., weekend) and 53.1% would be willing to travel to another location to get a vaccine. • 68.5% would be willing to get their vaccine while in their car and 76.6% would not mind waiting in a socially distanced line to get their vaccine. • 77.8% believe that HCWs should be prioritized to receive a vaccine and 82.8% believe that front-line staff directly treating patients should be prioritized over non-patient facing roles.
Manning (2021) (124) Cross-sectional study USA Aug-Sep 2020	Factors associated with intention to vaccinate were assessed using an online survey of 78 full-time nursing faculty, 105 adjunct nursing faculty, and 1029 nursing students. Question Topics: 1) Vaccine intentions 2) Vaccine perceptions 3) Vaccine hesitancy Survey tools available? No Formative research conducted? Yes Survey pre-tested? Yes	• Intention to vaccinate was highest in full-time faculty (60.3%) followed by students (45.3%), and adjunct faculty (44.8%). • Men were more likely than women to intend to vaccinate (60.3% vs 44.9%, P=0.002). • Those aged 60+ had the highest intention to vaccinate (85.7%, P=0.004). • The most common reasons to intend to vaccinate included a desire to protect family, self, patients, and community, and the belief that it would be the best way to avoid getting seriously ill from COVID-19. • The most common reasons for intending not to vaccinate included the belief that the vaccine was developed too quickly to be safe, and side effects. These concerns were more commonly reported by students and adjunct clinical faculty compared to full-time faculty (P <0.05). • Mandatory vaccination as a condition of employment was supported by 52% of full-time faculty, 39% of adjunct faculty, and 35% of students.
Parente (2021) (126) *new*	Associations with vaccine acceptance were assessed online for a hypothetical vaccine with	• 37.2% of respondents were early acceptors, wanting to be vaccinated within the first month of approval.

Cross-sectional study USA Aug 2020	considerations for delay periods (1 to more than 12 months after approval) in 3,347 HCWs in Kentucky. Question Topics: 1) Vaccine intentions 2) Vaccine hesitancy Survey tools available? No Formative research conducted? Yes Survey pre-tested? Yes	• 22.3% wanted to be vaccinated within 1-3 months, 11.4% within 4-6 months, 6.9% in 7-12 months, and 12.3% more than 12 months after approval. • 9.9% report that they never intend to be vaccinated. • Reasons for wanting to delay or refuse vaccination focused on the long term side effects (57.1%), the safety of the vaccine (55.0%), vaccine efficacy (37.1%), risk vs benefit of the vaccine (31.0%), cost of the vaccine (12.2%), and possible allergies (11.2%). • Asian respondents were 1.53 times more likely to report they wanted to receive a vaccine within 3 months compared to White respondents. In contrast, Black respondents were significantly less like to accept a vaccine in the same time period (OR 0.16, 95% CI: 0.10-0.25). • Early acceptance of a vaccine (within 3 months) was significantly associated with men (aOR 2.43, 95% CI: 2.00-2.95), those who got the flu shot in 2019/2020 (aOR 2.35, 95% CI: 1.75-3.18), more concern about COVID-19 (aOR 2.40, 95% CI: 2.07-2.79), and higher levels of education (aOR 1.41, 95% CI: 1.21-1.65).
Hoke (2021) (132) Cross-sectional study USA May 2020	An online survey of 350 Pennsylvania school nurses (18+) was used to evaluate intention to vaccinate and vaccine perceptions. Question Topics: 1) Vaccine intentions 2) Vaccine perceptions Survey tools available? No Formative research conducted? No Survey pre-tested? No	• 84.9% of nurses were willing to vaccinate when one becomes available, 14.5% were unlikely, and 0.6% did not respond. • 63.7% supported the return to school in the absence of a vaccine. • Compared to rural nurses, urban nurses were more willing to receive a vaccine when available (OR 2.21, 95% CI: 1.41-3.46) and were more concerned about returning to school without a vaccine (OR 1.58, 95% CI: 1.05-2.38).

Sathianathan (2020) (231) Cross-sectional study USA Mar 2020	COVID-19 vaccine knowledge was compared between 4966 HCWs and 854 non-HCWs from Pennsylvania using an online survey. Question Topics: 1) Vaccine knowledge Survey tools available? Yes Formative research conducted? Yes Survey pre-tested? Yes	• When asked if a vaccine for COVID-19 would be available within 3 months, HCWs were more likely to answer correctly (false) compared to non-HCWs.

aOR = adjusted odds ratio, CI = confidence interval, HCWs = healthcare workers, PSW = personal support worker

HIGH-RISK POPULATIONS

Table 5. Evidence of vaccine attitudes of high-risk populations (n=24)

STUDY	METHODS & SURVEY TOOLS	KEY KAB OUTCOMES
PREGNANT OR BREASTFEEDING		
Woolf (2021) *preprint* (114) Cross-sectional study and qualitative study UK Dec 2020-Mar 2021	To assess COVID-19 vaccine hesitancy and its predictors, an online survey was conducted with 11,584 HCWs (16+). Qualitative data was collected through interviews (n=24), focus groups (n=17), and open-ended survey responses (n=58). All HCW outcomes found in HCW section. Question Topics: 1) Vaccine hesitancy Survey tools available? Yes Formative research conducted? Yes Survey pre-tested? No	• Pregnant HCWs were 7.12 times more likely to be hesitant compared to non-pregnant HCWs (aOR 7.12, 95% CI: 4.74-10.70).

Skjefte (2021) (135) Cross-sectional study 16 countries: Australia, Africa, Argentina, Brazil, Chile, Colombia, India, Italy, Mexico, New Zealand, Peru, Philippines, Russia, Spain, UK, USA. Oct-Nov 2020	An online survey was used to evaluate the acceptance of COVID-19 vaccination among 5,294 pregnant women and 12,562 mothers of children younger than 18-years-old. Question Topics: 1) Vaccine intentions 2) Vaccine hesitancy Survey tools available? No Formative research conducted? No Survey pre-tested? No	• For a vaccine with 90% efficacy, 52.0% of pregnant women and 73.4% of non-pregnant women indicated an intention to receive the vaccine. • 69.2% of all women intended to vaccinate their children. Acceptance levels were above 85% in India, Mexico, Brazil and Colombia and below 52% for the USA, Australia, and Russia. • Intention to vaccinate in pregnant women varied by country with acceptance levels above 80% in Mexico and India and below 45% for the USA, Australia, and Russia. • Vaccine hesitancy was associated with younger age, lower income, lower education level, not being married, and having no health insurance. • The strongest predictors of intention to vaccinate were confidence in vaccine safety and efficacy, belief in the importance of vaccines to their own country, confidence in routine childhood vaccines, worry about COVID-19, trust of public health agencies/health science, and compliance to mask guidelines. • 53.0% of respondents were confident that a nationally approved COVID-19 vaccine would be safe and 60.4% were confident the vaccine would be effective. • For pregnant women, the most common reasons to decline a vaccine were potential side effects for their baby (65.9%), concern that approval of the vaccine would be rushed for political reasons (44.9%) and the lack of safety and effectiveness data among pregnant women (48.8%). • For mothers, the most common reasons to decline a vaccine were concern that approval of the vaccine will be rushed for political reasons (39.8%), lack of safety and effectiveness data among children (32.7%), and worry about safety and side effects (28.4%). • A recommendation from a healthcare provider had a limited impact on intention. 45.9% of pregnant

		women and 54.6% of non-pregnant women would be more likely to have themselves/children vaccinated if recommended by health care providers.
Skirrow (2021) *preprint* (19) Cross-sectional and qualitative study UK Aug – Oct 2020	An online survey and semi-structured interviews were conducted in a group of 1,181 pregnant women (aged 16+) to determine views on COVID-19 vaccine acceptability for themselves when pregnant, not pregnant, and for their babies. Question Topics: 1) Vaccine intentions 2) Vaccine hesitancy Survey tools available? No Formative research conducted? Yes Survey pre-tested? No	• 81.2% of women reported that they would definitely accept or were leaning towards accepting a vaccine when not pregnant. Vaccine acceptance was significantly lower during pregnancy (62.1%, P<0.005) and for their babies (69.9%, p<0.005). • Compared to White ethnic women, ethnic minority women were twice as likely to reject a vaccine for themselves when not pregnant, pregnant and for their babies (P>0.005). • Those from lower-income households, aged < 25 years, and from some geographic regions were more likely to reject a vaccine when not pregnant, pregnant, and for their babies. • Women unvaccinated against pertussis in pregnancy were over four times more likely to reject a vaccine when not pregnant, pregnant and for their babies. • Thematic analysis revealed the most common reasons for hesitancy were vaccine safety, and a wider mistrust of vaccines in general.
Battarbee (2021) *preprint* (136) Cross-sectional study USA Jul-Oct 2020	915 pregnant women in Utah, Alabama, and New York were surveyed over the telephone or at in person visits to measure attitudes toward the COVID-19 vaccine and vaccine acceptability. Question Topics: 1) Vaccine intentions 2) Vaccine attitudes Survey tools available? No Formative research conducted? No	• 41% of women would accept a vaccine and this did not vary by enrolment month. • Those willing to accept a vaccine cited reasons such as wanting to protect their pregnancy (95%), to protect themselves (85%), protecting family members (79%), and protecting their community (68%). • Those that are not willing to get a vaccine during their pregnancy were unwilling do so due to concerns about safety of the vaccine during pregnancy (82%), safety for themselves (68%), vaccine efficacy (52%), and the belief that they did not need the vaccine (22%).

	Survey pre-tested? No	• Having a graduate degree increased the odds of accepting a vaccine by 2.4 times compared to those with less than a high school diploma (95% CI: 1.3-4.7). • In multivariate modelling only receiving a flu vaccine in the past year (aOR 2.1, 95% CI: 1.5-3.0) was found to increase vaccine acceptance. Conversely, only ethnicity (Hispanic and Black respondents) was associated with not accepting a vaccine (aOR 0.4, 95% CI: 0.2-0.6 each).
PEOPLE EXPERIENCING HOMELESSNESS		
Kuhn (2021) *preprint* (41) Cross-sectional study USA Dec 2020-Feb 2021	The level of vaccine uptake and hesitancy among 90 individuals experiencing homelessness in Los Angeles (18+) was evaluated using a mobile phone survey. Question Topics: 1) Vaccine uptake 2) Vaccine hesitancy 3) Vaccine intentions Survey tools available? No Formative research conducted? No Survey pre-tested? No	• Of the 90 participants, 17 were offered a vaccine of which 10 accepted and 7 refused. • Among the 73 who were not offered the vaccine, 51% said they would take it if offered, 32% would refuse, and 17% refused to answer. • Together, 48% refused a vaccine when offered, would refuse when offered, or refused to answer and were deemed "vaccine hesitant". • Of those who were vaccine hesitant, the most common reasons were fear of side effects (37%), wanting to have more information (30%), and they don't get any vaccines (27%). • A multivariate analysis, those with a high COVID-19 threat perception (OR 0.25, P=0.02), and those who trusted official sources (OR 0.37, P=.08) were significantly less likely to be vaccine hesitant. Those who engaged in highly protective behavior (OR 3.63, P=0.02) and who trusted personal contacts (OR 2.70, P=0.07) were more likely to be hesitant.
Knight (2021) *preprint* (137) Qualitative study USA	To understand the facilitators and barriers to vaccine acceptability among homeless adults (aged 20-71) a qualitative study was conducted in two samples: 1) a longitudinal cohort of 37 homeless older adults in Oakland, CA and 2) a convenience sample of 57	• Many participants indicated they were willing to receive a vaccine when available. They cited a desire to return to routine life and civic responsibility as reasons they would vaccinate. • Four themes emerged regarding vaccine hesitancy including: 1) a desire for more data about vaccine testing, safety, and approval, 2) concerns that the vaccines made people sick, 3) a desire to wait until

Jul-Oct 2020	individuals during a mobile outreach COVID-19 testing event in San Francisco, CA. Question Topics: 1) Vaccine intentions 2) Vaccine hesitancy	others had taken the vaccine before agreeing to take it themselves, and 4) mistrust of the government. Some connected this mistrust to previous experiences of racism. • Despite social exclusion and lack of access to technology, participants followed news reports about the vaccine and desired information about vaccine efficacy and safety.
OLDER ADULTS		
Horizon Research (2021) *unpublished* (15, 195, 232) Longitudinal study New Zealand Mar-May 2021	An online survey of adults (16+) was conducted to measure vaccine intentions. Mar-Apr, n=1,350 Apr-May, n=1387 May, n=1,234 *new* Question Topics: 1) Vaccine intentions Survey tools available? Yes Formative research conducted? No Survey pre-tested? No	**May** • 9% of those aged 65-74 and 14% of those aged 75+ were unlikely to get vaccinated. • The top concerns of those aged 65-74 were side effects (30%), long term effects (28%), and concern for what would happen if they had an adverse reaction (26%). Similar concerns were seen with those over 75. **Apr-May** • 81% of those aged 65-74 and 88% of those 75+ were likely to accept a vaccine.
Australia Bureau of Statistics (2021) *unpublished* (141) *new* Longitudinal study Australia	The household impacts survey is a monthly survey which collects data online and by telephone from a panel of adults (18+) on COVID-19 related topics including attitudes towards vaccines. May: n=3,371 Question Topics: 1) Vaccine intentions	• 7.6% of those aged 70+ would definitely not receive a vaccine when offered and 9.4% were unlikely to vaccinate when offered. • A recommendation from their general practitioner was the most important factor in their decision to get vaccinated in 41.1% of those aged 70+.

Apr 2020-May 2021	Survey tools available? No Formative research conducted? No Survey pre-tested? No	
Office for National Statistics (2021) *unpublished* (140) Longitudinal study UK Feb-Mar 2021	17,201 responses from four waves of results collected from the online Opinions and Lifestyle Survey (196) were pooled to focus on demographic specific associations with vaccine hesitancy. Questions Topics: 1) Vaccine intentions 2) Vaccine hesitancy Survey tools available? Yes Formative research conducted? Yes Survey pre-tested? Yes	• 3% of those aged 65-69 and 5% of those aged 60-64 were vaccine hesitant. 4% of those aged 55-59 were hesitant. • Of those aged 75-79 years who were very or fairly unlikely to get a vaccine, 49% reported they were against vaccines in general, 46% cited worries about a pre-existing condition, and 31% had other reasons. • Worries among those aged 65-79 were more varied including concerns regarding side effects, long-term effects, worries about existing health conditions, not believing it to be unsafe, and wanting to see if the vaccine works. • Those aged 55-64 had additional beliefs about not being at risk or they believe they already had COVID-19.
Nikolovski (2021) (139) Cross-sectional study USA Nov 2020	A survey of 7402 older adults (65+) using a mobile health app was conducted to determine factors associated with intentions to vaccinate. Question Topics: 1) Vaccine intentions 2) Vaccine hesitancy Survey tools available? Yes Formative research conducted? No Survey pre-tested? No	• 91.3% of participants stated they were willing or somewhat willing to be vaccinated and 8.7% were unwilling or somewhat unwilling to vaccinate. • Hesitancy was highest amongst women (OR = 0.49, 95% CI: 0.45 – 0.54) and African American or Black respondents (OR = 0.24, 95% CI: 0.18 – 0.31). • Those reporting a higher income (OR = 2.60, 95% CI: 1.98 -3.42) or more education (OR = 2.31, 95% CI: 1.84 – 2.94) had higher odds for intentions to vaccinate. • Beliefs strongly associated with intention to vaccinate were protecting themselves and others (OR = 38.6, 95% CI: 32.4-46.1), safe and effective vaccine (OR = 21.6, 95% CI: 18.9-24.7), and comfortability with short term side effects (OR = 10.9, 95% CI: 9.1–13.1). • The majority of respondents wanted to talk to a healthcare provider before making a decision to vaccinate. This included both those willing to

		vaccinate (91.4% of women and 88.9% of men) and those not willing to vaccinate (68.4% of women and 62.3% of men). • Positive vaccine news was associated with an increase in intentions to vaccinate. After the results of the Pfizer phase 3 clinical trial were released, intention to vaccinate increased (OR = 1.46, 95% CI: 1.28-1.69).
Luo (2021) (150) *new* Cross-sectional study USA Oct-Nov 2020	Using the Medicare Current Beneficiary Survey, 6715 Medicare recipients (aged 65+) were asked by telephone about their COVID-19 vaccine intentions. Question Topics: 1) Vaccine intentions 2) Vaccine hesitancy Survey tools available? No Formative research conducted? No Survey pre-tested? No	• 61.0% (95% CI: 59.1-63.0) would be willing to get a vaccine when available and 39.0% (95% CI: 37.0-40.9) were hesitant to accept a vaccine. • 59.6% of those aged 65-74 reported they were willing to get a vaccine whereas 63.5% of those 75+ were willing. • Respondents who were aged 65-74 (aOR 0.83, 95% CI: 0.74-0.92), non-Hispanic Black (aOR 0.33, 95%, CI: 0.24-0.44), Hispanic (aOR 0.60, 95% CI: 0.47-0.77), female (aOR 0.56, 95% CI: 0.48-0.64), had an income of less than $25,000 (aOR 0.71, 95% CI: 0.62-0.81), and those who didn't think COVID-19 was more contagious (aOR 0.53, 95% CI: 0.41-0.69) or more deadly (aOR 0.51, 95% CI: 0.41-0.65) were significantly less likely to get a vaccine. • The top reasons cited for vaccine hesitancy were low trust in government (42.1%), concern for side effects (41.3%), and uncertainty about vaccine efficacy (11.3%). • Intention to receive a vaccine was significantly higher in those with internet access at home compared to those without (aOR 1.22, 95% CI: 1.01-1.49).
Callow (2021) (233) Cross-sectional study USA	To examine the impact of attitudes, subjective norms, and perceived behavioral control on attitudes towards vaccination, an online survey of 583 older adults (60+) from Delaware, Maryland, Washington DC, and Virginia was conducted.	• More favorable attitudes towards COVID-19 vaccines was seen in men ($\beta = 0.10$, $P < 0.01$), those who had previously received the flu vaccine ($\beta = 0.15$, $P < 0.001$), those who perceived the disease as more severe ($\beta = 0.11$, $P < 0.01$), and those who had a positive attitude towards vaccines in general ($\beta = 0.48$, $P < 0.001$).

Aug 2020	Question Topics: 1) Vaccine attitudes Survey tools available? No Formative research conducted? Yes Survey pre-tested? No	• Compared to those who identified as strong Democrats, vaccine attitude scores were less favorable among moderate Democrats (β = 0.08, P < 0.05), Independents (β = 0.26, P < 0.001), moderate Republicans (β = 0.16, P < 0.001), and strong Republicans (β = 0.44, P < 0.001).
Waite (2021) (92) Cross-sectional study Canada May 2020	An online survey of 1001 Canadians aged 50–64 years and 3,500 aged 65+ was conducted to evaluate intention to vaccinate against COVID-19. Question Topics: 1) Vaccine intentions 2) Vaccine attitudes Survey tools available? No Formative research conducted? Yes Survey pre-tested? No	• Among those aged 50-64 years, 69.1% intend to vaccinate when available, 11.3% would not vaccinate, and 19.6% were unsure. • 79.5% of those 65+ intend to receive a vaccine when available, 5.6% would not vaccinate, and 14.9% were unsure. • In both age groups, those who would accept a vaccine were significantly more likely to be male and more likely to have at least one chronic condition (P< 0.05). • The preferred location to receive a vaccine in both groups was family physician office, followed by pharmacy, workplace (for those 50–64 years), and public health clinics.
Williams (2020) (138) Cross-sectional study UK Apr 2020	Intention to vaccinate and perceptions on the vaccine were assessed in an online survey of 311 older adults (65+) and 216 patients with chronic respiratory disease (18-64 years old). Question Topics: 1) Vaccine intentions Survey tools available? Yes Formative research conducted? Yes Survey pre-tested? No	• Of the total population (n=527), 58% and 27% would definitely or probably want to receive a vaccine once it becomes available, respectively. There were no differences between the older adult group and the chronic respiratory group (p = 0.78). • Willingness to receive a COVID-19 vaccination was positively associated with the belief that the COVID-19 outbreak is going to continue for a long time (0.09, p<0.05), and negatively associated with the belief that the media has over-exaggerated the risks of catching COVID-19 (-0.122, p<0.05). • A thematic analysis of comments in the survey revealed that 'personal health' (n = 176), 'severity of COVID-19 disease' (n = 85), and 'health consequences to others' (n = 36) were viewed as factors which facilitated vaccination whereas

		'concerns about vaccine safety' (n = 158) was considered a barrier to vaccine uptake.
SUBSTANCE USE		
Yang (2021) (147) Cross-sectional study USA Dec 2020 – Jan 2021	Vaccine intentions and hesitancy among 387 adults (18+) across the USA with a history of using tobacco products or marijuana was evaluated using an online survey. Question Topics: 1) Vaccine intentions 2) Vaccine hesitancy Survey tools available? No Formative research conducted? No Survey pre-tested? No	• 49.1% were willing to receive a vaccine, 26.0% were not willing, and 24.9% were undecided. • The use of cigarettes, e-cigarettes, marijuana, and heavy drinking was not associated with vaccine hesitancy. • Those who were Black, lived in a suburban or rural community, who lived by themselves or with a family with five members or above, and those who were not stressed because of the COVID-19 pandemic were more likely not accept a vaccine when offered. • Compared to those who had received an influenza vaccine every year or almost every year, those who had never, only once, or in some years received an influenza vaccine were 7.0, 6.2, and 5.2 times more likely to not accept a vaccine.
Spechler (2021) *preprint* (146) Cross-sectional study USA Dec 2020-Jan 2021	A group of 45 cannabis users (reporting 10+ lifetime cannabis uses) were matched with 45 individuals who reported <10 lifetime cannabis uses to assess willingness to receive a COVID-19 vaccine using an online survey. Question Topics: 1) Vaccine intentions Survey tools available? No Formative research conducted? No Survey pre-tested? No	• Willingness to receive a vaccine did not significantly differ between cannabis users and controls (t_{88} = 0.33, P = 0.74; BF_{01} = 4.3). • Among cannabis users, increased lifetime cannabis use was correlated with decreased willingness to receive a vaccine (r_{43} = -0.33, P = 0.03).
Masson (2021) (234) *new*	258 Californians with substance abuse disorder (SUD) were distributed paper surveys in substance treatment programs	• 11.2% of participants completely trust, 28.3% somewhat trust, and 28.3% slightly trust that a COVID-19 vaccine would be safe and effective.

Cross-sectional study USA Aug-Dec 2020	were surveyed regarding their trust in COVID-19 vaccines. Question Topics: 1) Vaccine perceptions Survey tools available? No Formative research conducted? No Survey pre-tested? No	32.2% do not trust that a COVID-19 vaccine would be safe and effective. • In multivariate modelling only age (aOR 1.03, 95% CI = 1.02-1.05) and consistent mask wearing compared to less frequent mask wearing (aOR 2.48, 95% CI = 1.86-3.31) were significantly associated with vaccine trust whereas African Americans were less likely to trust vaccines compared to non-Hispanic Whites (aOR 0.41, 95 % CI = 0.23-0.70).
Jackson (2020) *preprint* (145) Cross-sectional study UK Sep-Oct 2020	As part of the COVID-19 Social Study an online survey of 29,148 current, former, and never smokers was conducted to determine general vaccine attitudes and vaccine intentions for the COVID-19 vaccine. Question Topics: 1) Vaccine attitudes 2) Vaccine intentions Survey tools available? No Formative research conducted? Yes Survey pre-tested? No	• Intention to vaccinate was 66% (95% CI: 64.9-67.1%) in former smokers, 65.8% (95% CI: 65.1-66.4%) in never smokers, and 50.9% (95% CI: 49.3-52.6%) in current smokers. • Current smokers were the both the most undecided (27.6%, 95% CI: 26.1-29.1%) and unwilling (21.5%, 95% CI: 20.2-22.9%) to intend to vaccinate once it was available. • Negative attitudes towards vaccines were highest among current smokers (10.6-24.0%), then former smokers (8.8-19.4%), and lowest among never smokers (5.9-17.7%). • Current smokers had the most concerns regarding unforeseen future effects, mistrust of vaccine benefit, commercial profiteering, and had a stronger preference for natural immunity.
Mellis (2021) (144) Cross-sectional study USA Sep 2020	Structured telephone and video interviews of 87 individuals who were either currently using substances, in treatment, or in recovery for substance use were conducted to determine trust and readiness for COVID-19 vaccination. Question Topics: 1) Vaccine intentions 2) Vaccine hesitancy	• 45% of respondents were immediately ready for vaccination, 8% were willing to vaccinate after a delay, 23% were uncertain, and 25% were not willing. • Respondents reported hesitancy due to the rush of the development of the vaccine, potential side-effects, not believing themselves to be high risk, and worry about interactions with pre-existing conditions. • Trusted sources for healthcare decisions included their doctor (including those that were hesitant), family, social media, television/newspapers, radio,

	Survey tools available? No Formative research conducted? No Survey pre-tested? No	official website(s), NIH/CDC, family, research data/medical journals, and the internet. • The potential of a vaccine requiring multiple doses did not change intention to vaccinate, however respondents cited potential barriers such as access to clinics and scheduling appointments.
VULNERABLE COMMUNITIES		
Marquez (2021) *preprint* (3) *new* Cross-sectional study USA Feb-May 2021	A community based vaccine site (Unidos en Salud UeS) was deployed in February to overcome barriers to COVID-19 vaccination faced by Latinx individuals in San Francisco. The community site was assessed through 997 in-person survey responses (May 2-19) for those older than 16 and city COVID-19 surveillance data. Question Topics: 1) Vaccine perceptions Survey tools available? No Formative research conducted? Yes Survey pre-tested? No	• 36.1% of respondents found out about the site from a friend, family member or co-worker, 21.0% by text, 17.8% seeing the site, and 11.4% by direct referral. Latinx respondents were more likely report seeing the site than having gotten a direct invite. • The top cited reason for choosing the community site was the location (28.6%), convenient scheduling (26.9%), and trusted recommendation (18.1%). • 99% of those going to the community site reported having a positive experience. • 58.4% of respondents report that they got vaccinated earlier because of the site (56.1% of Latinx and 63.2% of non-Latinx). • 90.1% of respondents felt they were more likely to recommend getting vaccine after having been vaccinated at UeS. • 65.3% of Latinx clients reached out to 3 or more people to recommend vaccination (55.9% non-Latinx).
Berenson (2021) (235) *new* Cross-sectional study USA Nov-Dec 2020	342 low income women (aged 18-45) were recruited from three reproductive clinics in Texas to anonymously fill out a paper survey in English or Spanish regarding COVID-19 vaccination intentions. Question Topics: 1) Vaccine intentions 2) Vaccine perceptions	• 33.5% of respondents would get a vaccine as soon as possible but this increased if it was employer recommended (33.9%), if friends or family recommended it (36.7%), if it was offered for free (41.8%), or if it was recommended by their doctor (49.5%). • Accepting a doctor recommended COVID-19 vaccine was associated with those that received an annual flu shot, having had the HPV vaccine, being afraid of catching COVID-19, and their feelings

	Survey tools available? No Formative research conducted? No Survey pre-tested? No	being related to information learned from social media. • In multivariate analysis only having had an HPV vaccine and getting the flu shot every year was significantly associated with increase likelihood of accepting a vaccine if it was recommended by a doctor (aOR 2.26 95% CI: 1.07-4.79 and aOR 2.78 95% CI: 1.39-5.58 respectively). • Most respondents reported that they needed more information on vaccine safety (69.2%) and proof that it works (48.1%).
Gehlbach (2021) *preprint* (236) *new* Qualitative study USA Nov-Dec 2021	Semi-structured focus groups conducted on the video-conferencing platform Zoom with 55 Lantinx/Indigenous farm workers in California aimed to elucidate common themes related to COVID-19 attitudes and behaviours. Question Topics: 1) Vaccine perceptions 3) Vaccine attitudes	• Themes encompassed misinformation and barriers to access information (internet access, information in their preferred language, knowledge of appropriate/correct information sources for COVID-19). • Political/institutional (government and public health) mistrust factored into myths related the vaccine as a control method or an expressed desire not to be a guinea pig. • A key factor for both testing and anticipated vaccination behaviour was worry about their documentation status.
Ekezie (2020) (237) Qualitative study UK Jun-July 2020	Three focus groups and 47 semi-structured interviews were used to evaluate the perceptions of ethnic minorities and vulnerable communities towards participation in vaccine trials. The 70 included participants were South Asian, African and Afro-Caribbean, White Polish, White British, and representatives of other vulnerable groups including those with mental health issues, homeless, and Gypsy, Roma and Travellers (GRT) communities.	• General apprehension, scepticism, and low levels of trust were observed within all groups. This was influenced by lack of information and speculation concerning the possible hidden agendas of vaccine developers and the government. • Most participants reported feeling anxious and scared of getting involved or were simply not interested in participating in vaccine trials. • Although hesitant, most South Asian participants were open to participating in research but not necessarily attending hospital-based research. This group was concerned with the vaccine potentially containing animal products which are prohibited in various religions. They also strongly advocated for

		the research to not fall during Ramadan or fasting festivals. • African and Caribbean participants were the most suspicious about the speed of the vaccine development and the intentions of companies involved. There was high mistrust on what would be done with their DNA, and some belief that the vaccine was developed to eradicate Black people. • Those with mental health issues expressed worry about disclosure of mental health details and loss of confidentiality. • The homeless community was reluctant to visit hospitals except for emergencies. This group is often hard to maintain contact with, so may require more face-to-face engagement at their communal locations like food banks. • The Gypsy, Roma and Traveller participants had a very limited interest in taking vaccines and tend to have a fatalistic approach to health issues, believing "what is meant to be, will be".
Scott (2021) (142) Cross-sectional study USA Apr 2020	A survey was mailed to 391 Amish families in Ohio to determine COVID-19 vaccine intentions. Question Topics: 1) Vaccine intentions 2) Vaccine hesitancy Survey tools available? No Formative research conducted? Yes Survey pre-tested? No	• 75.7% did not intend to vaccinate their children against COVID-19. • No significant differences in intention to get a COVID-19 vaccine were seen between those with and without special needs children (14.8% vs. 7.6%, P = 0.053). • Swartzentruber Amish were significantly less likely to intend to vaccinate compared to other Amish affiliations (0.0% vs. 11.7%, P< 0.001). • The top reasons for refusal of vaccines in general included too many side effects (83.9%), they contain dangerous chemicals/preservatives (46.0%), vaccinating means not putting faith in God to protect their children (13.0%), vaccinating introduces germs (9.6%), other families don't vaccinate (7.0%), and the diseases that are vaccinated for are not a problem in their community (6.1%).

		• Citing doctors or nurses as the most influential person in the decision to vaccinate were more likely to take all recommended vaccines compared to those who took no vaccines (52.2% vs. 2.6% P < 0.001). However, families that refused all recommended vaccinations were more likely to state their bishop or minister was the most influential person in the decision to vaccinate compared to families that took all vaccines (4.4% vs 0.0%, P=0.003).
GENERAL		
Horizon Research (2021) *unpublished* (15, 195) Longitudinal study New Zealand Mar-May 2021	An online survey of adults (16+) was conducted to measure vaccine intentions. Mar-Apr, n=1,350 Apr-May, n=1387 Question Topics: 1) Vaccine intentions Survey tools available? Yes Formative research conducted? No Survey pre-tested? No	• 83% of those at high risk for getting very ill were intending to get vaccinated or were already vaccinated and 5% reported they definitely will not get a vaccine.

CDC = Centers for Disease Control and Prevention, NIH = National Institutes of Health

INDIVIDUALS WITH COMORBIDITIES OR DISABILITIES

Table 6. Evidence of vaccine attitudes of individuals with comorbidities (n=23)

STUDY	METHODS & SURVEY TOOLS	KEY KAB OUTCOMES
CANADA		

Vallis (2021) (164) Cross-sectional study Canada Jun-Oct 2020	Attitudes and concerns towards COVID-19 vaccination in individuals living with overweight and obesity were evaluated using an online survey. Two samples were used: 1) representative sample of 1089 individuals living with overweight and obesity and 2) convenience sample of 980 individuals recruited from obesity clinical services or patient organizations throughout Canada. Question Topics: 1) Vaccine intentions 2) Vaccine hesitancy Survey tools available? No Formative research conducted? Yes Survey pre-tested? No	• 64.6% of those living with obesity were comfortable receiving a vaccine and 35.4% were hesitant. • Individuals were less comfortable with their children receiving the vaccine (58.5% comfortable, 41.6% hesitant, P<0.001). • The mean score on the confidence subscale of the vaccine hesitancy scale was significantly lower than any other measure (mean = 2.26). • Fear of COVID-19 was a predictor of vaccine attitudes for all dependent measures. • Comfort levels in receiving the vaccine were positively associated with male gender, having more comorbidities, having lower depression scores, not practicing social distancing, and past acceptance of influenza vaccinations.
AUSTRALIA & NEW ZEALAND		
Horizon Research (2021) *unpublished* (15, 195, 232) Longitudinal study New Zealand Mar-May 2021	An online survey of adults (16+) was conducted to measure vaccine intentions. Mar-Apr, n=1,350 Apr-May, n=1387 May, n=1,234 *new* Question Topics: 1) Vaccine intentions Survey tools available? Yes Formative research conducted? No Survey pre-tested? No	**May** • 13% of respondents who identified as being disabled or having chronic conditions reported they were unlikely to vaccinate. • Reasons not to vaccinate included safety concerns (49%), a belief that a vaccine was not needed (21%), and a mistrust of vaccines in general (18%). **Apr-May** • 77% of those living with impairments or long-term health conditions were likely to accept a vaccine or had been vaccinated compared to 5% report they definitely will not get a vaccine. • 70% identifying themselves to be disabled were likely to accept a vaccine or had been vaccinated compared to 5% report they definitely will not get a vaccine.

Australia Bureau of Statistics (2021) *unpublished* (141) *new* Longitudinal study Australia Apr 2020-May 2021	The household impacts survey is a monthly survey which collects data online and by telephone from a panel of adults (18+) on COVID-19 related topics including attitudes towards vaccines. May: n=3,371 Question Topics: 1) Vaccine intentions 2) Vaccine hesitancy Survey tools available? No Formative research conducted? No Survey pre-tested? No	• Those with disabilities or long term conditions were slightly more likely to intend to vaccinate compared to those without (68.6% for disabled vs 68.1% not disabled and 70.1% with long term health conditions vs 66.5% for those without long term health conditions). • The main factor for deciding to get a vaccine is a recommendation from their general practitioner (33.7% and 31.0% respectively for disability and chronic conditions). • Concerns for side effects dominated the reasons for not wanting to get vaccine (62.7% for those with disabilities and 62.1% with chronic conditions).
Bonner (2020) *preprint* (152) Longitudinal study Australia Apr & Jun 2020	People with self-reported hypertension (n=466) were compared to matched healthy controls (n=466) during COVID-19 lockdown to determine whether they have higher risk perceptions, anxiety, and prevention intentions. Using an online survey, vaccine intention was asked during the lockdown and again 2 months after restrictions eased. Question Topics: 1) Vaccine intentions Survey tools available? No Formative research conducted? No Survey pre-tested? No	• At baseline, 87% of the people with hypertension and 85% of the healthy matched controls stated they would get the COVID-19 vaccine. • There were no significant differences in willingness to vaccinate for COVID-19 between people with hypertension and healthy matched controls. • Despite a decrease in perceived seriousness and anxiety two months after lockdown restrictions lifted, intentions remained high (>80%) for COVID-19 vaccination at follow-up.
USA		

Ricotta (2021) *preprint* (153) Cross-sectional study USA Feb 2021	To assess vaccine acceptance in individuals with chronic respiratory or autoimmune diseases, an online survey was conducted in 1232 individuals with self-reported a chronic respiratory or autoimmune disease and 1303 healthy controls across the USA. Question Topics: 1) Vaccine intentions 2) Vaccine hesitancy Survey tools available? No Formative research conducted? Yes Survey pre-tested? No	• Compared to healthy controls, those who reported chronic respiratory diseases were 5.7% more willing to be vaccinated (95% CI: 0.05-0.09). • When asked about reasons for intending to vaccinate, those with chronic respiratory disease (OR 1.08, 95% CI: 1.03-1.13) and autoimmune diseases (OR 1.06, 95% CI: 1.01-1.11) were more likely to vaccinate to protect themselves from COVID-19 compared to controls. Those with chronic respiratory diseases were also more likely to want to safely return to work (OR 1.08, CI: 1.03-1.14). • Of those who do not intend to vaccinate, individuals with autoimmune diseases were the only group to have a significant association with a particular cause for hesitancy. These individuals were more likely to report fear of a bad vaccine reaction as the reason for hesitancy (OR 1.22, 95% CI: 1.06-1.41).
Garcia (2021) (156) Cross-sectional study USA Jan – Feb 2021	An online survey in 150 randomly selected dialysis facilities in the USA was conducted to evaluate vaccine intentions and hesitancy in 1,515 patients on hemodialysis. Question Topics: 1) Vaccine intentions 2) Vaccine hesitancy Survey tools available? Yes Formative research conducted? Yes Survey pre-tested? Yes	• 20% were reluctant to accept a vaccine even if it was considered safe for the general population. If the vaccine was offered at the dialysis facility, this hesitancy decreased to 18%. • Vaccine hesitancy was highest in patients aged 18–44 years (aOR 1.5, 95% CI, 1.0-2.3), women (aOR 1.6, 95% CI: 1.2-2.0), Black patients (aOR 1.9, 95% CI: 1.3-2.7), and patients identifying as other race or ethnicity (aOR 2.0, 95% CI: 1.1-3.7). • Vaccine hesitancy was lower in patients aged 80+ (aOR 0.4, 95% CI: 0.3-0.7), those with some college education (aOR 0.4, 95% CI: 0.2-0.6), and those who received the influenza vaccine (aOR 0.2, 95% CI: 0.1-0.3). • 53% of those who were vaccine hesitant expressed concerns about side effects.
Tsai (2021) *preprint* (160)	An international online survey was conducted to measure vaccine hesitancy among 21,943 individuals with high risk conditions such as	• 25% of respondents had received at least one vaccine with a further 7% trying to get the vaccine but unable to get one.

Cross-sectional study USA Jan-Feb 2021	with cancer, autoimmune disease, and other comorbid conditions. 74% of participants were from the USA and 4% from Canada. Question Topics: 1) Vaccine intentions 2) Vaccine hesitancy Survey tools available? No Formative research conducted? No Survey pre-tested? No	• 43% planned on definitely getting a vaccine, 5% probably will, 5% were unsure, 4% probably will not receive a vaccine, and 10% definitely will not accept. • Broken down by conditions, current smokers were the most hesitant (29%) followed by those with obesity (20%), type 2 diabetes (19%), hypertension (18%), and chronic lung disease (18%). • Those with past cancer treatment had a higher level hesitancy than those currently undergoing cancer treatment (13% vs 11%). • Vaccine hesitancy was associated with younger age, female gender, Black-Pacific-Island-Native American ethnicity, less education, conservative political tendencies, resistance to masks or routine influenza vaccinations, and distrust of media coverage. • Those who responded with some level of vaccine hesitancy indicated that the vaccine was too new (53%), were worried about side effects or discomfort (44%), felt the process had been implicated with politics (39%), and wanted to wait until others have taken it (33%). • 21% reported not trusting vaccines in general but were more negative towards the COVID-19 vaccine in particular (40%).
Iadarola (2021) *preprint* (157) Cross-sectional study USA Jan-Feb 2021	Intention to vaccinate was evaluated using an online survey of 825 individuals with intellectual and developmental disabilities (IDD) and their family members and care workers in New York State. Question Topics: 1) Vaccine intentions 2) Vaccine hesitancy Survey tools available? No	• 62% of respondents would definitely or probably get a COVID-19 vaccine and 13.9% had already received the vaccine. • Vaccine hesitancy was greater in those that were younger and those making decisions on behalf of a person with IDD. • Black respondents > 50 years old were more likely intend to vaccinate or already have received a vaccine compared to younger respondents (OR 3.72, 95% CI: 1.73-8.00), in addition to White respondents > 50 years old (OR 2.39, 95% CI: 1.36-4.17).

	Formative research conducted? Yes Survey pre-tested? No	• The most common reasons for vaccine hesitancy were concern about side effects (16%), belief that the vaccine was too new (15%), not wanting to be an 'experiment' for the vaccine (14%), and mistrust of the government (14%). • Hispanic and Black respondents (96% and 91%, respectively) reported concerns about being used as an 'experiment' more often than White or Asian respondents (76% and 67%, respectively). • Health professionals (92%) were the most trusted source of vaccine information followed by friends and family (74%).
McCabe (2021) *preprint* (166) Cross-sectional study USA Dec 2020-Feb 2021	A national app distributed survey was conducted in 34,470 healthcare workers and adults from the general population to measure intent to receive a vaccine and factors associated with acceptance and refusal. Number of healthcare workers was not reported. Question Topics: 1) Vaccine intentions 2) Vaccine hesitancy Survey tools available? Yes Formative research conducted? No Survey pre-tested? Yes	• Those with 3 or more pre-existing conditions were 1.19 times more likely than those without any to be vaccine hesitant (aOR 1.19, 95% CI: 1.06-1.34, P=0.0045).
Xiang (2021) (162) *new* Cross-sectional survey USA	An online survey of 401 multiple sclerosis patients across the USA (the majority in Oregon, Washington, and California) was conducted to assess vaccine intentions. Question Topics: 1) Vaccine intentions	• 70.1% were willing to get a vaccine, 7.2% would not be willing, and 22.7% were unsure. • Most respondents were motivated by wanting to protect themselves (77.6%) or their loved ones (58.7%), and to decrease chances of serious illness (53.4%). • Among those intending to decline a vaccine the top reasons included worry for potential side effects (55.2%), speed of vaccine development

Dec 2020-Jan 2021	2) Vaccine hesitancy 3) Vaccine perceptions Survey tools available? Yes Formative research conducted? No Survey pre-tested? No	(55.2%), and wanting more safety evidence due to the rushed development (44.8%). • Undecided respondents expressed wanting population safety information (57.1%). The undecided also held beliefs that political pressure factored into vaccine trials (37.4%) and wanted people without MS to get the vaccine due to safety concerns (29.7%). • Multivariate analysis found higher intention to vaccinate among those who have talked to or plan to talk to their MS doctor about the vaccine (aOR 2.93, 95% CI: 1.32- 6.49 and 2.57, 95% CI: 1.38-4.80, respectively), prior flu vaccination (most years aOR 5.59, 95% CI: 2.44-12.77 and every year aOR 8.96, 95% CI:4.39-18.31), any amount of concern about COVID-19, any level of worry about their risk of hospitalization or death, and not socializing in public but in the home (aOR 14.07, 95% CI:1.43-138.33) or only virtual socialization (aOR 17.53, 95% CI:1.80-170.60).
Kelkar (2021) (154) Before-and-after study USA Dec 2020 – Jan 2021	This study aimed to determine if a webinar would increase knowledge about COVID-19 vaccines and impact intention to vaccinate. 264 people with cancer or their caregivers in Florida participated in the webinar and registered to take at least one online survey (pre and post webinar), of which 105 answered both surveys. Question Topics: 1) Vaccine intentions 2) Vaccine hesitancy Survey tools available? Yes Formative research conducted? No Survey pre-tested? No	• Prior to the webinar, 71% intended to vaccinate, 5% would not receive a vaccine, and 24% were unsure. • 97/105 individuals answered the specific question about vaccine intention in both the pre- and post-webinar survey. After the webinar, 82.5% intended to vaccinate, 2.1% would not receive a vaccine, and 15.5% were unsure. • The most common reasons for hesitancy included concern about side effects vaccine (30%), a lack of information on vaccine effectiveness (14%), and a lack of trust that the vaccine is safe for cancer patients (8%).

Dalal (2021) (149) Cross-sectional study USA Dec 2020-Jan 2021	An online survey of 906 adults with an irritable bowel disease (IBD) from a Boston hospital or through IBD related social media (SM) was conducted to evaluate their intentions to be vaccinated and identify potential concerns. Question Topics: 1) Vaccine intentions 2) Vaccine hesitancy Survey tools available? No Formative research conducted? No Survey pre-tested? No	• Intention to get a vaccine was high among locally recruited respondents (80.9%) compared to 60.0% of those recruited from social media. • The most common reasons for hesitancy across both groups included worry about long term effects and adverse reactions, want to see how others tolerate the vaccine, worry that the vaccine did not have the regular amount of safety checks, concern that vaccine with interfere with IBD medication efficacy, and a personal history of allergic reactions. • A recommendation from their IBD healthcare provider was reported to be important in both locally acquired (92%) and social media respondents (80.6%). • From their IBD provider respondents wanted to hear about risks and benefits, receive a handout, provide information regarding safety/efficacy for those with IBD/other autoimmune disorders, and safety/efficacy with IBD medications. • Intention to vaccinate was positively associated with age (OR 2.21, 95% CI: 1.07–4.54), having a bachelors degree or more (OR 3.31, 95% CI: 1.36–8.06), being White (OR 2.13, 95% CI: 1.17–3.85), having had COVID-19 (OR 2.02, 95% CI: 1.09–3.73), or currently being on a biologic (OR 1.52 95% CI: 1.07–2.16).
Serper (2021) (159) Cross-sectional study USA Dec 2020	To assess attitudes and intentions regarding COVID-19 vaccines, an online survey was conducted with 1215 patients who receive care for chronic gastrointestinal and liver conditions (irritable bowel syndrome, cirrhosis, or liver transplant recipients) within a large healthcare system in Southeastern Pennsylvania.	• 85% completely or somewhat agreed that they would take the vaccine if available, 7% were neutral, and 8% completely or somewhat disagreed. • Reported vaccine concerns included safety (54%), effectiveness (26.7%), not being prioritized for the vaccine (39%), cost (17.4%), and inconvenience (10.3%). • Respondents were more likely to accept a COVID-19 vaccine at a medical office or pharmacy, compared to drive-through sites, places of

	Question Topics: 1) Vaccine intentions 2) Vaccine attitudes 3) Vaccine hesitancy Survey tools available? Yes Formative research conducted? Yes Survey pre-tested? No	employment, or community sites (e.g., church, school). • More than 75% would follow their government or doctor's recommendation about receiving the COVID-19 vaccine, 91% would follow their GI/liver specialist's recommendation, and 56% would follow their employer's recommendation. • Females (aOR 2.02, 95% CI: 1.40-2.92, P<0.001) and those with lower incomes (aOR 2.17, 95% CI: 1.26-3.74, P=0.005) were more likely to be vaccine hesitant and those aged 65+ (aOR 0.52, 95% CI: 0.30-0.92, P=0.024) and with prior receipt of annual flu vaccine (aOR 0.11, 95% CI: 0.07-0.10, p<0.0001) were less hesitant.
Ou (2021) (165) *new* Cross-sectional study USA Nov-Dec 2020	Attitudes towards a potential COVID-19 vaccine was assessed in 1308 solid organ transplant recipients (SOTRs) and 1617 non-SOTRs through an online survey. Question Topics: 1) Vaccine intentions 2) Vaccine attitudes Survey tools available? No Formative research conducted? Yes Survey pre-tested? Yes	• 50.5% of SOTRs and 60.7% of non-SOTRs intended to accept a vaccine. • 49.5% of SOTRs and 39.3% non-SOTRs did not intend to receive a vaccine. • In SOTRs, those who were unlikely or hesitant were more likely to be between 30-49 years old, women, Black, non-USA residents, had a high school diploma or less, were not married, had household income of less than $30,000, had not received a flu shot in the past year, did not plan on getting the flu vaccine in the current year, believed that transplant patients are at greater risk for illness from the vaccine, believed that the COVID-19 vaccine could lead to rejection, and did not believe vaccines to be safe for transplant patients. • 80.0% of SOTRs reported that they needed information from their doctor or an assurance of personal health/health compatibility with the vaccine (75.4%). This was 86.8% if recommended by their transplant surgeon, 71.9% if from another member of transplant team, and 64.1% if it was from their primary care doctor. • SOTRs were more likely to perceive vaccine as necessary and that vaccines work, express comfort with vaccines, not fear vaccines, trust

		pharmaceutical companies, the CDC, and vaccine in general as compared to non-SOTRs. • Fewer non-SOTRs living with an SOTR compared to those not living with an SOTR report that they intend to get vaccinated (57.6% vs 61.3%). This remained true if the vaccine was recommended by a doctor (73.9% vs 76.7%) but not if they felt that SOTRs should get a vaccine (52.2 vs 52.0%). • The announcement of Moderna efficacy slightly increased intention to vaccinate from 53.5% to 57.8% post announcement.
Rodriguez (2021) (238) *new* Cross-sectional study USA May-Dec 2020	A sample of 175 people with HIV (PWH) over the age of 18 were surveyed online to validate the Vaccine Hesitancy Scale (VHS) with a focus on understanding COVID-19 vaccine attitudes and willingness to get vaccinated. Question Topics: 1) Vaccine intentions 2) Vaccine attitudes 3) Vaccine hesitancy Survey tools available? Yes Formative research conducted? No Survey pre-tested? No	• Lack of confidence and risks respectively explained 45.55% and 12.31% of the variance in vaccine hesitancy responses. • Mean responses find that vaccine hesitancy scores were higher among those that didn't believe the vaccine would be effective, those that wouldn't be swayed by a healthcare provider recommendation, did not think it was important they got vaccinated due to their health conditions, and that they wouldn't get vaccinated if it was required to get back to ordinary life. • Mean vaccine hesitancy scores were lower for respondents who didn't believe their health conditions would be made worse by the vaccine.
Jones (2021) (239) Cross-sectional study USA Aug – Nov 2020	An online survey of 94 adults (18+) living with HIV in Miami, Florida from underrepresented ethno-racial groups was conducted to evaluate intention to vaccinate and factors associated with hesitancy. Participants were Black non-Latinx (60%) and non-Black Latinx (40%). Question Topics:	• Compared to non-Black Latinx, Black non-Latinx participants were less likely to agree with vaccinations being important for their health (92% vs 68%, P=0.009), to believe that vaccines are effective in preventing disease (84% vs 68% P=0.029), and to believe that vaccine information is reliable and trustworthy (71% vs 36%, P=0.002). • Intention to vaccinate was positively associated with the belief that vaccines are important (OR 12.0, 95% CI: 3.22-44.8, P<0.001) and effective (OR 5.71, 95% CI: 1.78-14.59, P=0.001), agreeing that

	1) Vaccine intentions 2) Vaccine hesitancy 3) Vaccine attitudes Survey tools available? Yes Formative research conducted? Yes Survey pre-tested? No	information about vaccines is reliable and trustworthy (OR 6.76, 95% CI: 2.71-16.88, P=0.001), belief they should follow doctors orders (OR 5.28, 95% CI: 1.57-17.71, P=0.001), and believing that a vaccine is the best way to protect from disease (OR 7.07, 95% CI: 2.14-23.42, P<0.001).
Bogart (2020) (158) Cross-sectional study USA May-Jul 2020	101 Black people living with HIV were surveyed by telephone to assess associations between medical mistrust, vaccine intentions, and vaccine hesitancy. Question Topics: 1) Vaccine intentions 2) Vaccine hesitancy Survey tools available? No Formative research conducted? No Survey pre-tested? No	• The most common COVID-19 vaccine beliefs were that the vaccine would be harmful (51%), they would not trust it (34%), and they would not want to get a vaccine (32%). • Multivariate analysis found that greater COVID-19 related mistrust was significantly associated with vaccine hesitancy [b (SE) = 0.85 (0.14), P < 0.000]). • Pearson correlations indicated that participants with less than a high school education showed higher levels of vaccine hesitancy (r = 0.20, P = 0.04).
Ehde (2021) (148) Cross-sectional study USA Apr-May 2020	Factors associated with intention to receive a COVID-19 vaccine was assessed in 486 adults (18+) living with multiple sclerosis using an online survey. Question Topics: 1) Vaccine intentions Survey tools available? No Formative research conducted? Yes Survey pre-tested? No	• 66.0% of participants were willing to take a vaccine when available, 18.5% were moderately willing, and 15.5% were not willing. • Statistically significant predictors of an increased willingness to vaccinate include higher education (β =0.20, P <0.001) and perceiving oneself to be at greater risk of contracting COVID-19 (β =0.18, P =0.001). • Participants believed that healthcare providers and the National MS Society had the highest perceived trustworthiness for COVID-19 information. The perceived trustworthiness of information sources was highly associated with intention to vaccinate.
Rungkitwattana kul (2021) (155)	To evaluate intentions to vaccinate, an online survey of 90 patients at an urban dialysis center in Washington DC which serves a	• 49% of respondents indicated they would be willing to receive a COVID-19 vaccine, 34% were unwilling, and 17% were unsure.

Cross-sectional study USA Date NR	predominately African American patient population was conducted. Question Topics: 1) Vaccine intentions 2) Vaccine hesitancy Survey tools available? No Formative research conducted? No Survey pre-tested? No	• Intention to receive a COVID-19 vaccine was associated with having received the influenza vaccine P < 0.001. • The most common reasons for vaccine hesitancy included a lack of adequate information regarding safety and efficacy (46.8%), lack of trust in the federal government (36.4%), and a lack of trust in the vaccine manufacturers (28.9%).
UNITED KINGDOM		
Office for National Statistics (2021) & Office of National Statistics (2021) *unpublished* (43, 140) Longitudinal study UK Feb-Apr 2021	Responses from four waves of results collected from the online Opinions and Lifestyle Survey (196) were pooled to focus on demographic specific associations with vaccine hesitancy. The number of disabled or clinically extremely vulnerable were not reported. Feb-Mar: 17,201 responses pooled Mar-Apr: 16,362 responses pooled Questions Topics: 1) Vaccine intentions 2) Vaccine hesitancy Survey tools available? Yes Formative research conducted? Yes Survey pre-tested? Yes	**Mar-Apr** • Disabled adults had slightly less vaccine hesitancy compared adults who were not disabled (5% vs 7%). Hesitancy has decreased since last reporting (8% and 9% respectively). • Clinically extremely vulnerable (CEV) respondents had significantly less hesitancy than non-CEV respondents (4% vs 7%). • Significantly more non-CEV respondents report they are likely to get a vaccine (31%) compared to less than 1% of CEV are unlikely to get vaccine. **Feb-Mar** • The most common reasons for hesitancy among disabled adults were concerns about existing health conditions (48%), followed by concerns about side effects (46%), and waiting to see if the vaccine works (43%). • The most common reasons for hesitancy among CEV adults were concerns about side effects (49%), followed by worries about long-term effects (47%), and concerns about existing health conditions (42%). • Respondents with underlying health conditions had less hesitancy that those without (6% vs 10%).
Saunders (2021)	Vaccine intentions and attitudes towards COVID-19 risks were	• 91.5% of respondents reported that they had been vaccinated (93.5% of these were first dose only).

(163) *new* Cross-sectional study UK Mar 2021	measured online in 964 individuals with chronic myeloproliferative neoplasm (MPN). Question Topics: 1) Vaccine intentions 2) Vaccine hesitancy Survey tools available? No Formative research conducted? No Survey pre-tested? No	• 0.03% (29/964) were booked for their first dose, 0.05% (53/964) were not booked for a dose, of which 14 had been offered and 38 had not been offered a dose. • 0.8% (n=8) refused vaccination for reasons including side effects (n=5), quick development of the vaccine (n=4), safety (n=3), and perceived efficacy for MPNs (n=2). Open text responses included possible immune stress with consideration of past COVID-19 infection, alternative medicine didn't recommend it, and wanted to discuss with their oncology doctor. • 16.7% of those who had been vaccinated expressed concern about vaccination due to potential serious reaction (30.6%), efficacy in MPN patients (15.4%), vaccine interfere with MPN condition (14.3%) or MPN medications (10.2%). • 82.9% of the vaccinated respondents had no overall vaccine preference, 65.2% preferred Pfizer, 30.4% AstraZeneca, 2.9% Moderna, and 1.4% other. • 89.0% of respondents trusted their healthcare provider to inform them of risks and benefits. • For the 97 respondents who didn't trust their healthcare provider the main reason is that they didn't not know enough about the vaccine (34.0%), benefits (30.0%), or knowledge of MPN or vaccines in patients with MPN (12.0%), and mistrust of their primary care physician.
Bateman (2021) (240) *new* Quasi-experimental study UK	An 8 minute educational video was sent via text to a cohort of 661 rheumatology patients to measure the impact of the video on intention to vaccinate. Questions Topics: 1) Vaccine intentions	• Of the 8886 patients sent the text message with video link 2358 had viewed the video (27%) and 661 completed the evaluation. • Pre-video, 36% of patients aged 30-49, 47% of those aged 50-69, and 52% aged 70+ reported that they were aware of COVID-19 vaccines and that they were recommended for them. After video viewing this increased to 88%, 92%, and 94% for these respective age categories.

Dec 2020	Survey tools available? No Formative research conducted? No Survey pre-tested? No	• On a scale of 1 (strongly disagree) to 5 (strongly agree) respondents felt more informed (mean = 4.1), more confident about getting a vaccine (mean = 4.2), reported that they would seek vaccination (mean= 4.1), and that the video was helpful for sharing information (mean = 4.4). • Older patients (50+) were more likely to report that they learned more, felt more confident, and were more likely to get vaccinated compared to those aged 30-49.
USA & UK		
Felten (2021) (161) Cross-sectional study 56 countries Dec 2020	Vaccine intentions and hesitancy in 1258 patients with autoimmune or inflammatory rheumatic diseases (AIIRD) was evaluated using an online survey. There were 327 individuals from the UK and 114 from the USA. Question Topics: 1) Vaccine intentions 2) Vaccine hesitancy Survey tools available? Yes Formative research conducted? Yes Survey pre-tested? No	• Among those with AIIRD in the UK, 39.4% would be willing to accept a vaccine, 31.3% were hesitant, and 10.5% were suspicious. • In the USA, 15.6% were willing to accept a vaccine, 9.2% were hesitant, and 5.9% were suspicious. • AIIRD patients who were suspicious of the vaccine were significantly more concerned about vaccination in general, thought it was less important to get vaccinated, were concerned about the use of a new vaccine technology, lack of hindsight regarding COVID vaccination, and potential financial links between governments and pharmaceutical companies. • Those who were hesitant or suspicious were significantly more concerned that the vaccine would induce a flare of their disease. • Men were more likely to intend to vaccinate compared to women (P<0.0001) and younger individuals were less likely than older individuals (P<0.0001).

OTHER POPULATIONS OF INTEREST

Table 7. Evidence of vaccine attitudes of other populations of interest (n=61)

STUDY	METHODS & SURVEY TOOLS	KEY KAB OUTCOMES
LGBTQ+		
CANADA		

Statistic Canada (2020) *unpublished* (78) Cross-sectional study Canada Sept-Oct 2020	A telephone survey of 120,000 (18+) was conducted to assess intention to vaccinate. Question Topics: 1) Vaccine intentions Survey tools available? Yes Formative research conducted? Yes Survey pre-tested? Yes	• 87.6% of LGBTQ2+ were willing to accept a vaccine compared to 76.4% non-LGBTQ2+.
Ogilvie (2021) (79) Cross-sectional study Canada Aug-Sep 2020	Intention to vaccinate was assessed in 4058 adults and healthcare workers from British Columbia (25-69 years old). Question Topics: 1) Vaccine intentions Survey tools available? Yes Formative research conducted? Yes Survey pre-tested? Yes	• Non-binary, gender queer, agender, two-spirit or other were more likely to be receive a vaccine (OR 3.04, 95% CI: 1.08-8.55, P<0.04).
Statistics Canada (2020) & Statistics Canada (2021) *unpublished* (65, 80) Longitudinal study Canada	An online survey conducted by Statistics Canada as part of the Canadian Community Health Survey (CCHS) assessed Canadians behaviors to safeguard their own health as well as the health of others. In the September survey, a question about vaccine intentions was added. The most recent report captures 20,000 responses from individuals aged 12+. Question Topics:	• Over the sampling period 77% were willing to receive a vaccine. This represents an increase from Sept (75.5%) to Oct (74.8%), and Nov/Dec (80.3%). • LGBTQ2+ were more likely to get a vaccine (83.3%).

Sep-Dec 2020	1) Vaccine intentions Survey tools available? Yes Formative research conducted? Yes Survey pre-tested? Yes	
USA		
Bogart (2021) (170) *new* Cross-sectional study USA Nov-Dec 2020	207 Black people drawn from the nationally representative RAND American Life Panel (ALP) and were surveyed online to assess associations between medical mistrust, vaccine intentions, and vaccine hesitancy. Question Topics: 1) Vaccine intentions Survey tools available? No Formative research conducted? No Survey pre-tested? No	• Sexual or gender minorities were not statistically predictive of negative or positive intentions to get a vaccine (positive intent P = 0.56 and negative intent P = 0.41).
Teixeira da Silva (2021) (167) Cross-sectional study USA Oct-Dec 2020	Vaccines acceptance was assessed in 1350 sexual and gender minority (SGM) individuals using an online survey across the USA. Question Topics: 1) Vaccine intentions Survey tools available? No Formative research conducted? No Survey pre-tested? No	• On a 10-point scale with 10 being "highly likely and 1 being "very unlikely", intention to vaccinate was moderately high (mean score = 7, SD = 3.12). • Compared to gay men, participants grouped in the "Other" sexual identity category were less likely to intend to vaccinate (β = −1.102, P = 0.047). There were no other differences by sexual identity (bisexual, queer, multiple identities, same-gender loving). • Compared to White participants, Black (β = −0.681, P < 0.001), American Indian/Alaskan Native (β = −2.482, P < 0.001), and participants identifying with another race (β = −1.174, P < 0.001) were more willing to intend to vaccinate. Asian participants (β = 0.718, P = 0.018) were more likely to intend to vaccinate compared to White.

		• Vaccine acceptance was negatively associated with more social concerns regarding the vaccine (β = −0.10, $p < 0.001$) and medical mistrust (β = −0.06, $p < 0.05$) and positively associated with altruistic motivations (β = 0.60, $p < 0.001$).
Phillips (2021) (169) *new* Cross-sectional study USA Apr-Aug 2020	Sexual/gender minority and people living HIV (PLWH) differences in acceptance of a COVID-19 vaccine were measured through an online survey of 932 adults (over 18). Question Topics: 1) Vaccine intentions Survey tools available? No Formative research conducted? No Survey pre-tested? No	• 91.8% would consider getting a COVID-19 vaccine and 8.2% would not. • Bisexual and pansexual respondents had significantly increased odds of considering a COVID-19 vaccine (OR 1.69, 95% CI: 1.01-2.82) as compared to gay or lesbian respondents as were gender non-binary (OR 4.38, 95% CI: 1.33–14.4) compared to respondents with male gender identies or transgender (OR 2.30 95% CI: 1.08–4.88) compared to non-transgender respondents. • HIV positive individuals were significantly less likely to consider COVID-19 vaccination (OR 0.40, 95% CI: 0.23–0.67) compared to HIV negative respondents.
Melin (2021) *preprint* (168) Cross-sectional study USA Jul 2020	Factors associated with the intention to vaccinate against COVID-19 among 1016 adults (21+) living in Puerto Rico was assessed using an online survey. Question Topics: 1) Vaccine intentions 2) Vaccine hesitancy Survey tools available? No Formative research conducted? No Survey pre-tested? No	• In the bivariate analysis, homosexual (81.8%), bisexual (85.7%), and other (90.9%) sexual identity were all associated with increased intention to be vaccinated when compared to heterosexual (66.4%), P<0.001. • After adjustment in the multivariate regression analysis, this relationship was not significant (homosexual: aOR 0.9, P=0.72; bisexual: aOR 2.1, P=0.08; other sexual identity: aOR 3.4, P=0.25).
PARENTS		
CANADA		
Government of Manitoba (2021)	An online research panel of 600 Manitobans were surveyed to understand attitudes towards	• In a group of 70 parents or guardians of children aged 12-17, 15% were not sure if they will vaccinate their children, and 13% will not vaccinate their children.

unpublished (11) *new* Longitudinal study Canada May 2021	vaccination and possible incentives to increase uptake. Question Topics: 1) Vaccine intentions 2) Vaccine perceptions Survey tools available? No Formative research conducted? No Survey pre-tested? No	• Those who did not intend to vaccinate their children were in households making less than $40,000, would not get the vaccine themselves, and didn't believe adults should get all the regular vaccines.
McKinnon (2021) *preprint* (18) Cross-sectional study Canada Jan – Apr 2021	Willingness to vaccinate children according to level of education, neighbourhood, and visible minority status was evaluated using an online survey in 380 parents with children aged 2-17 in Montreal. Question Topics: 1) Vaccine intentions 2) Vaccine hesitancy Survey tools available? No Formative research conducted? No Survey pre-tested? No	• Parents were 61% very likely, 25% somewhat likely, 9.2% somewhat unlikely, and 4.5% very unlikely to have their child vaccinated. • Concern over the lack of information about the vaccine's safety and possible side effects was the most common reason for hesitancy (48%). • Comparing visible minority to non-visible minority parents, 30.3% vs. 66.6% were very likely to vaccinate their children, 36.8% vs. 23.9% were somewhat likely, and 32.9% vs. 9.5% were unlikely to vaccinate, respectively.
Vallis (2021) (164) Cross-sectional study Canada Jun-Oct 2020	Attitudes and concerns towards COVID-19 vaccination in individuals living with overweight and obesity were evaluated using an online survey. Two samples were used: 1) representative sample of 1089 individuals living with overweight and obesity and 2) convenience sample of 980 individuals recruited from obesity clinical services or patient organizations.	• 64.6% of those living with obesity were comfortable receiving a vaccine and 35.4% were hesitant. • Individuals were less comfortable with their children receiving the vaccine (58.5% comfortable, 41.6% hesitant, $P<0.001$).

	Question Topics: 1) Vaccine intentions 2) Vaccine hesitancy Survey tools available? No Formative research conducted? Yes Survey pre-tested? No	
Drouin (2021) *preprint* (151) Cross-sectional study Canada Aug 2020	Parental intention to have their child with asthma vaccinated against COVID-19 was assessed using an online survey in 305 parents. Question Topics: 1) Vaccine intentions 2) Vaccine hesitancy Survey tools available? No Formative research conducted? No Survey pre-tested? No	• 63% of parents were likely to have their child vaccinated, 19.1% were unlikely, and 17% were unsure. For themselves, 64% were likely to get vaccinated, 21% were unlikely, and 15.1% were unsure. There was a strong relationship between a parents' intention to vaccinate their children and person intention to vaccinate. • Factors significantly associated with a parents' decision to vaccinate their child included higher level of education, being employed, sex of the child (female), presence of other chronic diseases, prior influenza vaccination, parental anxiety, and consultation with a health professional.
Lackner (2021) (189) Cross-sectional study Canada May-Jun 2020	The demographic, experiential, and psychological factors associated with the anticipated likelihood and speed of having children receive a COVID-19 vaccine was investigated in 455 families (857 children). Question Topics: 1) Vaccine intentions Survey tools available? No Formative research conducted? Yes Survey pre-tested? No	• Factors associated with a higher likelihood of having their children vaccinated include older parental age, living in the Prairies (relative to Central Canada), more complete child and parental vaccination history, positive attitudes towards vaccines in general, higher psychological avoidance of the pandemic, and a greater tendency to prioritize the risks of the disease relative to the risks of side-effects. • In some models, perceived COVID-19 risk and higher levels of state anxiety were associated with increased likelihood of having children vaccinated. • The above factors were also predictors of faster speed of intended vaccination. However, higher SES was a trend-level predictor.
GLOBAL		

Skjefte (2021) (135) Cross-sectional study 16 countries: Australia, Africa, Argentina, Brazil, Chile, Colombia, India, Italy, Mexico, New Zealand, Peru, Philippines, Russia, Spain, UK, USA. Oct-Nov 2020	An online survey was used to evaluate the acceptance of COVID-19 vaccination among 5,294 pregnant women and 12,562 mothers of children younger than 18-years-old. Question Topics: 1) Vaccine intentions 2) Vaccine hesitancy Survey tools available? No Formative research conducted? No Survey pre-tested? No	• 69.2% of all women intended to vaccinate their children. Acceptance levels were above 85% in India, Mexico, Brazil and Colombia and below 52% for the USA, Australia, and Russia. • For mothers, the most common reasons to decline a vaccine were concern that approval of the vaccine will be rushed for political reasons (39.8%), lack of safety and effectiveness data among children (32.7%), and worry about safety and side effects (28.4%).
UNITED KINGDOM		
Office for National Statistics (2021) & Office of National Statistics (2021) *unpublished* (43, 140) Longitudinal study UK Feb-Apr 2021	Responses from four waves of results collected from the online Opinions and Lifestyle Survey (196) were pooled to focus on demographic specific associations with vaccine hesitancy. The number of disabled or clinically extremely vulnerable were not reported. Feb-Mar: 17,201 responses pooled Mar-Apr: 16,362 responses pooled Questions Topics: 1) Vaccine intentions 2) Vaccine hesitancy	**Mar-Apr** • Vaccine hesitancy is highest among those with children aged 0-4 (12%) compared to 8% with children over 5 (8%), and among non-parents or those not living with dependent children (6%). Vaccine hesitancy has decreased since the last survey. • In those with children aged 0-4, vaccine hesitancy was more prevalent among women than men with children aged 0-4 (16% vs 8%). This has decreased since the last survey. • Positive vaccine sentiment is lowest among 0 to 4 (88%) compared to 92% with children over 5 and 94% among non-parents or those not living with dependent children **Feb-Mar**

	Survey tools available? Yes Formative research conducted? Yes Survey pre-tested? Yes	• The top reason for hesitancy was concern about side effects which was the same for both groups of parents.
Skirrow (2021) *preprint* (19) Cross-sectional and qualitative study UK Aug – Oct 2020	An online survey and semi-structured interviews were conducted in a group of 1,181 pregnant women (aged 16+) to determine views on COVID-19 vaccine acceptability for themselves when pregnant, not pregnant, and for their babies. Question Topics: 1) Vaccine intentions 2) Vaccine hesitancy Survey tools available? No Formative research conducted? Yes Survey pre-tested? No	• 81.2% of women reported that they would definitely accept or were leaning towards accepting a vaccine when not pregnant. Vaccine acceptance was significantly lower during pregnancy (62.1%, P<0.005) and for their babies (69.9%, p<0.005). • Compared to White ethnic women, ethnic minority women were twice as likely to reject a vaccine for themselves when not pregnant, pregnant and for their babies (P>0.005). • Those from lower-income households, aged < 25 years, and from some geographic regions were more likely to reject a vaccine when not pregnant, pregnant, and for their babies. • Women unvaccinated against pertussis in pregnancy were over four times more likely to reject a vaccine when not pregnant, pregnant and for their babies. • Thematic analysis revealed the most common reasons for hesitancy were vaccine safety, and a wider mistrust of vaccines in general.
Bell (2020) (185) Cross-sectional study England Apr-May 2020	The acceptability of a future vaccine was assessed in a group of 1252 parents and guardians (aged 16+ with a child <18 months old) using an online survey. Upon completion of the online survey, participants were asked if they were interested in taking part in a follow-up telephone interview. Nineteen individuals were included. Question Topics:	• Black, Asian, Chinese, Mixed or other ethnicity were almost 3 times more likely to reject a COVID-19 vaccine for themselves and their children compared to White British, White Irish, and White other participants. • 55.8% of respondents intend to vaccinate and 34.3% were unsure but leaning towards yes. • For vaccinating their children, 48.2% were willing to accept and 40.9% were unsure but leaning towards yes.

	1) Vaccine intentions 2) Vaccine hesitancy Survey tools available? Yes Formative research conducted? Yes Survey pre-tested? Yes	
NEW ZEALAND		
Horizon Research (2021) *unpublished* (15, 195, 232) Longitudinal study New Zealand Mar-May 2021	An online survey of adults (16+) was conducted to measure vaccine intentions. Mar-Apr, n=1,350 Apr-May, n=1387 May, n=1,234 *new* Question Topics: 1) Vaccine intentions 2) Vaccine hesitancy Survey tools available? Yes Formative research conducted? No Survey pre-tested? No	**May** • 55% of parents or caregivers of children aged 12-15 are likely to have their children vaccinated, a 1% decrease from April. • The major reasons included wanting assurances for the safety in children (59%), concern for long term effects in children (50%), and wanting to wait to see if there were side effects (28%). **Apr-May** • 56% of parents or caregivers of children aged 12-15 will allow their children to receive a vaccine. Parents who were willing to vaccinate themselves were more likely to vaccinate their children compared to those who would not vaccinate themselves (85% vs 6%). • The top concerns among those who were unsure or unlikely to vaccinate their children were a need for safety assurances (60%) and uncertainty about long-term effects (43%).
Horizon Research (2021) *unpublished* (187) Cross-sectional study New Zealand	An online survey of 1451 adults (18+) was conducted to measure vaccine acceptance for themselves and their children after vaccines were announced to available. Question Topics: 1) Vaccine intention Survey tools available? Yes	• Pasifika and Indian parents were most likely to give a vaccine to their children (72% and 68%) and Māori and Other European were least likely (40% and 41%).

Sep 2020	Formative research conducted? No Survey pre-tested? No	
Horizon Research (2021) *unpublished* (94) Cross-sectional study New Zealand Dec 2020	An online survey of 1438 adults (18+) was conducted to assess vaccine intentions, knowledge, and perceptions. Question Topics: 1) Vaccine intentions 2) Vaccine perceptions 3) Vaccine knowledge Survey tools available? Yes Formative research conducted? No Survey pre-tested? No	• 40% of parents were willing to get their children vaccinated once approved, 33% were unlikely, and 24% were unsure. The least likely to vaccinate their children were were Pasifika (39%) and Other Europeans (29%) followed by Māori (39%), NZ Europeans/Pakeha (41%), Asian (45%), and Indian (62%) parents.
USA		
Teasdale (2021) *preprint* (16) *new* Cross-sectional study USA Mar-Apr 2021	An online survey of 1,119 parents or caregivers (18+) of children under the age of 12 in New York was conducted to determine vaccine intentions for their youngest child. Question Topics: 1) Vaccine intentions Survey tools available? No Formative research conducted? No Survey pre-tested? No	• 61.9% intend to vaccinate their youngest child (mean age 4.7 years), 23.3% were unsure, and 14.8% did not intend to vaccinate. • Intention to vaccinate increased when children were older and were White non-Hispanic and parents were between 30 and 44, male, and White non-Hispanic. In multivariate modelling only female parents (aPR 0.72, 95% CI: 0.61-0.85) and non-Hispanic Black parents (aPR: 0.79, 95%CI: 0.63-0.99) were associated with decreased intentions to vaccinate. • Parents were more likely to vaccinate if their child didn't have health insurance, if the child attended daycare more than once a week, had 2 children under 12, completed college or more, had a household income of $100,000, and were living in Manhattan.

		• In the adjusted model only having children attend daycare more than once a week was associated with increased intentions (aPR 1.23, 95% CI: 1.05-1.45). • 20.2% of parents had received a vaccine, 47.1% intend to get a vaccine, 20.6% were unsure, and 9.1% said they don't intend to get vaccinated (3.0% declined to answer). • Of the parents that plan on being vaccinated or had been vaccinated, 82.4% will vaccinate their child as compared to 25.4% of unsure parents and 4.5% among parents not planning on getting vaccinated.
Teasdale (2021) *preprint* (14) Cross-sectional study USA Mar 2021	To evaluate parents (18+) intentions to vaccinate their children (aged 12 or under), an online survey of 2,074 adults across the USA was conducted. Question Topics: 1) Vaccine intentions 2) Vaccine hesitancy Survey tools available? No Formative research conducted? No Survey pre-tested? No	• 49.4% intend to vaccinate the youngest child in their household (median child age: 4.8 years, IQR: 4.5-5.1) when a pediatric vaccine is approved, 25.6% would not accept a vaccine for their child, and 25% were unsure. Parents were more likely to vaccinate children aged 7-12 (56.5%) compared to children aged 2-6 (48%) and <2 (37.2%). • Among parents who had received a vaccine or were intending to vaccinate, 85.2% would vaccinate their children, 4.8% would not, and 10% were unsure. Only 5.7% of parents who would not get vaccinated themselves reported planning to vaccinate their child. • Reasons for vaccine hesitancy included potential safety or effectiveness concerns (78.2%), a belief that children did not need to be vaccinated (23%), medical reasons (11.2%), and religious reasons (8.5%). • Asian parents were more likely to report intentions to vaccinate their children compared to non-Hispanic Whites (aOR 1.38, 95% CI: 1.19-1.60). • Parents less likely to intend to vaccinate their children were female (aOR 0.69, 95% CI: 0.62-0.77), were less educated (aOR 0.73, 95% CI: 0.62-0.86) and had lower incomes (aOR 0.75, 95% CI: 0.64-0.88).

Czeisler (2021) *preprint* (17) Longitudinal study USA Dec 2020 – Mar 2021	An online survey was used to assess COVID-19 vaccine intentions and vaccine hesitancy among adults (18+) for themselves and their children across the USA. The survey was answered by 5,188 adults in Dec 2020 and 5,256 adults in Mar 2021. Question Topics: 1) Vaccine intentions 2) Vaccine hesitancy Survey tools available? No Formative research conducted? No Survey pre-tested? No	• In March, 66.0% would definitely or most likely obtain vaccine as soon as possible, 20% would decline, and 14% were undecided. In Dec, 63.7% were willing to vaccinate, 17.5% would decline, and 18.8% were undecided. • Intentions for children and booster vaccines were similar to personal vaccine intentions. Among 2160 of individuals living with or caring for children aged 2-18 in the Mar survey, 60.4% would vaccinate those children, 21.4% would decline, and 18.1% were undecided. • Of those who would vaccinate their children, 93.5% would also vaccinate themselves. Of those who would not vaccinate their children, 56.5% would also decline the vaccine for themselves. • Vaccine hesitancy was significantly more common among adults who were younger (aOR 3.88, 95% CI: 2.02-7.46), female (aOR 1.51, 95% CI: 1.16-1.96), Black (aOR 1.60, 95% CI: 1.10-2.33), very politically conservative (aOR 3.58, 95% CI: 2.16-5.94), less educated (aOR 3.43, 95% CI: 2.11-5.59), less frequent mask usage (aOR 3.92, 95% CI: 2.52-6.10), less adherent to social gathering avoidance (aOR 2.65, 95% 1.95-3.60), had more medical mistrust (aOR 2.11, 95% CI: 1.10-4.07), or had not received influenza vaccines in 2020 (aOR 4.11, 95% CI: 3.05-5.54).
McCabe (2021) *preprint* (166) Cross-sectional study USA Dec 2020-Feb 2021	A national app distributed survey was conducted in 34,470 healthcare workers and adults from the general population to measure intent to receive a vaccine and factors associated with acceptance and refusal. Number of healthcare workers was not reported. Question Topics:	• Parents rather than non parents were more vaccine hesitant in multivariable analysis (aOR 1.24 95% CI: 1.13-1.36).

	1) Vaccine intentions 2) Vaccine hesitancy Survey tools available? Yes Formative research conducted? No Survey pre-tested? Yes	
Milan (2021) (13) Cross-sectional study USA Dec 2020	To determine how maternal post-traumatic stress disorder (PTSD) and trauma history impact a mothers' beliefs and intentions to vaccinate themselves and their children, an online survey of 240 mothers across the USA with a history of mental illness and children between 3-18 was conducted. Question Topics: 1) Vaccine intentions 2) Vaccine hesitancy Survey tools available? No Formative research conducted? Yes Survey pre-tested? No	• PTSD diagnosis history and total potentially traumatizing events (PTEs) were significantly positively correlated with all vaccine measures. • Mother and child vaccine intentions were highly correlated with each other ($r = 0.90$, $p < 0.001$). • Among mothers with a PTSD history, 40% were vaccine hesitant compared to 23.9% of mothers without a PTSD history, X^2 ($df = 1$, $N = 238$) = 6.45, $P < 0.01$ and for their children, 38.7% of mothers with a PTSD history were hesitant compared to 25.8% without a PTSD history, X^2 ($df = 2$, $N = 238$) = 4.08, $P < 0.05$. • The most common reasons for hesitancy included concern about side effects (31%) and a need for more information and observation (24%). • Differences in vaccine hesitancy were observed between those with and without previous PTSD diagnosis. Mothers with a PTSD history were less likely to mention believe in science and more likely to say their child has specific health concerns. • Mothers indicated that the strongest influences to increase vaccine confidence would be personally reading about trials and research and recommendations from a pediatrician.
Catma (2021) (241) Cross-sectional study USA	Parental perceptions towards a COVID-19 vaccine and willingness – to-pay (WTP) for a vaccine for themselves and their children under 18 were evaluated using an online survey across the USA.	• Parents were WTP $228-291 USD for a vaccine for themselves, and $243-321 USD for their children. • Income was positively associated with adults' WTP for a vaccine for both themselves and their children.

Nov 2020	Question Topics: 1) Vaccine intentions Survey tools available? No Formative research conducted? No Survey pre-tested? Yes	• As the number of children increased in a household, the WTP for child vaccination increased. • 72% of parents believed that vaccines were important in preventing disease.
Haeder (2021) (242) Cross-sectional study USA Oct-Nov 2020	Responses from 2,404 adults were collected from an online survey aimed to investigate attitudes toward vaccine mandates. Question Topics: 1) Vaccine attitudes Survey tools available? No Formative research conducted? No Survey pre-tested? No	• Households with children were less supportive for vaccination mandates for daycare and university but not for kindergarten to grade 12. • Having children in the household was predictive of favourable attitudes towards COVID-19 mandates when the attitudes about general vaccination mandates were subtracted for daycare, kindergarten to grade 12, and university.
Marques (2021) (243) *new* Cross-sectional study USA Sep-Nov 2020	99 parents and caregivers (aged 24-63) of children were approached in person in dental treatment rooms to complete a survey regarding their intention to get their children vaccinated for COVID-19. Question Topics: 1) Vaccine intentions 2) Vaccine hesitancy Survey tools available? No Formative research conducted? No Survey pre-tested? Yes	• 21.6% of parents say that they would allow their child to get vaccinated for COVID-19, 39.2% were unsure, and 42.3% would not allow their child to be vaccinated. • 19.6% of parents themselves say they will get vaccinated, 38.1% were not sure, and 42.3% would not get vaccinated. • 77.6% of parents reported the age of their children did not influence their decision to get a COVID-19 vaccine when available. • Intentions to vaccinate their child increased if they knew someone who had COVID-19 (OR 0.47, 95% CI: 0.24-0.93). • 40% of parents who got their child a flu vaccine every year would allow their child to be vaccinated for COVID-19. • 52.2% of parents would be influenced by a doctor recommendation for the COVID-19 vaccine compared to 42.4% who said no one would influence their decision.

Rhodes (2021) (184) Cross-sectional study USA Jul-Aug 2020	An online survey with open ended questions was used to measure vaccine hesitancy in 1381 vaccine hesitant parents (18+) with at least one child under 4 years of age across the USA. Question Topics: 1) Vaccine intentions 2) Vaccine hesitancy Survey tools available? No Formative research conducted? No Survey pre-tested? No	• Parents were slightly hesitant in their intentions to vaccinate their children (mean=3.55) and themselves (mean=3.58). • Those with a higher education level were more likely to accept a vaccine for both themselves and their children. • The most common source of vaccine information for parents were healthcare workers, personal research (online and traditional resources), personal beliefs and experience, and peer experts. • Open ended responses also indicate the influence non-traditional health sources such as naturopathic doctors and alternative medicine as well as sources such as forums, bloggers, personal intuition, and the experiences of friends or family.
Davis (2020) *preprint* (188) Cross-sectional study USA Jun 2020	Factors associated with 1008 parents' likelihood to vaccinate themselves and their children against COVID-19 was investigated using an online survey. Question Topics: 1) Vaccine intentions Survey tools available? No Formative research conducted? No Survey pre-tested? No	• Compared to Hispanic, non-Hispanic White and Black parents; parents who identified as Other were more likely to vaccinate. • 63% of parents reported they were likely to vaccinate their children against COVID-19 and 60% were likely to get a vaccine themselves. • Factors significantly associated with likelihood to vaccinate their children and themselves include older age, male gender, being married, and higher education and income levels.
Thunstrom (2021) (186) Randomized controlled trial USA Mar 2020	3133 adults participated in an online survey regarding their intentions to vaccinate themselves and their children for COVID-19. Participants were randomized into eight information treatment groups. Each group involved specific messaging in which the probability of infection, the	• 19.5% of participants would not vaccinate themselves. • Of the 1156 participants with children, 19.7% would not vaccinate their children.

	conditional mortality rate from COVID-19, and whether the different health authorities in the US provide consistent risk information varied. Question Topics: 1) Vaccine intentions 2) Vaccine hesitancy Survey tools available? No Formative research conducted? No Survey pre-tested? No	
RELIGIOUS AFFILIATIONS		
AUSTRALIA		
Edwards (2021) (244) & Biddle (2021) *preprint* (179) Longitudinal study Australia Aug 2020 & Jan 2021	Changes in intention to vaccinate over time and reasons for this change were assessed using two online and telephone surveys. In August 3061 adults (18+) completed the survey and 3459 adults completed a similar survey in January. Both surveys were completed by 2737 individuals. Question Topics: 1) Vaccine intentions Survey tools available? No Formative research conducted? No Survey pre-tested? No	• Those who had more populist views and higher levels of religiosity were less likely to intend to get the vaccine. • Those who were more religious were less likely to intend to get vaccinated (vaccine likelihood coefficient -0.022).
Smith (2021) (182) Cross-sectional study	Intention to vaccinate and reasons for hesitancy were assessed using an online survey of 1200 adults (18+).	• In bivariate analysis, less religious individuals were more likely to intend to vaccinate compared to religious people (P> 0.004). This variable was not significant in multivariate analysis.

Australia NR 2020	Question Topics: 1) Vaccine intentions 2) Vaccine hesitancy Survey tools available? No Formative research conducted? Yes Survey pre-tested? No	
UNITED KINGDOM		
de Figueiredo (2021) *preprint* (20) *new* Cross-sectional study UK Apr 2021	This national online survey of 17,611 adults (18+) used Bayesian multilevel regression to estimate the impact of vaccine passports on intention to get a COVID-19 vaccine among respondents who have not yet had two vaccination doses. Question Topics: 1) Vaccine intentions Survey tools available? Yes Formative research conducted? No Survey pre-tested? No	• In multilevel regression controlling for baseline vaccine intention, the likelihood of getting a vaccine if vaccine passports were introduced for domestic travel was significantly increased with those reporting Christian faith (aOR 1.23, 95% CI: 1.08-1.41) compared to atheists or agnostics. • If vaccine passports were introduced for international travel, Christian faith was significantly associated with an increased intention to vaccinate (aOR 1.22 95% CI: 1.07-1.39) compared to atheists or agnostics.
Rahman (2021) *preprint* (245) Cross-sectional study UK Jan 2021	This online survey sought to improve vaccine promotion activities by gathering information regarding knowledge, attitudes, and practices regarding COVID-19 from 151 mosque attendees at two mosques. Question Topics: 1) Vaccine attitudes Survey tools available? No Formative research conducted? Yes	• Attitudinal scores towards the vaccine were moderately positive at each mosque (62% and 69%). • Open ended questions regarding improvements to engagement and experiences with the vaccine rollout broadly encompass desires for increasing accessibility of information and vaccine sites, and hearing directly from community members. • Top sources for vaccine information included National Health Service or government websites followed by GPs.

	Survey pre-tested? No	
de Figueiredo (2020) *preprint* (178) Cross-sectional study UK Sep-Oct 2020	Using Bayesian statistical methods and an online national survey of 17,684 adults (18+), vaccine uptake was estimated and barriers to uptake were identified. Question Topics: 1) Vaccine intentions Survey tools available? Yes Formative research conducted? No Survey pre-tested? No	• Those who reported Hinduism or Judaism as their religion were more likely than atheists or agnostics to accept a vaccine (OR 1.66, 95% HPDI: 1.11-2.43) and those who reported their religion as Muslim (OR 0.75, 95% HPDI: 0.57-0.96) or other (OR 0.72, 95% HPDI: 0.62-0.82) were less likely to intend to vaccinate.
Chadwick (2021) (246) Cross-sectional study UK Sep-Oct 2020	This online survey of 5114 adults explored the relationship between media intake, socio-demographics, social and political attitudes, and likelihood of promoting or discouraging vaccination on social media. Question Topics: 1) Vaccine attitudes Survey tools available? No Formative research conducted? No Survey pre-tested? No	• Religiosity was associated with encouraging vaccination ($\beta = -0.032$, $p < .001$).
Garry (2020) (176) Cross-sectional study UK Jul 2020	Using an online survey of 2057 adults, intention to vaccinate was evaluated. The respondents were allocated into groups with different response options (positive skew – more positive options, negative skew – more negative options, and balanced – equal positive and negative options) to study the	• Respondents that were younger, had a lower income, lived in an urban area, and were religious were less likely to vaccinate.

	impact of vaccine conspiracy theories. Question Topics: 1) Vaccine intentions 2) Vaccine perceptions Survey tools available? Yes Formative research conducted? No Survey pre-tested? No	
Murphy (2021) (174) Cross-sectional study Ireland & UK Mar 2020	Using an online survey of 1041 adults (18+) in Ireland and 2025 in the UK, willingness to vaccinate against COVID-19 and reasons for vaccine hesitancy were investigated. Question Topics: 1) Vaccine intentions 2) Vaccine hesitancy Survey tools available? No Formative research conducted? Yes Survey pre-tested? No	• In Ireland, the vaccine hesitant and resistant group were more likely to have higher levels of conspiratorial (d = 0.21) and religious (d = 0.20) beliefs.
USA		
Viskupic (2021) *preprint* (21) *new* Quasi-experimental study USA	709 unvaccinated registered voters in South Dakota were sent identical messages encouraging vaccination either from a religious, political, or medical leader to assess the impact the messenger has on interest in vaccination. A control group was provided a message unrelated to COVID-19. Question Topics:	• Mean interest in vaccination was 1.86 (95% CI: 1.61 – 2.11) in the control group. • A religious messenger generated a mean interest in vaccination of 2.32 (95% CI: 1.94-2.71, P<0.05) which was the only messenger that had a statistical difference in interest. • All messengers had statistically significant effects in respondents identifying as evangelical Christians with the strongest effect seen with a religious messenger.

Apr 2021	1) Vaccine intentions Survey tools available? Yes Formative research conducted? No Survey pre-tested? No	• A religious messenger also had a statistical effect among respondents younger than 65.
King (2021) *preprint* (181) Longitudinal study USA Jan-Mar 2021	As part of a monthly ongoing national COVID-19 survey, questions to measure vaccine acceptance and related factors of acceptance were collected in samples of adults (age 18-64). The number of HCWs was not reported. Jan survey: n= 791,716 Feb survey: n= 710,529 Mar survey: n= 732,308 Question Topics: 1) Vaccine hesitancy Survey tools available? Yes Formative research conducted? No Survey pre-tested? No	• In a subset of individuals from this survey (n=143,297) by occupation categories with the highest percentage hesitant, 6.7% of individuals reported religion as a reason for vaccine hesitancy. This included construction, installation, farming/forestry/fishing, and transportation occupations.
Carmody (2021) (183) Cross-sectional study USA Dec 2020 – Jan 2021	A paper survey was used to assess vaccine attitudes and intentions in 102 Haredi-Orthodox Jewish adults (18+) in New York. Question Topics: 1) Vaccine intentions 2) Vaccine attitudes 3) Vaccine hesitancy Survey tools available? No Formative research conducted? Yes	• 12% of respondents would accept a vaccine for themselves and their family, 47% were strongly hesitant, and 41% were undecided. • 70% agreed that routine vaccinations were essential. • Apprehension about new vaccine technology was the most common concern about the vaccine. • There was a lack of confidence in government and health officials and only 17% agreed that mandates from the local health department would make them accept a vaccine. • Independent predictors of strong vaccine hesitancy were: 1) the belief that natural infection

	Survey pre-tested? No	was better than vaccine for developing immunity (aOR 4.28, 95% CI: 1.23–14.86, P=0.022), agreement that prior SARS-CoV-2 infection with antibodies precludes need to mask or practice social distancing (aOR 4.1, 95% CI: 1.22–13.77, P=0.022), and loss of trust in physicians resulting from the pandemic (aOR 5.01, 95% CI: 1.05–23.96, P=0.044).
Clark (2020) *preprint* (171) Cross-sectional study USA Nov-Dec 2020	An online survey of 655 adults from Oregon assessed intention to vaccinate intentions and reasons for hesitancy with an emphasis on comparing rural and urban residents. Question Topics: 1) Vaccine intentions 2) Vaccine hesitancy Survey tools available? No Formative research conducted? No Survey pre-tested? No	• Those reporting personal or religious concerns and those who believe COVID-19 is not serious are 9.5 and 10 times more likely to refuse a vaccine, respectively.
Graupensperger (2021) (180) Cross-sectional study USA Nov 2020	The vaccine intentions and attitudes of 647 students from a large public university in the northwest USA were evaluated using an online survey. Question Topics: 1) Vaccine intentions 2) Vaccine hesitancy Survey tools available? No Formative research conducted? Yes Survey pre-tested? No	• 91.6% of students reported an intention to receive a COVID-19 vaccine. • 2.78% of students felt that a COVID-19 vaccine was incongruent with their religious beliefs.

Parente (2021) (126) *new* Cross-sectional study USA Aug 2020	Associations with vaccine acceptance were assessed online for a hypothetical vaccine with considerations for delay periods (1 to more than 12 months after approval) in 3,347 HCWs in Kentucky. Question Topics: 1) Vaccine intentions 2) Vaccine hesitancy Survey tools available? No Formative research conducted? Yes Survey pre-tested? Yes	• 7.4% of respondents noted personal religious or ethical reasons as a reasons for wanting to delay or refuse vaccination.
Olagoke (2020) (177) Cross-sectional study USA Mar 2020	The relationship between religiosity and intention to vaccinate was examined using an online survey of 501 adults (18+). Question Topics: 1) Vaccine intentions Survey tools available? No Formative research conducted? Yes Survey pre-tested? No	• There was a significantly negative association between intention to vaccinate and religiosity (β = − 0.15, 95% CI: − 0.23 to − 0.08, P < 0.0001) and external health locus of control (beliefs based on past experiences and having external control over them) (β = − 0.24, 95% CI: − 0.33 to − 0.15, P < 0.0001). • External health locus of control mediated 40.97% of the relationship between religiosity and intention to vaccinate as an indirect effect of β = − 0.06, 95% CI: − 0.11 to − 0.02, P = 0.006.
RURAL VS URBAN COMMUNITIES		
CANADA		
Leger (2021) *unpublished* (9, 69-71, 73, 205, 206)	An online survey of Canadian and American adults (18+) was conducted to evaluate vaccine perceptions and intentions to vaccinate. See USA section for USA.	**Wave 12** • 16% of those residing in rural areas do not intend to vaccine compared to 11% of rural and 9% of suburban residents. **Wave 11**

Longitudinal study Canada & USA Nov 2020 & Jan-June 2021	Wave 1: Nov 2020, 1516 Canadians and 1002 Americans Wave 2: Jan 2021, 1516 Canadians and 1003 Americans Wave 3: Feb 2021, 1535 Canadians and 1002 Americans Wave 4: Feb 2021, 1,532 Canadians and 1002 Americans Wave 5: Apr 2021, 1,504 Canadians and 1,002 Americans Wave 7: May 2021, 1,529 Canadians, 1,003 Americans Wave 8: May 2021, 1,529 Canadians, 1,003 Americans Wave 9: May 2021, 1,624 Canadians and 1,002 Americans Wave 10: May 2021, 1,624 Canadians and 1,002 Americans Wave 11: June 2021, 1,539 Canadians, 1,004 Americans Wave 12: June 2021, 1,542 Canadians and 1,001 Americans *new* Question Topics: 1) Vaccine intentions 2) Vaccine perceptions Survey tools available? No Formative research conducted? No Survey pre-tested? No	• 22% of rural residents do not intend to vaccinate compared to 11% of urban and 15% of suburban residents. • 26% of rural residents were not comfortable with a different vaccine as a second dose compared to 24% of urban and 20% of suburban residents. **Wave 9** • Combined levels of vaccination and intention to receive a vaccine increased from 73% to 85% in those who lived in rural communities in the latest polling. **Wave 7** • Those who lived in suburban (85%) or urban (84%) communities were more likely to intend to vaccinate compared to those who lived in rural areas (73%). **Wave 5** • Rural participants (74%) were slightly less likely to accept a vaccine compared to urban (82%) and suburban participants (81%).
INSPQ (2020), INSPQ (2021), INSPQ (2021), INSPQ (2021) *unpublished* (86, 88, 91, 95)	Analysis of the acceptability of vaccination against COVID-19 was evaluated using an online survey of adults and healthcare workers in Quebec. Number of participants was not clearly stated (~3300 each collection period). There were	• Intention to vaccinate generally increased as communities increased in size, from living in small villages less than 10,000 (71%), towns 10,000 to 100k (73%), greater Montreal area (81%) and Montreal (79%).

Longitudinal study Canada Apr 2020 – Apr 2021	multiple collection periods, one in Apr-May 2020, Sep and Dec 2020, and Apr 2021. Articles in French. Question Topics: 1) Vaccine intentions 2) Vaccine hesitancy Survey tools available? No Formative research conducted? No Survey pre-tested? No	
Lang (2021) (87) Cross-sectional study Canada Aug 2020	An online survey of 60 adults (18+) in Alberta was conducted to assess their intention to vaccinate. Question Topics: 1) Vaccine intentions Survey tools available? Yes Formative research conducted? No Survey pre-tested? No	• Intention to vaccinate was lower in other urban centers (29%) and rural Alberta (50%) compared to Calgary (75%) and Edmonton (80%), (P= 0.030).
UNITED KINGDOM		
Sethi (2021) (247) Cross-sectional study UK Sep-Oct 2020	To understand the factors in participation and perception of COVID-19 vaccination trials, 4884 adults were surveyed online. Question Topics: 1) Vaccine intentions 2) Vaccine perceptions Survey tools available? Yes Formative research conducted? No Survey pre-tested? Yes	• 41.4% of respondents were interested in participating in vaccine trials, 27.6% were not interested, and 31.1% were unsure. • The largest percent of respondents that were not interested in participating were in villages (pop. >7500) whereas small towns (pop. 7500-24,999) were the most unsure about participating. • The odds of not participating is 0.66 times that of respondents from villages and 0.54 times for small towns. • 88% of small towns and 91% in villages aged 50-59 were not interested in participating in trials.

Garry (2020) (176) Cross-sectional study UK Jul 2020	Using an online survey of 2057 adults, intention to vaccinate was evaluated. The respondents were allocated into groups with different response options (positive skew – more positive options, negative skew – more negative options, and balanced – equal positive and negative options) to study the impact of vaccine conspiracy theories. Question Topics: 1) Vaccine intentions 2) Vaccine perceptions Survey tools available? Yes Formative research conducted? No Survey pre-tested? No	• Respondents that were younger, had a lower income, lived in an urban area, and were religious were less likely to vaccinate.
Murphy (2021) (174) Cross-sectional study Ireland & UK Mar 2020	Using an online survey of 1041 adults (18+) in Ireland and 2025 in the UK, willingness to vaccinate against COVID-19 and reasons for vaccine hesitancy were investigated. Question Topics: 1) Vaccine intentions 2) Vaccine hesitancy Survey tools available? No Formative research conducted? Yes Survey pre-tested? No	• Those who were vaccine hesitant were more likely to be residing in a suburb (aOR = 2.13, 95% CI: 1.01-4.49).
USA		
McCabe (2021) *preprint* (166)	A national app distributed survey was conducted in 34,470 healthcare workers and adults from the	• Respondents in less populated areas (population density 0-149) are more hesitant than those from

Cross-sectional study USA Dec 2020-Feb 2021	general population to measure intent to receive a vaccine and factors associated with acceptance and refusal. Number of healthcare workers was not reported. Question Topics: 1) Vaccine intentions 2) Vaccine hesitancy Survey tools available? Yes Formative research conducted? No Survey pre-tested? Yes	populated areas (population density over 1000) (aOR 1.31, 95% CI: 1.16-1.48).
Roess (2021) *preprint* (175) Cross-sectional study USA Dec 2020 – Jan 2021	An online survey was used to assess vaccine intentions in 1,181 parents and guardians aged 18–64 who currently have a child <18 years old at home across the USA. This study did not assess intention to vaccinate their children. Question Topics: 1) Vaccine intentions Survey tools available? No Formative research conducted? No Survey pre-tested? No	• Intention to vaccinate was higher in those who lived in urban (aOR 2.04, 95%CI: 1.24–3.09) and semiurban settings (aOR 1.45, 95% CI: 0.97–2.17) compared to those in rural settings.
Enwezor (2021) *preprint* (115) Cross-sectional study USA	Intention to vaccinate was assessed in 20,232 adults (15,062 non-HCWs and 5,170 HCWs) using an online survey. 476 of participants had a previous COVID-19 diagnosis. Question Topics: 1) Vaccine intentions	• Suburban (68%) and rural (71.2%) residents were less likely than urban (81%) residents to intend to vaccinate (aRR 0.85, 95% CI: 0.83-0.88, P<0.0001).

Dec 2020 – Jan 2021	Survey tools available? No Formative research conducted? No Survey pre-tested? No	
Clark (2020) *preprint* (171) Cross-sectional study USA Nov-Dec 2020	An online survey of 655 adults from Oregon assessed intention to vaccinate intentions and reasons for hesitancy with an emphasis on comparing rural and urban residents. Question Topics: 1) Vaccine intentions 2) Vaccine hesitancy Survey tools available? No Formative research conducted? No Survey pre-tested? No	• Intention to vaccinate was higher in urban residents compared to rural (47% vs 41%). • Those reporting personal or religious concerns and those who believe COVID-19 is not serious are 9.5 and 10 times more likely to refuse a vaccine, respectively.
Kuter (2021) (109) Cross-sectional study USA Nov-Dec 2020	To evaluate intentions to vaccinate, an online survey was conducted at two large, academic hospitals in Philadelphia in 12,034 hospital employees. Question Topics: 1) Vaccine intentions 2) Vaccine hesitancy Survey tools available? No Formative research conducted? Yes Survey pre-tested? Yes	• Those residing in urban areas were significantly more likely to intend to vaccinate compared to suburban (OR 0.71, 95% CI: 0.65-0.79) and rural (OR 0.41, 95% CI: 0.30-0.54) residents.
Haeder (2021) (242) Cross-sectional study	Responses from 2,404 adults were collected from an online survey aimed to investigate attitudes toward vaccine mandates.	• Rural residents have lower support for mandatory vaccinations for students in daycare (b = −0.418), those in kindergarten to grade 12 (b = −0.652), and for kindergarten to grade 12 teachers (b= −0.360).

USA Oct-Nov 2020	Question Topics: 1) Vaccine attitudes Survey tools available? No Formative research conducted? No Survey pre-tested? No	• Rural residents were less favourable towards COVID-19 mandates when the attitudes about general vaccination mandates were subtracted for kindergarten to grade 12.
Mora (2020) *preprint* (173) Cross-sectional study USA Jul-Nov 2020	Telephone interviews of 1115 adult farm workers in California were conducted to determine intention to vaccinate and reasons for hesitancy. Question Topics: 1) Vaccine intentions 2) Vaccine hesitancy Survey tools available? No Formative research conducted? No Survey pre-tested? No	• Living in more rural areas such as Greenfield was significantly associated intention not to vaccinate (RR 1.19, 95% CI: 1.02-1.39).
Khubchandani (2021) (172) Cross-sectional study USA Jun 2020	Intention to vaccinate and vaccine hesitancy was assessed in 1878 adults (18+) using an online survey. Question Topics: 1) Vaccine intentions 2) Vaccine hesitancy Survey tools available? No Formative research conducted? No Survey pre-tested? No	• In unadjusted analyses, vaccine hesitancy was higher rural dwellers (29%) compared to their counterparts.
YOUTH		
Afifi (2021) (213) *new*	Using survey respondents from the longitudinal Well-Being and Experiences study (2017-2020) vaccine intentions were recorded	• 65.4% of respondents intend to receive a vaccine, 26.1% were not sure, and 8.5% were not willing. • Parents with trade school, community college or less, with incomes of less than $49,999,

Cross-sectional study Canada Nov-Dec 2020	for Winnipeg adolescents aged 16-21 and their caregivers/parents using an online survey. Question Topics: 1) Vaccine intentions 2) Vaccine hesitancy Survey tools available? No Formative research conducted? No Survey pre-tested? No	experienced quite a bit COVID-19 financial strain, self-reported low knowledge of COVID-19 were associated with lower intentions to get a vaccine. • Having a self-reported health condition was associated with higher intentions to accept a vaccine. • After adjusting for sex, age and household income, children who had no experience with spanking (aRR 0.33, 95% CI: 0.17–0.62), no peer victimization (aRR 0.49, 95% CI: 0.25–0.96), no household substance abuse (aRR 0.41, 95% CI: 0.20–0.83), no contact with foster care/child protective office (aRR 0.34, 95% CI: 0.16–0.72), and no risk of their household running out of money (aRR 0.45 95% CI: 0.21–0.97) were more willing to get vaccinated. • Reporting no to any household challenge adverse childhood experience (ACE) was associated with willingness to vaccinate (aRR 0.45, 95% CI: 0.20–0.99). • The top concerns for being unwilling to accept a vaccine were for vaccine safety (64.5%), not knowing enough about the vaccine (60.6%), and not thinking the vaccine would be effective (23.4%).
Brandt (2021) (190) Cross-sectional study USA Oct 2020	A text message poll of 911 youth aged 14 to 24 years across the United States was conducted to evaluate barriers and facilitators for COVID-19 vaccination. Question Topics: 1) Vaccine intentions 2) Vaccine hesitancy Survey tools available? No Formative research conducted? Yes Survey pre-tested? No	• 42.7% and 33.3% reported unconditional willingness or conditional willingness to vaccinate, respectively, of which 80.7% reported willingness of vaccination if proven safe and recommended. • The most common reasons to vaccinate were protecting self (38.4%), protecting others (24.9%), vaccine importance (14.3%), and return to normalcy (11.7%). • Side effects (36.2%), efficacy (20.1%), rushed approval (18.8%), and safety (16.2%) were the most common concerns about the vaccine. • Compared to White youth, Black youth (OR = 3.31) were more likely to refuse vaccination and Asian youth (OR = 0.46) were less likely to refuse vaccination ($P < 0.001$).

		• CDC or WHO (42.3%) were the preferred sources of vaccine information, followed by healthcare providers and facilities (31.75%), the internet (17.8%), health officials (8.4%), news media (7.8%), and social media (2.5%).
IMMIGRANTS		
INSPQ (2020), INSPQ (2021), INSPQ (2021), INSPQ (2021), INSPQ (2021) *unpublished* (86, 88, 90, 91, 95) Longitudinal study Canada Apr 2020 – May 2021	Analysis of the acceptability of vaccination against COVID-19 was evaluated using an online survey of adults and healthcare workers in Quebec. Number of participants was not clearly stated (~3300 each collection period). There were multiple collection periods, one in Apr-May 2020, Sep and Dec 2020, Apr and May 2021. Articles in French. Question Topics: 1) Vaccine intentions 2) Vaccine hesitancy Survey tools available? No Formative research conducted? No Survey pre-tested? No	• Immigrants were more hesitant and more unsure about receiving a vaccine compared to non-immigrants.
Australia Bureau of Statistics (2021) *unpublished* (141) *new* Longitudinal study Australia	The household impacts survey is a monthly survey which collects data online and by telephone from a panel of adults (18+) on COVID-19 related topics including attitudes towards vaccines. May: n=3,371 Question Topics: 1) Vaccine intentions	• Those born overseas were more likely to report intention to vaccinate compared to those born in Australia (70.7% vs 67.2%). This was more apparent for those who arrived within the last ten years (74.6%) compared to those arriving more than 10 years ago (69.1%). • The top factor in deciding to get the vaccine was a recommendation from their general practitioner (25.8%). • 68.1% of immigrants were concerned about possible side effects.

Apr 2020-May 2021	Survey tools available? No Formative research conducted? No Survey pre-tested? No	
Deal (2021) (248) Cross-sectional study UK Sep 2020 – Mar 2021	In depth telephone interviews were conducted with 32 recent immigrants (less than 10 years) with a precarious immigration status to define barriers and vaccine perceptions as well as generate strategies to increase uptake. Question Topics: 1) Vaccine intentions 2) Vaccine perceptions 3) Vaccine hesitancy Survey tools available? No Formative research conducted? Yes Survey pre-tested? Yes	• 28% report they definitely will get a vaccine, 31% were unsure leaning to yes, 22% were unsure, 19% were unsure leaning towards no, and 6% would definitely not vaccinate. Of the two participants who definitely would decline one indicated it was due to a lack of clinical trials and the other because of religious reasons. • Intention varied greatly between those interviewed earlier (lower intentions to accept a vaccine) and those interviewed later (higher intentions to vaccinate). • Among those who were hesitant, worries included potential side-effects and insufficient testing of the vaccine. • Three common barriers to vaccination were identified: issues of access (such as language, trust, and perceived lack of entitlement), lack of trust (poor treatment by the NHS, being charged for care, or possible immigration checks), and feeling abandoned during the pandemic causing mental and physical strain. • Undocumented migrants were particularly concerned that they were not registered at a GP office and would miss vaccine roll out. Migrants indicate that charities and walk in clinics were frequently used. • Additional challenges noted were that migrants were unaware of announcements that vaccination would not entail immigration checks. • To increase uptake migrants report increasing the ease of vaccination by rolling out the vaccine at walk in clinics and charities, providing information on side effects in their own language, clearly indicating where and how vaccines would be made

		available, and emphasizing that the vaccine would provided at no cost.
Statistics Canada (2020) & Statistics Canada (2021) *unpublished* (65, 80) Longitudinal study Canada Sep-Dec 2020	An online survey conducted by Statistics Canada as part of the Canadian Community Health Survey (CCHS) assessed Canadians behaviors to safeguard their own health as well as the health of others. In the September survey, a question about vaccine intentions was added. The most recent report captures 20,000 responses from individuals aged 12+. Question Topics: 1) Vaccine intentions Survey tools available? Yes Formative research conducted? Yes Survey pre-tested? Yes	• Immigrants were slightly less likely to vaccinate (74.6%) but this varied greatly between older and younger immigrants (73.2% for 12-64 and 81.1% for those 65+).
Knights (2021) (192) Qualitative study UK Jun-Nov 2020	In depth semi-structured telephone interviews were conducted with 17 migrants of less than 10 years, 48 healthcare professionals, and 16 administrative staff were conducted through three phases of sampling (purposive, convenience, and snowball) to gain insights into vaccine access. Question Topics: 1) Vaccine perceptions 2) Vaccine hesitancy	• Increased digitalization of appointments and health information was felt differently by primary care professionals (PCPs) and migrants with issues of access to technology. PCPs reported that digitalization increased exclusion of marginalized groups while bringing in younger fitter patients. Conversely digitalization was also reported as an opportunity to communicate with translated targeted messages. • Migrants reported that language barriers have been increased due to lower access to friends who would translate where GPs were concerned about privacy during virtual consultations. • Migrants and PCPs felt that there was a lack of specific information for migrants regarding public health messages and the vaccine. This tied into issues of low health literacy, lack of understanding of changes in policy, mistrust in government or

		science, and gave space for misinformation and seeking information from social media about COVID-19 and vaccine. • The above issues and vaccines beliefs such as COVID-19 being a 'Western disease', fearing being a guinea pig, and reliance on home remedies also pose challenges to uptake. • Both migrants and PCPs noted that building trust between clinical practices and individuals was important which was a challenge during the pandemic. Migrants noted the tendency to seek religious or peer input into decision-making. • Migrants note the 'one size fits all' approach during the pandemic has been inflexible for dealing issues for the community around digitalization and where communication is failing.
Allen (2021) *preprint* (249) *new* Cross-sectional study USA Jul-Aug 2020	Vaccine intentions were measured In 364 Brazilian immigrants living in the USA through an online survey. Question Topics: 1) Vaccine intentions 2) Vaccine hesitancy Survey tools available? No Formative research conducted? No Survey pre-tested? No	• 70.9% of respondents reported that they would get a COVID-19 vaccine, 18.1% were unsure, and 11% would not get vaccinated. • Open text responses of those not planning to get the vaccine found that there was concern that the vaccine has not been tested (30.9%), may have side effects (17.6%), or would not be effective (8.8%). Other concerns were related to lack of trust with the industries in involved in its development (10.3%), the government (8.8%), and vaccines in general (8.8%). • 3.8% of those that have spent less than 4 years in the USA did not intend to vaccinate compared to 27.3% those born in the USA. More time in the country was generally associated with lower intentions and more unsure respondents. • Perception of COVID-19 pandemic also significantly impacted intention with 75.9% of those seeing it as of major significance wanting a vaccine compared to 52.6% who viewed it as a minor issue. • Those who trusted healthcare providers (73.9%) and public health agencies (76.8%) had higher

		intentions than those relying on social networks (63.6%), private networks (62.2%), or were missing trusted source response (61.9%).
PAST SARS-COV-2 INFECTION		
Enwezor (2021) *preprint* (115) Cross-sectional study USA Dec 2020 – Jan 2021	Intention to vaccinate was assessed in 20,232 adults (15,062 non-HCWs and 5,170 HCWs) using an online survey. 476 of participants had a previous COVID-19 diagnosis. Question Topics: 1) Vaccine intentions Survey tools available? No Formative research conducted? No Survey pre-tested? No	• Those with no previous COVID-19 diagnosis were more likely to intend to vaccinate compared to those that had a previous COVID-19 diagnosis, (76.6% vs 60.9%, aRR 1.20, 95% CI: 1.11-1.28, P<0.0001).
Olanipekun (2021) (193) Cross-sectional study USA Apr-May 2020	119 African Americans were surveyed after COVID-19 infection recovery and discharge to assess acceptance of a safe and effective vaccine. Question Topics: 1) Vaccine intentions Survey tools available? No Formative research conducted? Yes Survey pre-tested? No	• 54% did not intend to get vaccinated, 30% would get vaccinated, and 16% were unsure. • The top reason among those who do not intend to get vaccinated was a high level of distrust for both vaccine effectiveness and pharmaceutical industries (78.1%). Other top reasons included not trusting that the vaccine will be effective (68.8%) and fear of side effects (64.1%).

Preuves émergentes sur la COVID-19

Revue rapide et évolutive sur les attitudes à l'égard des vaccins et de l'adoption des vaccins contre la COVID-19 – Mise à jour 8

Introduction

Quelles sont les données mondiales sur les attitudes à l'égard des vaccins et l'adoption des vaccins contre la COVID-19 chez les Canadiens, ainsi que dans certaines populations?

Cette revue rapide et évolutive vise à cerner et à résumer la documentation sur l'adoption du vaccin contre la COVID-19 et les attitudes à l'égard de ce vaccin pour mieux comprendre les facteurs associés à l'adoption de ce vaccin au Canada. Elle met l'accent sur les données probantes canadiennes sur l'adoption et les attitudes, ainsi que sur les données probantes des pays partenaires du Groupe des cinq disponibles jusqu'au 1er juillet 2021. Des données probantes sur différentes populations prioritaires prédéfinies en Australie, en Nouvelle-Zélande, aux États-Unis et au Royaume-Uni ont été incluses pour compléter les domaines dans lesquels il y avait peu de recherche au Canada. Les populations prioritaires comprennent les travailleurs de la santé, les LGBTQ+, les groupes confessionnels, les nouveaux arrivants, les parents, les femmes enceintes ou qui allaitent, les personnes qui vivent dans les collectivités rurales, les adultes plus âgés, les personnes qui ont des comorbidités et celles qui se heurtent à de multiples obstacles en matière de santé. (p. ex., itinérance, troubles de santé mentale ou de toxicomanie).). Il est possible d'obtenir les versions antérieures de cette étude (mises à jour 1 à 7) qui présentent les données probantes disponibles jusqu'au 1er juin 2021 sur les connaissances, les attitudes et les comportements en matière de vaccination et de les demander en envoyant un courriel à cet effet à l'adresse phac.ocsoevidence-bcscdonneesprobantes.aspc@canada.ca. Les sections Quoi de neuf et Points clés ci-dessous mettent l'accent sur les résultats importants des études les plus récentes (au cours des cinq derniers mois).

Quoi de neuf

- Cette mise à jour a cerné 40 nouvelles études ou mises à jour d'études sur l'adoption du vaccin contre la COVID-19 et les attitudes à l'égard de celui-ci, dont six spécifiques au Canada. Les nouvelles études portent la mention *nouvelle* dans chacun des tableaux et tous les tableaux ont été déplacés dans les annexes pour aider les lecteurs à naviguer dans le document.

Adoption du vaccin

- Les tendances en matière d'adoption et de refus des vaccins continuent de refléter les tendances en matière d'intention vaccinale. Dans toutes les populations, la prise en charge du vaccin était positivement associée à l'augmentation de l'âge, au sexe masculin et aux antécédents de vaccination

contre la grippe. Les personnes ayant déjà été infectées par le SRAS-CoV-2 étaient moins susceptibles de se faire vacciner, alors que les Noirs et les groupes ethniques minoritaires affichaient les taux d'adoption de la vaccination les plus élevés.

- Jusqu'à présent, une étude sur l'adoption du vaccin chez les travailleurs de la santé canadiens a été réalisée en décembre 2020. À Montréal, 80,9 % des travailleurs de la santé à qui on a proposé un vaccin l'ont accepté et 19,1 % l'ont refusé. Du nombre de personnes qui ont refusé un vaccin, 74,1 % ont déclaré qu'elles accepteraient de se faire vacciner à l'avenir, 53,2 % voulant attendre quelques mois et 31,9 % voulant attendre un an (1). Les raisons les plus courantes du refus étaient la nouveauté du vaccin, la préférence pour que les autres se fassent vacciner en premier, le manque d'information à propos du vaccin et le manque de temps pour prendre une décision (1).
- Dans un groupe de 266 transplantés hépatiques en Italie, 96,6 % ont accepté de se faire vacciner lorsqu'il leur a été proposé. Bien qu'ils aient reçu des renseignements adéquats, cinq patients (1,8 %) ont refusé de se faire vacciner en raison d'inquiétudes quant au risque d'effets indésirables graves. Les obstacles en place pour les quatre patients restants (1,6 %) ont pu être éliminés soit en fournissant des détails supplémentaires concernant la vaccination, soit après avoir réglé des problèmes médicaux et logistiques (4).
- Dans un groupe de 85 patients psychiatriques hospitalisés au Royaume-Uni qui avaient la capacité de décider s'ils voulaient recevoir le vaccin contre la COVID-19, 80 % ont accepté et 20 % ont refusé. Les patients britanniques blancs étaient moins susceptibles de refuser que les patients noirs, asiatiques ou issus de minorités ethniques (16,9 % contre 30 %). Les raisons de leur refus comprenaient des inquiétudes quant à l'innocuité et aux effets secondaires du vaccin, la conviction que le risque pour leur santé personnelle de contracter la COVID-19 est faible, une méfiance plus générale envers les services de santé et des inquiétudes quant aux tests sur les animaux (5).

Stratégies d'intervention pour l'adoption des vaccins

- La mise en œuvre de deux rappels par message texte (portant soit sur les avantages personnels, soit sur les avantages sociaux de la vaccination) a permis d'augmenter les taux d'adoption du vaccin en Israël. L'effet global sur huit jours après l'intervention a révélé que le rappel des avantages personnels a entraîné une hausse relative de 9 % par rapport au rappel des avantages sociaux (23,8 % contre 21,7 %, P<0,0001) (2).
- L'Israël a mis en place une politique selon laquelle l'entrée dans certains lieux publics nécessitait la présentation d'un « laissez-passer vert » qui pouvait être obtenu soit en recevant un vaccin, soit par un résultat négatif à un test de dépistage de la COVID-19 récent. La mise en œuvre de cette politique en février a été associée à une hausse relative de 22,2 % de l'adoption du vaccin après trois jours (2).
- En février, un site de vaccination communautaire (Unidos en Salud UeS) a été déployé pour surmonter les obstacles à la vaccination contre la COVID-19 auxquels font face les LatinsX à San Francisco. De ce nombre, 56,1 % ont déclaré s'être fait vacciner plus tôt grâce au site et 65,3 % ont contacté trois personnes ou plus pour leur recommander le vaccin après leur expérience positive (3).

Respect des mesures de santé publique après la vaccination

- À l'aide d'un système de positionnement global (GPS) au Royaume-Uni, l'augmentation médiane quotidienne de la distance de déplacement moyenne à partir de l'adresse enregistrée d'un participant était de 45,0 m (IC à 95 % : de 25 à 65 m, P = <0,001) entre la date de vaccination et 99 jours après la vaccination (6).
- Au début de la campagne de vaccination (janvier) en Israël, les personnes infectées par la COVID-19 faisaient moins attention à la distanciation sociale (29,7 %) et au port du masque (18,8 %) par rapport à celles qui avaient reçu la première dose de vaccin (12,8 % et 8,2 %), ou à celles qui n'étaient ni vaccinées ni infectées (19,2 % et 11,6 %) (7).

Canada

- Deux enquêtes effectuées en juin montrent que 84 à 88 % des Canadiens ont reçu un vaccin ou souhaitent se faire vacciner dès que possible, ce qui représente une augmentation par rapport aux résultats d'avril et de mai (8, 9).
- En juin, 89 % des Canadiens ayant reçu une dose ont déclaré avoir l'intention de recevoir une deuxième dose, 9 % ont déjà reçu leur deuxième dose, 1 % ne le feront probablement pas et 1 % étaient incertains (10).
- Dans un groupe de 70 parents ou tuteurs d'enfants âgés de 12 à 17 ans du Manitoba, 15 % et 13 % étaient incertains de se faire vacciner ou ne feraient pas vacciner leurs enfants, respectivement (11). Les personnes qui sont réticentes à faire vacciner leurs enfants faisaient partie de ménages dont le revenu était inférieur à 40 000 dollars par an, ne se feraient pas vacciner elles-mêmes et ne pensaient pas que les adultes devaient recevoir tous les vaccins habituels (11).
- 48 % des Canadiens étaient mal à l'aise à l'idée de recevoir une marque différente de vaccin pour leur deuxième dose, tandis que 46 % étaient à l'aise et 6 % étaient incertains. Parmi ceux qui ont reçu AstraZeneca comme première dose, 50 % ont préféré recevoir AstraZeneca comme deuxième dose, 32 % ont préféré une autre marque comme deuxième dose, et 18 % étaient incertains (10).
- Les incitatifs financiers (argent, bons, articles gratuits, tirages de prix, rabais) n'ont pas été signalés comme augmentant la probabilité d'accepter de se faire vacciner dans une étude menée au Manitoba (entre 7 et 84 % des répondants ont déclaré que l'incitatif ne les rendrait pas plus susceptibles de se faire vacciner). Cependant, 70 % d'entre eux seraient inquiets si seules les personnes réticentes à se faire vacciner recevaient des incitatifs importants (de 50 à100 $) (11).
- Les passeports vaccinaux bénéficient d'un soutien important au Québec, 72 % des résidents y étant favorables (12).

Parents

- Il continue d'exister une forte corrélation entre l'intention des parents de se faire vacciner et l'intention de faire vacciner leurs enfants (13 à 16). Parmi un groupe de parents ou de soignants américains interrogés en avril, 61,9 % avaient l'intention de faire vacciner leur plus jeune enfant (âge moyen : 4,7 ans), 23,3 % étaient incertains de leur choix et 14,8 % ne savaient pas et 14,8 % n'en avaient pas l'intention. Le fait que l'enfant fréquente la garderie plus d'une fois par semaine était associé à une augmentation des intentions (aPR 1,23, IC à 95 % : de 1,05 à 1,45) (16).

- Tout comme dans la population en général, les parents qui sont dans des ménages à faible revenu, qui sont plus jeunes et moins instruits, qui ont déjà refusé d'autres vaccins, qui sont des femmes ou des membres de minorités ethniques, sont ceux qui étaient plus susceptibles de refuser un vaccin pour leurs enfants (14, 16-19).

Autres populations d'intérêt

- Dans une étude britannique, les personnes déclarant être de confession chrétienne étaient significativement plus susceptibles de se faire vacciner si des passeports vaccinaux étaient instaurés pour les voyages intérieurs (RCa 1,23, IC à 95 % : de 1,08 à 1,41) et internationaux (RCa 1,22 IC à 95 % : de 1,07 à 1,39) par rapport aux athées et aux agnostiques (20).
- Une étude quasi expérimentale menée auprès de 709 électeurs inscrits non vaccinés dans le Dakota du Sud, aux États-Unis, a montré que les messages émanant d'un chef religieux avaient un effet positif statistiquement significatif sur l'intention de se faire vacciner, alors que les messages émanant d'un chef politique ou médical n'avaient aucun effet (21).

Principaux points

- L'adoption du vaccin contre la COVID-19 et les différentes attitudes à l'égard de ce vaccin ont été évaluées dans la population canadienne en général, ainsi qu'auprès des travailleurs de la santé, des populations à risque élevé et d'autres populations d'intérêt au Canada, en Australie, en Nouvelle-Zélande, aux États-Unis et au Royaume-Uni et les résultats obtenus ont été publiés dans 205 études actuellement disponibles (tableaux 1 à 7). La majorité d'entre elles ont mis l'accent sur l'intention de se faire vacciner. Depuis que le déploiement du vaccin a commencé en décembre 2020, 29 études ont évalué l'adoption du vaccin alors que sept ont examiné le respect continu des mesures de santé publique après la vaccination.

Adoption des vaccins

- L'adoption du vaccin et les facteurs associés à cette adoption chez les travailleurs de la santé ont été évalués dans le cadre de 14 études effectuées aux États-Unis, au Royaume-Uni, au Canada et en Israël, ainsi que dans deux études portant sur des adultes de plus de 70 ans menées au Royaume-Uni et en Pologne (tableau 1). La proportion de travailleurs de la santé qui ont accepté et reçu une dose du vaccin variait entre 52 et 94 % entre les études. Les médecins étaient plus susceptibles de se faire vacciner que les infirmières et les travailleurs de la santé œuvrant dans des milieux non cliniques.
- L'adoption du vaccin et les facteurs associés à l'adoption ont été étudiés dans la population générale du Royaume-Uni, des États-Unis, d'Israël et de la Nouvelle-Zélande (n=6 études) et dans plusieurs populations spécifiques : une étude sur les personnes sans domicile fixe aux États-Unis, une étude sur les adultes handicapés au Royaume-Uni, une étude sur les survivants d'un accident vasculaire cérébral (AVC) ou d'un accident ischémique transitoire (AIT) au Royaume-Uni, une étude sur les personnes âgées et les populations à haut risque aux États-Unis, une étude sur les patients dialysés aux États-Unis, une étude sur les transplantés hépatiques en Italie, une étude sur les patients atteints du syndrome du côlon irritable en Italie, une étude sur la population d'un hôpital psychiatrique au

Royaume-Uni, deux études sur les prisons aux États-Unis et deux études sur les unités militaires en Israël (tableau 1).

- Dans toutes les populations, l'adoption du vaccin a été associée positivement à un âge plus avancé et au sexe masculin. Les personnes ayant déjà été infectées par le SRAS-CoV-2 étaient moins susceptibles de se faire vacciner, alors que les Noirs, les Asiatiques et les groupes ethniques minoritaires affichaient les taux d'adoption du vaccin les plus élevés.

L'intention en ce qui concerne la vaccination au Canada

- Quarante-neuf études sur l'intention en ce qui concerne la vaccination ont été réalisées au Canada, soit quatre qui ont porté sur les travailleurs de la santé, 36 sur le grand public, trois sur les travailleurs de la santé et le grand public, deux sur des parents, une sur les personnes atteintes d'obésité, une sur les jeunes (âgés de 16 à 21 ans) et deux sur l'opinion d'experts sur les personnes qui devraient d'abord se faire vacciner. Les études les plus récentes effectuées de mars à mai, démontrent que l'intention de se faire vacciner augmente et qu'à l'heure actuelle, elle varie entre 66 et 86 % dans le grand public et entre 57 et 82 % parmi les travailleurs de la santé dans l'ensemble du Canada. Les provinces de l'Atlantique, la Colombie-Britannique et le Québec sont les provinces dans lesquelles on voit le taux le plus élevé quant à l'intention de se faire vacciner.

Facilitateurs de l'intention de se faire vacciner et obstacles à cette intention

- Les facteurs les plus souvent associés positivement à l'intention de se faire vacciner au Canada et dans le monde étaient le sexe masculin, le fait d'être plus âgé, avoir fait des études supérieures, posséder des connaissances ou des connaissances adéquates en matière de santé, faire confiance aux experts et au gouvernement, avoir déjà reçu un vaccin contre la grippe, avoir un statut socioéconomique plus élevé et être plus préoccupé par la COVID-19.
- Comparativement aux infirmières et aux autres travailleurs de la santé, les médecins étaient beaucoup plus susceptibles d'accepter un vaccin contre la COVID-19.
- Trois études ont démontré que la communauté LGBTQ2+ était de 6 à 25 % plus disposée à accepter un vaccin que la communauté non-LGBTQ2+.
- La partisanerie a été associée à l'intention de se faire vacciner. Les personnes qui ont voté pour les partis libéraux ou démocrates ont exprimé une intention plus ferme de se faire vacciner que celles qui ont voté pour les autres partis.
- Une recommandation indiquant de se faire vacciner par un fournisseur de soins de santé (p. ex., un médecin) a eu un effet positif sur l'intention de se faire vacciner.
- L'intention de se faire vacciner variait grandement selon la race ou l'origine ethnique, les Blancs étant plus susceptibles de décider de se faire vacciner que d'autres groupes ethniques comme les Noirs, les Asiatiques et les Hispaniques, selon des études menées au Canada, aux États-Unis et au Royaume-Uni.
- Les parents avaient moins l'intention de faire vacciner leurs enfants qu'eux-mêmes. Il existe une forte corrélation entre l'intention des parents de se faire vacciner et l'intention de faire vacciner leurs enfants puisque les parents qui avaient l'intention de se faire vacciner étaient plus susceptibles de

vouloir faire vacciner leurs enfants. Les personnes qui ont des enfants plus jeunes (0 à 4 ans) étaient plus réticentes envers la vaccination que celles dont les enfants ont plus de 5 ans.

- La religion et la croyance en des théories du complot étaient associées à la réticence à se faire vacciner.
- Les préoccupations en ce qui concerne l'innocuité et l'efficacité du vaccin étaient les deux raisons les plus souvent invoquées pour justifier le refus de se faire vacciner. Parmi les autres raisons fréquemment citées, mentionnons la nouveauté du vaccin et la croyance qu'un vaccin contre la COVID-19 est inutile.
- Comparativement à la population en général, l'intention de se faire vacciner est plus faible dans certaines populations à risque élevé, comme les femmes enceintes, les personnes sans abri, les personnes atteintes de troubles liés à la consommation de substances et les populations vulnérables.
- Les participants ruraux étaient légèrement moins susceptibles d'accepter un vaccin que les participants qui vivent dans les villes et les banlieues.

Vue d'ensemble des éléments de preuve

Deux cent cinq articles portant sur l'adoption du vaccin contre la COVID-19 et les attitudes associées ont été recensés et inclus dans la présente revue. De ce nombre, 99 sont des préimpressions ou des études pour lesquelles le processus d'examen par les pairs n'est pas terminé. Cette revue rapide met l'accent sur les données mondiales sur l'adoption du vaccin contre la COVID-19 et sur les données canadiennes en ce qui concerne les attitudes à l'égard de ce vaccin. Des données probantes sur les populations prioritaires prédéfinies provenant de l'Australie, de la Nouvelle-Zélande, des États-Unis et du Royaume-Uni ont également été incluses afin de compléter les données fournies par les études réalisées au Canada. Cela inclut les travailleurs de la santé, les LGBTQ+, les groupes confessionnels, les nouveaux arrivants, les parents, les femmes enceintes ou qui allaitent, les personnes qui vivent dans les collectivités rurales, les adultes plus âgés, les personnes qui ont des comorbidités et celles qui se heurtent à de multiples obstacles en matière de santé. (p. ex., itinérance, troubles de santé mentale ou de toxicomanie).

Les publications qui portent sur l'adoption du vaccin contre la COVID-19 et les attitudes associées incluent principalement des études d'observation, quelques essais cliniques randomisés, des études contrôlées avant et après, ainsi que des études quasi expérimentales ayant examiné les facteurs associés à l'intention de se faire vacciner et à l'incidence des différents messages sur cette intention. Les résultats des études expérimentales n'ont pas évalué la prévalence, mais visaient plutôt à indiquer l'option la plus efficace parmi un éventail d'options. Les essais cliniques randomisés offrent l'avantage supplémentaire d'équilibrer les groupes de traitement pour éviter l'influence associée aux groupes non comparables (p. ex., confusion).

Aucune évaluation officielle du risque de biais n'a été effectuée. La fiabilité du résultat des études d'observation est fondée sur l'obtention d'un échantillon représentatif de la population cible suffisamment grand pour obtenir un spectre de résultats représentatif. Il est fréquent que les études ne démontrent pas la représentativité de leurs échantillons par rapport à la population cible, tant dans les études non publiées que

dans les études publiées. Les études longitudinales dans lesquelles une population cible est échantillonnée plus d'une fois afin de surveiller les changements dans l'attitude à l'égard de la vaccination et de l'adoption du vaccin dans le temps ont été le modèle d'étude d'observation le plus solide ayant été relevé. Bon nombre des études d'observation étaient des enquêtes transversales effectuées en ligne, auprès d'une population cible, à un moment donné. Ces modèles d'étude présentent un risque modéré/élevé de biais et sont donc vus comme étant de qualité moyenne à faible en raison de la taille de l'échantillon et du fait qu'il représente ou non la population cible, ainsi qu'en fonction de la capacité de l'outil d'enquête à mesurer le ou les résultats d'intérêt (par exemple, l'étude était-elle fondée sur une recherche formative ayant été validée et prétestée avant sa mise en œuvre). Pour la plupart des études incluses, les résultats sont autodéclarés et peuvent donc être biaisés en raison des réponses et de la désirabilité sociale. Les autres biais pris en compte dans ces études incluent le taux de réponse et les données manquantes. La plupart des études incluses dans cette revue rapide n'ont pas déclaré un ou plusieurs des critères indiqués ci-dessus ou n'en ont pas tenu compte en raison de la réalisation de l'étude ou de la façon dont elle a été déclarée. Bien que de nombreuses études montrent des tendances semblables, les conclusions pourraient changer avec des recherches supplémentaires, un plus vaste échantillon, des stratégies d'échantillonnage et des outils de collecte de données différents, ainsi que la progression notée pendant la pandémie.

Les études portant sur l'intention de se faire vacciner et les motifs associés à la réticence dans les populations à risque élevé et non desservies constituent une lacune clé dans les connaissances associées à la présente recherche. La majorité des études ont utilisé des sondages en ligne et, dans une moindre mesure, des sondages téléphoniques, ce qui peut limiter des segments de la population en raison d'un manque d'accès. Bien que le déploiement du vaccin soit en cours depuis quelques mois, peu d'études ont été publiées sur le refus de se faire vacciner et les connaissances et attitudes associées au rejet ou à l'adoption d'un vaccin. Cette information est cruciale pour déterminer la raison pour laquelle les gens acceptent ou refusent les vaccins et ainsi pouvoir continuer à élaborer des stratégies pour encourager l'adoption du vaccin chez les personnes qui hésitent.

CONTENU

ADOPTION DU VACCIN CONTRE LA COVID-19 ET RESPECT DES MESURES DE SANTÉ PUBLIQUE APRÈS LA VACCINATION

L'adoption du vaccin et les facteurs associés ont été étudiés dans 14 études menées aux États-Unis, au Royaume-Uni et en Israël (1, 22-34) chez les travailleurs de la santé. Deux études effectuées chez des adultes de plus de 70 ans au Royaume-Uni et en Pologne (35, 36), deux études réalisées dans des prisons aux États-Unis (37, 38), deux études effectuées dans des unités militaires en Israël (39, 40), une étude sur les personnes en situation d'itinérance aux États-Unis (41), une étude sur les survivants d'un accident vasculaire cérébral (AVC) ou d'un accident ischémique transitoire (AIT) au Royaume-Uni (42), une étude sur les adultes handicapés et les parents au Royaume-Uni (43), une étude sur les personnes âgées et les populations à haut risque aux États-Unis (44), une étude sur les patients en hémodialyse aux États-Unis (45), une étude sur les transplantés hépatiques en Italie (4), une étude sur des patients atteints du syndrome du côlon irritable en Italie (46), une étude sur des patients psychiatriques hospitalisés au Royaume-Uni (5) et six études dans la population générale du Royaume-Uni, aux États-Unis, en Israël et en Nouvelle-Zélande (2, 15, 44-49) ont toutes examiné l'adoption du vaccin et les facteurs associés. Seules les études où l'on peut établir ou déduire que tout le groupe s'est vu offrir un vaccin avant de mesurer le niveau d'adoption du vaccin ont été incluses. Cela inclut les études à partir du début du déploiement du vaccin (à partir de décembre 2020). Sept études ont évalué le respect des mesures de santé publique après la vaccination au Royaume-Uni et en Israël (6, 7, 35, 50-53). Les éléments généraux sont présentés ci-dessous alors que les résultats détaillés pour chacune des études figurent dans l'annexe (Tableau 1). Ces études doivent être interprétées avec prudence, car l'adoption et le refus du vaccin ont été signalés, dans quelques études, comme des résultats secondaires à d'autres résultats primaires axés notamment sur l'efficacité du vaccin alors que dans d'autres études, la mesure dans laquelle l'adoption et le refus n'étaient pas clairs en raison de la façon de déclarer les résultats ou de la nature préliminaire de ceux-ci.

Tendances générales

- L'adoption du vaccin a été associée positivement à un âge plus avancé (1, 15, 25, 26, 29, 30, 34, 38, 45, 50, 54) et au sexe masculin (1, 15, 22, 25, 26, 29, 30, 36, 45, 47).
- Les personnes qui avaient des antécédents d'infection par le SRAS-CoV-2 étaient moins susceptibles de se faire vacciner selon quatre études (25-27, 45). Les raisons de leur refus comprenaient des inquiétudes quant à la nouveauté du vaccin, de ses effets secondaires possibles, la conviction que le risque pour leur santé personnelle de contracter la COVID-19 est faible, une méfiance plus générale envers les services de santé et des inquiétudes quant aux tests sur les animaux et le fait d'être soumis à des expériences (1, 4, 5, 27, 28, 30, 32, 36, 46).
- Trois études effectuées aux États-Unis ont indiqué que les personnes qui n'ont pas reçu le vaccin antigrippal étaient moins susceptibles de vouloir recevoir le vaccin contre la COVID-19 que celles qui l'avaient reçu (30, 32, 45).

- Dix études ont évalué l'adoption du vaccin dans différents groupes ethniques/raciaux. Les Noirs et les groupes ethniques minoritaires affichaient les taux d'adoption de la vaccination les plus faibles (5, 22, 25-27, 29, 30, 32, 34, 38, 49).
- Ces tendances correspondent aux résultats en ce qui concerne l'intention de se faire vacciner.

Travailleurs de la santé

- Dans six études réalisées dans les hôpitaux des États-Unis, de 70 à 94 % des travailleurs de la santé ont dit qu'ils se feraient vacciner lorsque le vaccin serait disponible (22, 27, 30-33).
- Dans un sondage mené en décembre à Montréal, au Canada, 80,9 % des travailleurs de la santé à qui l'on a proposé un vaccin l'ont accepté et 19,1 % l'ont refusé. Du nombre de personnes qui ont refusé un vaccin, 74,1 % ont déclaré qu'elles accepteraient de se faire vacciner à l'avenir, 53,2 % voulant attendre quelques mois et 31,9 % voulant attendre un an (1).
- Des taux élevés de vaccination chez les travailleurs de la santé en Israël ont été déclarés dans deux études dans lesquelles tous les travailleurs de la santé s'étaient vu offrir un vaccin. Au 21 janvier et au 24 janvier, 90 % (n=1500) et 79 % (n=9109) des travailleurs de la santé avaient reçu au moins une dose de vaccin (23, 24).
- Dans le cadre de trois études sur des travailleurs de la santé qui se sont vus offrir un vaccin dans des hôpitaux au Royaume-Uni, de 63 à 89 % des travailleurs ont choisi de recevoir le vaccin (25, 26, 29).
- Dans 87 maisons de santé au Royaume-Uni où tous les membres du personnel se sont vus offrir un vaccin, 52,6 % (n = 1 119) avaient reçu une première dose pour un taux de vaccination moyen par maison de 51,4 % (IC à 95 % : 43,9 à 58,8 %). Le fait que le personnel était à l'extérieur du site pendant les cliniques de vaccination (36,5 %) est l'une des raisons courantes pour lesquelles certaines personnes n'ont pas été vaccinées. Si des problèmes logistiques comme celui-ci étaient résolus, le taux moyen de vaccination par maison de santé aurait alors pu atteindre 69,8 % (IC à 95 % : de 63,2 à 76,3 %) (28).
- Les médecins étaient plus susceptibles d'avoir accepté de se faire vacciner que les infirmières et les travailleurs de la santé œuvrant dans des milieux non cliniques (22, 27, 29, 30).

Adultes plus âgés (70 ans et plus)

- Dans une étude effectuée au Royaume-Uni auprès de personnes âgées (de 80 ans et plus) dans laquelle 99,8 % ont déclaré s'être vues offrir un vaccin, 99 % ont dit avoir reçu au moins une dose et 15 % avaient reçu au moins deux doses et 1 % a refusé (35, 54).
- Dans une étude réalisée en Pologne et portant sur 1 427 adultes âgés (de 70 ans et plus), 62,7 % ont dit avoir reçu le vaccin alors que 37,3 % ont déclaré ne pas vouloir se faire vacciner. Les prédicteurs indépendants les plus importants pour l'adoption du vaccin étaient le fait d'avoir reçu une explication d'un professionnel de la santé à savoir pourquoi la personne devrait se faire vacciner (RC = 4,23, IC à 95 % : 2,90 à 5,75), de vivre avec d'autres personnes (RC = 3,13, IC à 95 % : 2,03 à 4,26), de pouvoir se rendre par ses propres moyens chez un omnipraticien (RC = 1,92, IC à 95 % : 1,45 à 2,76), d'être atteinte de maladies chroniques (RC = 2,98, IC à 95 % : 2,05 à 4,01) et d'avoir un statut socioéconomique supérieur (RC = 1,79, IC à 95 % : 1,33 à 2,15) (36).

Personnes en situation d'itinérance

- Dans un groupe de 90 personnes sans abri de Los Angeles où 17 se sont fait offrir un vaccin, 10 ont accepté de le recevoir et 7 l'ont refusé. Les motifs du refus n'ont pas été examinés (41).

Prisons

- Dans des établissements correctionnels du Rhode Island et de la Californie, 66,5 à 76,4 % des personnes incarcérées ont accepté de se faire vacciner. Les motifs du refus n'ont pas été examinés (37, 38).

Population en général

- Une étude longitudinale effectuée dans la population générale du Royaume-Uni montre que les taux de refus du vaccin se situent entre 1 et 2 %. Parmi les personnes à qui on a offert un vaccin, les taux de refus du vaccin étaient de 2 % chez les 16 à 29 ans, de 1 % chez les 30 à 49 ans et de 2 % chez les 50 à 69 ans (50, 54).
- Dans le cadre d'un programme de vaccination mis en œuvre dans le nord-ouest de Londres, où 413 919 personnes se sont vu offrir un vaccin, 5,88 % des personnes ont refusé le vaccin et 0,7 % étaient réticente. La privation était associée négativement au refus du vaccin ($r = -0,94$, $P < 0,01$). Chez les personnes qui vivaient dans les régions défavorisées, les taux de refus les plus élevés ont été observés chez les personnes de 70 ans et plus (70 à 74 ans = 17,5 %; 75 à 80 ans = 19,0 %; 80 ans et plus = 25,9 %), les personnes extrêmement vulnérables sur le plan clinique (19,2 %) et les membres des communautés noires et noires britanniques (20,0 %) (49).
- Dans un sondage longitudinal mené auprès d'adultes néo-zélandais, le taux de refus de vaccin a chuté de 2 % en avril à 1 % en mai (15).
- Au Royaume-Uni, 5 % des personnes qui s'identifiaient comme ayant une autre religion et 4 % des bouddhistes à qui on avait offert un vaccin l'avaient refusé, comparativement à 1 % des personnes qui ne déclaraient aucune religion (47).
- Deux études ont été menées pour mesurer l'incidence des rappels par messages textes sur les taux de vaccination et de rendez-vous fixés aux États-Unis et en Israël. Dans le sondage effectué aux États-Unis, un premier rappel envoyé par texto le lendemain du jour où une personne a été avisée qu'elle pouvait recevoir le vaccin a fait augmenter les taux de rendez-vous et de vaccination de 86 % et 26 %, respectivement (44). Un deuxième rappel a été envoyé par message texte à celles qui n'avaient pas pris de rendez-vous huit jours après le premier message texte a eu pour effet de faire augmenter le nombre de rendez-vous et le taux de vaccination de 52 % et de 16 % respectivement (44). Dans l'étude israélienne, les personnes ont reçu l'un des deux rappels par messages textes concernant les avantages sociaux ou personnels de la vaccination (2). L'effet global sur huit jours après l'intervention a révélé que le rappel des avantages personnels a entraîné une hausse relative de 9 % par rapport au rappel des avantages sociaux (23,8 % contre 21,7 %, $P<0,0001$) (2).
- Israël a mis en place une politique de laissez-passer vert selon laquelle l'entrée dans certains lieux publics nécessite la présentation d'un « laissez-passer » qui peut être obtenu soit en recevant un vaccin, soit en présentant un laissez-passer récent indiquant un résultat négatif au test de la COVID-

19. La mise en œuvre de cette politique en février a été associée à une augmentation relative de 22,2 % de l'adoption du vaccin après trois jours (2).

Unités militaires

- Selon deux études effectuées en Israël (39,55), le taux d'adoption du vaccin était élevé (de 84,8 à 89,8 %) dans deux unités militaires. Dans un groupe de 28 soldats qui n'avaient pas l'intention de se faire vacciner, 47,4 % se sont finalement fait vacciner après avoir consulté un médecin et abordé leurs différentes préoccupations (P = 0,004) (39).

Autres populations

- Au Royaume-Uni, 1 % des personnes handicapées et 1 % des répondants extrêmement vulnérables sur le plan clinique se sont vu offrir un vaccin, mais l'ont refusé, un pourcentage légèrement plus élevé à celui de la population en général (2 %) (56). Trois pour cent des parents qui avaient des enfants âgés de 0 à 4 ans se sont vu offrir un vaccin et l'ont refusé, comparativement à 2 % de ceux qui avaient des enfants de plus de 5 ans ou à 1 % de ceux qui ne sont pas des parents et qui ne vivent pas avec des enfants à charge (43).
- Des personnes dialysées, 14,2 % qui ont pris part à une étude aux États-Unis ont refusé un vaccin lorsqu'il leur a été proposé. Les personnes dialysées depuis plus de 5 ans étaient plus susceptibles de refuser un vaccin (RC 1,7, IC à 95 % : de 1,08 à 2,70, P=0.023) (45).
- Chez 377 survivants d'accidents vasculaires cérébraux et d'accidents ischémiques transitoires (AIT) au Royaume-Uni, 2 % des personnes interrogées ont refusé le vaccin lorsqu'il leur a été proposé (42).
- Dans un groupe de 266 transplantés hépatiques en Italie, 96,6 % ont accepté de se faire vacciner lorsque le vaccin leur a été proposé. Bien qu'ils aient reçu des renseignements adéquats, cinq patients (1,8 %) ont refusé de se faire vacciner en raison d'inquiétudes quant au risque d'effets indésirables graves. Les obstacles en place pour les quatre patients restants (1,6 %) pourraient être éliminés soit en fournissant des détails supplémentaires concernant la vaccination, soit après avoir réglé des problèmes médicaux et logistiques (4).
- Dans un groupe de 85 patients psychiatriques hospitalisés au Royaume-Uni qui avaient la capacité de décider s'ils voulaient recevoir le vaccin contre la COVID-19, 80 % ont accepté et 20 % ont refusé. Les patients britanniques blancs étaient moins susceptibles de refuser que les patients noirs, asiatiques ou issus de minorités ethniques (16,9 % contre 30 %). Les raisons de leur refus comprenaient des inquiétudes quant à l'innocuité et aux effets secondaires du vaccin, la conviction que le risque pour leur santé personnelle de contracter la COVID-19 est faible, une méfiance plus générale envers les services de santé et des inquiétudes quant aux tests sur les animaux (5)..
- Sur 56 patients atteints du syndrome du côlon irritable en Italie, 96,4 % ont accepté de se faire vacciner lorsqu'un vaccin leur a été proposé. Le refus était attribuable aux inquiétudes concernant les effets indésirables potentiels (46).

Respect des mesures de santé publique après la vaccination

- Dans une étude effectuée au Royaume-Uni chez des adultes plus âgés (80 ans et plus) parmi ceux qui avaient reçu au moins une dose au cours des trois dernières semaines, 43 % avaient rencontré quelqu'un en dehors de leur bulle, de leur ménage ou du personnel soignant à l'intérieur plutôt qu'à

l'extérieur, 49 % avaient rencontré à l'extérieur une personne avec qui elles ne vivaient pas, 54 % étaient allées magasiner et 45 % étaient sorties de la maison pour participer à des activités de loisirs en plein air (35).

- Une étude longitudinale menée au Royaume-Uni a démontré que les adultes vaccinés (ayant reçu au moins une dose) étaient plus susceptibles que les adultes non vaccinés de se laver les mains à leur retour à la maison (90 % contre 82 %), de respecter la distanciation sociale lorsqu'ils rencontrent d'autres personnes à l'extérieur de leur ménage ou de leur bulle (90 % contre 72 %) et d'éviter les contacts physiques à l'extérieur de leur domicile (86 % comparativement à 74 %) (50).
- Après la deuxième dose de vaccin, 21,1 % et 47,3 % des personnes interrogées au Royaume-Uni ont déclaré moins porter leur couvre-visage et moins respecter la distanciation sociale depuis qu'elles ont été vaccinées alors que 75,7 % et 48,4 % respectivement n'ont pas changé leur comportement. Les personnes de 50 ans et plus étaient moins susceptibles de changer de comportement que celles de moins de 50 ans. Des tendances semblables ont été observées chez les travailleurs de la santé pour ce qui est de la distanciation sociale, mais la majorité (95,7 %) d'entre eux n'ont pas indiqué de changement dans le port du couvre-visage après la vaccination (51).
- Même s'ils avaient reçu au moins une dose du vaccin contre la COVID-19, 73,2 % des adultes américains n'ont pas changé leurs comportements en ce qui concerne la prévention, alors que 4,3 % des gens ont adopté des comportements plus stricts et que 21,9 % ont modéré les changements de comportements (53).
- Au début de la campagne de vaccination en Israël, les personnes infectées par la COVID-19 faisaient moins attention à la distanciation sociale (29,7 %) et au port du masque (18,8 %) par rapport à celles qui avaient reçu la première dose de vaccin (12,8 % et 8,2 %), ou à celles qui n'étaient ni vaccinées ni infectées (19,2 % et 11,6 %) (7).
- À l'aide d'un système de positionnement global (GPS) au Royaume-Uni, l'augmentation médiane quotidienne de la distance de déplacement moyenne à partir de l'adresse enregistrée d'un participant était de 45,0 m (IC à 95 % : de 25 à 65 m, P = <0,001) entre la date de vaccination et 99 jours après la vaccination (6).

ATTITUDES DE LA POPULATION MONDIALE À L'ÉGARD DU VACCIN CONTRE LA COVID-19

La comparaison des attitudes à l'égard du vaccin contre la COVID-19 dans la population générale de différents pays du monde a été présentée dans six articles. Seules les études incluant le Canada et les résultats par pays ont été incluses. Les éléments généraux d'études les plus récentes (à partir de janvier 2021) sont présentés ci-dessous alors que les résultats détaillés pour chacune des études figurent dans l'annexe (Tableau 2).

- En janvier, le Royaume-Uni, le Danemark et les Pays-Bas comptaient parmi les pays dans lesquels la population indiquait avoir la plus forte intention de se faire vacciner (63 à 77 %). À ce moment-là, au Canada, l'intention de se faire vacciner atteignait 55 % (57).

- On a pu voir une augmentation de l'intention de se faire vacciner entre novembre et janvier en Espagne (24,1 %), au Royaume-Uni (23,2 %), en Suède (22,7 %), en Finlande (20,4 %), aux Pays-Bas (18,5 %), en Italie (15,4 %), en Norvège (14,6 %), en France (14,2 %), au Danemark (13,3 %), en Allemagne (13,0 %), au Canada (11 %) et au Japon (0,8 %) (57).
- Dans 11 des 15 pays, on a vu une diminution importante de la proportion de personnes qui se sont dites préoccupées par les effets secondaires d'un vaccin. Au Canada, cette préoccupation a diminué, passant de 53,3 % en novembre à 47,9 % en janvier (57).

ATTITUDES DE LA POPULATION CANADIENNE GÉNÉRALE À L'ÉGARD DU VACCIN CONTRE LA COVID-19

La majorité de la recherche sur les attitudes à l'égard du vaccin contre la COVID-19 a été effectuée auprès du grand public. Des quarante-deux études propres à la population canadienne, 27 sont de la littérature grise et sept sont des préimpressions. Les éléments généraux de janvier 2021 sont présentés ci-dessous et les résultats détaillés pour chacune des études figurent dans l'annexe (Tableau 3).

Intentions de se faire vacciner

- Selon les études canadiennes les plus récentes, datant de juin 2021, l'intention de se faire vacciner se situait entre 84 et 88 % (8, 10). Les provinces de l'Atlantique, la Colombie-Britannique et le Québec sont les provinces dans lesquelles l'intention de se faire vacciner atteint son niveau le plus élevé (58-73).
- Trois études longitudinales ont démontré que l'intention de se faire vacciner au Canada avait continué à augmenter à partir de niveaux de référence enregistrés entre septembre et décembre (10, 74, 75).
- En juin, 89 % des Canadiens ayant reçu une dose ont déclaré avoir l'intention de recevoir une deuxième dose, 9 % ont déjà reçu leur deuxième dose, 1 % ne le feront probablement pas et 1 % étaient incertains (10).
- Dans un groupe de 70 parents ou tuteurs d'enfants âgés de 12 à 17 ans du Manitoba, 15 % et 13 % étaient incertains de faire vacciner ou ne feraient pas vacciner leurs enfants, respectivement (11). Les personnes qui étaient réticentes à faire vacciner leurs enfants faisaient partie de ménages dont le revenu était inférieur à 40 000 dollars par an, ne se feraient pas vacciner elles-mêmes et ne pensaient pas que les adultes devaient recevoir tous les vaccins habituels (11).
- 48 % des Canadiens étaient mal à l'aise à l'idée de recevoir une marque différente de vaccin pour leur deuxième dose, tandis que 46 % étaient à l'aise et 6 % étaient incertains. Parmi ceux qui ont reçu AstraZeneca comme première dose, 50 % ont préféré recevoir AstraZeneca comme deuxième dose, 32 % ont préféré une autre marque comme deuxième dose, et 18 % étaient incertains (10).
- Les incitatifs financiers (argent, bons, articles gratuits, tirages de prix, rabais) n'ont pas été signalés comme augmentant la probabilité d'accepter de se faire vacciner dans une étude menée au Manitoba (entre 7 et 84 % des répondants ont déclaré que l'incitatif ne les rendrait pas plus susceptibles de se

faire vacciner). Cependant, 70 % d'entre eux seraient inquiets si seules les personnes réticentes à se faire vacciner recevaient des incitatifs importants (de 50 à100 $) (11).

- La réticence à se faire vacciner a chuté de façon spectaculaire en Alberta, passant de 45 % en janvier à 25 % en avril et à 17 % en mai (76).
- Une étude effectuée en janvier et en février 2021 dans le sud de l'Ontario a indiqué que 82,8 % des personnes étaient prêtes à recevoir un vaccin alors que 17,2 % n'étaient pas disposées à le faire (77).
- Une étude menée en mai 2021 a démontré que la plupart des gens se sentaient à l'aise avec les vaccins Pfizer (93 %) et Moderna (89 %), mais l'étaient moins avec les vaccins Johnson et Johnson (49 %) et AstraZeneca (35 %). Les femmes et les personnes de 55 ans et plus étaient plus mal à l'aise avec les vaccins AstraZeneca (AZ) et Johnson and Johnson (J&J) que les hommes et les personnes de moins de 55 ans. Parmi les personnes qui n'étaient pas à l'aise avec les vaccins AZ et J&J, 40 % des femmes et 31 % des hommes ont déclaré qu'ils accepteraient quand même ces vaccins s'ils leur étaient offerts (76).
- Selon trois études, les membres de la communauté LGBTQ2+ étaient plus disposés à accepter de se faire vacciner que les personnes n'appartenant pas à cette communauté (87,6 % contre 76,4 % dans une étude, RC=3,04, IC à 95 % : de 1,08 à 8,55, p=0,04 dans un autre, et 83,3 % contre 77 % dans un troisième) (78-80).
- Dans le cadre d'un sondage effectué en janvier et en février 2021, 71 % des jeunes de 12 à 17 ans ont dit avoir l'intention de se faire vacciner (81).
- Comparativement aux non-immigrants (75,9 %), les immigrants qui vivent au Canada depuis moins de 10 ans (80,3 %) et plus de 10 ans (70,7 %) ont dit avoir un intérêt comparable pour la vaccination (78). Une autre étude a montré que les immigrants étaient un peu moins susceptibles de se faire vacciner (74,6 %) que le grand public (77 %), mais cela variait grandement entre les immigrants plus âgés et les plus jeunes (73,2 % pour les 12 à 64 ans et 81,1 % pour les 65 ans et plus) (80).
- Au sein des groupes des minorités visibles au Canada, l'intention de se faire vacciner était la suivante, de la plus faible à la plus forte : les Noirs (57,0 %), les Latino-Américains (58,5 %), les Philippins (64,2 %), les Asiatiques du Sud-Est (75,8 %), les autres minorités visibles (77,6 %), les Chinois (85,5 %) et les Arabes (88,3 %). Parmi les personnes déclarant une identité autochtone, 69,3 % acceptent de se faire vacciner, contre 77,6 % des personnes n'ayant pas déclaré une telle identité (78).
- Les personnes appartenant aux minorités visibles qui avaient la plus grande intention de se faire vacciner étaient les Japonais (86,5 %), les Coréens (85,6 %), les Asiatiques du Sud (82,5 %), les Chinois (79,3 %), les minorités visibles non indiquées/multiples (79,1 %), les Asiatiques du Sud-Est (78,3 %), les Asiatiques de l'Ouest (78,3 %), les Philippins (75,1 %), les Arabes (68,1 %), les gens d'Amérique latine (66,0 %) et les Noirs (56,6 %). L'intention de se faire vacciner des membres d'une minorité non visible était de 77,6 % (82).
- Chez les répondants autochtones, 71,8 % ont dit qu'ils se feraient vacciner, ce qui est nettement inférieur au taux de réponse des répondants non autochtones (77,1 %). 74,2 % des membres des

Premières Nations qui vivent hors réserve étaient prêts à se faire vacciner, comparativement à 67,8 % des Métis et à 72,5 % des Inuits. Les Autochtones plus âgés (65 ans et plus) étaient plus susceptibles de vouloir se faire vacciner que les plus jeunes (74,9 % contre 71,3 %) (82).

- Dans un sondage effectué auprès des résidents autochtones de la Colombie-Britannique, 68 % ont déclaré qu'ils aimeraient se faire vacciner le plus tôt possible ou qu'ils l'ont déjà été, comparativement à 58 % des répondants asiatiques et 66 % des répondants sud-asiatiques (83).
- En Colombie-Britannique, l'intention de se faire vacciner était la plus forte chez les travailleurs en soins continus venus de l'Asie de l'Est (61 %) et du Sud (70 %). Les répondants latins et les Noirs étaient les plus susceptibles de refuser le vaccin (30 %) alors que ceux qui ont des antécédents autochtones sont ceux qui avaient le plus tendance à être incertains quant à la décision à savoir s'ils se feraient ou non vacciner (40 %). Les répondants autochtones étaient ceux qui avaient le moins confiance aux différentes sources d'information, y compris les fournisseurs de soins de santé (84).
- Au Canada, les personnes qui ont voté pour le Parti libéral ou le NPD aux élections de 2019 étaient plus susceptibles d'indiquer leur intention de se faire vacciner que celles qui ont voté pour d'autres partis (58-60, 85).
- Dans trois études, les participants ruraux étaient moins susceptibles d'accepter un vaccin que les participants qui vivent dans les villes et les banlieues (10, 86, 87).
- Selon onze études, les hommes étaient plus susceptibles d'avoir l'intention de se faire vacciner que les femmes (58, 61, 77-79, 81, 88-92).
- Les facteurs les plus courants associés positivement à l'intention de se faire vacciner étaient le fait d'être plus âgé, le fait d'avoir fait des études supérieures, d'avoir des connaissances ou une littéracie adéquates en matière de santé, de faire confiance aux experts et au gouvernement, d'avoir un statut socioéconomique plus élevé, d'avoir déjà reçu un vaccin contre la grippe et d'être plus préoccupé par la COVID-19.
- Les préoccupations en ce qui concerne l'innocuité et l'efficacité du vaccin étaient les deux raisons les plus souvent invoquées pour justifier le refus de se faire vacciner. Parmi les autres raisons fréquemment citées, mentionnons la nouveauté du vaccin et la croyance qu'un vaccin contre la COVID-19 est inutile.
- Une recommandation indiquant de se faire vacciner par un fournisseur de soins de santé (p. ex., un, médecin) a eu un effet positif sur l'intention de se faire vacciner dans cinq études (74, 79, 83, 93, 94).
- Les croyances associées à la conspiration et au complot étaient directement liées à l'intention de ne pas se faire vacciner (59, 90, 95).

Attitudes à l'égard du déploiement du vaccin et des passeports vaccinaux

- Les passeports vaccinaux bénéficient d'un soutien important au Québec, 72 % des résidents y étant favorables (12).

- Parmi les répondants, 61 % sont maintenant d'accord pour dire que le Canada devrait instaurer un passeport vaccinal, un chiffre en augmentation par rapport au 54 % enregistré en avril (73).
- Deux études ont démontré un appui élevé au fait de devoir présenter une preuve de vaccination lors d'un voyage en avion (79 à 82 %), d'événements où l'on retrouve une foule importante (69 à 75 %) et de la fréquentation en présentiel d'une université (71 %) alors que l'appui est plus faible en ce qui concerne le fait d'utiliser la preuve de vaccination pour pouvoir séjourner dans un hôtel (68 %), aller au bureau (55 à 68 %) ou dans des endroits publics comme des restaurants, des bars et des salles de cinéma (55 à 64 %) (73, 96).
- Parmi ceux qui étaient réticents à se faire vacciner, entre 7 et 18 % des répondants aux deux sondages ont dit que leur décision pourrait être influencée par le fait qu'un vaccin leur permettrait de pouvoir voyager, d'assister à des événements sportifs ou culturels ou de rendre visite à des êtres chers (11 %) (96, 97).
- Parmi les personnes qui ont reçu le vaccin AstraZeneca, 2 % ont dit le regretter complètement alors que 66 % ont de sérieux doutes à l'égard du vaccin (76).
- De 51 à 55 % estiment que le Canada a fait un bon travail pour obtenir des doses de vaccin (75, 86).
- Lorsqu'on leur a posé des questions sur le plan de déploiement du vaccin en Colombie-Britannique, 5 % des résidents ont jugé que le déploiement de la vaccination était excellent, 30 % ont dit qu'il était bon, 51 % ont indiqué qu'il était passable, 14 % ont dit qu'il était mauvais alors que 7 % ont mentionné qu'il était très mauvais. On a observé des tendances semblables pour ce qui est des perceptions sur la clarté des niveaux de déploiement et d'établissement des priorités (98).
- 71 % des répondants sont à l'aise avec la façon dont le gouvernement du Manitoba détermine les groupes prioritaires pour la vaccination initiale (99).
- Le taux d'approbation en ce qui concerne le déploiement global du vaccin en Alberta était divisé puisque 48 % se sont dit satisfait alors que 43 % étaient insatisfaits. En ce qui concerne l'ordre de priorité établi par le gouvernement, 64 % des répondants étaient satisfaits et 28 % étaient insatisfaits (100).
- Pour ce qui est de la distribution des vaccins, 42 % des Canadiens croient que leur gouvernement provincial fait du bon travail contrairement à 39 % qui disent l'inverse. L'insatisfaction était la plus élevée en Alberta, au Manitoba et en Ontario. Les résidents de la Colombie-Britannique et du Québec ont donné de meilleures notes à cet égard (68).
- Deux études ont analysé le point de vue des experts sur les stratégies de vaccination contre la COVID-19. Les experts de la santé publique s'accordent à dire que les personnes les plus vulnérables aux maladies graves et aux décès en raison de la COVID-19 (p. ex., les résidents des établissements de soins de longue durée, les travailleurs de la santé, les personnes souffrant de maladies chroniques) devraient avoir la priorité en ce qui concerne la vaccination (101, 102).

ATTITUDES DES TRAVAILLEURS DE LA SANTÉ À L'ÉGARD DU VACCIN CONTRE LA COVID-19

Les données probantes sur les attitudes des travailleurs de la santé à l'égard du vaccin contre la COVID-19 au Canada, en Australie, en Nouvelle-Zélande, au Royaume-Uni et aux États-Unis proviennent de 42 études. Toutes ces études ciblaient les travailleurs de la santé, y compris les infirmières, les médecins et les préposés aux services de soutien à la personne. Les éléments généraux de janvier 2021 sont présentés ci-dessous et les résultats détaillés pour chacune des études figurent dans l'annexe (Tableau 4).

- Les études les plus récentes montrent que l'intention de se faire vacciner chez les travailleurs de la santé canadiens varie de 57 à 82 % (103 à 105). Aux États-Unis, l'intention de se faire vacciner se situe entre 55 et 93 % (106-117).
- Selon une étude, aucune différence n'a été notée en ce qui concerne l'adoption ou le rejet d'un vaccin contre la COVID-19 par les participants, qu'ils travaillent ou non dans le secteur des soins de santé Canada (88). Aux États-Unis, deux études ont montré que les travailleurs de la santé étaient moins susceptibles d'avoir l'intention de se faire vacciner comparativement à la population en général (115, 118) alors que deux autres études ont montré le contraire, soit que les travailleurs de la santé avaient plus l'intention de se faire vacciner comparativement à la population en général (112, 119).
- Les travailleuses de la santé enceintes étaient 7,12 fois plus susceptibles d'hésiter que les travailleuses de la santé non enceintes (RCa 7,12, IC à 95 % : de 4,74 à 10,70) (114).
- Les médecins étaient beaucoup plus susceptibles que les infirmières et les autres travailleurs de la santé d'avoir l'intention de se faire vacciner (37, 107, 110, 116, 117, 120).
- Dix-sept études ont démontré que les travailleurs de la santé sont plus susceptibles d'avoir l'intention de se faire vacciner que les travailleuses de la santé (37, 84, 88, 105, 106, 109, 110, 114, 116, 117, 120-126).
- La proportion de personnes susceptibles de se faire vacciner contre la COVID-19 était directement liée au fait que ces personnes soient plus âgées (37, 84, 88, 103, 105, 109, 110, 114, 116, 121, 123, 124), au fait qu'elles aient déjà eu un vaccin antigrippal (37, 84, 105, 109, 114, 126, 127) et à la perception de pouvoir être infectées par la COVID-19 (105, 117, 123, 126).
- Les principales préoccupations en ce qui concerne la vaccination comprennent l'innocuité, l'efficacité, le manque de connaissances sur le vaccin, les effets secondaires, la vitesse du développement du vaccin et la croyance selon laquelle la vaccination n'était pas nécessaire (37, 84, 88, 103, 105, 106, 108-110, 112-114, 116, 119-121, 124, 126-130).
- Dans une étude sur les employés des services sociaux qui offrent du soutien aux personnes ayant une déficience intellectuelle en Ontario, les Autochtones, les Premières Nations et les Métis (RCa 1,73, IC à 95 % : de 0,67 à 4,43), les Latins (RCa 1,22, IC à 95 % : de 0,21 à 7,24) et les ethnies mixtes (RCa 1,11, IC à 95 % : de 0,27 à 4,55) étaient plus susceptibles de refuser un vaccin que les personnes d'origine européenne (105).

- Dans une étude sur les préposés aux services de soutien à la personne au Canada, 64,2 % des répondants ont dit avoir l'intention de se faire vacciner lorsque le vaccin sera disponible, 16,2 % ne veulent pas se faire vacciner, 10,7 % sont incertains et 8,9 % n'accepteront le vaccin que s'il est obligatoire. La majorité (71,7 %) de ces personnes ne croit cependant pas qu'il y ait suffisamment d'information claire à propos du vaccin (131).
- Dans une étude portant sur 8 634 travailleurs de la santé qui n'étaient pas médecins en Ontario, 80,4 % ont déclaré avoir l'intention de se faire vacciner. Les travailleurs de la santé étaient plus susceptibles d'avoir l'intention de se faire vacciner s'ils pouvaient avoir accès à un soutien financier direct, comme des congés de maladie payés (103). Les travailleurs de la santé non médecins en Ontario, au Canada, qui se sont identifiés comme étant d'origine philippine (RC 1,07, IC à 95 % : 0,41 à 2,76, P < 0,001), caraïbéenne (RC 3,20, IC à 95 % : 1,52 à 6,75, P < 0,001) ou autre (RC 1,44, IC à 95 % : 0,93 à 2,22, P < 0,001) étaient plus susceptibles de refuser un vaccin que ceux qui se sont identifiés comme étant d'origine européenne (103).
- Au Québec, 79,6 % des infirmières recommanderaient certainement ou probablement à leurs patients de se faire vacciner, 3,1 % ne le feraient pas et 17,2 % étaient incertaines. En ce qui les concerne, 70,4 % d'entre elles seraient certainement ou probablement prêtes à recevoir le vaccin, 11,8 % le refuseraient, et 17,8 % ont dit être incertaines (127).
- Deux études menées aux États-Unis ont démontré que les infirmières en milieu urbain étaient plus disposées à recevoir un vaccin que les infirmières en milieu rural lorsque celui-ci sera disponible (109, 132).
- Onze études ont évalué l'intention de se faire vacciner des travailleurs de la santé aux États-Unis. Les travailleurs noirs se sont dits de 12 à 84 % moins disposés à accepter le vaccin que les travailleurs blancs et asiatiques (106, 109, 112, 116, 118, 119, 121, 123, 125, 126, 133).
- Les personnes qui croyaient que le vaccin réduirait leur isolement social avaient plus de chances de conseiller à leurs patients de recevoir le vaccin (RCa 2,95, IC à 95 % : 1,32 à 6,59, P < 0,008) (113).
- Dans un sondage mené au Royaume-Uni auprès de 220 omnipraticiens, plus de 50 % d'entre eux n'avaient que peu confiance dans le fait de conseiller les patients au sujet des vaccins contre la COVID-19 (134).

COVID-19 ATTITUDES DES POPULATIONS À RISQUE ÉLEVÉ À L'ÉGARD DU VACCIN CONTRE LA COVID-19

Il est important de développer des stratégies fondées sur des données probantes pour cibler les populations à risque élevé afin qu'elles puissent être vaccinées. Vingt-quatre études sur les attitudes des populations à risque élevé en ce qui concerne le vaccin contre la COVID-19 ont été recensées au Canada, en Australie, au Royaume-Uni et aux États-Unis, en plus d'une étude mondiale portant sur 16 pays. Elles portaient sur des personnes âgées, des personnes ayant des troubles liés à la consommation de substances, des femmes enceintes ou qui allaitent, des personnes sans abri et des collectivités vulnérables. Les éléments généraux de

janvier 2021 sont présentés ci-dessous et les résultats détaillés pour chacune des études figurent dans l'annexe (Tableau 5).

- Trois études ont indiqué que les femmes enceintes avaient moins l'intention de se faire vacciner (41 à 62,1 %) (19, 135, 136). Les travailleuses de la santé enceintes étaient 7,12 fois plus susceptibles d'hésiter que les travailleuses de la santé non enceintes (RCa 7,12, IC à 95 % : de 4,74 à 10,70) (114). Les raisons les plus courantes pour hésiter étaient les effets secondaires potentiels pour leur bébé et le manque de données sur l'innocuité et l'efficacité chez les femmes enceintes (19, 135, 136). Tes raisons les plus courantes de leur réticence étaient les effets secondaires potentiels pour leur bébé et le manque de données sur l'innocuité et l'efficacité chez les femmes enceintes (19, 135, 136). Tout comme dans la population en général, les femmes qui sont dans des ménages à faible revenu, qui sont âgées de moins de 25 ans, qui n'ont jamais accepté d'autres vaccins, et les membres de minorités ethniques étaient plus susceptibles de refuser un vaccin pendant leur grossesse (19, 135, 136).
- L'intention de se faire vacciner et les raisons de la réticence ont été évaluées dans le cadre de deux études réalisées sur des personnes en situation d'itinérance aux États-Unis (41, 137). L'une d'elles a montré que 51 % de ces personnes accepteraient un vaccin s'il était offert, 32 % le refuseraient alors que 17 % ont refusé de répondre (41). Parmi les raisons courantes pour hésiter à se faire vacciner, mentionnons la peur des effets secondaires, le désir d'obtenir plus d'information sur le vaccin, les inquiétudes à savoir si le vaccin rend les gens malades et la méfiance à l'égard du gouvernement (41, 137). En dépit de l'exclusion sociale et du manque d'accès à la technologie, les participants ont suivi les reportages sur le vaccin et l'information souhaitée sur l'efficacité et l'innocuité du vaccin (41).
- L'intention de se faire vacciner était élevée (plus de79 %) dans six études portant sur des adultes plus âgés (65 ans et plus) (15, 92, 138-141).
- En février, un site de vaccination communautaire (Unidos en Salud UeS) a été déployé pour surmonter les obstacles à la vaccination contre la COVID-19 auxquels font face les LatinsX à San Francisco. De ce nombre, 56,1 % ont déclaré s'être fait vacciner plus tôt grâce au site et 65,3 % ont contacté trois personnes ou plus pour leur recommander le vaccin après leur expérience positive (3).
- Dans un sondage mené auprès de 391 familles amish de l'Ohio, 75,7 % ont dit ne pas avoir l'intention de faire vacciner leurs enfants contre la COVID-19 et les Amish Swartzentruber ont dit être beaucoup moins susceptibles de se faire vacciner comparativement aux autres groupes amish (142).
- Une étude qualitative portant sur les communautés vulnérables (p. ex., les sans-abri, les personnes ayant des problèmes de santé mentale, les Tziganes, les Roms et les Traveller) révèle l'appréhension et le scepticisme généraux, tout comme le faible niveau de confiance à l'égard des essais du vaccin contre la COVID-19. Des obstacles uniques ont été mentionnés pour chaque groupe, comme la réticence à se rendre à l'hôpital, la perte de confidentialité, les préoccupations au sujet des produits animaux dans les vaccins et le fait de croire que les concepteurs de vaccins et les gouvernements aient des intentions cachées. Ces éléments devraient être pris en compte au moment de développer des plans visant à donner confiance à la population à l'égard du vaccin (143).

- Dans un groupe de 87 personnes ayant des troubles liés à la consommation de drogues ou d'alcool aux États-Unis, 48 % se sont dits incertains ou peu disposés à se faire vacciner lorsque le vaccin sera disponible. Plusieurs réticences ont été indiquées, notamment la précipitation à développer les vaccins, les effets secondaires potentiels, ne pas avoir l'impression d'être à risque d'attraper le virus et l'inquiétude quant aux interactions avec des conditions préexistantes (144).
- Comparativement aux anciens fumeurs et à ceux qui n'ont jamais fumé, les fumeurs actuels étaient à la fois les plus indécis (27,6 (IC à 95 % : 26,1 à 29,1)) et réticents (21,5 % (IC à 95 % : 20,2 à 22,9 %)) à avoir l'intention de se faire vacciner (145). Dans une autre étude, la volonté de recevoir un vaccin ne différait pas de façon significative entre les consommateurs de cannabis et les témoins (t88 = 0,33, P = 0,74; BF01 = 4,3) (146). Une étude menée aux États-Unis a révélé que la consommation de cigarettes, de cigarettes électroniques, de marijuana et de boissons alcoolisées n'était pas associée à la réticence à se faire vacciner (147).
- La volonté de recevoir un vaccin contre la COVID-19 était associée positivement à la croyance que l'éclosion de la COVID-19 va se poursuivre pendant longtemps, à la gravité perçue de la maladie, aux conséquences pour la santé personnelle et aux conséquences pour la santé des autres (138, 139, 148, 149).
- Tout comme dans la population en général, l'intention de se faire vacciner était associée positivement au sexe masculin (139, 150), au niveau d'études supérieures (135, 136, 139), à un revenu plus élevé (135, 139, 150), à l'origine ethnique blanche (136, 139), à l'adoption antérieure de la vaccination contre la grippe (136) et à l'âge plus avancé (135).
- Une recommandation indiquant de se faire vacciner par un fournisseur de soins de santé (p. ex., un médecin) a eu un effet positif sur l'intention de se faire vacciner dans deux études portant sur des adultes plus âgés (139, 141), mais n'a eu que peu d'effet chez les femmes enceintes (135).

ATTITUDES DES PERSONNES ATTEINTES DE COMORBIDITÉS À L'ÉGARD DU VACCIN CONTRE LA COVID-19

Vingt-trois études avec des données probantes portant sur les attitudes à l'égard du vaccin contre la COVID-19 chez des personnes ayant des comorbidités et réalisées au Canada, en Australie, au Royaume-Uni et aux États-Unis ont été identifiées. Ces études couvraient un vaste éventail de comorbidités, y compris l'obésité, l'hypertension, les maladies respiratoires chroniques ou auto-immunes, le VIH et les déficiences intellectuelles et développementales. Les éléments généraux de janvier 2021 sont présentés ci-dessous et les résultats détaillés pour chacune des études figurent dans l'annexe (Tableau 6).

- La majorité des études (15 sur 23) ont été menées aux États-Unis, puis au Canada (1 sur 23), en Australie (2 sur 23), au Royaume-Uni (4 sur 23) ainsi que dans des études américaines et britanniques combinées (1 sur 23).
- Dans une étude réalisée au Canada, 64,6 % des personnes en surpoids ou atteintes d'obésité ont dit se sentir à l'aise de se faire vacciner alors que 35,4 % étaient réticentes (151). On a établi un lien positif entre

le degré d'adoption du vaccin et le sexe masculin, le fait d'avoir un plus grand nombre de comorbidités, des niveaux de dépression plus faibles, le fait de ne pas pratiquer la distanciation sociale et le fait d'avoir déjà reçu un vaccin contre la grippe (151).

- Une étude a montré qu'il n'y avait pas de différences significatives dans la volonté de se faire vacciner contre la COVID-19 entre les personnes souffrant d'hypertension et les témoins sains (152). Un autre a indiqué que les personnes qui ont dit être atteintes de maladies respiratoires chroniques étaient 5,7 % plus disposées à se faire vacciner (IC à 95 % : 0,05 à 0,09) que les témoins sains (153).
- Dans un groupe de 97 patients atteints de cancer et de leurs soignants des États-Unis, l'intention de se faire vacciner est passée de 71 % à 82,5 % après avoir assisté à un webinaire éducatif sur les vaccins contre la COVID-19 destinés spécifiquement aux patients atteints de cancer et à leurs soignants (154).
- Dans une étude menée dans un centre de dialyse urbain qui dessert une population de patients principalement noirs aux États-Unis, 49 % des répondants ont indiqué qu'ils seraient disposés à recevoir un vaccin contre la COVID 19, 34 % ont dit ne pas être disposés à le recevoir et 17 % étaient incertains (155).
- Si un vaccin avait été offert dans un centre de dialyse, la réticence à le recevoir chez les patients en hémodialyse aux États-Unis aurait diminué de 20 % à 18 % (156).
- Trois études ont analysé l'intention de se faire vacciner des adultes handicapés. Deux ont démontré que les adultes handicapés étaient un peu moins réticents à se faire vacciner que les adultes non handicapés (5 % contre 7 %) au Royaume-Uni (43, 140) et en Australie (141). L'autre étude, effectuée aux États-Unis, a indiqué que 62 % de ces adultes recevraient certainement ou probablement un vaccin contre la COVID-19 (157).
- Une étude menée auprès de 101 participants noirs vivant avec le VIH aux États-Unis a révélé de faibles intentions de se faire vacciner (32 %). Le faible niveau de scolarité et la méfiance à l'égard de la COVID-19 ont tous deux été associés à une augmentation de la réticence à se faire vacciner (158).
- Un groupe de patients qui ont reçu des soins pour des problèmes gastro-intestinaux et hépatiques chroniques aux États-Unis étaient plus susceptibles de suivre la recommandation de leur spécialiste au sujet de l'administration d'un vaccin (91 %) que le gouvernement ou leur médecin (75 %) ou leur employeur (56 %) (159).
- Les raisons les plus courantes pour hésiter à se faire vacciner étaient les préoccupations au sujet des effets secondaires, les préoccupations au sujet des problèmes de santé existants, le manque d'information adéquate, la méfiance à l'égard du gouvernement et les inquiétudes au sujet des effets à long terme (140, 141, 155, 156, 158-163).
- Tout comme dans la population en général, l'intention de se faire vacciner était associée positivement au sexe masculin (156, 159-161, 164, 165), à un plus grand nombre de comorbidités (164, 166), à un niveau d'études supérieures (148, 149, 156, 160, 165), à des revenus plus élevés (149, 159, 165), à l'origine ethnique blanche (149, 156, 160), au fait de s'être déjà fait vacciner contre la grippe (155, 156, 159, 160, 162, 164, 165), et d'avoir d'un âge plus avancé (149, 156, 157, 159-161).

ATTITUDES D'AUTRES POPULATIONS D'INTÉRÊT À L'ÉGARD DU VACCIN CONTRE LA COVID-19

Soixante-et-une études provenant du Canada, de l'Australie, de la Nouvelle-Zélande, du Royaume-Uni et des États-Unis ont été recensées en ce qui concerne les attitudes à l'égard de la COVID-19 dans d'autres populations d'intérêt. Ces populations comprennent la communauté LGBTQ+, les parents, ceux qui ont des affiliations religieuses, les immigrants, les jeunes (âgés de 14 à 24 ans), les personnes qui ont déjà eu une infection au SRAS-CoV-2, ainsi que les communautés urbaines et rurales. Les éléments généraux de janvier 2021 sont présentés ci-dessous et les résultats détaillés pour chacune des études figurent dans l'annexe (Tableau 7).

LGBTQ+

- Sept études ont évalué l'intention de se faire vacciner des personnes LGBTQ+ au Canada (78 à 80) et aux États-Unis (167 à 170). Trois études ont démontré que les membres de la communauté LGBTQ2+ étaient de 6 à 25 % plus disposés à accepter un vaccin que ceux de la communauté non-LGBTQ2+ (78, 80, 168). Deux études ont indiqué que les personnes non binaires, pansexuelles, allosexuelles, non-genrées, bispirituelles ou autres étaient plus susceptibles de se faire vacciner (1,6 à 4,38 %) (79, 169). Comparativement aux homosexuels, les participants regroupés dans la catégorie « Autre » identité sexuelle (p. ex., bisexuel, queer, multiples identités, amour du même genre) étaient moins susceptibles d'avoir l'intention de se faire vacciner (β = 1 102, P = 0,047) (167).

Communautés rurales et urbaines

- Douze études ont analysé les différences dans les intentions de se faire vacciner chez des résidents de la ville et de la campagne. Onze ont démontré que les résidents des villes étaient légèrement plus susceptibles d'avoir l'intention de se faire vacciner que les résidents de la campagne (10, 86, 87, 109, 115, 166, 171-175), alors qu'une a indiqué le contraire (176).

Affiliations religieuses

- Alors que douze études réalisées aux États-Unis et au Royaume-Uni ont évalué l'impact de la religion sur l'intention de se faire vacciner, toutes ces études ont associé certaines religions à la réticence à se faire vacciner (126, 171, 174, 176-183). Une étude a démontré que les personnes qui ont déclaré l'hindouisme ou le judaïsme comme religion étaient plus susceptibles que les athées ou les agnostiques d'accepter un vaccin (RC 1,66, HPDI à 95 % : 1,11 à 2,43) alors que celles qui ont déclaré que leur religion était musulmane (RC 0,75, HPDI à 95 % : 0,57 à 0,96) ou autre (RC 0,72, HPDI à 95 % : 0,62 à 0,82) étaient moins susceptibles d'avoir l'intention de se faire vacciner (178).
- Dans une étude britannique, les personnes déclarant être de confession chrétienne étaient significativement plus susceptibles de se faire vacciner si des passeports vaccinaux étaient instaurés pour les voyages intérieurs (RCa 1,23, IC à 95 % : de 1,08 à 1,41) et internationaux (RCa 1,22 IC à 95 % : de 1,07 à 1,39) par rapport aux athées et aux agnostiques (20).

- Une étude quasi expérimentale menée auprès de 709 électeurs inscrits non vaccinés dans le Dakota du Sud, aux États-Unis, a montré que les messages émanant d'un chef religieux avaient un effet positif statistiquement significatif sur l'intention de se faire vacciner, alors que les messages émanant d'un chef politique ou médical n'en avaient pas (21).
- Une étude réalisée auprès de 102 adultes juifs Haredi (ultra-orthodoxes) de New York entre décembre 2020 et janvier 2021 a révélé une forte réticence à se faire vacciner alors que 12 % des répondants étant prêts à accepter de se faire vacciner et de faire vacciner les membres de leur famille, que 47 % étaient très réticents et que 41 % étaient indécis. Les prédicteurs indépendants de la réticence à se faire vacciner étaient la croyance que l'infection naturelle était meilleure qu'un vaccin pour développer l'immunité, être d'accord avec le fait que l'infection antérieure au SRAS-CoV-2 avait créé des anticorps qui évitaient de devoir porter un couvre-visage ou de respecter la distanciation sociale, ainsi que la perte de confiance envers les médecins en raison de la pandémie (183).
- Dans une étude réalisée au Québec, 28 % des répondants qui n'avaient pas l'intention de se faire vacciner croyaient que la vaccination était incompatible avec leurs croyances religieuses ou leurs principes personnels (90).

Parents

- Dix études ont révélé que les participants étaient plus disposés à accepter un vaccin contre la COVID-19 pour eux-mêmes que pour leurs enfants (16, 19, 94, 135, 151, 164, 184-187). Une étude a montré que les parents étaient plus susceptibles de faire vacciner leurs enfants qu'eux-mêmes (188). Les personnes qui ont des enfants plus jeunes (0 à 4 ans) étaient plus réticentes envers la vaccination que celles dont les enfants ont plus de 5 ans (14, 16, 43).
- L'intention de se faire vacciner des parents et des enfants sont fortement corrélées les unes avec les autres, puisque les parents qui avaient l'intention de se faire vacciner étant plus susceptibles de vouloir faire vacciner leurs enfants (11, 13-16, 151). Tout comme dans la population en général, les parents qui sont dans des ménages à faible revenu (11, 14, 16, 19, 188), qui sont plus jeunes (17, 19, 188, 189), et moins instruits (14, 16, 17, 184, 188), qui ont déjà refusé d'autres vaccins (17, 19, 189), qui sont des femmes (14, 16, 17, 188) ou des membres de minorités ethniques (16-19, 185) sont ceux qui étaient plus susceptibles de refuser un vaccin pour leurs enfants.
- Une étude effectuée à Montréal auprès de 380 parents d'enfants de 2 à 17 ans a révélé que 61 % d'entre eux étaient très susceptibles, 25 % étaient assez susceptibles, 9,2 % étaient assez peu susceptibles et 4,5 % étaient très peu susceptibles de faire vacciner leurs enfants. Ceux qui appartenaient à une minorité visible étaient plus susceptibles de refuser de faire vacciner leurs enfants que les autres (32,9 % c. 9,5 %) (18).

Jeunes

- Dans un sondage effectué par texto auprès de 911 jeunes âgés de 14 à 24 ans aux États-Unis, 80,7 % se sont dits disposés à se faire vacciner si le vaccin était sécuritaire et qu'il était recommandé de le recevoir. Les jeunes Noirs (RC = 3,31) étaient plus susceptibles de refuser la vaccination alors que les jeunes Asiatiques (RC = 0,46) étaient moins susceptibles de refuser la vaccination que les jeunes Blancs (P < 0,001) (190).

- Dans le cadre d'un sondage effectué en janvier et en février 2021, 71 % des jeunes canadiens de 12 à 17 ans ont dit avoir l'intention de se faire vacciner (81).

Immigrants

- Dans un échantillon de 32 immigrants au Royaume-Uni, 28 % ont dit qu'ils se feront certainement vacciner, 59 % étaient incertains et 6 % refuseraient le vaccin (191). Deux études menées au Royaume-Uni font état de multiples obstacles à la vaccination des migrants, comme l'accès à la technologie, le fait de ne pas avoir de médecin, l'accès à l'information sur les vaccins dans leur propre langue, l'absence de vaccination dans des endroits où ils se rendent souvent comme les cliniques sans rendez-vous et les organismes de bienfaisance, ainsi que l'absence de communication claire selon laquelle le vaccin serait fourni gratuitement (191, 192).
- Dans une étude australienne, les personnes nées à l'étranger étaient plus susceptibles de déclarer leur intention de se faire vacciner que celles nées en Australie (70,7 % contre 67,2 %). Cela était plus évident pour les personnes arrivées au cours des dix dernières années (74,6 %) par rapport à celles qui sont arrivées il y a plus de dix ans (69,1 %) (141).

Infection antérieure au SRAS-CoV-2

- Deux études réalisées aux États-Unis ont démontré que les personnes qui avaient déjà été infectées par le SRAS-CoV-2 étaient moins susceptibles d'avoir l'intention de se faire vacciner que celles qui n'avaient pas été infectées (115, 193).

Méthodologie

Avant le début de cette revue rapide, un protocole prédéfini pour ce type de revue a été élaboré pour s'assurer que les méthodes étaient reproductibles, transparentes et uniformes. Le protocole est disponible sur demande. Cette revue rapide sera tenue à jour et les mises à jour contiendront des articles de recherche clé publiés jusqu'à la dernière date de recherche.

Publications et préimpressions

Une analyse documentaire quotidienne (ouvrages publiés et en prépublication) est effectuée par le Groupe des sciences émergentes de l'ASPC. L'analyse a compilé les ouvrages sur la COVID-19 depuis le début de l'éclosion et est mise à jour quotidiennement. Les recherches visant à extraire les ouvrages pertinents sur la COVID-19 sont menées dans Pubmed, Scopus, BioRxiv, MedRxiv, ArXiv, SSRN et Research Square, et les résultats sont recoupés avec les ouvrages figurant sur la liste de la documentation sur la COVID de l'Organisation mondiale de la Santé et des centres d'information sur la COVID-19 gérés par Lancet, BMJ, Elsevier et Wiley. Les résultats complets de l'analyse sont conservés dans une base de données RefWorks et dans une liste Excel consultable. Des détails sur cette stratégie de recherche sont disponibles sur demande. Une recherche ciblée par mot-clé dans les titres et les résumés des articles a été effectuée dans ces bases de données et dans la liste en Excel. Les termes de recherche utilisés comprenaient : (« vaccin* » OU « immuni* ») ET (« accept* » OU « hesitan* » OU « preference » OU « confidence » OU « intent* » OU « willing* » OU « readiness » OU « behavio* » OU « knowledge » OU « attitude* » OU « belief* » OU « believe* » OU « perception » OU « influence* » OU « reject* » OU « refus* » OU « oppos* » OU « consent* » OU « fear » OU

« motiv* » OU « anti vax* » OU « antivax* » OU « trust* » OU « mistrust* » OU « anti vaccin* » OU « pro vaccine* » OU « provax* » OU « pro vax » OU « decision* » OU « decid* » OU « uptake »). La recherche a été effectuée le 16 octobre 2020. La première mise à jour a été effectuée le 30 novembre 2020, la deuxième, le 5 janvier 2021, la troisième, le 3 février 2021, la quatrième, le 2 mars 2021, la cinquième, le 2 avril 2021, la sixième le 3 mai 2021, la septième le 3 juin 2021 et la huitième le 2 juillet 2021.

Littérature grise

Une recherche dans la littérature grise a été effectuée afin de compléter la recherche dans la base de données. La recherche dans la littérature grise portait uniquement sur les recherches effectuées au Canada. Lorsque le temps le permettra, la recherche dans la littérature grise sera étendue à la recherche effectuée en Australie, en Nouvelle-Zélande, aux États-Unis et au Royaume-Uni. Une liste détaillée des sites Web inclus dans la recherche est disponible dans le protocole. La recherche dans la littérature grise a été effectuée les 5 et 6 novembre 2020. La première recherche dans la littérature grise mise à jour a été effectuée les 9 et 10 décembre 2020, la deuxième, le 4 janvier 2021, la troisième, les 1er et 2 février 2021, la quatrième, le 7 mars 2021, la cinquième, entre le 13 et le 22 avril 2021, la sixième, du 3 au 7 mai 2021 et la septième, entre le 9 et le 11 juin.

Qualité de l'instrument d'enquête

Trois critères utilisés pour déterminer la qualité de l'instrument d'enquête ont été indiqués. Il s'agit notamment de la disponibilité de l'outil d'enquête utilisé dans le rapport, de l'utilisation de la recherche formative pour concevoir l'enquête et des preuves pré-test associées à l'enquête. Un oui ou un non a été fourni pour chaque critère. Si l'information n'a pas été communiquée, « non » a alors été sélectionné. Ces critères permettent d'évaluer dans quelle mesure les éléments de l'enquête évaluent les concepts théoriques sur lesquels l'enquête est axée, sont comparables à ceux d'autres enquêtes et permettent de déterminer si l'instrument était complet, clair et valable lorsqu'il était appliqué à la population cible. Il y a un risque accru de biais lorsque ces caractéristiques sont manquantes (194).

Examen par les pairs

Ce document a fait l'objet d'un examen par les pairs dirigé par un expert en la matière et d'un examen en ce qui concerne la rédaction et la science par le Bureau de la Conseillère scientifique en chef.

Préparée par : Tricia Corrin et Austyn Baumeister, LNM, Groupe des sciences émergentes, ASPC.

ANNEXE : TABLEAUX DES DONNÉES PROBANTES

ADOPTION DU VACCIN ET RESPECT DES MESURES DE SANTÉ PUBLIQUE APRÈS LA VACCINATION

Tableau 1. Éléments de preuve sur l'adoption du vaccin et de l'adhésion aux mesures de santé publique après la vaccination (n=37)

ÉTUDE	MÉTHODES ET OUTILS DE SONDAGE	RÉSULTATS CLÉS DE CAC
ADOPTION DE VACCINS		
TRAVAILLEURS DE LA SANTÉ		
CANADA		
Dzieciolowska (2021) (1) *nouveau* Étude transversale Canada	L'adoption du vaccin a été évaluée par un sondage en ligne menée auprès de 2 761 infirmières, médecins, aides-soignants et membres de l'administration hospitalière travaillant dans 17 établissements de santé de Montréal, afin de déterminer les facteurs prédictifs de l'adoption du	• 80,9 % des personnes à qui l'on a proposé un vaccin l'ont accepté et 19,1 % l'ont refusé. • L'analyse multivariée a révélé que les hommes (RCa 1,62, IC à 95 % : de 1,16 à 2,26), ceux âgés de 50 à 59 ans (RCa 1,62, IC à 95 % : de 1,07 à 2,44) ou 60 ans et plus (RCa 3,28, IC à 95 % : de 1,74 à 6,18), avaient des contacts professionnels avec des patients atteints de la COVID-19 (RCa 3,88, IC à 95 % : de 2,29 à 6,58), ou ont travaillé dans des centres de réadaptation (RCa 1,76, IC à

Déc. 2020	vaccin. Le vaccin a été proposé à tous les travailleurs de la santé. Sujets des questions : 1) Adoption du vaccin 2) Réticence à se faire vacciner Outils de sondage disponibles? Oui Recherches formatives menées? Non Enquête prétestée? Non	95 % : de 1,17 à 2,66) étaient plus susceptibles de se faire vacciner lorsqu'on le leur proposait. • Les préoccupations ou les raisons de refus les plus courantes chez les personnes qui n'ont pas accepté de se faire vacciner étaient la nouveauté du vaccin (82 %), le fait qu'elles préféraient que d'autres personnes soient vaccinées en premier (77 %), le fait qu'elles estimaient manquer de renseignements concernant le vaccin (74 %) et le fait qu'elles n'avaient pas assez de temps pour prendre une décision (60 %). • 74,1 % des personnes ont déclaré qu'elles accepteraient de se faire vacciner à l'avenir, 53,2 % voulant attendre quelques mois et 31,9 % voulant attendre un an. • Les personnes qui ne prévoient jamais d'accepter de se faire vacciner étaient plus susceptibles de citer le fait de ne pas faire confiance aux experts ou aux sociétés pharmaceutiques, de préférer l'immunité naturelle, de croire que le risque de la vaccination l'emporte sur le risque d'être infecté par la COVID, ou d'avoir déjà eu une mauvaise réaction à un vaccin.
États-Unis		
Fossen (2021) (34) Étude transversale États-Unis Janvier à mars 2021	Cette étude visait à évaluer l'adoption du vaccin chez 3 401 employés d'un hôpital de 437 lits à Arlington, en Virginie, qui pouvaient recevoir un vaccin contre la COVID-19 à compter de janvier 2021. Sujets des questions : 1) Adoption du vaccin	• En date du 10 mars 2021, 71 % avaient accepté la première dose d'un vaccin contre la COVID-19. • L'adoption du vaccin a été associée positivement à l'âge (50 ans et plus) (RC 1,85, IC à 95 % : 1,53 à 2,24, P < 0,01), au travail dans un service d'hospitalisation (RC 1,19, IC à 95 % : 1,01 à 1,42, P = 0,02) et à la race blanche (RC 4,55, IC à 95 % : 3,74 à 5,52, P < 0,01).
Jameson (2021) (31) Étude de cohorte	Au cours d'un programme de vaccination dans un hôpital urbain de taille moyenne dans la région du Midwest des États-Unis à partir de décembre 2020, le	• Au 24 mars 2021, 70 % avaient accepté un vaccin et 30 % l'avaient refusé.

É.-U. Décembre 2020 à mars 2021	vaccin BNT162b2 a été proposé à l'ensemble des 4 318 travailleurs de la santé. L'étude visait à déterminer l'utilisation du vaccin et l'efficacité du vaccin chez les personnes vaccinées.	
Oliver (2021) *préimpression* (30) Étude transversale ÉTATS-UNIS Décembre 2020 à février 2021	Tous les employés de deux grands systèmes de soins de santé intégrés (un privé et un public) à New York étaient admissibles à recevoir un vaccin contre la COVID-19 à compter du 14 décembre 2020. Un sondage en ligne a été réalisé auprès de 1 933 travailleurs de la santé à qui le vaccin a été offert afin d'évaluer l'adoption du vaccin, ainsi que les raisons de son acceptation et de son refus. Sujets des questions : 1) Adoption du vaccin Outils d'enquête disponibles? Non Recherches formatives effectuées? Oui Enquête prétestée? Oui	• Parmi les répondants à qui le vaccin a été offert, 81 % ont dit l'avoir reçu, 11 % prévoient l'obtenir, mais n'ont pas encore pris de rendez-vous, et 8 % ont choisi de ne pas se faire vacciner. • Dans l'analyse bidirectionnelle, l'adoption du vaccin était plus élevée chez les hommes que chez les femmes (88 % comparativement à 80 %, p < 0,001). Les personnes de moins de 40 ans (86 %) et de plus de 60 ans (85 %) affichaient des taux de participation plus élevés que celles de 40 à 49 ans (79 %) et de 50 à 59 ans (74 %), P < 0,001. En outre, les personnes d'origine ethnique non hispanique ou non déclarée (84 %) étaient plus susceptibles de se faire vacciner que les travailleurs de la santé hispaniques (69 %), P < 0,001. • Dans l'analyse multivariée, les travailleurs de la santé noirs étaient moins susceptibles de se faire vacciner que les travailleurs de la santé blancs (RC = 0,38, IC à 95 % : 0,24 à 0,59, P < 0,001). Comparativement aux médecins, les infirmières (RC = 0,37, IC à 95 % : 0,21 à 0,65, P = 0,001), les personnes occupant des postes administratifs, de logistique et de gestion (RC = 0,46, IC à 95 % : 0,36 à 0,78, P = 0,006) et les professionnels paramédicaux (RC = 0,48, IC à 95 % : 0,27 à 0,81, CP = 0,007) étaient moins susceptibles de se faire vacciner. • Les personnes qui n'ont pas reçu le vaccin antigrippal étaient moins susceptibles de vouloir recevoir le vaccin contre la COVID-19 que celles qui l'avaient reçu (RC = 0,28, IC à 95 % : 0,18 à 0,44, P < 0,001).

		• Celles qui se sont dites préoccupées par l'innocuité du vaccin (RC = 0,39, IC à 95 % : 0,28 à 0,55, P < 0,001), celles qui craignent d'être des cobayes (RC = 0,44, IC à 95 % : 0,31 à 0,60, P < 0,001) et celles qui n'étaient pas d'accord avec les déclarations sur l'importance du vaccin pour protéger les autres (RC = 0,37, IC à 95 % : 0,27 à 0,52, P < 0,001) étaient moins susceptibles de se faire vacciner.
Amin (2021) (27) Étude transversale ÉTATS-UNIS Janvier 2021	À compter du 17 décembre 2020, tous les travailleurs de la santé du service d'urgence d'un grand hôpital urbain de Chicago, en Illinois, pouvaient se faire vacciner. Les liens avec l'adoption du vaccin ont été évalués dans un sondage en ligne réalisé auprès de 240 travailleurs de la santé. Sujets des questions : 2) Adoption du vaccin Outils d'enquête disponibles? Non Recherches formatives effectuées? Non Enquête prétestée? Non	• 92 % ont déclaré avoir reçu le vaccin ou prévoir se faire vacciner alors que 8 % ont déclaré qu'ils ne se feront pas vacciner. • Les taux d'acceptation du vaccin variaient selon la profession, puisque les médecins avaient des taux d'acceptation plus élevés que les infirmières et les techniciens en radiologie. • Parmi les 8 % qui ont refusé la vaccination, la majorité s'est identifiée comme étant Noirs (65 %), était âgée entre 51 et 60 ans et occupait des postes dans des catégories variées. • Parmi les raisons pour refuser le vaccin, mentionnons une infection antérieure à la COVID-19, ainsi que des préoccupations au sujet de la nouveauté du vaccin et des effets secondaires. •
Schrading (2021) (22) Étude transversale ÉTATS-UNIS Janvier 2021	Trois semaines après que le vaccin contre la COVID-19 ait été offert aux professionnels de la santé œuvrant dans les services d'urgence dans 20 centres médicaux universitaires urbains des États-Unis, un sondage en ligne a été effectué auprès de 1 321 de ces professionnels. L'objectif était de décrire les différences dans les taux de vaccination entre les divers types de professionnels de la santé œuvrant dans les services	• 86 % des personnes à qui on a offert le vaccin ont choisi de le recevoir et 14 % ont refusé. • Parmi les médecins et les fournisseurs de soins en pratique avancée, 37 sur 674 (5,5 %) ont refusé le vaccin comparativement à 77 sur 345 (22,3 %) des infirmières et à 71 sur 302 (23,5 %) des professionnels de la santé qui œuvraient dans des milieux non cliniques. Parmi ceux qui ont refusé le vaccin, les raisons les plus courantes étaient des préoccupations relatives à l'innocuité (45,4 %), des problèmes de santé (13,5 %) et un diagnostic antérieur de COVID-19 (13,5 %).

	d'urgence et les raisons pour lesquelles ils ont refusé le vaccin. Sujets des questions : 1) Adoption du vaccin Outils d'enquête disponibles? Non Recherches formatives effectuées? Non Enquête prétestée? Non	• Les professionnels de la santé noirs non hispaniques affichaient les taux d'adoption les plus faibles (65,4 %), suivis des Hispaniques ou des Latinx (76,7 %). Les taux d'adoption les plus élevés ont été observés chez les professionnels de la santé non hispaniques autres (88,9 %), blancs non hispaniques (88,5 %) et asiatiques non hispaniques (87,3 %). • Les hommes affichaient des taux d'adoption plus élevés (93,5 %) que les femmes (88,5 %). • Après la vaccination, les personnes vaccinées ont déclaré qu'elles se sentaient plus en sécurité (86,7 %) et que les membres de leur ménage se sentaient aussi plus en sécurité (87,1 %). Les personnes vaccinées prévoyaient utiliser la même quantité d'ÉPI au travail (89,8 %) et en public (91,8 %).
Pamplona (2021) (33) Étude transversale É.-U. Janvier 2021	L'adoption du vaccin et les hésitations au cours d'un programme de vaccination mis en œuvre entre le 13 et le 21 janvier 2021 ont été enregistrées auprès de 157 membres du personnel de quatre cliniques du Renal Research Institute et d'un programme de dialyse à domicile à New York. Sujets des questions : 1) Prise du vaccin 2) Hésitation à se faire vacciner Outils d'enquête disponibles? Non Des recherches formatives ont-elles été menées? Non Enquête prétestée? Non	• 73,2 % étaient vaccinés et 26,8 % n'étaient pas vaccinés. • 3,8 % du personnel a déclaré avoir hésité à se faire vacciner et n'a pas reçu de vaccin. Les raisons n'ont pas été rapportées. • Le reste du personnel qui n'a pas été vacciné comprend : les personnes en congé (2,5 %), les femmes enceintes ou qui allaitent (5,1 %) et les personnes ayant déjà été infectées par le SRAS-CoV-2 (15,3 %). • Le personnel ayant des antécédents d'infection confirmée par le SRAS-CoV-2 il y a plus de 90 jours ou à un moment inconnu dans le passé s'est vu proposer la vaccination, mais a souhaité recevoir le vaccin plus tard.
ROYAUME-UNI		

Bell (2021) *préimpression* (32) Étude transversale et qualitative ROYAUME-UNI Janvier à mars 2021	1 658 travailleurs de la santé et 261 travailleurs sociaux ont répondu à une enquête en ligne et 20 participants ont été interviewés afin de mieux comprendre les croyances, les attitudes et les comportements en matière de vaccination. Thèmes des questions : 1) Prise du vaccin 2) Perception à l'égard des vaccins Outils d'enquête disponibles? Oui Des recherches formatives ont-elles été menées? Oui Enquête prétestée? Oui	• 1 762 (91,9 %) participants se sont vus proposer la vaccination. Parmi eux, 6,6 % ont refusé ou vont refuser le vaccin. • Par rapport à leurs homologues, des taux plus élevés de refus du vaccin ont été observés chez les Noirs ou les Noirs des Caraïbes (22 %), les personnes âgées de 25 à 35 ans (8,4 %) et les chrétiens (6,7 %). • La probabilité de refuser un vaccin était significativement plus élevée si les personnes interrogées étaient noires, britanniques ou noires mixtes (RR ajusté 5,5, IC 95 % : 2,2 % à 13,4 %), se sentaient sous pression de leur employeur pour se faire vacciner (RR ajusté 1,75, IC 95 % : 1,2 % à 2,4 %), ou s'inquiétaient des effets secondaires (RR ajusté 1,68, IC 95 % : 1,1 % à 2,4 %). • Les probabilités d'accepter un vaccin étaient significativement plus élevées si un vaccin contre la grippe avait été pris au cours des deux dernières années (RR ajusté 0,27, IC 95 % : 0,1 % à 0,47 %) et la conviction combinée que les vaccins sont sûrs, importants et efficaces (RR ajusté 0,51, IC 95 % : 0,3 % à 0,8 %). • Les raisons du refus ou de l'intention de refuser un vaccin comprennent la crainte des effets secondaires (51 %), le manque de recherche (50 %) et l'efficacité (21 %). • Les raisons les plus courantes de la vaccination sont la protection des amis et des familles (64 %), la protection personnelle (57 %) et la protection des patients (28 %). • Les répondants noirs ou métis étaient moins susceptibles de percevoir le vaccin comme sûr, comme important pour se protéger ou protéger leur famille, de croire que la vaccination est nécessaire pour revenir à la normale, de croire que leurs amis et leur famille ne s'attendent pas à ce qu'ils se fassent vacciner et de s'inquiéter davantage des effets secondaires.

		• Pour la partie entretien, tous les participants s'étaient vus proposer la vaccination, 13 avaient été vaccinés et 7 avaient refusé. • Les entretiens ont révélé des problèmes d'accès (manque de clarté pour ceux qui ne font pas partie du National Health Service pour se faire vacciner), de perception du risque et de la gravité (faible perception du risque associé au fait de ne pas avoir besoin d'un vaccin), de manque de confiance (dans le vaccin, les décideurs politiques et l'industrie pharmaceutique et de la santé), d'efficacité du vaccin, d'importance du vaccin pour protéger les autres ou pour revenir à la normale, de pression pour se faire vacciner, de préoccupations concernant les allergies, de répercussions sur la procréation, de désir de plus d'informations sur le vaccin et de désir d'avoir l'assurance que le vaccin est halal.
Martin (2021) *préimpression* (25) Étude transversale ROYAUME-UNI Décembre 2020 à février 2021	Les liens avec l'adoption du vaccin ont été évalués chez 19 044 travailleurs de la santé de l'une des plus importantes fiducies d'hôpitaux de soins actifs au Royaume-Uni. Tous les membres du personnel étaient admissibles à recevoir le vaccin ARNm BNT162b2 ChAdOx1 nCoV-19 à compter du 12 décembre 2020. Sujets des questions : 1) Adoption du vaccin	• Au 3 février 2021, la proportion des travailleurs de la santé qui avaient reçu une dose du vaccin était de 64,5 %. • Le nombre de vaccins par semaine a atteint un sommet pendant la semaine du 11 au 17 janvier et diminue depuis. • L'adoption du vaccin a été associée positivement à une augmentation de l'âge (30 ans : RCa = 0,48, IC à 95 % : 0,44 à 0,53; 51 à 60 ans : RCa = 1,19, IC à 95 % : 1,07 à 1,31 comparativement à 41 à 50 ans) et au sexe masculin (RCa = 1,24, IC à 95 % : 1,15 à 1,35). • Comparativement aux travailleurs de la santé blancs, l'adoption du vaccin était plus faible chez les Noirs (RCa = 0,30, IC à 95 % : 0,26 à 0,34) et les Asiatiques du Sud (RCa = 0,67, IC à 95 % : 0,62 à 0,72). • Les personnes qui avaient des antécédents d'infection par le SRAS-CoV-2 étaient moins susceptibles de se faire vacciner (RCa = 0,71 [IC à 95 % : 0,60 à 0,85).

		• Les personnes vivant dans les régions les plus démunies étaient moins susceptibles de se faire vacciner (p < 0,001).
Hall (2021) *préimpression* (26) Étude de cohorte ROYAUME-UNI Décembre 2020 à février 2021	L'étude SARS-CoV-2 Immunity and Reinfection Evaluation (SIREN) est une étude de cohorte prospective portant sur 23 324 membres du personnel travaillant dans 36 hôpitaux financés par le secteur public. À compter d'août 2020, les facteurs de risque de référence, l'état de la vaccination, les symptômes et les résultats des tests PCR et des tests d'anticorps ont été consignés toutes les deux semaines. L'étude visait à déterminer les facteurs associés à l'adoption du vaccin ARNm BNT162b2 et à son efficacité chez les personnes vaccinées. Sujets des questions : 1) Adoption du vaccin	• Au 5 février 2021, les proportions de membres du personnel qui avaient reçu une dose et deux doses du vaccin étaient 89 % et 8 %, respectivement. • L'adoption du vaccin a été significativement plus faible chez les personnes ayant déjà eu une infection au SRAS-CoV-2 (RCa = 0,59, IC à 95 % : 0,54 à 0,64), les femmes (RCa = 0,72, IC à 95 % : 0,63 à 0,82), les moins de 35 ans (RCa = 0,78, IC à 95 % : 0,64 à 0,96), les Noirs, les Asiatiques ou les membres des groupes ethniques minoritaires (RCa = 0,26, IC à 95 % : 0,21 à 0,32), celles qui vivent dans des quartiers plus défavorisés (RCa = 0,75, IC à 95 % : 0,65 à 0,87) et qui travaillent comme portiers/gardiens de sécurité/gardiens dans des domaines (RCa = 0,61, IC à 95 % : 0,42 à 0,90) ou sages-femmes (RCa = 0,74, IC à 95 % : 0,57 à 0,97).
Tulloch (2021) *préimpression* (28) Étude transversale ROYAUME-UNI Janvier 2021	Tous les membres du personnel et les résidents de 87 maisons de santé de la région du Conseil municipal de Liverpool pouvaient se faire vacciner contre le COVID-19 à compter du 23 décembre 2020. On a effectué un sondage en ligne auprès de 46 gestionnaires du personnel afin de déterminer les liens avec l'adoption du vaccin et les raisons qui ont fait hésiter les gens à se faire vacciner. Ce sondage était autodéclaré et les opinions des membres du personnel ont été compilées par un membre de la	• 52,6 % (n = 1 119) ont reçu leur première dose du vaccin avec un taux de vaccination moyen par maison de santé de 51,4 % (IC à 95 % : 43,9 à 58,8 %). • Les raisons les plus courantes pour ne pas s'être fait vacciner étaient les préoccupations au sujet du manque de recherche sur le vaccin (37,0 %), le fait que le personnel était à l'extérieur du site pendant les séances de vaccination (36,5 %), les préoccupations en ce qui concerne la grossesse et la fertilité (5,6 %) et les préoccupations au sujet des réactions allergiques (3,2 %). • Si les problèmes logistiques étaient résolus (p. ex., membre du personnel qui n'était pas sur place le jour où le vaccin était administré), le taux moyen de vaccination par maison de santé aurait

	direction de la maison de santé. Il est donc possible qu'il ne reflète pas le point de vue de tous les membres du personnel. Sujets des questions : 1) Adoption du vaccin	pu augmenter à 69,8 % (IC à 95 % : 63,2 à 76,3 %). • Les membres du personnel ont déclaré que les méthodes qui aideraient à réduire la réticence à l'égard de la vaccination comprenaient des réunions individuelles pour discuter des préoccupations (34,8 % des maisons de santé), des réunions destinées aux membres du personnel (15,2 %), du matériel éducatif (15,2 %), des discussions individuelles avec les omnipraticiens ou les membres de l'équipe de vaccination (10,9 %) et des gestionnaires qui prêchent par l'exemple et encouragent les membres du personnel (6,5 %).
Azamgarhi (2021) (29) Étude de cohorte ROYAUME-UNI Janvier 2021	Cette étude visait à évaluer l'adoption et l'efficacité du vaccin BioNTech de Pfizer chez 2 577 travailleurs de la santé dans un hôpital de soins tertiaires. Tous les membres du personnel ont reçu leur première dose du vaccin sur une période de 8 jours jusqu'au 14 janvier 2021. Sujets des questions : 1) Adoption du vaccin	• 60,8 % du personnel a reçu une dose du vaccin. • L'adoption du vaccin était plus élevée chez les hommes que chez les femmes (65,0 % comparativement à 58,9 %, P = 0,006). • Les travailleurs de la santé blancs (70,4 %) et asiatiques (67,1 %) étaient les groupes ethniques les plus susceptibles de se faire vacciner. Les Noirs/Afro-Caraïbéens (27 %) et les races mixtes (43 %) étaient les moins susceptibles (P = 0,001) de le faire. • Selon la profession, les plus forts taux d'adoption du vaccin ont été observés chez les chirurgiens et le personnel médical (76 %), les professionnels paramédicaux (75,4 %), ainsi que le personnel administratif et de bureau (71,5 %) Les taux les plus faibles ont été observés chez les infirmières (52,9 %), le personnel de soutien clinique (49,2 %) et les porteurs, le personnel responsable de l'entretien et celui qui s'occupe de la restauration (30,5 %) (P = 0,001). • L'adoption du vaccin a augmenté avec l'âge. 74,4 % des 55 ans et plus ont reçu le vaccin, 64,6 % des 35 à 54 ans et 50,6 % des 16 à 34 ans.
ISRAËL		

Jabal (2021) (23) Étude de cohorte Israël Décembre 2020 à janvier 2021	Cette étude avait deux objectifs : 1) faire rapport sur l'adoption du vaccin chez environ 1 500 travailleurs de la santé dans un seul centre médical, et 2) décrire l'immunogénicité 21 jours après l'administration du vaccin ARNm BNT162b21 1 contre la COVID-19 chez 514 travailleurs de la santé. À compter de décembre 2020, le vaccin a été offert à tout le personnel. Sujets des questions : 1) Adoption du vaccin	• Au 21 janvier 2021, la proportion des travailleurs de la santé qui avaient reçu une dose du vaccin était d'environ 90 %.
Amit (2021) (24) Étude de cohorte Israël Décembre 2020 à janvier 2021	Cette étude avait deux objectifs : 1) faire rapport sur l'adoption du vaccin chez les 9 109 travailleurs de la santé dans un seul centre médical, et 2) évaluer les réductions des taux d'infection par le SRAS-CoV-2 et les taux de COVID-19 chez les travailleurs de la santé ayant reçu le vaccin BNT162b2 contre la COVID-19. À compter de décembre 2020, le vaccin a été offert à tout le personnel. Sujets des questions : 1) Adoption du vaccin	• Au 24 janvier 2021, les proportions de travailleurs de la santé qui avaient reçu une dose et deux doses du vaccin étaient de 79 % et de 66 %, respectivement.
PERSONNES EN SITUATION D'ITINÉRANCE		
Kuhn (2021) *préimpression* (41) Étude transversale	Le niveau d'adoption du vaccin et d'hésitation chez 90 personnes sans abri de Los Angeles (âgées de 18 ans et plus) a été évalué à l'aide d'un sondage effectué par téléphone cellulaire.	• Parmi les 90 participants, 17 se sont vus offrir un vaccin et de ce nombre, 10 ont accepté et 7 ont refusé. • Parmi les 73 participants à qui le vaccin n'a pas été offert, 51 % ont dit qu'ils le prendraient s'il leur était offert, 32 % ont dit qu'ils ne se feraient pas vacciner et 17 % ont refusé de répondre.

ÉTATS-UNIS Décembre 2020 à février 2021	Sujets des questions : 1) Adoption du vaccin 2) Hésitation par rapport à la vaccination 3) Intentions en ce qui concerne les vaccins Outils d'enquête disponibles? Non Recherches formatives effectuées? Non Enquête prétestée? Non	• Dans l'ensemble, 48 % des personnes ont refusé un vaccin lorsqu'il leur était offert, ont dit qu'elles le refuseraient s'il leur était offert ou ont refusé de répondre et ont donc été jugées « hésitantes face à la vaccination ». • Parmi les participants qui hésitaient à se faire vacciner, les raisons les plus souvent mentionnées étaient la peur des effets secondaires (37 %), le désir d'avoir plus d'information (30 %) et le fait qu'ils ne veulent pas recevoir de vaccin (27 %). • Selon une analyse multivariée, les personnes qui ont une perception élevée de la menace que représente la COVID-19 (RC = 0,25, P = 0,02) et celles qui faisaient confiance à des sources officielles (RC = 0,37, P = 0,08) étaient beaucoup moins susceptibles d'hésiter à se faire vacciner. Celles qui avaient un comportement hautement protecteur (RC = 3,63, P = 0,02) et celles qui faisaient confiance à leurs contacts personnels (RC = 2,70, P = 0,07) étaient plus susceptibles d'hésiter.
PRISONS		
Chin (2021) (38) Étude transversale États-Unis Décembre 2020 à mars 2021	Le 22 décembre 2020, le California Department of Corrections and Rehabilitation (CDCR) a lancé un programme de vaccination pour les résidents de ses 35 établissements carcéraux. Des 97 779 personnes incarcérées, 64 633 ont reçu un vaccin. Sujets des questions : 1) Adoption du vaccin	• 66,5 % ont accepté au moins une dose de vaccin alors que 33,5 % l'ont refusée. Parmi ceux qui avaient refusé au départ et à qui le vaccin a de nouveau été offert (n = 1 962), 45,9 % alors ont accepté au moins une dose. • L'adoption du vaccin a été la plus élevée chez les Hispaniques (72,6 %, IC à 99,6 % : 72,1 à 73,1) et les Blancs (72,1 %, IC à 99,6 % : 71,3 à 72,9), suivis des Amérindiens ou des résidents de l'Alaska (67,7 %, IC à 99,6 % : 64,4 à 71,0), des Asiatiques ou des insulaires du Pacifique (67,7 %, IC à 99,6 % : 64,8 à 70,6), et des Noirs (54,9 %, IC à 99,6 % : 54,3 à 55,5). • Les personnes plus âgées et vulnérables sur le plan médical étaient plus susceptibles d'accepter

		un vaccin que les personnes plus jeunes et en meilleure santé.
Berk (2021) *préimpression* (37) Étude transversale États-Unis Décembre 2020 à février 2021	L'adoption du vaccin a été évaluée chez 1 474 membres du personnel et 1 447 personnes incarcérées au Rhode Island Department of Corrections à qui un vaccin a été offert. Le programme de vaccination a débuté le 22 décembre 2020. Toutes les premières doses ont été administrées au plus tard le 5 février et les deuxièmes, au plus tard le 5 mars 2021. Le vaccin a été offert en 4 phases : 1) les personnes à risque élevé (65 ans et plus ou 55 ans et plus avec des comorbidités particulières); 2) les plus petits établissements afin d'obtenir l'immunité collective; 3) le plus grand établissement à sécurité moyenne restant; 4) toutes les personnes qui avaient déjà obtenu un résultat positif au test de dépistage de COVID-19 dans les jours et les personnes qui avaient initialement refusé le vaccin, mais qui l'ont ensuite accepté. Sujets des questions : 1) Adoption du vaccin	• Parmi le personnel correctionnel, 68,4 % des gens ont accepté un vaccin et 31,6 % l'ont refusé. Les motifs du refus n'ont pas été indiqués. • Parmi toutes les personnes incarcérées, 76,4 % des gens ont accepté un vaccin et 23,6 % l'ont refusé. Les motifs du refus n'ont pas été indiqués. • Dans la première phase de vaccination, 90,9 % des personnes incarcérées à haut risque (n = 143) ont accepté le vaccin et 9,1 % l'ont refusé. • Dans la deuxième phase, soit celle qui a eu lieu dans les plus petits établissements, 64,5 % des gens ont accepté de se faire vacciner et 34,6 % l'ont refusé (n = 222). • Dans la troisième phase, parmi ceux qui se trouvaient dans le plus grand établissement (n = 730), 82,9 % ont accepté le vaccin et 17,1 % l'ont refusé. • Dans la dernière phase destinée aux personnes incarcérées restantes (n = 352), 64,8 % ont accepté le vaccin et 35,2 % l'ont refusé.
UNITÉS MILITAIRES		
Segal (2021) (55) Étude transversale	Les taux d'adoption du vaccin entre les bataillons en première ligne et les unités militaires hautement essentielles (groupe A, n = 12 642) et les unités militaires de la zone	• En date du 18 février 2021, 84,8 % de l'ensemble de la population à l'étude avait reçu la première dose d'un vaccin contre la COVID-19, 3,88 % avaient déjà eu une infection au SRAS-CoV-2 et 11,34 % avaient refusé le vaccin.

Israël Décembre 2020 à février 2021	administrative arrière et de soutien (groupe B, n = 6 077) ont été comparés. Ces 70 unités étaient composées de 18 719 personnes des deux sexes, la plupart sans comorbidités importantes. Le programme de vaccination a débuté à la fin de décembre 2020. Sujets des questions : 1) Adoption du vaccin	• L'adoption du vaccin était plus élevée dans le groupe A que dans le groupe B (86,4 % comparativement à 81,4 %, P < 0,001). L'âge moyen des membres du groupe A était légèrement inférieur et comprenait un plus grand nombre d'hommes (P < 0,001), mais les deux groupes avaient des taux cumulatifs similaires de SRAS-CoV-2 (P = 0,677).
Talmy (2021) (39) Étude transversale Israël Décembre 2020 à février 2021	Cette étude visait à évaluer l'adoption réelle du vaccin et les efforts de communication en soins primaires associés, ce qui incluait des conférences de groupe, des consultations sur place et des visites dans des bureaux de soins primaires. Les intentions en ce qui concerne la vaccination ont été recueillies par sondage téléphonique avant la campagne de vaccination. Pendant la campagne, 511 soldats d'une unité militaire se sont vu offrir un vaccin. Le site de vaccination a été accessible pendant deux périodes différentes. Les personnes qui ont refusé la vaccination après la séance initiale ont été contactées pour fixer des rendez-vous à titre volontaire pour des visites à la clinique afin de discuter de leurs préoccupations particulières. Sujets des questions : 1) Adoption du vaccin 2) Intentions en ce qui concerne la vaccination	• Avant la campagne de vaccination, 77,7 % des soldats avaient l'intention de se faire vacciner, 17,6 % avaient l'intention de refuser et 4,7 % étaient incertains. • 70,3 % ont assisté à une conférence de groupe, 6,5 % sont venus consulter un médecin sur place et 3,7 % se sont rendus dans une clinique de soins primaires. • Parmi les 90 soldats qui ont déclaré ne pas avoir l'intention de se faire vacciner, 60,0 % ont assisté aux conférences de groupe, 31,1 % sont venus pour une consultation sur place et 16,7 % ont participé à des visites de soins primaires pour discuter de leurs motifs et de leurs préoccupations. • Entre le 3 janvier et le 18 février 2021, 89,8 % des soldats ont reçu au moins une dose du vaccin. • Sur les 90 soldats qui n'avaient pas l'intention de se faire vacciner, 42,2 % ont décidé de se faire vacciner. • 47,4 % des 28 soldats qui n'ont pas l'intention de se faire vacciner et qui sont venus pour consulter un médecin ont décidé de se faire vacciner (P = 0,004).

	3)	
ADULTES PLUS ÂGÉS (70 ANS ET PLUS)		
Office for National Statistics (2021) *non publiée* (35) Enquête transversale ROYAUME-UNI Février 2021	Les réponses de 2 070 adultes de plus de 80 ans ont été recueillies au moyen d'un sondage en ligne afin de déterminer la couverture vaccinale, les attitudes et l'effet de la vaccination sur les comportements de protection. Sujets des questions : 1) Adoption du vaccin 2) Attitudes à l'égard des vaccins 3) Comportements à l'égard des vaccins Outils d'enquête disponibles? Non Recherches formatives effectuées? Non Enquête prétestée? Non	• 99,8 % des personnes ont déclaré qu'on leur avait offert un vaccin, 99 % ont ajouté avoir reçu au moins une dose et 15 % ont reçu au moins deux doses (6). • 41 % ont signalé des effets secondaires courants, incluant la sensibilité du bras à l'endroit où ils ont reçu l'injection (26 %). • 63 % ont déclaré que les effets secondaires subis n'influeraient pas sur leur décision d'obtenir la deuxième dose et 35 % ont affirmé que les effets secondaires les ont rendus plus susceptibles d'obtenir une deuxième dose. • Parmi les personnes qui avaient reçu au moins une dose, 43 % avaient rencontré quelqu'un en dehors de leur bulle, de leur ménage ou du personnel soignant à l'intérieur plutôt qu'à l'extérieur. • Parmi celles qui avaient reçu au moins une dose et qui s'étaient aventurées à l'extérieur de leur maison pour faire une activité, 49 % avaient rencontré à l'extérieur quelqu'un avec qui elles ne vivaient pas, 54 % étaient allés magasiner et 45 % étaient sorties de la maison pour participer à des activités de loisirs en plein air). Seulement 20 % ont déclaré ne pas avoir quitté la maison pour quelque raison que ce soit. • 25 % des personnes qui ont reçu leur première dose et 33 % de celles qui ont reçu les deux doses étaient prêtes à aller à l'hôpital pour une raison médicale. • 96 % encourageraient d'autres personnes à se faire vacciner. • 86 % subiraient probablement un test de dépistage de la COVID-19 s'ils présentaient des symptômes de COVID-19.

		• Près de la moitié (49 %) ont perçu la COVID-19 comme un risque majeur pour elles-mêmes avant de se faire vacciner. Ce pourcentage a diminué à 19 % après avoir reçu une dose.
Malesza (2021) *préimpression* (36) Étude transversale Pologne Janvier et février 2021	Les associations avec l'adoption du vaccin ont été évaluées chez 1 477 adultes âgés (70 ans et plus) grâce à des entrevues structurées. Un programme de vaccination de masse a été lancé pendant les dernières semaines de 2020. Le ministre de la Santé a recommandé que chaque personne de 70 ans et plus soit encouragée à recevoir le vaccin contre la COVID-19. On suppose qu'au moment de ces entrevues, toutes les personnes âgées de 70 ans et plus avaient été encouragées à se faire vacciner et étaient en mesure de le faire. Sujets des questions : 1) Adoption du vaccin Outils d'enquête disponibles? Non Recherches formatives effectuées? Non Enquête prétestée? Non	• 62,7 % des personnes ont reçu le vaccin et 37,3 % ont dit ne pas vouloir se faire vacciner. • Les deux prédicteurs indépendants les plus importants pour l'adoption du vaccin étaient l'explication par un professionnel de la santé des raisons pour lesquelles elles devraient se faire vacciner (RC = 4,23, IC à 95 % : 2,90 à 5,75) et le fait de vivre avec d'autres personnes (RC = 3,13, IC à 95 % : 2,03 à 4,26). Parmi les autres prédicteurs, mentionnons la possibilité de se rendre par leurs propres moyens chez un omnipraticien (RC = 1,92, IC à 95 % : 1,45 à 2,76), le fait d'être atteintes de maladies chroniques (RC = 2,98, IC à 95 % : 2,05 à 4,01), le statut socioéconomique supérieur (RC = 1,79, IC à 95 % : 1,33 à 2,15) et le sexe masculin (RC = 1,22, IC à 95 % : 0,67 à 1,98). • Les principales raisons pour lesquelles les gens ont accepté de se faire vacciner étaient pour se protéger eux-mêmes (90,6 %), la protection des proches (69,3 %), un rappel reçu d'un médecin (67,7 %) et les conseils reçus d'un professionnel de la santé (65,0 %) ou d'un ami (49,9 %). • Parmi les raisons invoquées pour ne pas se faire vacciner, mentionnons des préoccupations au sujet de l'innocuité (91,4 %), la crainte d'effets secondaires (89,7 %), la croyance que la COVID-19 n'est pas une maladie grave (75,4 %), le fait de ne pas vouloir être utilisé comme cobaye (69,5 %), la croyance que les vaccins sont inefficaces (66,7 %), le fait d'avoir des problèmes médicaux qui rendaient les vaccins contre-indiqués (53 %), le fait d'avoir de la famille ou des amis qui avaient eu une mauvaise expérience avec le vaccin (57,1 %), le fait de ne pas aimer les

		injections (35,3 %) et le fait de croire que le vaccin était dérangeant (30,8 %).
POPULATION GÉNÉRALE		
Horizon Research (2021) *non publiée* (15, 195) Étude transversale Nouvelle-Zélande Mars à mai 2021	Un sondage en ligne a été mené auprès d'adultes (âgés de 16 ans et plus) afin de mesurer le taux d'adoption des vaccins. Mars-Avr, n=1 350 Avr-Mai, n=1 387 Sujets des questions : 1) Adoption du vaccin Outils d'enquête disponibles? Oui Recherches formatives effectuées? Oui Enquête prétestée? Oui	**Avril et mai** • 1 % des répondants ont déclaré qu'on leur avait offert un vaccin, mais que ce pourcentage avait diminué (baisse de 1 % depuis le mois précédent). • Les personnes peu susceptibles d'accepter le vaccin qui leur a été offert étaient des femmes, elles étaient plus jeunes que l'âge moyen, avaient des revenus plus faibles, des qualifications moins élevées et des enfants dans leur ménage. **Mar-Apr** • 2 % des adultes à qui on avait offert un vaccin et qui l'ont refusé.
Office for National Statistics (2021) *non publiée* (43, 47) Étude longitudinale ROYAUME-UNI Mars à Mai 2021	Les réponses de quatre vagues de résultats recueillies dans le cadre du sondage en ligne sur les opinions et les modes de vie (167) ont été regroupées pour se concentrer sur les associations démographiques spécifiques à l'hésitation à se faire vacciner. Le nombre de personnes handicapées, cliniquement extrêmement vulnérables et de parents n'a pas été communiqué. Févr.-mars : 17 201 réponses regroupées Mars-avril : 16 362 réponses regroupées Avril-mai : 15 170 réponses regroupées	**Avril et mai** • 2 % des adultes à qui on avait offert un vaccin et qui l'ont refusé. • Les taux de refus du vaccin étaient de 1 % chez les 16 à 29 ans, de 2 % chez les 30 à 49 ans et de 1 % chez les 50 ans et plus. • 2 % des femmes ont refusé le vaccin comparativement à 1 % des hommes. • 5 % des personnes qui s'identifiaient comme ayant une autre religion et 4 % des bouddhistes à qui on avait offert un vaccin l'avaient refusé, comparativement à 1 % des personnes qui ne déclaraient aucune religion. • 63 % des personnes qui ont déclaré être de confession musulmane et qui étaient peu susceptibles d'être vaccinées ou qui ont refusé le vaccin étaient préoccupées par les effets secondaires.

	Sujets des questions : 1) Adoption du vaccin Outils d'enquête disponibles? Oui Recherches formatives effectuées? Oui Enquête prétestée? Oui	• Les personnes dans les quintiles les plus démunis ont refusé de recevoir des vaccins plus fréquemment que celles qui se trouvaient dans les quintiles de privation les plus élevés (3 % dans le quintile inférieur et 1 % dans le quintile le moins pauvre). • Par profession, 3 % des personnes qui œuvrent dans les ventes et le service à la clientèle, ainsi que les ouvriers ont refusé le vaccin comparativement à la moyenne de 2 %. **Mars-Avril** • 3 % des parents qui avaient des enfants âgés de 0 à 4 ans se sont vu offrir un vaccin et l'ont refusé, comparativement à 2 % de ceux qui avaient des enfants de plus de 5 ans ou à 1 % de ceux qui ne sont pas des parents et qui ne vivent pas avec des enfants à charge.
Office for National Statistics (2021) *non publiée* (48, 50, 54, 197) Étude longitudinale ROYAUME-UNI Décembre 2020 à mai 2021	Un sondage hebdomadaire en ligne sur les intentions de se faire vacciner a été effectué auprès d'un échantillon national représentatif d'adultes britanniques. Du 7 au 11 avril: n= 6,030 Du 28 avril au 3 mai:: n=3,830 Du 19 au 23 mai: n= 3,070 Du 2 au 6 juin n=4,010 Du 9 au 13 juin: n=3,600 *nouvelle* Sujets des questions : 1) Adoption du vaccin Outils d'enquête disponibles? Oui Recherches formatives effectuées? Oui Enquête prétestée? Oui	**Du 9 au 13 juin** • 2 % des personnes âgées de 50 à 69 ans se sont fait offrir un vaccin et l'ont refusé comparativement à 1 % des personnes âgées de 70 ans et plus et à la moyenne globale de 3 %. **Du 19 au 23 mai** • 18 % des 50 à 69 ans ont reçu une dose de vaccin et 80 % (comparativement à 25 %) en ont reçu deux. 1 % des personnes à qui un vaccin a été offert l'ont refusé. 58 % des personnes de ce groupe d'âge sont préoccupées par les effets secondaires. • <1 % des personnes âgées de 70 ans et plus ont reçu une dose de vaccin et 99 % en ont reçu deux. <1 % de personnes se sont vu offrir un vaccin et ont refusé de se faire vacciner. **Du 28 avril au 3 mai** • 69 % des personnes âgées de 50 à 69 ans ont reçu une dose de vaccin et 25 % ont reçu deux doses. 2 % se sont vu proposer un vaccin et ont refusé de se faire vacciner et 1 % ne s'est pas vu proposer de vaccin.

		Du 7 au 11 avril • 39 % des adultes âgés entre 30 et 49 ans ont reçu au moins une dose et 1 % se sont vus offrir un vaccin et attendent d'être vaccinés. 1 % se sont vus offrir un vaccin et ont décliné l'offre. • 19 % des 16 à 29 ans ont reçu au moins une dose et 1 % se sont vus offrir un vaccin et attendent d'être vaccinés. 2 % se sont vus offrir un vaccin et ont décliné l'offre. • 98 % des personnes âgées de 50 à 69 ans ont reçu un vaccin ou ont l'intention d'en accepter un. 1 % se sont vues offrir un vaccin et attendent d'être vaccinées et 1 % se sont vues offrir un vaccin et l'ont refusé. • 99 % des personnes de 70 ans et plus ont reçu un vaccin ou sont susceptibles d'en accepter un. 1 % se sont vus offrir un vaccin et ont décliné l'offre.
Dai (2021) *préimpression* (44) Essai de contrôle randomisé É.-U. Janvier à mars 2021	Un essai contrôlé randomisé a été mené pour mesurer l'impact des interventions (rappel par message texte) dans l'augmentation de la vaccination dans les populations admissibles (les personnes âgées de 65 ans et plus, les patients ayant subi une transplantation, et les patients à risque élevé avec des conditions préexistantes admissibles) en Californie. ECR 1 : Rappel par message texte comprenant un lien pour prendre le rendez-vous et soit un texte simple, soit un message d'appartenance, soit un texte simple avec vidéo, soit un message d'appartenance avec vidéo, un jour après avoir reçu l'avis d'admissibilité au vaccin (n = 132 337).	• La réception d'un message texte de base a augmenté de manière significative les taux de prise de rendez-vous dans les 6 jours de 5,14 de points de pourcentage ($p < 0,001$), et les taux de vaccination dans les 4 semaines de 2,89 de points de pourcentage ($p < 0,001$) par rapport au groupe témoin. Cela représente une augmentation relative de 85,5 % et 26,3 %, respectivement. • La réception d'un message texte a également augmenté la vitesse réelle des vaccinations, le groupe témoin ayant mis 27 jours pour atteindre le taux de vaccination du groupe ayant reçu un message texte au jour 17. • L'inclusion d'une vidéo n'a pas augmenté de manière significative le nombre de rendez-vous ou de vaccinations par rapport aux messages sans vidéo éducative, probablement en raison du faible taux de visionnement (21 %). • C'est parmi les personnes ayant reçu au moins un vaccin contre la grippe au cours des deux années

	ECR 2 : Un deuxième rappel par message texte a été envoyé huit jours après le premier rappel aux participants qui n'avaient pas pris rendez-vous pour la première dose (n = 102 675). Les messages se répartissent en 6 catégories : (1) texte simple (2) prosocial (3) exclusivité de l'accès précoce (4) accès précoce et prosocial (5) nouveau départ (6) nouveau départ et prosocial. Sujets des questions : 1) Prise du vaccin	précédentes que l'impact des messages texte a été le plus fort. • 12 % des personnes qui ont pris rendez-vous après le premier message ont annulé leur rendez-vous sans le reporter et 0,1 % ne se sont pas rendues à leur rendez-vous. • Un deuxième rappel par message texte a augmenté de manière significative la prise de rendez-vous pour la première dose de 1,26 % (augmentation de 52,3 %, P < 0,001) dans les 6 jours et l'obtention de la première dose dans les 4 semaines de 0,68 % (augmentation de 15,9 %, P < 0,001) par rapport au groupe témoin. • Tous les types de messages ont permis d'augmenter les taux de rendez-vous et de vaccination.
Senderey (2021) *préimpression* (2) *nouveau* Avant et après l'étude Israël Févr. 2021	Les taux d'adoption du vaccin ont été comparés avant et après la mise en œuvre du rappel par message texte. Les personnes admissibles non vaccinées (16 ans et plus) ont été choisies au hasard pour recevoir l'un des deux rappels (après avoir reçu le rappel de base). Il y avait deux types de rappels, l'un soulignant l'avantage du vaccin sur le plan social et l'autre, l'avantage sur le plan personnel. Les vaccins étaient disponibles pour toutes les personnes âgées de plus de 16 ans. Les taux d'adoption du vaccin ont également été comparés avant et après la mise en œuvre de la politique du laissez-passer vert, selon lequel l'entrée dans certains lieux publics nécessitait la présentation du « laissez-passer	• L'adoption du vaccin est passée de 2,3 % deux jours avant l'intervention à 3,6 % deux jours après l'intervention (P<0,001). • Le message sur les avantages sur le plan personnel était plus efficace que celui sur les avantages sur le plan social. • L'effet global sur huit jours après l'intervention a révélé que le rappel des avantages sur le plan personnel a entraîné une hausse relative de 9 % par rapport au rappel des avantages sur le plan social (23,8 % contre 21,7 %, P<0,0001). • Si l'on compare trois jours avant et après la mise en œuvre de la politique du laissez-passer vert, on constate une augmentation relative de 22,2 % (de 3,6 % à 4,4 %).

	vert », qui pouvait être obtenu en recevant un vaccin ou un résultat négatif récent au test de dépistage de la COVID-19. Sujets des questions : 1) Adoption du vaccin	
Glampson (2021) *préimpression* (49) Étude de cohorte ROYAUME-UNI Décembre 2020 à février 2021	Cette étude visait à évaluer la prise vaccinale et l'efficacité de l'efficacité théorique sur une période de suivi de dix semaines dans un système de soins intégrés de huit Collaboration of Clinical Commissioning Groups (CCG) exploitant un ensemble unique de données sur les soins au niveau de la population dans le nord-ouest de Londres. Pendant la période du programme de vaccination, 413 919 adultes (16 et +) se sont vus offrir un vaccin. Les personnes ont été considérées comme refusant un vaccin si elles ont indiqué à leur médecin généraliste qu'ils ne voulaient pas du vaccin lorsqu'il leur a été proposé, puis n'ont pas été vaccinés. Sujets des questions : 1) Prise du vaccin	• Parmi les personnes à qui un vaccin a été proposé, 24 332 (5,88 %) ont refusé et n'ont pas été vaccinées. • Dans le groupe vacciné, 2 957 personnes avaient initialement refusé de se faire vacciner, mais l'ont fait par la suite, soit un taux d'hésitation de 0,71 %. • Le groupe des Noirs ou des Britanniques noirs présentait les taux de refus de vaccination les plus élevés (16,1 %), suivi du groupe ethnies mixtes (10,4 %), d'un autre groupe ethnique (9,95 %) et du groupe d'ethnie non enregistrée (8,5 %). Les taux de refus les plus faibles ont été observés dans les groupes des Blancs (4,9 %) et des Asiatiques et Britanniques asiatiques (3,2 %). • Dans le groupe des Noirs ou des Britanniques noirs, ceux qui étaient âgés de plus de 80 ans (27,9 %) ou qui étaient cliniquement extrêmement vulnérables (24,0 %) présentaient les taux de refus les plus élevés. • Aucune différence dans l'ensemble des taux de refus n'a été observée entre les hommes et les femmes (5,9 % contre 5,8 %), les hommes plus jeunes (< 65 ans) étaient plus susceptibles de refuser que les femmes plus jeunes (3,2 % contre 2,2 %), et les femmes plus âgées (65 ans et plus) étaient plus susceptibles de refuser que les hommes plus âgés (7,9 % contre 7,1 %). • La défavorisation était négativement associée au refus de la vaccination (r = -0,94, P < 0,01). Dans les zones les plus défavorisées, 13,5 % des

		individus ont refusé la vaccination, contre 1,0 % dans les zones les moins défavorisées. • Pour les personnes vivant dans les zones défavorisées, les taux de refus les plus élevés concernaient les personnes âgées de plus de 70 ans (70 à 74 = 17,5 %; 75 à 80 = 19,0 %; 80 et + = 25,9 %), les personnes cliniquement extrêmement vulnérables (19,2 %) et les communautés noires et noires britanniques (20,0 %).
AUTRES POPULATIONS		
Office for National Statistics (2021) *non publiée* (43, 47) Étude longitudinale ROYAUME-UNI Mars à mai 2021	Les réponses provenant de quatre vagues de résultats recueillis dans le cadre du sondage en ligne Opinions and Lifestyle Survey (196) ont été mises en commun pour mettre l'accent sur les associations démographiques spécifiques et la réticence à se faire vacciner. Le nombre de personnes handicapées ou extrêmement vulnérables au niveau clinique n'a pas été déclaré. Février et mars : 17 201 réponses ont été mises en commun Mars et avril : 16 362 réponses ont été mises en commun Avril et mai : 15,170 réponses ont été mises en commun Sujets des questions : 1) Prise du vaccin Outils d'enquête disponibles? Oui Recherches formatives effectuées? Oui Enquête prétestée? Oui	**Avril et mai** • Comparativement à la moyenne (2 %), le taux de refus du vaccin était légèrement inférieur chez les répondants handicapés (1 %) et extrêmement vulnérables sur le plan clinique (1 %). • 58 % des répondants handicapés avaient des préoccupations générales quant à l'innocuité du vaccin, alors que les répondants extrêmement vulnérables sur le plan clinique étaient les plus préoccupés par les préoccupations en matière de fertilité (28 %). • La plus grande difficulté prévue pour l'obtention d'un vaccin était la longue attente et le fait de devoir s'absenter du travail (8 %). **Mars-avril** • 2 % des personnes handicapées se sont vu offrir un vaccin, mais l'ont refusé, soit 1 % de plus que les personnes non handicapées. • 3 % des répondants extrêmement vulnérables sur le plan clinique (VPC) se sont vu offrir un vaccin et l'ont refusé, comparativement à 1 % des répondants non VPC. • 3 % des parents qui avaient des enfants âgés de 0 à 4 ans se sont vu offrir un vaccin et l'ont refusé, comparativement à 2 % de ceux qui avaient des enfants de plus de 5 ans ou à 1 % de ceux qui ne sont pas des parents et qui ne vivent pas avec des enfants à charge.

Turner (2021) *préimpression* (42) *nouvelle* Étude transversale Royaume-Uni Fev à Avr 2021	À l'aide d'un sondage en ligne, on a évalué les facteurs qui influencent l'adoption du vaccin contre la COVID-19 et la perception à l'égard de ce vaccin chez 377 survivants d'un accident vasculaire cérébral et d'une attaque ischémique transitoire pendant une période précoce de déploiement du vaccin au Royaume-Uni. Sujets des questions : 1) Adoption du vaccin 2) Hésitation par rapport à la vaccination Outils d'enquête disponibles? Oui Recherches formatives effectuées? Oui Enquête prétestée? Oui	• 87 % des répondants avaient reçu au moins une première dose ou avaient un rendez-vous alors que 8 % n'avaient pas encore reçu de vaccin. • 2 % des répondants avaient refusé le vaccin et 3 % s'étaient vus offrir le vaccin, mais ne l'avaient pas encore accepté. • Les préoccupations qui empêchaient l'atteinte d'un pourcentage élevé de personnes vaccinées comprenaient l'inquiétude au sujet des effets secondaires (36 %), le fait que le vaccin augmentait le risque d'accident vasculaire cérébral (34 %), l'innocuité du vaccin (32 %), la nouveauté du vaccin (29 %) et l'effet du vaccin sur les anticoagulants (28 %). • La plupart des répondants étaient d'avis que le vaccin était la bonne chose à faire (92 %), ont dit connaître d'autres personnes qui avaient reçu le vaccin (98 %), que le vaccin réduirait la propagation de la COVID-19 (85 %) et qu'il les protégerait (87 %). • On a pu voir une bonne compréhension de la manière d'obtenir un rendez-vous pour se faire vacciner (91 %). Bon nombre de personnes n'étaient pas d'accord pour dire qu'elles devaient consulter leur médecin (61 %), qu'elles auraient de la difficulté à obtenir un rendez-vous (64 %) ou qu'elles n'auraient pas le temps d'obtenir un rendez-vous (74 %). • Dans les réponses en texte libre, on a pu voir des préoccupations en ce qui concerne le lien entre le vaccin AstraZeneca et les caillots sanguins, les effets secondaires, la méfiance à l'égard du gouvernement, l'efficacité du vaccin, l'incertitude au sujet du lien entre les AVC/AIT et la COVID-19, l'accès aux rendez-vous pour le vaccin, et les difficultés à obtenir des renseignements spécifiquement adaptés à ces personnes.

Bowman (2021) *préimpression* (45) Étude transversale États-Unis Janvier à mars 2021	Un programme de vaccination mis en œuvre dans le cadre d'un programme de dialyse comprenant une série de quatre visites dans 12 cliniques de dialyse en Virginie a été mis en œuvre. Dans le cadre de ce programme, on a offert un vaccin à 859 patients âgés de 18 ans et plus. Sujets des questions : 1) Adoption du vaccin	• En date du 16 mars, 79,6 % des patients en dialyse à qui on avait offert un vaccin l'avaient accepté alors que 14,2 % l'avaient refusé. 6,2 % des personnes n'avaient ni accepté ni refusé le vaccin en raison d'une hospitalisation ou de l'absence de traitement le jour de la clinique de vaccination. • La probabilité de refus du vaccin a diminué de 13 % pour chaque tranche d'âge de cinq ans (RC 0,87, IC à 95 % : 0,80 à 0,95, P = 0,002). • Les femmes étaient plus susceptibles de refuser un vaccin que les hommes (RC 2,40, IC à 95 % : 1,64 à 3,50, P < 0,0001). • On a observé une probabilité accrue de refus du vaccin chez les patients qui n'ont pas reçu le vaccin antigrippal en 2020 (RC 5,44, IC à 95 % : 3,15 à 9,39, P < 0,0001), ceux qui ont été en dialyse pendant plus de 5 ans (RC 1,7, IC à 95 % : 1,08 à 2,70, P = 0,023) et ceux qui ont obtenu un résultat positif au test PCR pour la COVID-19 (RC 1,56, IC à 95 % : 0,97 à 2,52, P = 0,067).
Giannini (2021) (4) *nouveau* Étude transversale Italie NR 2021	Les taux d'adoption et de refus d'un vaccin contre la COVID-19 ont été évalués dans un groupe de 266 personnes ayant subi une transplantation hépatique. Sujets des questions : 1) Adoption du vaccin	• 96,6 % des patients ont accepté et reçu un vaccin contre la COVID-19 et 3,4 % n'ont pas reçu de vaccin. • 5 patients ont refusé de se faire vacciner en raison de crainte d'effets indésirables graves. Ces patients avaient reçu des renseignements adéquats sur le vaccin et avaient reçu les vaccins recommandés pour les transplantés hépatiques avant de refuser. • Deux patients ont demandé plus de temps pour décider de recevoir ou non le vaccin en raison de préoccupations quant aux risques potentiels. • Un patient a dû subir des examens complémentaires en raison de réactions allergiques antérieures aux vaccins, et un patient séjournait temporairement à l'étranger pendant que les vaccins étaient offerts.

Gibbon (2021) (5) *nouveau* Étude transversale R.-U. NR 2021	L'adoption du vaccin contre la COVID-19 et les raisons du refus ont été évaluées chez 92 patients hospitalisés en psychiatrie dans un hôpital de sécurité moyenne au Royaume-Uni. Sujets des questions : 1) Adoption du vaccin	• 85 patients avaient la capacité de décider s'ils voulaient recevoir le vaccin contre la COVID-19. • 80 % ont accepté de se faire vacciner et 20 % ont refusé. • Les patients britanniques blancs étaient moins susceptibles de refuser que les patients noirs, asiatiques ou issus de minorités ethniques (16,9 % contre 30 %). • Parmi les 17 patients qui ont refusé de se faire vacciner, les raisons étaient les suivantes : inquiétude quant à l'innocuité et aux effets secondaires du vaccin (n=5), conviction que le risque de contracter la COVID-19 est faible pour leur santé personnelle (n=4), méfiance générale envers les services de santé (n=2) et inquiétude quant à l'expérimentation animale (n=1). Cinq personnes n'ont pas voulu expliquer les raisons de leur refus.
Giannini (2021) (46) *nouveau* Étude transversale Italie NR 2021	Les taux d'adoption du vaccin ont été évalués chez 56 patients atteints du syndrome de l'intestin irritable et suivis dans un centre de l'intestin irritable. Sujets des questions : 1) Adoption du vaccin	• 92,6 % ont accepté de se faire vacciner et 7,4 % ont refusé. • Les deux patients qui ont refusé l'ont fait en raison de préoccupations concernant les effets indésirables potentiels.
RESPECT DES MESURES DE SANTÉ PUBLIQUE APRÈS LA VACCINATION		
United Status Census Bureaus (2021) *non publiée* (53) Étude longitudinale États-Unis	Les estimations en ce qui concerne les comportements préventifs des personnes qui ont reçu au moins une dose de vaccin ont été recueillies dans le cadre de la phase 3.1 du Household Pulse Survey effectuée toutes les deux semaines, en ligne.	• 73,2 % des personnes qui avaient reçu au moins une dose du vaccin n'ont pas modifié leurs comportements préventifs après la vaccination, 21,9 % les ont réduits et 4,3 % ont plutôt décidé de les renforcer. • La diminution des comportements préventifs a été mentionnée davantage chez les personnes âgées de 18 à 39 ans (24 à 25 %), les hommes (23 %), les Blancs non hispaniques (27 %), les personnes mariées (24 %), les titulaires d'un

Mai 2021	Semaine 30, du 12 au 24 mai, n = 192 277 515 Sujets des questions : 1) Adoption du vaccin Outils d'enquête disponibles? Oui Recherches formatives effectuées? Oui Enquête prétestée? Oui	baccalauréat ou plus (30 %), dans les ménages comptant 2 (25 %) et 4 personnes (23 %), chez les personnes occupant un emploi (24 %) et ayant un revenu du ménage supérieur à 75 000 $ (entre 23 % et 37 % lorsque le revenu est de 200 000 $ et plus) comparativement à leurs homologues.
Office for National Statistics (2021) *non publiée* (50, 54, 197, 198) Étude longitudinale ROYAUME-UNI Déc 2020 à May 2021	Un sondage hebdomadaire en ligne sur les intentions de se faire vacciner a été effectué auprès d'un échantillon national représentatif d'adultes britanniques. Avril 7-11: n= 6,030 Avril 28-Mai 3: n=3,830 Juin 2-6: n= 4,153 Juin 9-13: n=3,600 *nouvelle* Sujets des questions : 1) Adoption du vaccin Outils d'enquête disponibles? Oui Recherches formatives effectuées? Oui Enquête prétestée? Oui	**Du 9 au 13 juin** • La distanciation sociale avec les personnes à l'extérieur de leur ménage a continué de diminuer, passant de 74 % dans le sondage de mai à 66 % dans celui de juin (88 % au début d'avril). • Les contacts physiques à l'extérieur de la maison ont chuté de 1 % dans le dernier sondage pour s'établir à 71 %. • 46 % (en baisse par rapport à 50 %) des adultes rencontraient à l'intérieur des gens n'appartenant pas à leur ménage, à leur service de garde ou à leur bulle de soutien. **Du 2 au 6 juin** • La distanciation sociale avec les personnes à l'extérieur de leur ménage a continué de diminuer, passant de 74 % dans le sondage de mai à 68 % dans celui de juin (88 % au début d'avril). • Les contacts physiques à l'extérieur de la maison ont chuté de 1 % dans le dernier sondage pour s'établir à 72 %. • 50 % des adultes rencontraient à l'intérieur des gens n'appartenant pas à leur ménage, à leur service de garde ou à leur bulle de soutien.

		• Les rassemblements en plein air avec des adultes sont passés de 53 % à 65 % depuis le dernier sondage. **Du 28 avril au 3 mai** • 90 % des personnes vaccinées (au moins une dose) se lavent toujours ou souvent les mains en rentrant chez elles, contre 82 % des personnes non vaccinées. • 90 % des personnes vaccinées (au moins une dose) ont toujours ou souvent maintenu une distance sociale lorsqu'elles rencontrent des personnes extérieures à leur foyer, à leur entourage ou à leur bulle de garde, contre 72 % des non-vaccinés. • Les personnes ayant reçu au moins une dose ont évité les contacts physiques en dehors de leur domicile par rapport aux personnes non vaccinées (86 % contre 74 %). • 25 % des adultes vaccinés (au moins une dose) sont restés chez eux ou ne sont sortis que pour le travail, l'exercice, les achats essentiels ou les besoins médicaux, contre 15 % des adultes non vaccinés. • Les adultes vaccinés sont moins nombreux à travailler à domicile que les non-vaccinés (33 % contre 43 %).
Rahamin-Cohen (2021) *préimpression* (51) Étude transversale Israël Mars à avril 2021	Pour évaluer les changements de comportement au sein de la population vaccinée, 185 personnes de la population générale (18 et +) et 23 travailleurs sociaux (18 et +) ont répondu à une enquête en ligne envoyée par message texte. Les résultats pour les travailleurs de la santé dans la section travailleurs de la santé. Sujets des questions :	• Après la deuxième dose, 21,1 % des répondants ont déclaré porter un masque moins souvent qu'avant la vaccination et 75,7 % n'ont pas modifié leur comportement. Les personnes âgées de moins de 50 ans sont plus nombreuses à diminuer leur port du masque (28,1 %) que les personnes âgées de 50 ans et plus (17,2 %). Seulement 1 répondant sur 23 (4,3 %) des travailleurs de la santé a déclaré porter moins le masque après la vaccination. • En comparant le comportement de distanciation sociale avant et après la vaccination, 48,4 % des personnes interrogées n'ont signalé aucun

	1) Comportements post-vaccination Outils d'enquête disponibles? Non Des recherches formatives ont-elles été menées? Non Enquête prétestée? Non	changement et 47,3 % ont signalé une diminution de la distanciation sociale. Ces résultats diffèrent selon l'âge : 41,8 % des personnes âgées de 50 ans et plus ont signalé une diminution de la distanciation sociale et 53,3 % n'ont signalé aucun changement, contre 56,1 % et 40,4 % respectivement dans le groupe des moins de 50 ans. Chez les travailleurs de la santé, 43,5 % ont signalé une diminution de la distanciation sociale et 52,2 % n'ont signalé aucun changement après la vaccination.
Wright (2021) *préimpression* (52) Étude longitudinale ROYAUME-UNI Octobre 2020 à mars 2021	Les résultats d'une enquête mensuelle en ligne portant sur 70 000 adultes (18 et +) ont été utilisés pour étudier l'évolution de l'observance après la vaccination. Sujets des questions : 1) Comportements post-vaccination Outils d'enquête disponibles? Non Des recherches formatives ont-elles été menées? Non Enquête prétestée? Non	• Aucune donnée probante n'a démontré que le fait de recevoir un vaccin contre la COVID-19 réduisait les comportements d'observance. • Une augmentation de l'observance dès le début de la deuxième vague de COVID-19 a été démontrée à la fois chez les personnes vaccinées et non vaccinées.
Office for National Statistics (2021) *non publiée* (35) Étude transversale ROYAUME-UNI	Les réponses de 2 070 adultes de plus de 80 ans ont été recueillies au moyen d'un sondage en ligne afin de déterminer la couverture vaccinale, les attitudes et l'effet de la vaccination sur les comportements de protection. Sujets des questions : 1) Comportements post-vaccination	• Parmi les personnes qui avaient reçu au moins une dose, 43 % avaient rencontré quelqu'un en dehors de leur bulle, de leur ménage ou du personnel soignant à l'intérieur plutôt qu'à l'extérieur. • Parmi celles qui avaient reçu au moins une dose et qui s'étaient aventurées à l'extérieur de leur maison pour faire une activité, 49 % avaient rencontré à l'extérieur quelqu'un avec qui elles ne vivaient pas, 54 % étaient allés magasiner et 45 % étaient sorties de la maison pour participer à des activités de loisirs en plein air). Seulement

Fev 2021	Outils d'enquête disponibles? Non Des recherches formatives ont-elles été menées? Non Enquête prétestée? Non	20 % ont déclaré ne pas avoir quitté la maison pour quelque raison que ce soit. • 25 % des personnes qui ont reçu leur première dose et 33 % de celles qui ont reçu les deux doses étaient prêtes à aller à l'hôpital pour une raison médicale.
Nguyen (2021) *préimpression* (6) *nouveau* Étude de cohorte R.-U. Sept. 2020-févr. 2021	Le taux de changement de la distance moyenne de déplacement quotidien à partir de l'adresse enregistrée d'un participant avant et après la vaccination contre le SRAS-CoV-2 a été mesuré à l'aide de Virus Watch. Virus Watch a utilisé le système de positionnement global (GPS) pour recueillir des données sur les déplacements de 228 personnes vaccinées.	• La distance médiane parcourue quotidiennement était de 8,9 km (IQR : 3,50 km, 24,17 km) entre 157 jours avant la vaccination et la veille de la vaccination. • Entre le jour de la vaccination et 100 jours après la vaccination, la distance médiane parcourue quotidiennement était de 10,30 km (IQR : 4,11, 27,53 km). • Après suppression des données hors norme, on constate une augmentation médiane quotidienne des déplacements de 45,0 m (IC à 95 % : 25 m, 65 m, P = <0,001) entre la date de vaccination et 99 jours après la vaccination. • Après avoir restreint l'analyse au 3e confinement national (du 4 janvier au 5 avril 2021), on a constaté une augmentation médiane du mouvement quotidien de 9m (IC à 95 % : -25 m, 45 m, P = 0,57) dans les 30 jours précédant la vaccination et la date de vaccination, et une augmentation médiane des mouvements quotidiens de 10 m (IC à 95 % : -60 m, 94 m, valeur p = 0,69) dans les 30 jours suivant la vaccination.
Kaim (2021) (7) *nouveau* Étude transversale Israël	Les ajustements comportementaux de protection (c'est-à-dire le port du masque et la distanciation sociale) pendant la phase initiale de la campagne de vaccination ont été évalués dans un groupe de 1 120 adultes à l'aide d'un sondage en ligne. Parmi ces personnes, 64 étaient infectées par la COVID-19,	• Au début de la campagne de vaccination, les personnes infectées faisaient moins attention à la distanciation sociale (29,7 %) par rapport à celles qui avaient reçu la première dose de vaccin (12,8 %), ou celles qui n'étaient ni vaccinées ni infectées (19,2 %) (χ^2 = 19,32, P = 0,001). • De même, les personnes qui étaient infectées faisaient moins attention au port du masque (18,8 %) par rapport à celles qui avaient reçu la

Janv. 2021	453 étaient vaccinées et 603 n'étaient pas vaccinées. Sujets des questions : 1) Comportements après avoir reçu le vaccin Outils de sondage disponibles? Non Des recherches formatives ont-elles été menées? Non Sondage prétesté? Non	première dose du vaccin (8,2 %) et celles qui n'étaient ni vaccinées ni infectées (11,6 %) (χ^2 = 13,02, P = 0,011). • Un niveau plus élevé de distanciation sociale a été maintenu chez les personnes non-juives par rapport aux personnes juives : les personnes qui ont été vaccinées (41,7 % chez les non-juives contre 14,3 % chez les juives χ^2 = 22,9, P < 0,001), celles qui étaient infectées (33,1 % chez les non-juives contre 8,3 % chez les juives $\chi^{2=}$7,29, P = 0,026), et celles qui n'étaient ni vaccinées ni infectées (24,3 % chez les non-juives et 8,8 % chez les juives χ^2 = 28,81, P < 0,001). Des tendances similaires ont été observées pour le port du masque.

ÉTUDE	MÉTHODES ET OUTILS D'ENQUÊTE	RÉSULTATS CLÉS POUR LES CONNAISSANCES, LES ATTITUDES ET LES COMPORTEMENTS
Études quasi expérimentales (n = 1)		
Duch (2021) *préimpression* (199) Étude quasi-expérimentale 13 pays (Australie, Brésil, Canada, Chili, Chine, Colombie, France, Inde, Italie, Espagne,	Afin de comprendre l'opinion publique sur les aspects clés de la distribution des vaccins, une expérience en ligne a été menée auprès de 15 536 adultes (âgés de 18 ans et plus) dans 13 pays. Les participants devaient faire huit choix binaires en ce qui concerne des personnes qui recevraient hypothétiquement des vaccins qui variaient aléatoirement selon cinq attributs, notamment la profession, l'âge, l'état de transmission, le risque de décès attribuable à la COVID-19 et le revenu.	• Dans l'ensemble, il y a eu consensus à propos des segments de la population qui devraient avoir la priorité pour recevoir un vaccin contre la COVID-19. • Dans presque tous les pays et parmi les participants ayant différents niveaux d'éducation et de revenus et différentes idéologies politiques, les résultats montrent que le public privilégie le fait que les travailleurs de la santé, les personnes à haut risque, les personnes à faible revenu et les populations plus âgées reçoivent le vaccin. • Au moins deux tiers des participants dans chacun des pays (80 % au Canada) croyaient que le gouvernement devrait jouer un rôle de premier plan dans la distribution des vaccins contre la

Ouganda, Royaume-Uni, États-Unis) Novembre et décembre 2020	Sujets des questions : 1) Perception des vaccins Outils d'enquête disponibles? Oui Recherches formatives effectuées? Oui Enquête prétestée? Non	COVID-19. Cependant, il y a des preuves qu'une grande proportion de personnes seraient prêtes à payer pour un vaccin s'il était offert en privé. Ce pourcentage variait de 18 % des participants en France à environ 79 % en Inde et en Ouganda. 35 % des personnes seraient prêtes à payer pour un vaccin. • Il n'y a cependant pas eu de consensus quant au soutien à la vaccination obligatoire, que ce soit à l'échelle mondiale ou nationale. Dans l'échantillon pris à l'échelle mondiale, 24 % étaient fortement opposés et 38 % étaient fortement en faveur. En France, 60 % des participants se sont opposés à la vaccination obligatoire, alors qu'en Chine, en Inde et en Ouganda, très peu de gens s'y sont opposés fermement.
Études transversales (n=5)		
Crespo (2021) *préimpression* (57) Études transversales 15 pays : Allemagne, Australie, Canada, Danemark, Finlande, France, Italie, Japon, Pays-Bas, Norvège, Singapour, Corée du Sud, Espagne, Suède, Royaume-Uni	Les variations dans l'intention de se faire vacciner au fil du temps ont été évaluées à l'aide de deux sondages en ligne, l'un effectué en novembre 2020 et l'autre en janvier 2021 dans 15 pays. Rien n'indique le nombre de personnes qui ont répondu aux deux sondages et si des gens ont répondu aux deux. Sujets des questions : 1) Intentions en ce qui concerne les vaccins Outils d'enquête disponibles? Non Recherches formatives effectuées? Non Enquête prétestée? Non	• Au Canada, l'intention de se faire vacciner a augmenté, passant de 44,2 % en novembre à 55,2 % en janvier. • Dans le sondage réalisé en janvier, les pays dans lesquels on retrouvait le plus haut niveau en ce qui concerne l'intention de se faire vacciner étaient le Royaume-Uni (77,5 %), le Danemark (67 %) et les Pays-Bas (63,1 %). Quant au niveau le plus faible, on le retrouvait en Corée du Sud (43,7 %), en France (39,2 %) et à Singapour (34,8 %). • On a pu voir une augmentation de l'intention de se faire vacciner entre novembre et janvier en Espagne (24,1 %), au Royaume-Uni (23,2 %), en Suède (22,7 %), en Finlande (20,4 %), aux Pays-Bas (18,5 %), en Italie (15,4 %), en Norvège (14,6 %), en France (14,2 %), au Danemark (13,3 %), en Allemagne (13,0 %), au Canada (11 %) et au Japon (0,8 %). • Les pays dans lesquels l'intention a diminué entre novembre et janvier étaient l'Australie (-6,6 %), la Corée du Sud (-5,0 %) et Singapour (-1,3 %).

Novembre à janvier 2021		• Dans 11 des 15 pays, on a vu une diminution importante de la proportion de personnes qui se sont dites préoccupées par les effets secondaires d'un vaccin. Au Canada, ce niveau de préoccupation a diminué, passant de 53,3 % en novembre à 47,9 % en janvier.
Clarke (2021) (200) Étude transversale Australie, Canada, France, Italie, Espagne, Royaume-Uni et États-Unis Novembre à décembre 2020	Une enquête internationale en ligne a été menée auprès de 8 209 adultes de pays à revenu élevé dans le but d'évaluer les perceptions de la priorisation de l'allocation mondiale des vaccins sur une échelle de 0 (« très en désaccord ») à 100 (« très en accord »). Thèmes des questions : 1) Perception à l'égard des vaccins Outils d'enquête disponibles? Non Des recherches formatives ont-elles été menées? Non Enquête prétestée? Non	• Tous les pays sont favorisés par ordre de soutien : allocation en fonction des besoins, de l'accessibilité financière et du pays qui a développé le vaccin. • C'est au Royaume-Uni que l'on trouve le plus grand pourcentage de personnes interrogées qui ne sont pas en faveur de faire dons de vaccins achetés à d'autres pays (26 %) et en Italie et en Espagne que l'on trouve le plus faible pourcentage (15 %). • Entre 48 % et 56 % des personnes interrogées seraient prêtes à donner les vaccins de leur pays dans une certaine mesure. Le taux le plus élevé était celui du Canada (56 %) et le plus bas celui de la France (48 %).
World Economic Forum (2020) *non publiée* (201) Étude transversale 15 pays (Australie, Brésil, Canada, Chine, France, Allemagne, Inde, Italie, Japon,	Un sondage en ligne effectué auprès de 18 526 personnes dans le monde a été utilisé pour analyser l'intention de se faire vacciner et les perceptions à l'égard du vaccin. De ceux-ci, 1 000 participants étaient canadiens. Sujets des questions : 1) Intentions en ce qui concerne les vaccins 2) Perception des vaccins 3) Hésitation par rapport à la vaccination	• 73 % des personnes ont déclaré qu'elles se feraient vacciner contre la COVID-19 si le vaccin était disponible. Comparativement aux données obtenues trois mois plus tôt (août), il s'agit d'une baisse de 4 %. • L'intention de se faire vacciner a diminué entre août et octobre dans 10 des 15 pays, notamment en Chine, en Australie, en Espagne et au Brésil. • L'Inde (87 %), la Chine (85 %), la Corée du Sud (83 %) et le Brésil (81 %) sont les pays où l'on trouve le niveau d'intention le plus élevé. • La France est le pays dans lequel les gens ont le moins l'intention de se faire vacciner (54 %). Elle

Mexique, Afrique du Sud, Corée du Sud, Espagne, Royaume-Uni et États-Unis) Octobre 2020	Outils d'enquête disponibles? Oui Recherches formatives effectuées? Oui Enquête prétestée? Oui	est suivie des États-Unis (64 %) et de l'Espagne (64 %). • 52 % des gens ont indiqué qu'ils se feraient vacciner dans les trois mois de la date à laquelle un vaccin sera disponible pour tout le monde. • 55 % des gens croient qu'un vaccin ne sera pas disponible sur le marché avant le troisième trimestre de 2021. • À l'échelle mondiale, les motifs d'hésitation les plus courants sont les préoccupations à propos des effets secondaires (34 %) et les préoccupations liées au fait que les essais cliniques progressent trop rapidement (33 %).
Mannan (2021) *préimpression* (202) Étude transversale 60 pays : (Afghanistan, Algérie, Argentine, Australie, Bangladesh, Belgique, Bolivie, Botswana, Brésil, Canada, Chili, Chine, Colombie, Cuba, République dominicaine, Équateur, Égypte, El Salvador, Angleterre, Fidji, France,	Soixante sondages téléphoniques et en ligne représentatifs de chacun des pays ont permis de recueillir 26 852 réponses d'adultes (âgés de 19 ans et plus) en ce qui concerne l'acceptation du vaccin et des attitudes à cet égard. Sujets des questions : 1) Intentions en ce qui concerne les vaccins 2) Hésitation par rapport à la vaccination 3) Attitudes à l'égard des vaccins Outils d'enquête disponibles? Oui Recherches formatives effectuées? Oui Enquête prétestée? Non	• 62,6 % des Canadiens ont fortement accepté un vaccin contre la COVID-19, soit le taux d'acceptation le plus faible parmi les pays d'Amérique du Nord. • 65,5 % étaient fortement d'accord pour dire qu'il était important d'obtenir un vaccin pour protéger les autres, 57,6 % étaient d'accord pour dire que les sociétés pharmaceutiques mettront au point un vaccin sûr, et 31,7 % étaient d'avis que les vaccins étaient plus sûrs s'ils étaient fabriqués en Amérique ou en Europe que dans d'autres pays. • La réticence a été démontrée puisque 48,7 % des répondants s'inquiétaient des effets secondaires, 44,7 % s'inquiétaient des effets imprévus, 43,7 % s'inquiétaient des profits commerciaux, 42,6 % avaient une méfiance générale à l'égard des bienfaits du vaccin et 34,6 % avaient une préférence pour l'immunité naturelle. • Acceptation du vaccin par pays : **Afrique** Algérie (66,3 %), Égypte (43,6 %), Botswana (71,2 %), Kenya (61,3 %), Libye (49,6 %), Mali (62,4 %), Maurice (82,8 %), Maroc (48,4 %), Nigéria (61,5 %), Afrique du Sud (79,3 %) **Asie** Afghanistan (47,2 %), Bangladesh (49,8 %), Chine (87,4 %), Inde (73,9 %), Japon (71,4 %), Malaisie (52,7 %), Arabie saoudite (51,1 %),

Allemagne, Guatemala, Inde. Italie, Jamaïque, Japon, Kenya, Kiribati, Libye, Mali, Malaisie, Maurice, Mexique, Maroc, Nauru, Nouvelle-Zélande, Nicaragua, Nigeria, Palau, Panama, Papouasie-Nouvelle-Guinée, Paraguay, Pérou, Pologne, Russie, Afrique du Sud, Arabie saoudite, Singapour, Espagne, Corée du Sud, Suède, Suisse, Turquie, Tonga, Tuvalu, États-Unis d'Amérique, Uruguay, Venezuela) Juin à septembre 2020		Singapour (66,8 %), Corée du Sud (76,2 %), Turquie (59,2 %) **Océanie** Australie (89,9 %), Fidji (87,2 %), Nouvelle-Zélande (88,4 %), Kiribati (89,8 %), Nauru (88,3 %), Palaos (89,2 %), Papouasie-Nouvelle-Guinée (91,9 %), Îles Salomon (92,6 %), Tonga (92,9 %), Tuvalu (90,5 %) **Amérique du Nord** Canada (62,6 %), Cuba (77,9 %), République dominicaine (79,5 %), El Salvador (71,8 %), Guatemala (75,0 %), Jamaïque (71,0 %), Mexique (73,3 %), Nicaragua (81,2 %), Panama (87,4 %), États-Unis (74,8 %) **Amérique du Sud** Argentine (81,3 %), Brésil (86,2 %), Bolivie (82,8 %), Chili (79,2 %), Colombie (81,8 %), Équateur (70,2 %), Paraguay (67,7 %), Pérou (77,8 %), Uruguay (75,6 %), Venezuela (74,8 %) **Europe** Angleterre (69,3 %), Belgique (60,4 %), Allemagne (65,2 %), Italie (68,4 %), France (51,9 %), Pologne (52,3 %), Espagne (72,5 %), Suède (62,7 %), Suisse (60,2 %), Russie (51,3 %)
Lazarus (2020) (203) Lazarus (2021) (204)	Un sondage en ligne effectué auprès de 13 426 adultes a été utilisé pour analyser les taux d'acceptation du vaccin et les facteurs qui influent sur l'acceptation de ce vaccin contre la	• 71,5 % des participants ont déclaré qu'ils seraient « très susceptibles » ou « assez susceptibles » de se faire vacciner contre la COVID-19.

Étude transversale 19 pays : (Brésil, Canada, Chine, Équateur, France, Allemagne, Inde, Italie, Mexique, Nigéria, Pologne, Russie, Singapour, Afrique du Sud, Corée du Sud, Suède, Royaume-Uni, États-Unis) Juin 2020	COVID-19. Les données de ce sondage ont été analysées différemment dans deux publications. Sujets des questions : 1) Intentions en ce qui concerne les vaccins Outils d'enquête disponibles? Oui Recherches formatives effectuées? Oui Enquête prétestée? Oui	• 48,1 % ont déclaré qu'ils accepteraient la recommandation de leur employeur de se faire vacciner. • La Chine (88,6 %), le Brésil (85,4 %) et l'Afrique du Sud (81,6 %) ont affiché les taux d'acceptation les plus élevés, tandis que le Nigéria (58,9 %), la Pologne (56,3 %) et la Russie (54,9 %) ont affiché les taux les plus faibles. • Le taux d'acceptation au Canada était de 68,7 %. • Les personnes de 25 ans et plus étaient plus susceptibles d'accepter de se faire vacciner que celles qui ont entre 18 et 24 ans. La différence la plus marquée a été observée (RC = 1,73, IC à 95 %, de 1,48 à 2,02) lorsque les réponses de la cohorte de personnes plus âgées (65 ans et plus) ont été comparées à celles de la cohorte formée de personnes plus jeunes (18 à 24 ans). • Les personnes ayant fait des études supérieures, les femmes, celles qui gagnaient plus d'argent, celles qui ont déclaré que certains membres de leur famille avaient attrapé la COVID-19 et celles qui avaient confiance en leur gouvernement étaient plus susceptibles d'accepter de se faire vacciner. • Le fait d'avoir un niveau de scolarité élevé ou très élevé peut être lié à une baisse de l'acceptation des vaccins au Canada, en Espagne et au Royaume-Uni.

POPULATION GÉNÉRALE AU CANADA

Tableau 3. Éléments de preuve sur les attitudes du grand public à l'égard des vaccins (n = 42)

ÉTUDE	MÉTHODES ET OUTILS D'ENQUÊTE	RÉSULTATS CLÉS RELATIFS AUX CONNAISSANCES, ATTITUDES ET COMPORTEMENTS
Études longitudinales (n = 8)		
Leger (2021) *non publiée*	Un sondage en ligne a été mené auprès d'adultes canadiens et américains (âgés de 18 ans et plus)	**Vague 12**

(10, 69-73, 205, 206) Étude longitudinale Canada et États-Unis Novembre 2020 et janvier 2021-juin 2021	pour évaluer les perceptions et les intentions quant à la vaccination. Vague 1 : Novembre 2020, 1 516 Canadiens et 1 002 Américains Vague 2 : Janvier 2021, 1 516 Canadiens et 1 003 Américains Vague 3 :: Février 2021, 1 535 Canadiens et 1 002 Américains Vague 4 :: Février 2021, 1 532 Canadiens et 1 002 Américains Vague 5 : Avril 2021, 1 504 Canadiens et 1 002 Américains Vague 6: Avril 2021, 1,548 Canadiens and 1,003 Américains Vague 7: Mai 2021, 1,529 Canadiens, 1,003 Américains Vague 8: Mai 2021, 1,529 Canadiens, 1,003 Américains Vague 9: Mai 2021, 1,624 Canadiens, 1,002 Américains Vague 10: Mai 2021, 1,624 Canadiens, 1,002 Américains Vague 11: Juin 2021, 1,539 Canadiens, 1,004 Américains *nouvelle* Vague 12: Juin 2021, 1,542 Canadiens, 1,001 Américains *nouvelle* Sujets des questions : 1) Intentions en ce qui concerne les vaccins 2) Perception des vaccins	• Le pourcentage des Canadiens qui ont l'intention de se faire vacciner ou qui ont été vaccinés est passé à 88 % par rapport à mai. • Le pourcentage des personnes qui n'avaient pas l'intention de se faire vacciner était le plus élevé au Manitoba et en Saskatchewan (18 %), suivis de l'Alberta (16 %), des personnes âgées de 18 à 34 ans (14 %, en baisse par rapport aux 18 % du dernier scrutin) et des résidents ruraux (16 %, en baisse par rapport aux 22 % du dernier scrutin). • La croyance que les vaccins sont dangereux est restée à 7 % depuis mai (81 % croient que les vaccins sont sûrs et 12 % ne savent pas). **Vague 11** • Le nombre de Canadiens qui ont l'intention de se faire vacciner ou qui ont été vaccinés se maintient à 86 % (aucun changement par rapport à mai). • Le pourcentage de personnes qui n'avaient pas l'intention de se faire vacciner était le plus élevé en Alberta (20 %), suivie des provinces de l'Atlantique (19 %), chez les 18 à 34 ans (18 %) et chez les résidents ruraux (22 %). • 89 % des gens ont dit qu'ils recevront certainement ou probablement une deuxième dose, 1 % ont dit qu'ils n'en recevront probablement pas, 9 % ont dit avoir déjà reçu une deuxième dose et 1 % n'étaient pas certains. • 3 % des personnes qui résident au Québec et 3 % des personnes âgées de 18 à 24 ans ont indiqué qu'elles ne recevront probablement pas ou certainement pas de deuxième dose. • 48 % des Canadiens étaient mal à l'aise à l'idée de recevoir une autre marque de vaccin comme deuxième dose, tandis que 46 % étaient à l'aise et 6 % se sont dits incertains. • Les personnes du Manitoba et de la Saskatchewan (34 %), les personnes âgées de 35 à 55 ans (25 %) et les résidents ruraux (26 %) présentaient les niveaux les plus élevés de malaise à l'égard d'un vaccin différent comme deuxième dose.

	Outils d'enquête disponibles? Non Recherches formatives effectuées? Non Enquête prétestée? Non	• 50 % de ceux qui ont reçu une première dose d'AstraZeneca préféreraient recevoir une deuxième dose d'AstraZeneca, comparativement à 32 % qui aimeraient recevoir une deuxième dose d'une autre marque, alors que 18 % ont dit ne pas savoir. • La croyance selon laquelle les vaccins sont dangereux est passée de 1 % à 7 % depuis mai (82 % croyaient que les vaccins sont sécuritaires et 11 % ont dit ne pas savoir). **Vague 10 :** • Les Canadiens étaient divisés à parts égales sur la question de savoir s'ils étaient à l'aise avec l'idée que certains de leurs collègues ne soient pas vaccinés. • L'inconfort à l'égard des collègues non vaccinés était le plus élevé en Colombie-Britannique (62 %) alors que 60 % des habitants des provinces de l'Atlantique, du Manitoba et de la Saskatchewan étaient à l'aise avec cette idée. • Les Canadiens plus âgés (55 ans et plus) étaient moins à l'aise avec l'idée des collègues non vaccinés (52 %), tout comme les résidents urbains (53 %) comparativement aux résidents ruraux (44 %). **Vague 9 :** • 51 % des répondants étaient d'avis que la campagne de vaccination dans leur province se déroulait à peu près de la même façon que dans les autres provinces. Les résidents du Québec étaient d'avis qu'ils s'en tiraient mieux que ceux des autres provinces, tandis que ceux de l'Ontario et de l'Alberta étaient d'avis que la vaccination s'effectuait plus lentement. • Les Canadiens étaient fortement favorables à l'idée de devoir présenter une preuve de vaccination lorsqu'ils prenaient l'avion (82 %), qu'ils assistaient à des événements où l'on retrouvait une foule (75 %) et s'ils fréquentaient une université en présentiel (71 %) alors qu'ils étaient moins

		favorables à l'idée de devoir présenter cette preuve lorsqu'ils devaient se rendre au travail (68 %), au moment de séjourner à l'hôtel (68 %) et de manger dans un restaurant (64 %). L'appui à la vaccination était toujours plus élevé chez les 55 ans et plus. • Depuis le sondage précédent effectué en mai, il y a eu une augmentation de 4 % (à 86 %) des personnes qui avaient été vaccinées ou avaient l'intention de se faire vacciner. • Les provinces ayant le niveau combiné de vaccination ou d'intention de se faire vacciner le plus élevé étaient le Québec (90 %), suivi de l'Alberta (87 %), des provinces de l'Atlantique (86 %), de la Colombie-Britannique (85 %) et du Manitoba et de la Saskatchewan (84 %). • La croyance selon laquelle les vaccins sont sécuritaires et devraient être administrés est demeurée stable à 81 %, mais le pourcentage des personnes incertaines est passé de 1 % à 12 %. • Les vagues 1 à 8 sont résumées dans les versions précédentes du présent rapport.
Angus Reid (2021) *non publiée* (8, 60, 61, 66, 68, 76, 82, 83, 85) Étude longitudinale Canada Juillet, septembre et décembre 2020 et janvier, février et mai-juin 2021	Un sondage en ligne a été utilisé pour analyser l'intention en ce qui concerne la vaccination et les perceptions concernant le vaccin chez des Canadiens (âgés de 18 ans et plus). Vague 1 : Juillet 2020, n = 1 519 Vague 2 : Septembre 2020, n = 1 660 Vague 3 : Décembre 2020, n = 1 603 Vague 4 :: Janvier 2021, n = 1 580 Vague 5 : Février 2021, n = 1 201 Vague 6 : Mars 2021, n = 1 748 Vague 7 : Avril 2021, n = n.d.	**Vague 10** • 84 % ont reçu au moins un vaccin ou se feront vacciner dès que possible (soit une augmentation de 2 % par rapport au mois de mai), 4 % se feront vacciner, mais souhaitent attendre (contre 6 % auparavant), 9 % ne se feront pas vacciner (aucun changement) et 3 % sont incertains (aucun changement). • La réticence à se faire vacciner reste la plus forte en Alberta et en Saskatchewan (18 %). Depuis mai, ce chiffre a augmenté de 1 % en Alberta et diminué de 6 % en Saskatchewan. • 57 % des répondants souhaitent que l'on mette autant l'accent sur la distribution des premières et des deuxièmes doses, 26 % préfèrent que l'on donne la priorité à l'administration de toutes les premières doses admissibles et 16 % souhaitent que l'on se concentre sur les deuxièmes doses et

	Vague 8: Apr 2021, n=1594 Vague 9: May 2011, n= 1,319 Vague 10: June 2021, n=4,948 *nouvelle* Sujets des questions : 1) Intentions en ce qui concerne les vaccins 2) Perception des vaccins 3) Vaccine hesitancy Outils d'enquête disponibles? Oui Recherches formatives effectuées? Non Enquête prétestée? Non	que l'on revienne aux premières doses. Le soutien à l'idée de se concentrer sur l'administration des premières doses était plus élevé parmi les personnes en attente de vaccination (39 %) et parmi les personnes âgées de 18 à 24 ans (40 %). • Les Canadiens sont favorables à la poursuite de la vaccination jusqu'à ce que tous les Canadiens aient été vaccinés (72 %), 18 % souhaitent que l'on se concentre sur les populations à risque au niveau mondial et 10 % sont incertains. • Les personnes interrogées ont estimé que les vaccinations de la deuxième dose progressaient aussi bien qu'on pouvait s'y attendre (49 %), avec une répartition presque égale entre le sentiment que cela prenait trop de temps (27 %) et que cela allait très vite (24 %). 55 % des résidents du Québec ont estimé que les choses allaient bien alors que 40 % des résidents de l'Ontario estimaient que les choses allaient trop lentement. • 51 % des personnes interrogées estiment que le Canada a fait un bon travail pour obtenir les doses de vaccin et 41 % estiment qu'il a fait un mauvais travail. Cependant, 60 % et 69 % ont encore confiance dans la capacité des gouvernements fédéral et provinciaux à gérer la distribution des vaccins, respectivement. **Vague 9 :** • 82 % des répondants ont soit reçu un vaccin ou souhaitent le recevoir le plus tôt possible, une augmentation par rapport au chiffre de 71 % obtenu en avril. • Moins de répondants ont dit être incertains au sujet de la vaccination (en baisse de 3 % par rapport à 13 % obtenu en avril), vouloir attendre avant de recevoir un vaccin (en baisse de 6 % par rapport à 13 % obtenu en avril) ou ont dit ne pas vouloir recevoir de vaccin (en baisse de 9 % par rapport à 13 % obtenu en avril)

		• 53 % des répondants ont reçu au moins une dose du vaccin, soit une augmentation de 36 % par rapport à avril. • La réticence à se faire vacciner est la plus forte en Saskatchewan (24 %) où le niveau demeure stable (22 % en avril et 26 % en janvier). • La réticence à se faire vacciner a chuté de façon spectaculaire en Alberta, passant de 45 % en janvier à 25 % en avril et à 17 % en mai. • La réticence en Colombie-Britannique, au Manitoba, en Ontario, au Québec et dans les provinces de l'Atlantique a varié entre 10 % et 12 % en mai. • La réticence à se faire vacciner était la plus forte chez les hommes de 35 à 54 ans (18 %), puis chez les femmes de 18 à 34 ans (15 %). • Parmi les personnes qui ont reçu le vaccin AstraZeneca, 2 % ont dit le regretter complètement alors que 66 % ont de sérieux doutes à l'égard du vaccin. • Les Canadiens demeurent très à l'aise avec les vaccins Pfizer et Moderna (93 % et 89 % respectivement), mais ils ont perdu confiance en AstraZeneca (52 % en avril et 35 % en mai) et en Janssen (54 % et 49 %). • Les hommes non vaccinés sont plus à l'aise que les femmes de recevoir le vaccin AstraZeneca (29 % contre 36 % qui sont extrêmement mal à l'aise), mais 40 % des femmes accepteraient un vaccin avec lequel elles sont mal à l'aise comparativement à 31 % des hommes. • Les vagues 1 à 8 sont résumées dans les versions précédentes du présent rapport.
Engage Manitoba (2021) *non publiée* (97, 207)	Une série de sondages en ligne au Manitoba a été mise en œuvre pour évaluer les intentions de se faire vacciner dans le cadre du sondage effectué sur le Plan de	**Sondage 5** • 86 % des répondants ont reçu au moins une dose d'un vaccin (contre 9 % dans le sondage 4). • 2 % ont pris rendez-vous pour la première dose, 2 % recevront le vaccin, mais ne sont pas pressés

Étude longitudinale Canada Janvier à juin 2021	rétablissement sécuritaire des services du Manitoba. Sondage 1 10 au 15 janvier, n = 73 351 Sondage 2 4 au 9 février, n = 33 687 Sondage 3 25 février au 2 mars, n = 26 909 Sondage 4 18 au 23 mars, n = 31 776 Sondage 5: 4 au 8 juin, n= 33,904 Sujets des questions : 1) Intentions en ce qui concerne les vaccins 2) Perception des vaccins Outils d'enquête disponibles? Oui Recherches formatives effectuées? Non Enquête prétestée? Non	de le recevoir (contre 13 %), 4 % ne sont pas certains de se faire vacciner (contre 12 %) et 5 % ne se feront pas vacciner. • Parmi ceux qui n'étaient pas certains ou qui n'avaient pas l'intention de se faire vacciner, très peu étaient influencés par la capacité de voyager au Canada (9 %), d'assister à des événements sportifs ou culturels (7 % à 9 %), de visiter des installations ou des événements (10 %) ou de rendre visite à des êtres chers (11 %). **Sondage 4** • 9,0 % des répondants ont déjà reçu un vaccin (en hausse de 4 % depuis le troisième sondage). • 56 % ont l'intention de s'inscrire pour se faire vacciner dès qu'ils sont admissibles (hausse de 1,9 %). • 13 % ont déclaré qu'ils se feraient vacciner, mais qu'ils ne sont pas pressés (comparativement à 16,2 %). • 12 % ont dit ne pas être certains de vouloir se faire vacciner lorsqu'un vaccin sera disponible (en baisse par rapport à 14,2 %). • 10 % ont dit qu'ils refuseraient de se faire vacciner (comparativement à 10,5 %). • Le taux d'approbation de l'approche du gouvernement du Manitoba en matière de vaccination est élevé dans le dernier sondage : 33 % l'approuvent fortement, 47 % l'approuvent quelque peu, 13 % le désapprouvent quelque peu et 7 % le désapprouvent fortement.
Gouvernement du Manitoba (2021) *Non publié* (11) *nouveau*	Un groupe de recherche en ligne composé de 600 Manitobains a été interrogé pour comprendre les attitudes envers les vaccins et les mesures incitatives possibles pour augmenter le taux d'adoption.	• 87 % ont reçu un vaccin ou ont l'intention de se faire vacciner (74 % ont reçu un vaccin et 13 % ont l'intention de se faire vacciner), soit une augmentation de 11 % par rapport au mois d'avril. • 5 % se feront vacciner, mais ne sont pas pressés de le faire (par rapport à 12 %), 5 % ne sont pas

Étude longitudinale Canada Mai 2021	Sujets des questions : 1) Intentions de se faire vacciner 2) Perception des vaccins Outils de sondage disponibles? Non Des recherches formatives ont-elles été menées? Non Sondage prétesté? Non	certains de se faire vacciner (par rapport à 7 %) et 4 % ne se feront pas vacciner (par rapport à 5 %). • D'avril à juin, il y a eu une baisse de 18 % du nombre de personnes approuvant fortement la distribution des vaccins au Manitoba (de 42 % à 24 %), 49 % l'approuvant quelque peu (en hausse par rapport à 43 %), 17 % la désapprouvant quelque peu (en hausse par rapport à 11 %) et 10 % la désapprouvant fortement (en hausse par rapport à 4 %). • Dans un groupe de 70 parents ou tuteurs d'enfants âgés de 12 à 17 ans, 15 % sont incertains de faire vacciner leurs enfants et 13 % ne le feront pas. • Les parents qui n'avaient pas l'intention de faire vacciner leurs enfants faisaient partie de ménages dont le revenu était inférieur à 40 000 dollars, ne se feraient pas vacciner eux-mêmes et ne pensaient pas que les adultes devaient recevoir tous les vaccins habituels. • 31 % des personnes interrogées avaient un avis beaucoup plus positif sur le vaccin contre la COVID-19 maintenant qu'au moment de sa mise en place, 19 % avaient un avis légèrement plus positif, 45 % un avis identique, 3 % un avis légèrement plus négatif et 2 % un avis beaucoup plus négatif. • 55 % ont estimé que le fait de se faire vacciner ou non devrait être un choix, 42 % ont estimé que cela ne devrait pas être un choix, et 3 % étaient incertains. • Les personnes qui encouragent la vaccination ont tendance à avoir moins de 30 ans ou plus de 65 ans et pensent que les adultes devraient recevoir tous les vaccins habituels. • Les types de renseignements les plus susceptibles d'influencer la décision de se faire vacciner sont ceux sur les effets secondaires possibles (42 %), la possibilité de choisir le vaccin (42 %), l'information

		sur les tests (41 %) et l'information sur le fonctionnement du vaccin (36 %). • Le type d'information le moins convaincant était d'entendre les histoires de célébrités qui ont reçu leur vaccin (90 % d'incidence improbable). • Les femmes seraient les plus influencées par le fait de pouvoir choisir le vaccin. • Les résidents de Winnipeg ont été plus influencés que ceux des régions rurales par le fait d'obtenir un vaccin auprès d'un médecin de famille/pharmacien, de parler à leur médecin de famille/pharmacien, de faire venir quelqu'un à leur domicile et d'entendre les histoires de célébrités. • Les Manitobains n'ont pas été influencés par les incitatifs communautaires, comme la possibilité de voyager sans avoir à s'isoler (50 % pas plus susceptibles de se faire vacciner), la possibilité de visiter les maisons de soins de longue durée sans restrictions (52 % pas plus susceptibles), l'entrée dans les provinces ou les pays (48 % pas plus susceptibles), la possibilité d'assister à de grands événements (60 % pas plus susceptibles), la participation à de grands rassemblements (54 % pas plus susceptibles), l'accès à certaines entreprises ou installations pour les personnes vaccinées (61 % pas plus susceptibles). • Les personnes âgées de 30 à 44 ans étaient plus susceptibles d'être influencées par la possibilité de participer à des rassemblements plus importants (communautaires, religieux ou personnels). • Les incitatifs financiers (argent, bons, articles gratuits, tirages au sort, remises) n'ont pas été signalés comme un facteur qui augmenterait la probabilité de se faire vacciner (entre 75 % et 84 % déclarant qu'ils ne sont pas plus susceptibles de se faire vacciner par un incitatif financier). • 70 % des répondants sont préoccupés si seules les personnes réticentes reçoivent des incitatifs importants (50 à 100 dollars).

Statistics Canada (2020) & Statistics Canada (2021) *non publiée* (65, 80, 81) Étude longitudinale Canada Septembre 2020 à février 2021	Un sondage en ligne mené par Statistique Canada dans le cadre de l'Enquête sur la santé dans les collectivités canadiennes (ESCC) a évalué les comportements des Canadiens pour protéger leur propre santé et celle des autres. Une question sur les intentions de vaccination a été ajoutée au sondage de septembre. Le plus récent rapport fait état de 20 000 réponses reçues de personnes âgées de 12 ans et plus. Sujets des questions : 1) Intentions en ce qui concerne les vaccins Outils d'enquête disponibles? Oui Recherches formatives effectuées? Oui Enquête prétestée? Oui	**Janvier-février 2021** • 82,3 % des répondants étaient très ou probablement prêts à se faire vacciner contre la COVID-19. • L'intention de se faire vacciner était la plus élevée chez les personnes âgées de plus de 65 ans (88,1 %), avec un niveau d'intention décroissant chez les personnes âgées de 12 à 17 ans (71,0 %). • L'intention de se faire vacciner était similaire chez les hommes et les femmes (82,8 % contre 81,9 %, respectivement). **Sept à Déc. 2020** • Pendant la période d'échantillonnage, 77 % des personnes ont dit être prêtes à se faire vacciner. Cela représente une augmentation par rapport à septembre (75,5 %) à octobre (74,8 %) et à novembre-décembre (80,3 %). • L'intention de se faire vacciner était la plus élevée à l'Île-du-Prince-Édouard (89,1 %), en Nouvelle-Écosse (81,5 %) et en Colombie-Britannique (81,4 %). L'intention de se faire vacciner était la plus basse dans les Prairies (75,2 %) • Les hommes étaient plus susceptibles de se faire vacciner que les femmes (77,9 % contre 75,8 %). • Les immigrants étaient légèrement moins susceptibles de se faire vacciner (74,6 %), mais cela variait grandement entre les immigrants plus âgés et les plus jeunes (73,2 % pour les 12 à 64 ans et 81,1 % pour les 65 ans et plus). • Les membres de la communauté LGBTQ2+ étaient plus susceptibles de se faire vacciner (83,3 %). • Les personnes des minorités visibles ayant la plus forte intention de se faire vacciner étaient les Japonais (86,5 %), les Coréens (85,6 %), les Asiatiques du Sud (82,5 %), les Chinois (79,3 %), les minorités visibles non indiquées/multiples (79,1 %), les Asiatiques du Sud-Est (78,3 %), les Asiatiques de l'Ouest (78,3 %), les Philippins (75,1 %), les Arabes (68,1 %), les gens d'Amérique latine (66,0 %) et les Noirs (56,6 %). L'intention des

		non-membres d'une minorité visible de se faire vacciner était de 77,6 %. • Les minorités visibles plus âgées étaient plus susceptibles de se faire vacciner que les 12 à 64 ans (77,4 % contre 74,6 %). • Chez les répondants autochtones, 71,8 % ont dit qu'ils se feraient vacciner, ce qui est nettement inférieur au taux de réponse des répondants non autochtones (77,1 %). 74,2 % des membres des Premières Nations qui vivent hors réserve étaient prêts à se faire vacciner, comparativement à 67,8 % des Métis et à 72,5 % des Inuits*. • Les Autochtones plus âgés (65 ans et plus) étaient plus susceptibles de vouloir se faire vacciner que les plus jeunes (74,9 % contre 71,3 %). *Utiliser avec prudence. Coefficient de variation (CV) de 15,1 % à 35,0 %.
Impact Canada (2020) *non publiée* (74) Étude longitudinale Canada Avril 2020 à février 2021	La confiance et l'hésitation face au vaccin dans le contexte canadien ont été examinées par la mise en œuvre de l'Outil de l'OMS pour l'analyse des comportements face à la COVID-19 chez huit vagues d'adultes (âgés de 18 ans et plus) utilisant pour ce faire les mêmes participants, dans la mesure du possible. Vague 1 : n = 2 023, Vague 2 : n = 2 098, Vague 3 : n = 2 000, Vague 4 : n = 2 152, Vague 5 : n = 2 169, Vague 6 : n = 2 141, Vague 7 : n = 2 129, Vague 8 : n = 2 117, Vague 9 : n = 2 055, Vague 10 : n = 2 125, Vague 11: n= 2 037 Sujets des questions :	**Vague 11** • L'intention de se faire vacciner immédiatement a atteint 58 % (contre 49 % à la vague 10). 24 % ont dit avoir l'intention de se faire vacciner, mais préféraient attendre, 9 % ont dit qu'ils ne le feraient pas et 8 % se sont dits incertains. • Ceux qui prévoyaient attendre ont dit qu'ils attendraient probablement un ou deux mois avant de se faire vacciner (33 %). • 68 % des gens avaient décidé si oui ou non ils se feraient vacciner alors que 25 % avaient besoin de plus de renseignements avant de finaliser leur décision. • Les deux raisons les plus fréquentes en ce qui concerne la réticence à se faire vacciner étaient l'absence de tests ou de recherches (26 %) et la croyance que le vaccin n'était pas sécuritaire (15 %). • 47 % déclarent que le vaccin le plus efficace est le critère le plus important pour choisir un vaccin, suivi du vaccin disponible en premier (15 %) et du plus petit nombre d'effets secondaires (12 %).

	1) Intentions en ce qui concerne les vaccins 2) Perception des vaccins 3) Hésitation par rapport à la vaccination Outils d'enquête disponibles? Oui Recherches formatives effectuées? Oui Enquête prétestée? Non	• 56 % et 22 % ont dit qu'ils aimeraient obtenir plus d'information sur l'innocuité et l'efficacité du vaccin, respectivement. • Une recommandation d'un fournisseur de soins de santé à l'égard du vaccin influencerait probablement 45 % des répondants. **Vague 10** • L'acceptation du vaccin a légèrement augmenté entre la vague 9 (61 %) et la vague 10 (65 %). • L'intention de se faire vacciner immédiatement a atteint 49 % (contre 43 % à la vague 9). 31 % ont dit avoir l'intention de se faire vacciner, mais préféraient attendre, 11 % ont dit qu'ils ne le feraient pas et 8 % se sont dits incertains. • Parmi ceux qui voulaient attendre avant de se faire vacciner, 42 % voulaient attendre plusieurs mois (comparativement à 27 % à la vague 9). • Les principales raisons données par les gens pour attendre avant de se faire vacciner étaient qu'ils voulaient s'assurer de l'innocuité (80 %) et de l'efficacité (64 %) de ce vaccin. • On a posé des questions sur les incitatifs hypothétiques aux personnes qui ont dit qu'elles refuseraient de se faire vacciner. 58 % d'entre elles ont dit qu'elles aimeraient avoir l'assurance que le vaccin ne présente pas de risque d'exposition à la COVID-19, 56 % voulaient un système de réservation pratique et 52 % voulaient un endroit pratique où se faire vacciner. • 56 % des participants ont déclaré qu'ils se feraient vacciner pour pouvoir retourner au travail, voyager ou assister à de grands rassemblements. • 63 % ont déclaré qu'ils avaient décidé de se faire vacciner ou non et 32 % aimeraient obtenir plus d'information avant de prendre leur décision.
INSPQ (2020), INSPQ (2021), INSPQ (2021),	travailleurs de la santé au Québec. Le nombre de participants n'a pas été indiqué de façon claire (environ	**Juin** • 49 % étaient d'accord pour que les adultes vaccinés puissent se réunir sans masque en privé,

INSPQ (2021), INSPQ (2021), INSPQ (2021) *non publiée* (12, 86, 88, 90, 91, 95) Étude longitudinale Canada Avril 2020 à juin 2021	3 300 par période de collecte). Il y a eu plusieurs périodes de collecte, soit en avril-mai 2020, en septembre et en décembre 2020, et en avril-juin 2021. Ces articles sont en français. Sujets des questions : 1) Intentions en ce qui concerne les vaccins 2) Hésitation par rapport à la vaccination Outils d'enquête disponibles? Non Recherches formatives effectuées? Non Enquête prétestée? Non	44 % n'étaient pas d'accord et 6 % étaient incertains. • Près de la moitié des personnes interrogées estiment que les personnes vaccinées devraient pouvoir se réunir sans masque en privé (49 %), mais sont également d'accord pour que les masques soient portés à l'extérieur avec des personnes avec lesquelles elles ne vivent pas (56 %). • Les passeports vaccinaux bénéficient d'un soutien important au Québec, 72 % des résidents y étant favorables (23 % ne sont pas d'accord et 4 % sont incertaines). • 73 % des répondants ne sont pas d'accord avec le fait qu'il est important de suivre les mesures de protection compte tenu du taux de vaccination et de la diminution des cas de COVID-19. **Mai** • 74 % des personnes interrogées qui n'ont pas encore été vaccinées ont l'intention de se faire vacciner, soit une baisse de 3 % depuis fin avril. 18 % n'ont pas l'intention de se faire vacciner (augmentation de 4 %), et 8 % ne savent pas (diminution de 1 %). • L'intention de se faire vacciner était la plus faible chez les personnes âgées de 25 à 34 ans, les femmes, les personnes n'ayant pas fait d'études secondaires, les personnes sans emploi, les personnes plus démunies, celles qui ne s'inquiétaient pas d'être infectées par la COVID-19, celles qui avaient des idées conspiratrices et celles qui consultent les médias sociaux une fois par semaine ou moins. • Les ménages avec des mineurs avaient moins l'intention de se faire vacciner que les ménages composés d'une seule personne et que les ménages sans mineurs.

		• Les immigrants étaient plus réticents et incertains à l'idée de se faire vacciner que les non-immigrants. • Les trois principales raisons invoquées par les personnes qui n'avaient pas l'intention de se faire vacciner étaient la crainte des effets secondaires, le manque de confiance dans les vaccins en général et la nouveauté du vaccin. • 28 % de personnes qui n'ont pas l'intention de se faire vacciner estiment que cela est incompatible avec leurs croyances religieuses ou leurs principes personnels. **Plus tôt** • 77 % des personnes interrogées qui ne se sont pas encore fait vacciner ont l'intention de se faire vacciner, soit une baisse de 1 % depuis début avril. 14 % n'ont pas l'intention de se faire vacciner (aucun changement), et 9 % ne savent pas (augmentation de 1 %). L'intention a gagné 7 % depuis décembre. • L'intention de se faire vacciner était plus élevée chez les hommes que chez les femmes (78 % contre 76 %), chez les répondants plus âgés (79 % pour les 60 ans et plus contre 75 % pour les 18 à 25 ans) et chez les personnes ayant un diplôme universitaire (85 % pour les universitaires, 78 % pour les collégiens). • L'intention de se faire vacciner augmente généralement à mesure que la taille des collectivités s'accroît : petits villages de moins de 10 000 habitants (71 %), villes de 10 000 à 100 000 habitants (73 %), grande région de Montréal (81 %) et Montréal (79 %). • 68 % ne sont pas d'accord avec l'affirmation « les personnes vaccinées contre la COVID-19 devraient avoir le droit de se réunir en privé et de ne plus porter de masque en public », tandis que 25 % sont d'accord et 7 % sont incertaines.

		• En décembre, les personnes ayant une faible intention de se faire vacciner étaient préoccupées par les effets secondaires (27 %), la nouveauté du vaccin (24 %) et le manque de confiance dans les vaccins en général (24 %). • Les personnes ayant une vision conspiratrice du monde étaient moins susceptibles d'accepter un vaccin (51 % contre 76 %). • Le fait d'être d'accord avec la vaccination obligatoire continue d'être à la baisse avec 54 % de personnes d'accord en décembre.
Saskatchewan Population Health and Evaluation Research Unit (2020) *non publiée* (208) Étude longitudinale Canada Mai à septembre 2020	Un sondage en ligne a été utilisé pour évaluer l'intention de se faire vacciner des résidents de la Saskatchewan au fil du temps. Les sondages ont été effectués de mai à septembre. Le nombre de personnes n'est pas précisé et on ne sait pas trop si ce sont les mêmes participants au fil du temps. Sujets des questions : 1) Intentions en ce qui concerne les vaccins Outils d'enquête disponibles? Non Recherches formatives effectuées? Non Enquête prétestée? Non	• De mai à septembre, l'intention de se faire vacciner est passée de 84,9 % à 56,5 %. • L'intention de se faire vacciner est la plus élevée chez les 65 à 74 ans et la plus faible chez les moins de 48 ans.
Études transversales (n = 29)		
Angus Reid (2021) *non publiée* (96) Étude transversale	1 601 adultes canadiens ont été interrogés en ligne sur ce qu'ils pensent des politiques relatives à la vaccination (preuves et passeports vaccinaux). Sujets des questions :	• 79 % des Canadiens sont favorables à la présentation d'une preuve de vaccination pour les voyages internationaux (à l'exception des États-Unis), 78 % pour les vols commerciaux et 76 % pour les voyages aux États-Unis. • L'idée d'avoir une preuve de vaccination pour assister à de grands événements publics (69 %), dans des endroits publics comme les restaurants,

Canada Mai 2021	1) Intentions en ce qui concerne la vaccination 2) Perception des vaccins 3) Hésitation par rapport à la vaccination Outils d'enquête disponibles? Oui Recherches formatives effectuées? Non Enquête prétestée? Non	les bars et les salles de cinéma (55 %) et sur les lieux de travail (55 %) est moins soutenue. • Les personnes qui hésitaient à se faire vacciner étaient beaucoup moins favorables à la preuve de la vaccination dans tous les scénarios présentés. • 18 % des personnes qui ne sont pas disposées à se faire vacciner seraient être influencées à le faire si une preuve de vaccination était exigée dans de nombreux scénarios.
Leger (2021) *non publiée* (209) Étude transversale Canada Avril 2021	Un sondage en ligne a été mené auprès de 1 044 participants en Colombie-Britannique afin d'évaluer les points de vue sur les vaccins, les passeports vaccinaux et le déploiement des vaccins. Sujets des questions : 1) Intentions en ce qui concerne les vaccins 2) Perception des vaccins Outils d'enquête disponibles? Non Recherches formatives effectuées? Non Enquête prétestée? Non	• 16 % ont déclaré avoir reçu un vaccin. • 49 % ont l'intention de dire à tout le monde qu'ils connaissent lorsqu'ils auront reçu leur vaccin. Cela est particulièrement vrai pour les répondants des régions urbaines (53 %) comparativement aux répondants des régions rurales (40 %). Un moins grand nombre de répondants en parleraient uniquement à leur famille immédiate et à leurs amis (42 %). • 24 % ont dit avoir l'intention de publier sur les médias sociaux le fait qu'ils se sont fait vacciner. • La plupart ne croient pas qu'ils devraient être vaccinés avant les autres (27 %), ou sont jaloux (25 %) des autres personnes vaccinées ou éprouvent de l'anxiété à leur égard (25 %). • Les voyageurs internationaux qui arrivent en Colombie-Britannique (77 %) et de voyageurs de la Colombie-Britannique qui se rendent à l'étranger (75 %) ont fortement appuyé l'idée des passeports vaccinaux. Les Canadiens qui voyagent au Canada (68 %) et en Colombie-Britannique (56 %) appuyaient beaucoup moins une telle mesure. • Le passeport vaccinal dans quelque situation que ce soit a reçu un fort appui des 55 ans et plus. • 70 % des gens sont satisfaits de l'ordre de priorité de la vaccination en Colombie-Britannique et 44 % sont satisfaits du déploiement. • Le soutien aux dirigeants ou aux responsables en matière de santé a diminué depuis décembre 2020

		(Dre Bonnie Henry : 65 %, Adrian Dix : 58 %, Dre Theresa Tam : 53 %, Justin Trudeau : 45 %).
Statistics Canada (2021) *non publiée* (210) Étude transversale Canada Mars et avril 2021	Les intentions et les perceptions relatives au vaccin ont été analysées chez 1 025 adultes canadiens (âgés de 18 ans et plus) résidant dans les capitales des territoires en réponse à des invitations reçues par la poste et dans le cadre d'entrevues téléphoniques assistées par ordinateur pour les personnes qui n'ont pas répondu. Sujets des questions : 4) Intentions en ce qui concerne la vaccination 5) Perception des vaccins 6) Hésitation par rapport à la vaccination Outils d'enquête disponibles? Oui Recherches formatives effectuées? Oui Enquête prétestée? Oui	• La majorité des répondants avaient déjà reçu une dose (80 %), alors que 16 % étaient susceptibles de se faire vacciner et qu'un petit nombre de gens ont dit qu'ils ne se feraient pas vacciner (4 %). • Les répondants étaient plus susceptibles d'avoir reçu un vaccin ou d'être vaccinés s'ils détenaient un diplôme d'études postsecondaires ou plus élevé (85 % comparativement à 68 % pour le vaccin et 13 % comparativement à 23 % pour la probabilité de se faire vacciner, respectivement). • 10 % des personnes peu susceptibles de se faire vacciner avaient un revenu du ménage inférieur à 60 000 $, comparativement à 2 % des personnes dont le revenu se situait entre 60 000 $ et plus de 120 000 $. • La plupart des répondants étaient d'avis que les vaccins en général étaient sécuritaires (95 %) et efficaces (97 %) comparativement au vaccin contre la COVID-19, pour lequel l'innocuité (86 %) et l'efficacité (88 %) obtenaient un plus faible taux. • 94 % des répondants étaient convaincus que le processus du Canada ne permettait d'approuver que des vaccins sûrs et efficaces (94 %). • Les principales sources d'information sur la vaccination contre la COVID-19 étaient l'Agence de la santé publique du Canada et Santé Canada (89 %) et les régies de la santé au niveau provincial, territorial ou régional (85 %).
Centre for Addiction and Mental Health (2021) *non publiée* (211) Étude longitudinale	Un sondage en ligne a été mené auprès de 1 000 Canadiens dans le cadre du panel Web Qu'en pensez-vous afin de mesurer les intentions en matière de vaccination et les questions de santé mentale. Sujets des questions :	• 66,4 % des répondants qui n'ont pas encore reçu de vaccin ont dit avoir certainement l'intention de se faire vacciner, 21,8 % ont dit qu'ils se feront probablement vacciner et 11,8 % ont dit ne pas vouloir se faire vacciner.

Canada Mars 2021	1) Intentions en ce qui concerne les vaccins Outils d'enquête disponibles? Non Recherches formatives effectuées? Non Enquête prétestée? Non	
Tang (2021) *préimpression* (212) Étude transversale Canada Janvier à mars 2021	Afin d'évaluer la réticence à se faire vacciner dans les sous-groupes de population au Canada, un sondage en ligne a été mené auprès de 14 621 membres du Forum Angus Reid, qui est représentatif à l'échelle nationale. Sujets des questions : 1) Intentions en ce qui concerne la vaccination 2) Hésitation par rapport à la vaccination Outils d'enquête disponibles? Non Recherches formatives effectuées? Non Enquête prétestée? Non	• Dans l'ensemble, 9,3 % des répondants n'ont pas l'intention de se faire vacciner. Ce pourcentage était le plus élevé en Alberta (16,4 %), au Manitoba et en Saskatchewan (13,8 %) et le plus faible au Québec (8,3 %), dans les provinces de l'Atlantique (8 %), en Ontario (7,8 %) et en Colombie-Britannique (7,2 %). • La réticence à se faire vacciner était fortement associée aux personnes âgées de 40 à 59 ans (RC 0,87, IC à 95 % : 0,78 à 0,97), aux membres d'une minorité visible (RC 0,56, IC à 95 % : 0,37 à 0,84), aux personnes moins scolarisées et aux membres d'un ménage de cinq personnes ou plus (RC 0,82, IC à 95 % : 0,76 à 0,88).
Syan (2021) *préimpression* (77) Étude transversale Canada Janvier et février 2021	Un sondage en ligne a été utilisé pour évaluer les facteurs associés à l'intention de recevoir ou non un vaccin contre la COVID-19 chez 1 367 adultes (âgés de 18 ans et plus) qui vivaient dans le sud de l'Ontario. Sujets des questions : 1) Intentions en ce qui concerne la vaccination	• 82,8 % des répondants se sont dits prêts à recevoir un vaccin et 17,2 % ne voulaient pas se faire vacciner. • Les raisons les plus courantes de la réticence par rapport à la vaccination étaient les effets secondaires à long terme (65,5 %) et immédiats (60,5 %) et le manque de confiance dans le vaccin (55,2 %). • Une plus grande intention de se faire vacciner était fortement associée au sexe masculin (P = 0,002) et au fait d'avoir un plus grand niveau de scolarité (P < 0,001).

	2) Hésitation par rapport à la vaccination 3) Attitudes à l'égard des vaccins Outils d'enquête disponibles? Non Recherches formatives effectuées? Non Enquête prétestée? Non	• La perception de l'innocuité du vaccin contre la COVID-19 était beaucoup plus faible (-10,7 %) que celle des vaccins en général. Les femmes, les adultes plus âgés et les personnes moins scolarisées ont déclaré avoir moins confiance en l'innocuité du vaccin contre la COVID-19.
Leger (2021) *non publiée* (99) Étude transversale Canada Janvier 2021	Un sondage en ligne a été mené auprès de 800 participants du Manitoba (âgés de 18 ans et plus) pour sonder les perceptions et les intentions quant à la vaccination. Sujets des questions : 1) Intentions en ce qui concerne les vaccins 2) Perception des vaccins 3) Perceptions à propos du déploiement de la vaccination Outils d'enquête disponibles? Non Recherches formatives effectuées? Non Enquête prétestée? Non	• 72 % des répondants ont dit avoir l'intention de se faire vacciner lorsqu'un vaccin sera disponible. • L'intention de se faire vacciner augmente avec l'âge. 82 % des 55 ans et plus ont déclaré qu'ils auraient certainement ou probablement l'intention de se faire vacciner, comparativement à 65 % des 18 à 51 ans. • Les études supérieures et un revenu supérieur étaient associés à une intention accrue de se faire vacciner. • L'innocuité du vaccin demeure une préoccupation, car 57 % des gens ne veulent pas faire partie de la première vague de personnes vaccinées et veulent attendre que l'innocuité soit établie. 49 % ont des préoccupations au sujet de l'innocuité, mais ont généralement des opinions favorables à la vaccination. • Plus de 66 % des répondants conviennent que le vaccin devrait être obligatoire pour tous les travailleurs de la santé. • 71 % des répondants sont à l'aise avec la façon dont le gouvernement du Manitoba détermine les groupes prioritaires pour la vaccination précoce.
Leger (2021) *non publiée* (100) Étude transversale	Plus de 1 000 résidents de l'Alberta (18 ans et plus) ont été sondés en ligne afin de connaître leur perception du déploiement du vaccin.	• Le taux d'approbation en ce qui concerne le déploiement global du vaccin en Alberta était divisé puisque 48 % se sont dit satisfait alors que 43 % étaient insatisfaits. • En ce qui concerne l'ordre de priorité établi par le gouvernement, 64 % des répondants étaient satisfaits et 28 % étaient insatisfaits.

Canada Janvier 2021	Sujets des questions : 1) Perceptions à propos du déploiement de la vaccination Outils d'enquête disponibles? Non Recherches formatives effectuées? Non Enquête prétestée? Non	• 44 % étaient satisfaits de la communication du plan de mise en œuvre par le gouvernement alors que 48 % ne l'étaient pas. • Un plus grand nombre de personnes étaient insatisfaites (56 %) du rythme du déploiement comparativement à celles qui étaient satisfaites (35 %). • 53 % des répondants croient qu'ils auront la possibilité de recevoir un vaccin après septembre.
Insights West (2021) *non publiée* (67) Étude transversale Canada Janvier 2021	Un sondage en ligne effectué auprès de 824 résidents de la Colombie-Britannique a analysé leur intention de se faire vacciner. Sujets des questions : 1) Intentions en ce qui concerne les vaccins 2) Perceptions à propos du déploiement de la vaccination Outils d'enquête disponibles? Oui Recherches formatives effectuées? Non Enquête prétestée? Non	• 58 % des répondants ont dit être certainement prêts à se faire vacciner, 22 % ont dit être probablement prêts, 5 % ne se feront probablement pas vacciner et 7 % ne se feront certainement pas vacciner. • 67 % des répondants âgés (âgés de 55 ans et plus) étaient plus susceptibles de se faire vacciner que ceux des groupes d'âge plus jeunes (52 % chez les 18 à 34 ans). • 69 % étaient d'avis que ceux qui avaient des problèmes sous-jacents auraient dû passer avant les autres sur la liste. • Lorsqu'on leur a posé des questions sur le plan de déploiement du vaccin, 5 % des résidents ont jugé que le déploiement de la vaccination était excellent, 30 % ont dit qu'il était bon, 51 % ont indiqué qu'il était passable, 14 % ont dit qu'il était mauvais alors que 7 % ont mentionné qu'il était très mauvais. On a observé des tendances semblables pour ce qui est des perceptions sur la clarté des niveaux de déploiement et d'établissement des priorités.
Afifi (2021) (213) *nouveau* Étude transversale Canada	Grâce aux répondants de l'étude longitudinale Well-Being and Experiences (2017-2020), les intentions de se faire vacciner ont été consignées pour les adolescents de Winnipeg âgés de 16 à 21 ans et leurs	• 65,4 % des répondants ont l'intention de se faire vacciner, 26,1 % sont incertains et 8,5 % ne sont pas disposés à le faire. • Les parents ayant fréquenté une école de métiers, un collège communautaire ou ayant une éducation inférieure, ayant un revenu inférieur à 49 999 $, ayant subi une certaine pression financière à cause de la COVID-19, ayant déclaré avoir une faible

Nov.-déc. 2020	soignants/parents à l'aide d'un sondage en ligne. Sujets des questions : 1) Intentions de se faire vacciner 2) Réticence à se faire vacciner Outils de sondage disponibles? Non Des recherches formatives ont-elles été menées? Non Sondage prétesté? Non	connaissance de la COVID-19 étaient associés à de plus faibles intentions de se faire vacciner. • Le fait d'avoir un problème de santé autodéclaré était associé à des intentions plus élevées d'accepter un vaccin. • Après correction pour tenir compte du genre, de l'âge et du revenu du ménage, les enfants qui n'avaient jamais reçu de fessée (RRa 0,33, IC à 95 % : de 0,17 à 0,62), jamais connu de victimisation par les pairs (RRa 0,49, IC à 95 % : de 0,25 à 0,96), jamais connu de toxicomanie dans le ménage (RRa 0,41, IC à 95 % : de 0,20 à 0,83), n'ayant jamais eu de contact avec une famille d'accueil ou un bureau de protection de l'enfance (RRa 0,34, IC à 95 % : de 0,16 à 0,72), et n'ayant eu aucun risque que leur ménage soit à court d'argent (RRa 0,45 IC à 95 % : de 0,21 à 0,97) étaient plus disposés à se faire vacciner. • Le fait de déclarer n'avoir eu aucune expérience négative durant l'enfance au sein du foyer est associé à la volonté de se faire vacciner (RRa 0,45, IC à 95 % : de 0,20 à 0,99). • Les principaux motifs de réticence à accepter un vaccin sont l'innocuité du vaccin (64,5 %), le manque de connaissances sur le vaccin (60,6 %) et le fait de ne pas penser que le vaccin serait efficace (23,4 %).
Province of Manitoba (2020) *non publiée* (214) Étude transversale Canada Novembre 2020	Un sondage en ligne a été effectué auprès de 9 872 adultes au Manitoba pour évaluer les perceptions à l'égard du vaccin contre la COVID-19 et l'intention de se faire vacciner. Sujets des questions : 3) Intentions en ce qui concerne les vaccins 4) Perception des vaccins	• 55 % et 19 % respectivement des participants ont dit qu'ils se feraient « certainement » ou « probablement » vacciner lorsque le vaccin contre la COVID-19 sera disponible. Les autres participants ont déclaré qu'ils étaient indécis (8 %), qu'ils ne se feraient probablement pas vacciner (7 %) ou qu'ils ne se feraient certainement pas vacciner (12 %). • 61 % des participants étaient d'accord avec l'énoncé [Traduction libre] « Les vaccins sont sûrs et je n'ai aucun doute quant à la possibilité de me faire vacciner ou que ma famille se fasse vacciner, comme l'a recommandé mon médecin ».

	Outils d'enquête disponibles? Oui Recherches formatives effectuées? Non Enquête prétestée? Non	
Independent Polling System of Society (IPSOS)/Radio Canada (2020) *non publiée* (215) Étude transversale Canada Novembre 2020	Un sondage en ligne effectué auprès de 3 001 adultes (âgés de 18 ans et plus) a analysé l'intention de se faire vacciner et les perceptions à l'égard du vaccin. Sujets des questions : 1) Intentions en ce qui concerne les vaccins 2) Perception des vaccins Outils d'enquête disponibles? Non Recherches formatives effectuées? Non Enquête prétestée? Non	• 64 % des participants se feraient probablement ou certainement vacciner, 16 % ont dit qu'ils ne se feraient certainement pas vacciner et 21 % étaient incertains. • Parmi ceux qui se feraient vacciner, 36 % le feraient le plus tôt possible, 38 % attendraient un ou deux mois pour voir ce qui se passe, 15 % attendraient plusieurs mois et 11 % se sont dits indécis. • La majorité des répondants s'inquiétaient des effets secondaires possibles et des risques associés au vaccin.
Independent Polling System of Society (2020) *non publiée* (93) Étude transversale Canada Novembre 2020	Un sondage en ligne effectué auprès de 1 001 adultes (âgés de 18 ans et plus) a analysé l'intention de se faire vacciner et les perceptions à l'égard du vaccin. Sujets des questions : 1) Intentions en ce qui concerne les vaccins 2) Perception des vaccins 3) Hésitation par rapport à la vaccination Outils d'enquête disponibles? Non Recherches formatives effectuées? Non Enquête prétestée? Non	• 52 % des répondants ont dit qu'ils accepteraient sans hésiter un vaccin contre la COVID-19. Cependant, lorsque d'autres options s'offrent à eux, 36 % accepteraient de se faire vacciner, mais attendraient de voir s'il a des effets secondaires indésirables alors que 28 % le prendraient, mais attendraient de voir s'il est efficace. • 13 % des participants refuseraient le vaccin, dans quelques circonstances que ce soit. • 71 % des participants disent que le fait d'accepter un vaccin qui a été créé et approuvé si rapidement les rend nerveux alors que 69 % ont dit s'inquiéter des effets à long terme. • 59 % des participants appuyaient la vaccination obligatoire contre la COVID-19, en baisse par rapport à 61 % en septembre et à 72 % en juillet. • Certains participants ont déclaré qu'une recommandation d'un médecin de famille (21 %) ou le fait de voir des amis et des membres de la

		famille recevoir le vaccin (10 %) les inciterait à se faire vacciner. • La plupart conviennent que les travailleurs de la santé de première ligne (62 %) et les premiers intervenants (52 %) devraient être les premiers à recevoir le vaccin. Cependant, en dehors de ces groupes cibles, les Canadiens sont divisés quant à savoir qui devrait être en priorité. • Trois personnes sur dix (30 %) croient que nous pouvons vaincre la COVID-19 sans vaccin, comparativement à 40 % en octobre.
Independent Polling System of Society (2020) *non publiée* (62) Étude transversale Canada Octobre 2020	Un sondage en ligne effectué auprès de 1000 adultes a analysé l'intention de se faire vacciner et les perceptions à l'égard du vaccin. De ceux-ci, 1 000 participants étaient canadiens. Sujets des questions : 1) Intentions en ce qui concerne les vaccins 2) Perception des vaccins 3) Hésitation par rapport à la vaccination Outils d'enquête disponibles? Non Recherches formatives effectuées? Non Enquête prétestée? Non	• 54 % des Canadiens seraient prêts à recevoir un vaccin dès qu'il sera disponible. Les provinces atlantiques sont celles où les intentions de se faire vacciner sont les plus élevées (75 %), suivies de la Saskatchewan et du Manitoba (65 %), du Québec (63 %), de la Colombie-Britannique (60 %), de l'Alberta (58 %) et de l'Ontario (57 %). • 61 % des participants appuient la vaccination obligatoire contre la COVID-19, en baisse alors que ce niveau atteignant 72 % en juillet. • 82 % indiquent qu'ils attendraient les rapports sur l'efficacité ou les effets secondaires d'un vaccin contre la COVID-19 avant de le prendre. • La majorité (88 %) des participants conviennent que les personnes âgées et d'autres collectivités vulnérables devraient avoir la priorité absolue pour recevoir le vaccin. • Quatre sur dix (40 %) croient que nous pouvons vaincre la COVID-19 sans vaccin.
Toronto Public Health (2020) *non publiée* (216) Étude transversale	L'intention de recevoir un vaccin contre la COVID-19 a été évaluée au moyen d'un sondage en ligne effectué auprès de 1 201 résidents de Toronto (Ontario). Sujets des questions : 1) Intentions en ce qui concerne les vaccins	• 73 % des participants déclarent que lorsqu'un vaccin contre la COVID-19 sera disponible, ils se feront « certainement » ou « probablement » vacciner. 20 % ont dit qu'ils ne l'accepteront « certainement » ou « probablement » pas alors que 11 % sont indécis.

Canada Octobre 2020	Outils d'enquête disponibles? Non Recherches formatives effectuées? Non Enquête prétestée? Non	
Statistic Canada (2020) *non publiée* (78) Étude transversale Canada Septembre et octobre 2020	Un sondage téléphonique a été effectué auprès de 120 000 participants (âgés de 18 ans et plus) pour évaluer leur intention de se faire vacciner. Sujets des questions : 1) Intentions en ce qui concerne les vaccins Outils d'enquête disponibles? Oui Recherches formatives effectuées? Oui Enquête prétestée? Oui	• Comparativement aux non-immigrants (75,9 %), les immigrants qui vivent au Canada depuis moins de 10 ans (80,3 %) et plus de 10 ans (70,7 %) ont dit avoir un intérêt comparable pour la vaccination. • Les femmes qui n'étaient pas immigrantes ou qui ont immigré il y a moins de 10 ans avaient moins l'intention de se faire vacciner que les hommes (74,7 % contre 77,2 % pour les non-immigrants et 78,1 % contre 82,9 % pour les moins de 10 ans). • Lorsqu'on compare toutes les minorités visibles à la race blanche, les intentions en ce qui concerne la vaccination étaient presque identiques (77,3 % contre 77,0 %). • Au sein des groupes des minorités visibles, l'intention de se faire vacciner allait, de la plus faible à la plus forte, chez les Noirs (57,0 %), les Latino-Américains (58,5 %), les Philippins (64,2 %), les Asiatiques du Sud-Est (75,8 %), les autres minorités visibles (77,6 %), les Chinois (85,5 %) et les Arabes (88,3 %). • 69,3 % des personnes ayant déclaré une identité autochtone acceptaient un vaccin, comparativement à 77,6 % des personnes n'ayant pas déclaré une telle identité. • 87,6 % des membres de la communauté LGBTQ2+ étaient prêts à accepter un vaccin, comparativement à 76,4 % des personnes non membres de cette communauté. • Des niveaux de scolarité plus élevés et une condition médicale sous-jacente étaient associés à une plus grande acceptation.

Ogilvie (2021) (79) Étude transversale Canada Août et septembre 2020	On a évalué l'intention de se faire vacciner chez 4 058 adultes et travailleurs de la santé de la Colombie-Britannique (âgés de 25 à 69 ans). Sujets des questions : 1) Intentions en ce qui concerne les vaccins 2) Perception des vaccins 3) Hésitation par rapport à la vaccination Outils d'enquête disponibles? Oui Recherches formatives effectuées? Oui Enquête prétestée? Oui	• 79,8 % des répondants étaient assez ou très susceptibles de se faire vacciner si le vaccin était disponible et s'il était recommandé pour eux. • 81,8 % des travailleurs de la santé ont dit avoir l'intention de se faire vacciner. • Les personnes non binaires, allosexuelles, agentes, bispirituelles ou autres étaient plus susceptibles de recevoir un vaccin (RC = 3,04, IC à 95 % : 1,08 à 8,55). • Les ménages comptant deux adultes (RC = 1,2, IC à 95 % : 1,00 à 1,43) étaient plus susceptibles de se faire vacciner, mais il n'y a pas eu de changement important dans l'intention par rapport au nombre d'enfants. • L'analyse multivariée a démontré que les jeunes répondants (de 30 à 40 ans, RCa = 0,64, IC à 95 % : 0,49 à 0,83, de 40 à 50 ans, RCa = 0,78, IC à 95 % : 0,62 à 0,97, de 50 à 60 ans, RCa = 0,67, IC à 95 % : 0,55 à 0,82), les femmes (RCa = 0,7, IC à 95 % : 0,55 à 0,89), les personnes ayant un niveau de scolarité inférieur (RCa = 0,62, IC à 95 % : 0,51 à 0,77), les sud-asiatiques (RCa = 0,65, IC à 95 % : 0,39-1,07), les non-blancs (RCa = 0,76, IC à 95 % : 0,61-0,95), les personnes qui s'identifient comme Autochtones (RCa = 0,58, IC à 95 % : 0,38 à 0,87), les autres travailleurs essentiels n'œuvrant pas dans le domaine des soins de santé (RCa = 0,72, IC à 95 % : 0,6 à 0,87) et les personnes qui soupçonnaient avoir eu la COVID-19 (RCa = 0,76, IC à 95 % : 0,61 à 0,96) étaient beaucoup moins susceptibles de se faire vacciner. • Le manque de confiance dans les vaccins (RCa = 0,66, IC à 95 % : 0,57 à 0,75) et le fait de croire aux risques liés aux vaccins (RCa = 0,72, IC à 95 % : 0,66 à 0,0,80) ont été associés à une diminution de l'intention de se faire vacciner. • L'intention de se faire vacciner a été associée positivement à des scores attitudinaux plus élevés envers le vaccin (RCa = 1,06, IC à 95 % : 1,04 à 1,08), à l'influence des normes sociales directes

		(RCa = 1,06, IC à 95 % : 1,03 à 1,08), aux opinions indirectes des médecins de famille et des médecins de premier recours (RCa = 1,04, IC à 95 % : 1,00 à 1,08), aux normes indirectes établies par le médecin-hygiéniste de la province (RCa = 1,04, IC à 95 % : 1,01 à 1,08) et aux normes familiales indirectes (RCa = 1,09, IC à 95 % : 1,06 à 1,13).
Lang (2021) (87) Étude transversale Canada Août 2020	Une enquête en ligne a été menée auprès de 60 adultes (18 et +) de l'Alberta pour évaluer leur intention de se faire vacciner. Sujets des questions : 1) Intentions de se faire vacciner Outils d'enquête disponibles? Oui Des recherches formatives ont-elles été menées? Non Enquête prétestée? Non	• 68 % des personnes interrogées accepteraient un vaccin s'il était disponible, 20 % ne l'accepteraient pas et 12 % étaient incertaines. • Les répondants blancs étaient moins susceptibles d'accepter un vaccin (63 %) par rapport aux autres ethnies (100 %). • Les personnes ayant fait des études supérieures (collège ou université) étaient moins susceptibles d'accepter un vaccin (63 %) que celles ayant fréquenté une école technique postsecondaire (100 %) ou ayant un diplôme d'études secondaires (70 %). • L'intention de se faire vacciner était positivement associée aux craintes de contracter la COVID-19 (P < 0,001) et de propager le virus (P = 0,006), et au respect des mesures de santé publique telles que rester à la maison en cas de maladie (P = 0,033), porter le masque en public (P < 0.001) et la distanciation physique (P = 0,005). • Les répondants qui ont reçu leur information sur la COVID-19 lors des séances d'information aux médias du médecin hygiéniste en chef (P = 0,030) et sur les sites Web d'Alberta Health ou d'Alberta Health Services (P = 0,040) étaient significativement plus susceptibles d'accepter un vaccin contre la COVID-19. • L'intention de se faire vacciner était plus faible dans les autres centres urbains (29 %) et dans les régions rurales de l'Alberta (50 %) que dans les villes de Calgary (75 %) et d'Edmonton (80 %) *(P* = 0,030).

Carleton University (2020) *non publiée* (217) Étude transversale Canada Juillet 2020	Un sondage d'opinion publique sur l'intention et les perceptions concernant le vaccin a été effectué en ligne auprès de 2 000 personnes. Sujets des questions : 1) Intentions en ce qui concerne les vaccins 2) Hésitation par rapport à la vaccination 3) Perception des vaccins Outils d'enquête disponibles? Non Recherches formatives effectuées? Non Enquête prétestée? Non	• 45 % ont dit qu'ils se feraient probablement vacciner, 24 % ont dit qu'ils le prendraient probablement, 5 % ont dit qu'ils ne se feraient probablement pas vacciner alors que 9 % ont dit qu'ils ne le recevront certainement pas. • La résistance au vaccin est la plus élevée au Manitoba et en Saskatchewan, où seuls 37 % des participants ont dit qu'ils se feraient assurément vacciner dans les deux provinces. • En ce qui concerne l'opinion sur la vaccination obligatoire, 36 % se sont dits tout à fait d'accord, 26 % sont plutôt d'accord, 14 % sont tout à fait en désaccord et 7 % sont plutôt en désaccord. • La raison la plus courante (40 %) de leur hésitation était la possibilité d'effets secondaires dangereux. • Parmi les 9 % de répondants qui ont exprimé de fortes opinions contre le vaccin, les soupçons quant à l'influence de l'industrie pharmaceutique sur les soins de santé publique (41 %) et les préoccupations au sujet de l'innocuité du vaccin et de la possibilité d'effets secondaires nocifs (29 %) étaient les raisons les plus fréquentes du refus.
Frank (2020) *non publiée* (63) Étude transversale Canada Juin 2020	Les facteurs associés à la volonté de se faire vacciner ont été examinés dans un sondage en ligne effectué auprès d'environ 4 000 adultes. Sujets des questions : 1) Intentions en ce qui concerne les vaccins 2) Hésitation par rapport à la vaccination Outils d'enquête disponibles? Non Recherches formatives effectuées? Oui Enquête prétestée? Non	• 57,5 % et 19 % respectivement des répondants ont indiqué qu'ils sont très susceptibles ou assez susceptibles de se faire vacciner contre la COVID-19 lorsque le vaccin il sera disponible. • Les Canadiens âgés (65 ans et plus) ont déclaré qu'ils étaient plus susceptibles de se faire vacciner (70,3 %) que les 15 à 64 ans (52 à 58 %). • Les personnes nées au Canada étaient plus susceptibles de se faire vacciner que les immigrants (59,4 % contre 52,0 %). • Les résidents des provinces de l'Atlantique sont les plus susceptibles de se faire vacciner (67,7 %), suivis de ceux de l'Ontario (58,8 %), des Prairies (56,2 %), de la Colombie-Britannique (55,5 %) et du Québec (54,3 %). • Parmi les autres facteurs associés à une plus grande intention de se faire vacciner, mentionnons

		l'éducation supérieure et le fait de ne pas avoir d'enfants de moins de 18 ans. • Les deux principales raisons de ne pas avoir l'intention de se faire vacciner étaient le manque de confiance dans l'innocuité du vaccin (54,2 %) et les préoccupations au sujet de ses risques et de ses effets secondaires (51,7 %).
Hetherington (2021) (218) Étude transversale Canada Mai et juin 2020	Les participants à l'étude de cohorte longitudinale All Our Families (n = 1 321) en Alberta ont été invités à participer à un sondage d'impact en ligne sur la COVID-19 afin de comprendre les facteurs associés aux intentions de faire vacciner contre la COVID-19 chez les parents d'enfants âgés de 9 à 12 ans. Sujets des questions : 1) Intentions en ce qui concerne les vaccins 2) Hésitation par rapport à la vaccination Outils d'enquête disponibles? Non Recherches formatives effectuées? Non Enquête prétestée? Non	• 60,4 % des parents avaient l'intention de faire vacciner leurs enfants, 8,6 % ont dit qu'ils n'avaient pas l'intention de le faire et 31 % étaient incertains. • Les participants moins scolarisés étaient plus susceptibles de ne pas vouloir se faire vacciner (RC = 2,80, IC à 95 % : 1,78 à 4,40) ou étaient incertains (RC = 1,98, IC à 95 % : 1,47 à 2,71). On a observé une tendance semblable pour le revenu. • Des antécédents de vaccination partielle ou non-vaccination étaient associés à l'intention de ne pas se faire vacciner (RC = 2,81, IC à 95 % : 1,78 à 4,40). Il n'y avait aucun lien entre les antécédents de vaccination et l'incertitude concernant un vaccin contre la COVID-19 (RC = 1,29, IC à 95 % : 0,92 à 1,80). • On a signalé des préoccupations au sujet de l'innocuité et de l'efficacité des vaccins, des effets à long terme et d'un processus de vaccination précipité.
Frank (2020) *non publiée* (219) Étude transversale Canada	Un sondage en ligne a été effectué auprès d'environ 36 000 adultes pour étudier les facteurs associés à la volonté de se faire vacciner. Sujets des questions : 1) Intentions en ce qui concerne les vaccins Outils d'enquête disponibles? Non	• 68,2 % et 15,2 % respectivement des participants ont déclaré qu'ils étaient très susceptibles ou assez susceptibles d'accepter un vaccin contre la COVID-19. 12 % étaient peu susceptibles ou très peu susceptibles de se faire vacciner. • Les personnes qui ont un niveau élevé de confiance dans le gouvernement fédéral étaient plus susceptibles d'être disposées à se faire vacciner que celles qui avaient un faible niveau de confiance (77,3 % comparativement à 53,8 %).

Mai et juin 2020	Recherches formatives effectuées? Oui Enquête prétestée? Non	• Des tendances semblables ont également été observées en ce qui concerne la confiance envers les autres et la confiance envers les autorités fédérales en matière de santé publique.
Lackner (2021) (189) Étude transversale Canada Mai et juin 2020	Les facteurs démographiques, expérientiels et psychologiques associés à la probabilité et à la rapidité prévues de recevoir un vaccin contre la COVID-19 ont été examinés dans 455 familles (857 enfants). Sujets des questions : 1) Intentions en ce qui concerne les vaccins Outils d'enquête disponibles? Non Recherches formatives effectuées? Oui Enquête prétestée? Non	• Les facteurs associés à une plus grande probabilité de faire vacciner les enfants comprennent l'âge plus avancé des parents, la vie dans les Prairies (comparativement au centre du Canada), des antécédents de vaccination plus complets pour les enfants et les parents, des attitudes positives à l'égard des vaccins en général, un plus grand évitement psychologique de la pandémie et une plus grande tendance à prioriser les risques de la maladie comparativement aux risques des effets secondaires. • Dans certains modèles, le risque perçu de COVID-19 et les niveaux plus élevés d'anxiété au pays étaient associés à une probabilité accrue de faire vacciner les enfants. • Les facteurs ci-dessus étaient également des prédicteurs de la vitesse plus rapide de la vaccination prévue. Toutefois, un statut socio-économique plus élevé était un prédicteur de tendance.
Taylor (2021) (220) Étude transversale Canada et États-Unis Juin et juillet 2020	Un sondage en ligne réalisé auprès de 2 078 adultes (âgés de 18 ans et plus) a été utilisé pour explorer le lien possible entre les attitudes à l'égard du port d'un couvre-visage et la vaccination contre la COVID-19. L'échantillon comprenait 1 036 participants des États-Unis et 1 042 du Canada. Sujets des questions : 1) Attitudes à l'égard des vaccins	• Le réseau des attitudes anti-masques est lié à d'autres variables telles que le mépris pour la distanciation sociale et les attitudes anti-vaccination.

	Outils d'enquête disponibles? Non Recherches formatives effectuées? Oui Enquête prétestée? Non	
Waite (2021) (92) Étude transversale Canada Mai 2020	Un sondage en ligne a été effectué auprès de 1 001 Canadiens âgés de 50 à 64 ans et auprès de 3 500 Canadiens âgés de 65 ans et plus afin d'évaluer les intentions de se faire vacciner contre la COVID-19. Sujets des questions : 1) Intentions en ce qui concerne la vaccination 2) Attitudes à l'égard des vaccins Outils d'enquête disponibles? Non Recherches formatives effectuées? Oui Enquête prétestée? Non	• Parmi les 50 à 64 ans, 69,1 % ont dit avoir l'intention de se faire vacciner lorsque les vaccins seront disponibles, 11,3 % ne se feront pas vacciner et 19,6 % étaient incertains. • 79,5 % des 65 ans et plus ont l'intention de se faire vacciner lorsque le vaccin sera disponible, 5,6 % refuseront de le faire et 14,9 % ont dit être incertains. • Dans les deux groupes d'âge, les personnes qui acceptaient de se faire vacciner étaient beaucoup plus susceptibles d'être de sexe masculin et d'avoir au moins un problème de santé chronique ($P < 0,05$). • L'endroit privilégié pour recevoir un vaccin chez ces deux groupes était le bureau du médecin de famille, suivi de la pharmacie, du lieu de travail (pour les 50 à 64 ans) et des cliniques de santé publique.
Taylor (2020) (89) Étude transversale Canada et États-Unis Mai 2020	Les intentions de se faire vacciner et les attitudes à l'égard des vaccins ont été mesurées dans un sondage en ligne réalisé auprès de 3 674 adultes (Canada = 1 902, États-Unis = 1 772). Sujets des questions : 1) Intentions en ce qui concerne les vaccins 2) Hésitation par rapport à la vaccination 3) Attitudes à l'égard des vaccins	• Beaucoup plus d'Américains (25 %) que de Canadiens (20 %) ont répondu qu'ils ne se feraient pas vacciner même si un vaccin était disponible, χ^2 (*df* = 1) = 12,41, $p < 0,001$. • Les attitudes négatives à l'égard d'un vaccin contre la COVID-19 et de la vaccination en général étaient fortement corrélées ($p < 0,001$) avec l'intention de ne pas se faire vacciner. La méfiance à l'égard des avantages d'un vaccin contre la COVID-19 a été le facteur le plus important en ce qui concerne l'attitude quant à la décision de ne pas se faire vacciner. • Le refus de se faire vacciner a été associé de façon significative au sexe féminin, à l'âge, aux études collégiales complètes ou partielles (plutôt qu'aux études non terminées), au chômage et à

	Outils d'enquête disponibles? Non Recherches formatives effectuées? Oui Enquête prétestée? Non	l'appartenance à une minorité (plutôt qu'à la race blanche). • Parmi ceux qui ont indiqué qu'ils ne se feraient pas vacciner (n = 812), 38 % se feraient vacciner s'ils étaient convaincus que le vaccin a été rigoureusement testé et 36 % se feraient vacciner s'ils constataient qu'un nombre suffisant de personnes ont été vaccinées sans qu'il y ait d'effets secondaires graves. • Comparativement à l'origine ethnique blanche, l'appartenance à une minorité (Asiatique, Afro-Américain/Noir, Latino/Hispanique ou autre) était fortement associée au refus de se faire vacciner (r = 0,04, p < 0,05).
Carleton University (2020) *non publiée* (59) Étude transversale Canada Mai 2020	Un sondage d'opinion publique sur l'intention et les perceptions concernant le vaccin a été effectué en ligne auprès de 2 000 personnes. Sujets des questions : 1) Intentions en ce qui concerne les vaccins 2) Perception des vaccins Outils d'enquête disponibles? Non Recherches formatives effectuées? Non Enquête prétestée? Non	• 49 % et 24 % respectivement des participants ont dit qu'ils se feraient « certainement » ou « probablement » vacciner lorsque le vaccin sera disponible. • 17 % ont exprimé de l'incertitude et 10 % ont dit qu'ils n'étaient pas disposés à le faire. • 65 % croient que le vaccin devrait être obligatoire • L'âge et l'affiliation politique étaient fortement associés à l'intention de se faire vacciner. Les personnes âgées étaient plus disposées que les plus jeunes à se faire vacciner. Ceux qui ont voté pour le Parti libéral ou le NPD aux élections de 2019 étaient plus susceptibles de se faire vacciner que ceux qui ont voté pour d'autres partis. • Les répondants qui vivent dans les provinces atlantiques affichent les niveaux les plus élevés d'intention de se faire vacciner comparativement à ceux des autres provinces. • Ceux qui croyaient à l'un des quatre mythes ou théories du complot en matière de santé concernant la COVID-19 étaient moins susceptibles d'avoir l'intention de se faire vacciner que ceux qui ne croyaient pas aux

		affirmations inexactes sur le plan scientifique au sujet de la COVID-19.
Parsons Leigh (2020) (64) Étude transversale Canada Avril et mai 2020	Un sondage en ligne a été effectué auprès de 1 996 participants (âgés de 18 ans et plus) pour analyser les connaissances, les attitudes et les comportements en ce qui concerne la COVID-19. Sujets des questions : 1) Intentions en ce qui concerne les vaccins 2) Connaissance des vaccins Outils d'enquête disponibles? Oui Recherches formatives effectuées? Oui Enquête prétestée? Oui	• 75,8 % (n = 1 436) des répondants ont déclaré qu'ils se feraient vacciner lorsqu'un vaccin serait disponible. • Les participants ont répondu qu'ils étaient « fortement d'accord » ou « d'accord » pour dire qu'ils se feraient vacciner en Colombie-Britannique (72,1 %), en Alberta (69,9 %), au Manitoba et en Saskatchewan (69,9 %), en Ontario (66,1 %), dans la région atlantique (63,1 %) et au Québec (41,9 %). • Les participants ont répondu qu'ils étaient « fortement d'accord » ou « d'accord » pour dire qu'ils ne se feront pas vacciner en Alberta (12,4 %), au Québec (12,1 %), en Ontario (8,1 %), dans la région de l'Atlantique (6,6 %), au Manitoba et en Saskatchewan (6 %) et en Colombie-Britannique (4,8 %). • Les renseignements sur les vaccins et les traitements étaient les plus fréquemment cités comme sujets de désinformation (n = 933, 48,9 %, IC à 95 % : 46,7 à 51,2 %), mais seulement la moitié (n = 937, 47,4 %, IC à 95 % : 45,2 à 49,6 %) des répondants se sont sentis modérément ou extrêmement sûrs de pouvoir identifier des renseignements inexacts ou trompeurs au sujet de la COVID-19.
Underschultz (2021) (221) Étude transversale Canada Avril 2020	Un sondage en ligne a été effectué auprès de 1 593 participants (âgés de 16 ans et plus) pour analyser les connaissances, les attitudes et les comportements en ce qui concerne la COVID-19. L'enquête était principalement destinée aux résidents de l'Alberta et de l'Ontario. Sujets des questions :	• 93 % des répondants estiment qu'un vaccin est nécessaire au Canada et 81 % appuient une stratégie de vaccination à grande échelle (vacciner tout le monde). • On a établi un lien important entre l'acceptation du vaccin et des résultats plus élevé en ce qui concerne les connaissances ($p < 0,001$), l'inquiétude au sujet de la COVID-19 (RC = 20,4; IC à 95 % : 8,4 à 49,5, $p < 0,001$), l'optimisme dans la lutte contre la pandémie (RC = 8,1; IC à 95 % : 3,4 à 19,7, $p < 0,001$) et le sentiment d'être informé au

	1) Perception des vaccins Outils d'enquête disponibles? Non Recherches formatives effectuées? Oui Enquête prétestée? Non	sujet de la COVID-19 (RC = 3,9; IC à 95 : 1,7 à 9,3, p = 0,0049).
Research Co (2020) *non publiée* (58) Étude transversale Canada Avril 2020	Un sondage en ligne a été utilisé pour évaluer l'intention de se faire vacciner. Sujets des questions : 1) Intentions en ce qui concerne les vaccins Outils d'enquête disponibles? Non Recherches formatives effectuées? Non Enquête prétestée? Non	• Si un vaccin devenait disponible, 42 % et 31 % respectivement des répondants accepteraient « certainement » ou « probablement » de se faire vacciner. • Les hommes étaient plus susceptibles de se faire vacciner que les femmes (78 % contre 68 %). • C'est dans la région de l'Atlantique (79 %) et en Alberta (78 %) que l'intention de se faire vacciner était la plus forte alors qu'elle était la plus faible en Saskatchewan et au Manitoba (65 %). • L'intention de se faire vacciner était la plus élevée chez les personnes qui ont voté pour le Parti libéral (79 %) aux élections de 2019, suivis du NPD (76 %) et des conservateurs (69 %).
Études qualitatives (n = 1)		
Benham (2021) (222) **Étude qualitative** **Canada** **Août et septembre 2020**	Neuf groupes de discussion ont été tenus auprès de 50 adultes (âgés de 18 ans et plus) de l'Alberta afin d'évaluer les attitudes à l'égard des mesures de santé publique, y compris la vaccination. Sujets des questions : 1) Intentions en ce qui concerne les vaccins 2) Perception des vaccins	• L'intention de se faire vacciner les réponses était mitigée. Certains ont déclaré qu'ils se feraient vacciner immédiatement, tandis que d'autres ne le feraient pas, car ils croyaient que la COVID-19 n'aurait pas d'incidence sur leur santé ou celle des membres de leur famille. • Certains participants ont déclaré qu'ils seraient disposés à se faire vacciner, mais pas immédiatement. Ce phénomène était plus marqué dans les groupes d'âge plus âgés. • Les participants qui recevaient régulièrement le vaccin annuel contre la grippe étaient plus susceptibles de dire qu'ils prendraient un vaccin contre la COVID-19 lorsqu'il serait disponible. Cependant, quelques-uns ont subi des effets secondaires avec le vaccin annuel contre la grippe (p. ex., maladie), ce qui les rendrait moins

		susceptibles de recevoir un vaccin contre la COVID-19. • Parmi les obstacles à l'adoption du vaccin, mentionnons le manque de confiance quant à son efficacité et à son effet nocif.
Études quasi-expérimentales (n = 1)		
Poder (2021) *non publiée* (223) Étude quasi-expérimentale Canada Octobre et novembre 2020	Un sondage en ligne portant sur les intentions de vaccination de 1 695 adultes québécois a été mené. La méthode utilisée est celle du choix expérimental discret où chaque participant a fait face à une série de 12 cartes présentant chacun deux scénarios (pour un total de 20 350 réponses) Sujets des questions : 1) Intentions en ce qui concerne les vaccins Outils d'enquête disponibles? Oui Recherches formatives effectuées? Oui Enquête prétestée? Non	• Au moins 7,2 % ont toujours choisi de ne pas se faire vacciner, quel que soit le scénario choisi. • Selon le scénario, 69 à 93 % des participants opteraient pour le vaccin lorsqu'il sera disponible. • 24 % des participants choisiraient de refuser le vaccin si certaines conditions n'étaient pas respectées (indiquées ici par ordre de priorité :) 1) l'efficacité du vaccin 2) les effets secondaires possibles du vaccin 3) la durée d'efficacité (minimum de 9 mois pour l'acceptabilité) 4) l'organisme recommandant le vaccin (Direction de santé publique du Québec et OMS) 5) l'origine géographique du vaccin (Union européenne ou États-Unis) 6) le délai d'attente pour être vacciné une fois le vaccin disponible au Québec (4 mois au maximum) 7) les populations très prioritaires (aucune préférence)
Intervenants experts		
Études transversales (n = 2)		
MacDonald (2020) *préimpression* (101) Étude transversale Canada	Dix-huit entrevues en téléconférence avec 25 chefs de file en santé publique de 10 des 13 provinces et territoires ont été menées afin d'évaluer les points de vue sur les groupes prioritaires pour la vaccination précoce. On a demandé aux participants de classer, par ordre d'importance,	• Les dix provinces et territoires ont classé les résidents de longue durée et les travailleurs de la santé dans leurs cinq premiers groupes prioritaires pour recevoir la vaccination. • Neuf provinces et huit territoires ont aussi classé les personnes ayant des problèmes de santé chroniques et les personnes âgées dans les cinq premiers groupes prioritaires. • Dans une moindre mesure, les personnes d'ascendance autochtone (n = 4), ayant un

Août à octobre 2020	leurs cinq principaux groupes prioritaires pour la vaccination. Sujets des questions : 1) Perceptions à propos de la stratégie de vaccination Outils d'enquête disponibles? Non Recherches formatives effectuées? Non Enquête prétestée? Non	désavantage socioéconomique (n = 3), ayant des nourrissons ou des enfants (n = 2), vivant dans des collectivités éloignées (n = 2) et de nouveaux immigrants et réfugiés (n = 1) ont aussi été classées dans les cinq premiers groupes prioritaires.
Zhao (2020) *préimpression* (102) Étude transversale Canada Juillet et août 2020	Un sondage en ligne a été effectué parmi 74 intervenants experts pour obtenir leur point de vue quant à l'importance relative des stratégies de vaccination contre la pandémie pour différents scénarios de pandémie de COVID-19 au moment de la disponibilité initiale du vaccin contre la COVID-19. Les répondants devaient classer, par ordre d'importance, quatre stratégies prédéfinies de vaccination contre la pandémie de COVID-19. Sujets des questions : 1) Perceptions à propos de la stratégie de vaccination Outils d'enquête disponibles? Non Recherches formatives effectuées? Non Enquête prétestée? Non	• Pour tous les scénarios de pandémie, les intervenants ont généralement classé les stratégies dans l'ordre suivant, du plus important au moins important : ○ protéger les personnes les plus vulnérables contre les maladies graves et les décès causés par la COVID-19 ○ protéger la capacité d'offrir des soins de santé ○ réduire au minimum la transmission de la COVID-19 • protéger les infrastructures essentielles

RCa = rapport de cotes ajusté, IC = intervalle de confiance, n.d. = non déclaré, RR = risque relatif

TRAVAILLEURS DE LA SANTÉ

AMÉRIQUE DU NORD		
CANADA		
Lunsky (2021) (105) Étude transversale Canada Janvier à février 2021	Pour évaluer l'intention de vaccination et les facteurs prédictifs de cette intention, une enquête en ligne a été menée auprès de 3 371 employés de services sociaux soutenant des personnes ayant une déficience intellectuelle en Ontario. Sujets des questions : 1) Intentions de se faire vacciner 2) Hésitation à se faire vacciner Outils d'enquête disponibles? Non Des recherches formatives ont-elles été menées? Oui Enquête prétestée? Non	• 62 % et 20 % ont déclaré qu'il était très probable ou assez probable qu'ils acceptent un vaccin, et 7 % et 11 % qu'il était assez improbable ou très improbable qu'ils se fassent vacciner, respectivement. • Par rapport aux personnes âgées de 50 ans et plus, les jeunes personnes de 18 à 29 ans (RR ajusté 2,74, IC 95 % : 1,70 % à 4,43 %) et 30 à 39 (RR ajusté 1,75, IC 95 % : 1,16 % à 2,64 %) étaient plus susceptibles de refuser un vaccin lorsqu'il était disponible. • Les femmes étaient plus susceptibles de refuser un vaccin que les hommes (RR ajusté 1,58, IC 95 % : 0,97 % à 2,59 %). • Par rapport aux répondants européens, les Asiatiques (RR ajusté 0,88, IC 95 % : 0,33 % à 2,36 %), d'Afrique et des Caraïbes (RR ajusté 0,81, IC 95 % : 0,35 % à 1,86 %), et les ethnies non précisées (RR ajusté 0,88, IC 95 % : 0,36 % à 2,17 %) étaient moins susceptibles de refuser un vaccin et les autochtones, les Premières Nations et les Métis (RR ajusté 1,73, IC 95 % : 0,67 % à 4,43 %), les latinos (RR ajusté 1,22, IC 95 % : 0,21 à 7,24), et les gens des ethnies mixtes (RR ajusté 1,11, IC 95 % : 0,27 % à 4,55 %) étaient plus susceptibles de refuser. • Les raisons de refuser un vaccin comprennent le manque de confiance dans le vaccin (RR 5,72, IC 95 % : 3,84 à 8,53), la peur des effets secondaires du vaccin (RR 2,30, IC 95 % : 1,56 % à 3,39 %), et la conviction qu'il n'est pas nécessaire de se faire

		vacciner en raison d'une bonne santé (RR 4,22, IC 95 % : 2,66 % à 6,68 %). • Les personnes qui refuseraient un vaccin étaient moins susceptibles de croire que la vaccination protégerait les clients (RR 0,36, IC 95 % : 0,24 % à 0,54 %) ou de la famille (RR 0,19, IC 95 % : 0,13 % à 0,28 %), être préoccupé par les clients (RR 0,57, IC 95 % : 0,34 % à 0,97 %) ou eux-mêmes (OR 0,51, IC 95 % : 0,34 % à 0,76 %) tombant malade de la COVID-19, se faire vacciner contre la grippe dans une année normale (RR 0,61, IC 95 % : 0,43 % à 0,88 %), et se font vacciner si leurs collègues le font (RR 0,16, IC 95 % : 0,08 % à 0,29 %).
Desveaux 2021 *préimpression* (103) Étude transversale Canada Janvier 2021	Un sondage en ligne a été utilisé en Ontario pour évaluer les facteurs associés à l'intention de se faire vacciner chez 8 634 travailleurs de la santé (âgés de 18 ans et plus). Sujets des questions : 1) Intentions en ce qui concerne les vaccins 2) Hésitation par rapport à la vaccination Outils d'enquête disponibles? Non Recherches formatives effectuées? Non Enquête prétestée? Non	• 80,4 % des participants ont déclaré avoir l'intention d'obtenir un vaccin contre la COVID-19. • Comparativement à leurs homologues, les personnes plus jeunes (moins de 40 ans) et moins scolarisées (moins d'un diplôme d'études secondaires) étaient plus susceptibles de ne pas avoir l'intention de se faire vacciner ($p < 0,001$). • Les travailleurs de la santé qui se sont identifiés comme étant d'origine philippine (RC = 1,07, IC à 95 % : 0,41 à 2,76, $P < 0,001$), caraïbéenne (RC = 3,20, IC à 95 % : 1,52 à 6,75, $P < 0,001$) ou autre (RC = 1,44, IC à 95 % : 0,93 à 2,22, $P < 0,001$) étaient plus susceptibles de ne pas vouloir se faire vacciner que ceux qui se sont identifiés comme étant d'origine européenne. • La réticence à se faire vacciner était fortement associée à la méfiance quant à la rapidité de la mise au point des vaccins et aux préoccupations relatives à l'innocuité des vaccins. Elle était également associée à diverses croyances, comme le fait de ne pas avoir besoin d'un vaccin en raison de sa propre bonne santé, la faible confiance que le vaccin protégerait sa famille et ses patients, et le fait que se faire vacciner n'était pas une responsabilité professionnelle.

		• Les travailleurs de la santé étaient plus susceptibles d'avoir l'intention de se faire vacciner s'ils pouvaient avoir accès à un soutien financier direct, comme des congés de maladie payés (74 % contre 25 %, P < 0,001).
SafeCare BC (2021) *non publiée* (104) Étude transversale Canada Décembre 2020	Un sondage en ligne a été effectué auprès de 1 500 travailleurs en soins continus de la Colombie-Britannique pour évaluer les attitudes à l'égard de la vaccination contre la COVID-19. Sujets des questions : 1) Intentions en ce qui concerne les vaccins 2) Hésitation par rapport à la vaccination Outils d'enquête disponibles? Non Recherches formatives effectuées? Non Enquête prétestée? Non	• 57 % des répondants avaient l'intention de se faire vacciner, 28 % n'étaient pas certains et 15 % n'avaient pas l'intention de se faire vacciner. • Les hommes (72 % contre 56 %), l'âge plus élevé (65 ans et plus) et l'acceptation du vaccin antigrippal étaient des prédicteurs de l'intention de se faire vacciner. • Les gestionnaires et les cadres supérieurs avaient la plus forte intention de se faire vacciner (71 %). Les aides-soignants étaient les plus incertains (30 %) alors que les infirmières étaient les plus susceptibles de dire non à un vaccin (20 %). • Les raisons de l'hésitation étaient les effets secondaires (84,6 %), la nouveauté du vaccin (64,6 %), la méfiance à l'égard des autorités (23,5 %), la croyance que le vaccin ne fonctionnera pas (16 %), les remèdes naturels préférés (10,5 %) et les croyances personnelles ou religieuses (8 %). • Les intentions de vaccination étaient les plus élevées chez les Asiatiques de l'Est (61 %) et du Sud (70 %). Les répondants latinos et les Noirs étaient les plus susceptibles de refuser le vaccin (30 %) alors que les autochtones sont ceux qui avaient le plus tendance à être incertains quant à la décision à savoir s'ils se feraient ou non vacciner (40 %). • Les répondants de l'Asie de l'Est et du Sud étaient plus préoccupés par les effets secondaires (93 %), tandis que les répondants blancs ou autochtones étaient plus préoccupés par la nouveauté (72 % et 62 %, respectivement). • 33 % ont dit qu'il faut plus de soutien pour les vaccins, p. ex., plus d'information pour comprendre le processus de développement, l'efficacité et la

		transparence de la déclaration des événements indésirables. • Le plus grand obstacle perçu à l'administration du vaccin était les contraintes associées au stockage et à la manipulation (66 %). • Les répondants autochtones étaient ceux qui avaient le moins confiance aux différentes sources d'information, y compris les fournisseurs de soins de santé.
INSPQ (2020) & INSPQ (2021) *non publiée* (88, 95) Étude longitudinale Canada Avril à décembre 2020	L'analyse de l'acceptabilité de la vaccination contre la COVID-19 a été évaluée à l'aide d'un sondage en ligne réalisé auprès d'adultes et de travailleurs de la santé au Québec. Le nombre de participants n'a pas été indiqué de façon claire (environ 3 300 par période de collecte). Il y a eu plusieurs périodes de collecte de données, une en avril et en mai, et une autre en septembre et une autre en décembre. Cet article est en français. Sujets des questions : 1) Intentions en ce qui concerne les vaccins 2) Hésitation par rapport à la vaccination Outils d'enquête disponibles? Non Recherches formatives effectuées? Non Enquête prétestée? Non	• En mai, 73 % des travailleurs de la santé ont répondu qu'ils avaient l'intention de se faire vacciner. En décembre, ce pourcentage est descendu à 65 % avant de remonter à 71 % en décembre. • L'intention de se faire vacciner ne différait pas entre le grand public et les travailleurs de la santé et les facteurs associés à l'intention de se faire vacciner n'étaient pas différenciés entre les deux groupes. • Les personnes plus âgées (70 ans et plus) étaient plus susceptibles de se faire vacciner que celles qui avaient entre 25 et 44 ans (83 % contre 57 %). • Les hommes, notamment ceux qui ont fait des études universitaires et ceux qui ont une ou plusieurs maladies chroniques, sont plus susceptibles d'avoir l'intention de se faire vacciner. • Les raisons les plus courantes de ne pas vouloir se faire vacciner comprennent les craintes liées à un nouveau vaccin et les préoccupations au sujet de l'efficacité et des effets secondaires.
Verger (2021) (127)	L'intention de se faire vacciner et l'intention de recommander la vaccination aux patients ont été évaluées dans un sondage effectué	• Au Canada, 79,6 % des infirmières recommanderaient certainement ou probablement à leurs patients de se faire vacciner, 3,1 % ne le feraient pas et 17,2 % étaient incertaines. En ce qui

Étude transversale Belgique, France et Canada Octobre et novembre 2020	en ligne et par téléphone auprès des omnipraticiens en France (n = 1 209) et dans les régions francophones de la Belgique (n = 414) et auprès des infirmières du Québec, au Canada (n = 1 055). Les résultats pour la Belgique et la France sont disponibles dans la section Europe. Sujets des questions : 1) Intentions en ce qui concerne les vaccins 2) Hésitation par rapport à la vaccination Outils d'enquête disponibles? Oui Recherches formatives effectuées? Non Enquête prétestée? Oui	les concerne, 70,4 % d'entre elles seraient certainement ou probablement prêtes à recevoir le vaccin, 11,8 % le refuseraient, et 17,8 % ont dit être incertaines. • 40,9 % des participants ont déclaré que l'innocuité des vaccins mis au point en urgence pendant une épidémie ne peut être garantie. • L'opinion sur l'innocuité des vaccins mis au point en urgence et la méfiance à l'égard du ministère de la Santé pour assurer l'innocuité des vaccins étaient les deux facteurs les plus importants, indépendamment, associés à l'hésitation et à la réticence à l'égard des vaccins. • L'intention de se faire vacciner a été associée positivement à des antécédents de vaccination personnelle contre la grippe.
Ogilvie (2021) (79) Étude transversale Canada Août et septembre 2020	On a évalué l'intention de se faire vacciner chez 4 058 adultes et travailleurs de la santé de la Colombie-Britannique (âgés de 25 à 69 ans). Le nombre de travailleurs de la santé qui ont pris part au sondage n'est pas indiqué clairement. Sujets des questions : 1) Intentions en ce qui concerne les vaccins 2) Perception des vaccins 3) Hésitation par rapport à la vaccination	• 81,8 % des travailleurs de la santé ont dit avoir l'intention de se faire vacciner. • Autres résultats observés dans la population en général. • L'analyse multivariée a démontré que les Sud-Asiatiques (RCa = 0,65, IC à 95 % : 0,39 à 1,07), les non-blancs (RCa = 0,76, IC à 95 % : 0,61 à 0,95) et ceux qui se sont identifiés comme Autochtones (RCa = 0,58, IC à 95 % : 0,38 à 0,87) étaient beaucoup moins susceptibles d'avoir l'intention de se faire vacciner.

	Outils d'enquête disponibles? Oui Recherches formatives effectuées? Oui Enquête prétestée? Oui	
The Canadian PSW Network (2020) *non publiée* (131) Étude transversale Canada s.d. 2020	Utilise un sondage en ligne pour connaître l'intention de 562 préposés aux services de soutien à la personne, infirmières et travailleurs de la santé de se faire vacciner. 84 % de l'échantillon étaient des préposés aux services de soutien à la personne. Sujets des questions : 1) Intentions en ce qui concerne les vaccins 2) Perception des vaccins Outils d'enquête disponibles? Non Recherches formatives effectuées? Non Enquête prétestée? Non	• 64,2 % des répondants ont dit avoir l'intention de se faire vacciner lorsque le vaccin sera disponible, 16,2 % ne veulent pas se faire vacciner, 10,7 % sont incertains et 8,9 % ne prendront le vaccin que s'il est obligatoire. • 71,7 % ne croient pas qu'il y ait suffisamment d'information claire à propos du vaccin.
ÉTATS-UNIS ET ROYAUME-UNI		
Abohelwa (2021) (224) *nouveau* Étude transversale É.-U. Mars 2021	Les données sur l'adoption du vaccin et l'intention de se faire vacciner ont été recueillies en ligne auprès de 81 résidents et étudiants du campus de Lubbock du Texas Tech University Health Sciences Center. Sujets des questions : 1) Intentions de se faire vacciner 2) Attitudes envers les vaccins	• 95,1 % avaient déjà reçu le vaccin et 96,3 % ont déclaré qu'ils étaient favorables à la vaccination. • 3,7 % ne voulaient pas se faire vacciner. Les raisons n'ont pas été explorées.

	Outils de sondage disponibles? Non Des recherches formatives ont-elles été menées? Non Sondage prétesté? Non	
King (2021) *préimpression* (181) Étude longitudinale É.-U. Janvier à mars 2021	Dans le cadre d'une enquête nationale continue mensuelle sur la COVID-19, des questions visant à mesurer l'acceptation des vaccins et les facteurs connexes d'acceptation ont été recueillies auprès d'échantillons d'adultes (âgés de 18 à 64 ans). Le nombre de travailleurs de la santé n'a pas été communiqué. Enquête de janvier : n = 791 716 Enquête de février : n = 710 529 Enquête de mars : n = 732 308 Sujets des questions : 1) Hésitation à se faire vacciner Outils d'enquête disponibles? Oui Des recherches formatives ont-elles été menées? Non Enquête prétestée? Non	• Dans un sous-ensemble d'individus de cette enquête (n = 143 297) par catégories professionnelles présentant le plus fort pourcentage d'hésitation, 6,7 % des individus ont déclaré la religion comme raison de leur hésitation à se faire vacciner. Il s'agit notamment des professions de la construction, de l'installation, de l'agriculture, de la sylviculture et de la pêche, et des transports.
Pacella-LaBarbara (2021) (117) *nouveau* Étude transversale É.-U.	Un sondage en ligne a été mené auprès de 475 employés de services des urgences et de services médicaux d'urgence de l'Ohio, du Maryland, de la Virginie-Occidentale et de New York afin de déterminer les intentions de se faire vacciner et les facteurs associés à ces intentions.	• 79 % des travailleurs de la santé s'étaient fait vacciner ou prévoyaient se faire vacciner contre la COVID-19 et 21 % ne prévoyaient pas se faire vacciner. • L'intention de se faire vacciner était plus faible chez les femmes (OR 0,34, IC à 95 % : de 0,34 à 0,91, P =0,02) et les personnes ayant des antécédents d'infection à la COVID-19 (OR 0,55, IC à 95 % : de 0,31 à 0,98, P=0,04), et plus élevée chez

Janv.-févr. 2021	Sujets des questions : 1) Intentions de se faire vacciner 2) Réticence à se faire vacciner Outils de sondage disponibles? Non Des recherches formatives ont-elles été menées? Non Sondage prétesté? Non	les personnes ayant fait des études supérieures (OR 3,53, IC à 95 % : 1,16, 10,77, P = 0,03) et une vulnérabilité à la COVID-19 perçue élevée (OR 1,99, IC à 95 % : 1,37, 2,90). • Tous les médecins étaient soit vaccinés, soit avaient l'intention de le faire (100 %), contre 27 % des infirmières, 21 % des employés des services médicaux d'urgence et 27 % des autres cliniciens et personnels.
Woolf (2021) *préimpression* (114) Étude transversale et étude qualitative ROYAUME-UNI Décembre 2020 à mars 2021	Pour évaluer l'hésitation à se faire vacciner contre la COVID-19 et les prédicteurs à cette hésitation, une enquête en ligne a été menée auprès de 11 584 travailleurs de la santé (16 et +). Les données qualitatives ont été recueillies par le biais d'entretiens (n = 24), de groupes de discussion (n = 17) et de réponses à des enquêtes ouvertes (n = 58). Sujets des questions : 1) Hésitation à se faire vacciner Outils d'enquête disponibles? Oui Des recherches formatives ont-elles été menées? Oui Enquête prétestée? Non	• 23,3 % des travailleurs de la santé ont hésité à se faire vacciner. • Les travailleurs de la santé plus âgés (RR ajusté 0,74, IC 95 % : 0,70 % à 0,78 % pour chaque décennie d'augmentation) et ceux ayant déjà reçu le vaccin contre la grippe (RR ajusté 0,51, IC 95 % : 0,46 % à 0,57 %) étaient moins hésitants. • Par rapport aux travailleurs sanitaires britanniques blancs, ceux issus des Caraïbes noires (RR ajusté 3,37, IC 95 % : 2,11 à 5,37), Africains noirs (RR ajusté 2,05, IC 95 % : 1,49 % à 2,82 %), et Blancs autres (RR ajusté 1,48, IC 95 % : 1,19 % à 1,84 %), les groupes ethniques étaient plus susceptibles d'être hésitants. • Le personnel de la santé féminin (RR ajusté 1,42, IC 95 % : 1,24 % à 1,62 %), les travailleuses de la santé enceintes (RR ajusté 7,12, IC 95 % : 4,74 % à 10,70 %), et ceux qui avaient été testés positifs pour le SRAS-CoV-2 (RR ajusté 1,30, IC 95 % : 1,14 % à 1,47 %) étaient plus susceptibles d'être hésitants. • Les professionnels de la santé ayant obtenu des cotes plus élevées sur l'échelle des croyances conspirationnistes envers la COVID-19 étaient plus susceptibles d'être hésitants (RR ajusté 1,12, IC 95 % : 1,08 % à 1,16 % pour chaque augmentation de 1 point sur l'échelle).

		• Au cours des entrevues et des groupes de discussion, les travailleurs de la santé ont suggéré une communication inclusive en matière de santé (p. ex., en plusieurs langues) et la participation au déploiement du vaccin de travailleurs de la santé ayant des antécédents diversifiés provenant de communautés minoritaires afin d'améliorer la participation à la vaccination dans les communautés ethniques minoritaires.
Manby (2021) *préimpression* (128) Étude qualitative ROYAUME-UNI Décembre 2020 à mars 2021	Des entretiens téléphoniques ont été menés auprès de 24 travailleurs de la santé afin d'évaluer les facteurs influençant leurs attitudes envers le programme de vaccination contre la COVID-19 du Royaume-Uni. Sujets des questions : 1) Attitudes à l'égard des vaccins	• Le manque de données probantes disponibles était un facteur clé de l'hésitation à se faire vacciner. • La conviction que les décisions du gouvernement concernant le déploiement des vaccins ne sont pas étayées par des données scientifiques probantes et les messages contradictoires et changeants du gouvernement ont eu un impact négatif sur le niveau de confiance des travailleurs de la santé dans le programme de vaccination. • Bien que la majorité ait déclaré que les données probantes étaient suffisantes pour démontrer la sécurité à court terme des vaccins contre la COVID-19, des inquiétudes ont été soulevées quant aux répercussions des souches mutantes sur l'efficacité du vaccin et les effets secondaires inconnus à long terme, tels que sur la fertilité. • La désinformation en ligne a eu un impact négatif sur les attitudes à l'égard des vaccins, en particulier chez les travailleurs de la santé de niveau inférieur et les Noirs, les Asiatiques et les minorités ethniques, avec des rapports de théories de conspiration en ligne visant précisément ces groupes. • La plupart se sentaient motivés pour promouvoir la vaccination auprès de leurs patients et beaucoup estimaient que c'était leur obligation morale.

Moniz (2021) *préimpression* (116) Étude transversale États-Unis Février 2021	Les facteurs associés à l'intention de se faire vacciner contre la COVID-19 ont été évalués chez 11 387 adultes (âgés de 18 ans et plus) dans un centre de soins de santé universitaire du Midwest américain au moyen d'un sondage en ligne. Sujets des questions : 1) Intentions en ce qui concerne la vaccination 2) Hésitation par rapport à la vaccination Outils d'enquête disponibles? Oui Recherches formatives effectuées? Oui Enquête prétestée? Oui	• 79,8 % des répondants avaient reçu le vaccin, 4,8 % avaient l'intention de se faire vacciner le plus tôt possible, 8,4 % n'avaient pas l'intention de le recevoir bientôt, mais pourraient se faire vacciner plus tard et 3,2 % ne voulaient absolument pas se faire vacciner. • Les médecins (RCa 22,2, IC à 95 % : 9,1 à 54,3), les stagiaires (RCa 5,9, IC à 95 % : 3,0 à 11,4) et les infirmières praticiennes, infirmières sages-femmes, adjointes aux médecins (RCa 1,9, IC à 95 % : 1,2 à 3,0) étaient beaucoup plus susceptibles d'accepter un vaccin que les infirmières alors que les autres membres du personnel clinique (RCa 0,8, 0,6 à 0,9) et tous les autres employés (RCa 0,8, 0,6 à 1,0) étaient moins susceptibles de l'accepter. • Les personnes qui avaient déjà contracté la COVID-19 étaient moins susceptibles d'accepter un vaccin (RCa 0,4, IC à 95 % : 0,3 à 0,4). • Les travailleurs de la santé étaient presque deux fois plus susceptibles d'accepter des vaccins que les travailleuses de la santé (RCa 1,9, IC à 95 % : 1,6 à 2,4). • Comparativement aux répondants blancs non hispaniques, les répondants asiatiques non hispaniques étaient plus susceptibles d'accepter un vaccin (RCa 2,3, IC à 95 % : 1,5 à 3,4) et les répondants noirs, mixtes, autres non hispaniques étaient moins susceptibles (RCa 0,4, IC à 95 % : 0,4 à 0,5). • La méfiance à l'égard du vaccin en raison de la rapidité avec laquelle il a été mis au point et les préoccupations relatives à l'innocuité étaient les deux raisons les plus courantes de réticence à se faire vacciner.
McCabe (2021) *préimpression* (166)	Une enquête nationale distribuée par voie électronique a été menée auprès de 34 470 travailleurs de la santé et d'adultes de la population générale afin de mesurer l'intention	• 19 % des professionnels de la santé sont indécis, peu ou très peu enclins à se faire vacciner. • Les travailleurs de la santé essentiels étaient 1,18 fois plus susceptibles que les travailleurs non

Étude transversale É.-U. Décembre 2020 à février 2021	de recevoir un vaccin et les facteurs liés à l'acceptation et au refus. Le nombre de travailleurs de la santé n'a pas été indiqué. Sujets des questions : 1) Intentions de se faire vacciner 2) Hésitation à se faire vacciner Outils d'enquête disponibles? Oui Des recherches formatives ont-elles été menées? Non Enquête prétestée? Oui	essentiels d'hésiter à se faire vacciner (RR ajusté = 1,18 95 % CI : 1,06 % à 1,32 %).
Nguyen (2021) *préimpression* (118) Étude transversale É.-U. et R.-U. Janvier 2021	Pour évaluer l'intention de se faire vacciner et les raisons de l'hésitation, un sondage en ligne a été mené auprès de 73 650 et de 1 154 988 adultes et travailleurs de la santé aux États-Unis et au Royaume-Uni, respectivement. Le nombre de travailleurs de la santé dans la population générale n'était pas précisé. Sujets des questions : 1) Intentions en ce qui concerne les vaccins Outils d'enquête disponibles? Oui Recherches formatives effectuées? Non Enquête prétestée? Non	• Aux États-Unis, les travailleurs de la santé de première ligne étaient moins susceptibles d'avoir l'intention de se faire vacciner (6 % ne veulent pas et 11 % sont incertains) comparativement à la population générale (2 % ne veulent pas et 7 % ne sont pas sûrs). • Comparativement aux travailleurs de la santé des États-Unis, ceux du Royaume-Uni ont indiqué une plus grande volonté de se faire vacciner. Comparativement aux personnes de race blanche, les Noirs (RCa = 3,00, IC à 95 % : 2,86 à 3,16), les Hispaniques (RCa = 1,59, IC à 95 % : 1,51 à 1,67), les Asiatiques (RCa = 1,83, IC à 95 % : 1,70 à 1,97) et les personnes ayant déclaré plus d'une race (RCa = 1,43, IC à 95 % : 1,36 à 1,52) étaient plus susceptibles d'hésiter à se faire vacciner dans l'analyse ajustée en fonction de l'âge. • • Dans toutes les races et origines ethniques, les raisons les plus fréquemment invoquées pour justifier l'hésitation à se faire vacciner comprenaient des préoccupations au sujet des effets secondaires à long terme (50 % à 57 %) et

		des effets indésirables (45 % à 54 %). Les Noirs et les Hispaniques ont mentionné un manque de connaissances sur le vaccin (45 à 51 %) à un taux plus élevé que les Blancs (37 à 42 %).
Kociolek (2021) (106) Étude transversale ÉTATS-UNIS Janvier 2021	Un sondage en ligne a été utilisé pour évaluer la fréquence de la réticence à se faire vacciner, les raisons de la réticence et les caractéristiques des personnes qui ont dit hésiter chez 4 448 travailleurs de la santé dans un hôpital pour enfants à Chicago (Illinois). Sujets des questions : 1) Intentions en ce qui concerne les vaccins 2) Hésitation par rapport à la vaccination Outils d'enquête disponibles? Non Recherches formatives effectuées? Non Enquête prétestée? Non	• Sur 4 277 participants, 59,8 % ont déclaré avoir l'intention de se faire vacciner, 8,6 % avaient déjà reçu le vaccin, 8,8 % ne se feront pas vacciner et 10,1 % étaient incertains. • Comparativement à leurs homologues, la proportion de personnes qui hésitaient à se faire vacciner était des femmes, avait des antécédents confirmés ou soupçonnés de COVID-19, avait des problèmes de santé à risque élevé et ne s'inquiétait pas de la gravité de la COVID-19. • Les participants noirs étaient plus susceptibles d'hésiter à se faire vacciner que les personnes qui n'étaient pas noires (50,4 % c. 15,6 %) et les Hispaniques/Latinx étaient plus hésitants que les personnes non hispaniques/Latinx (29,9 % c. 17,1 %). • Ceux qui occupaient des postes non cliniques étaient plus hésitants que ceux qui occupaient des postes cliniques (28,7 % contre 11,9 %) et les employés horaires étaient plus hésitants que les salariés (27,6 % contre 11,4 %). • Les raisons les plus fréquemment citées pour justifier la réticence à l'égard du vaccin étaient les effets secondaires à long terme (76,3 %), l'innocuité (50,7 %) et le fait que la méthode avec ARNm est trop nouvelle (47,8 %). • Parmi ceux qui ont dit hésiter à se faire vacciner, les ressources les plus importantes pour l'information sur le vaccin contre la COVID-19 étaient la recherche autoguidée (46,5 %), les fournisseurs de soins primaires (33 %) et les organismes fédéraux et gouvernementaux (28,8 %). Les sites Web d'autoapprentissage (46,9 %), les mises à jour par courriel (36,7 %) et les mises à jour vidéo de dirigeants d'hôpitaux et

		d'experts en vaccins (34,7 %) étaient la méthode de communication préférée des dirigeants d'hôpitaux pour obtenir de l'information sur les vaccins.
Ciardi (2021) (125) *nouveau* Étude transversale É.-U. Déc. 2020-janv. 2021	428 travailleurs de la santé ont été interrogés en ligne sur leurs intentions, leurs connaissances et leurs attitudes envers le vaccin contre la COVID-19. Sujets des questions : 1) Intentions de se faire vacciner 2) Attitudes envers les vaccins Outils de sondage disponibles? Oui Des recherches formatives ont-elles été menées? Non Sondage prétesté? Non	• 64 % prévoient de se faire vacciner dans les 30 jours et 73 % dans les six prochains mois. • Les répondants qui ont plus de 65 ans (95 %), qui sont asiatiques (79 %), de sexe masculin (79 %) et ceux qui vivent à Manhattan (81 %) étaient significativement plus susceptibles d'accepter de se faire vacciner dans les 30 jours. • Les personnes les moins disposées à se faire vacciner dans les 30 prochains jours sont celles âgées de 36 à 45 ans (57 %), les Afro-Américains (40 %), les femmes (60 %) et les personnes habitant dans le Bronx (51 %). • L'intention de se faire vacciner était fortement corrélée à la confiance dans les ÉPI et les mesures de santé publique *(r* = 0,222), les mesures de santé publique (r = 0,208), la confiance dans les ÉPI au travail (r = 0,0988) et les personnes qui pensent que les ÉPI et les pratiques devront être maintenus même après la vaccination (r = 0,158). • Des notes plus élevées des connaissances sur l'infection à la COVID-19 et le fait de suivre de près les informations étaient corrélés à une intention positive de se faire vacciner (r = 0,18 et r = 0,183 respectivement) (r = 0,18 et r = 0,183, respectivement). • L'expérience personnelle avec la COVID-19 a été associée à une plus grande intention de se faire vacciner. • Les attitudes générales positives envers le vaccin et le risque personnel étaient positivement et significativement associés aux attitudes envers le vaccin contre la COVID-19, tandis que la préoccupation concernant la rapidité du test était associée négativement.

Enwezor (2021) *préimpression* (115) Étude transversale États-Unis Décembre 2020 à janvier 2021	Un sondage en ligne a évalué l'intention de se faire vacciner chez 20 232 adultes (5 170 travailleurs de la santé et 15 062 autres personnes). 476 des participants avaient déjà reçu un diagnostic de COVID-19. Sujets des questions : 1) Intentions en ce qui concerne la vaccination Outils d'enquête disponibles? Non Recherches formatives effectuées? Non Enquête prétestée? Non	• L'intention de se faire vacciner était très différente entre les travailleurs de la santé (74 %) et ceux qui travaillaient dans d'autres domaines (77 %), P = 0,0014.
Dugani (2021) (113) Étude transversale É.-U. Décembre 2020 à janvier 2021	Une enquête en ligne a été menée auprès de 128 spécialistes en soins de courte durée, dont 75 médecins et 53 prestataires de pratiques avancées, notamment des infirmières praticiennes et infirmiers praticiens ainsi que des assistants médicaux en Arizona, en Floride, au Minnesota et au Wisconsin. Cette étude visait à évaluer les différences potentielles entre les médecins et les prestataires de pratiques avancées dans leurs attitudes envers les vaccins contre la COVID-19. Sujets des questions : 1) Intentions de se faire vacciner 2) Attitudes à l'égard des vaccins	• 93,7 % des spécialistes en soins de courte durée ont déclaré avoir reçu ou prévu de recevoir le vaccin contre la COVID-19 (88,7 % des prestataires de pratiques avancées et 97,3 % des médecins). • Les spécialistes en soins de courte durée étaient moins susceptibles de conseiller à 100 % des patients de recevoir le vaccin contre la COVID-19 (66 % des prestataires de pratiques avancées, 74,7 % des médecins) que le vaccin contre la grippe (83 % des prestataires de pratiques avancées, 80 % des médecins). Des tendances similaires ont été observées pour le conseil aux patients, à la famille et aux amis. • Les obstacles signalés pour recommander le vaccin aux patients comprenaient des restrictions en matière de santé pour les patients (17 % des prestataires de pratiques avancées, 10,7 % des médecins) et le profil de sécurité du vaccin inconnu (11,3 % des prestataires de pratiques avancées, 6,7 % des médecins). • Les spécialistes de soins de courte durée ont déclaré que les patients et les collègues recevant le

	Outils d'enquête disponibles? Oui Des recherches formatives ont-elles été menées? Non Enquête prétestée? Non	vaccin réduiraient leur niveau d'anxiété (83 % des prestataires de pratiques avancées, 75,3 % des médecins), réduiraient l'isolement social (60,4 % des prestataires de pratiques avancées, 60,3 % des médecins) et augmenteraient le soutien émotionnel (35,8 % des prestataires de pratiques avancées, 41,1 % des médecins). • Ceux qui pensaient que le vaccin réduirait leur isolement social avaient plus de chances de conseiller à leurs patients de se faire vacciner (RR ajusté 2,95, IC 95 % : 1,32 % à 6,59 %, P < 0,008).
Armitage (2021) (134) Étude transversale ROYAUME-UNI Décembre 2020 à janvier 2021	Une enquête en ligne a été menée auprès de 220 médecins généralistes afin d'évaluer leur confiance dans le fait de conseiller leurs patients sur les vaccins contre la COVID-19. Sujets des questions : 1) Attitudes à l'égard des vaccins Outils d'enquête disponibles? Non Des recherches formatives ont-elles été menées? Non Enquête prétestée? Non	• Plus de 50 % des médecins généralistes avaient peu confiance dans le fait de conseiller leurs patients sur les vaccins contre la COVID-19. • De nombreux médecins généralistes ont déclaré n'avoir aucune ou peu de confiance pour conseiller les patients sur l'inclusion de patients cliniquement vulnérables dans les essais de vaccins (58,2 %), la sécurité des vaccins dans des groupes précis (67,3 %), le potentiel d'effets indésirables non encore observés dans les essais cliniques (74,5 %), la possibilité pour les personnes participant aux essais de recevoir un vaccin approuvé (78,2 %) et la signification de l'efficacité des vaccins (81 %). • 52,7 % et 54,5 % des médecins généralistes ont déclaré n'avoir aucune ou peu de confiance pour accéder à des informations crédibles sur les vaccins pour eux-mêmes et pour orienter les patients vers des informations similaires, respectivement.
Berry (2021) (225) Étude qualitative ÉTATS-UNIS	Les préoccupations soulevées par 193 travailleurs de la santé et membres du personnel d'établissements de soins infirmiers spécialisés lors des assemblées publiques locales ont été déclarées. La localisation aux États-Unis n'a pas été indiquée.	• Parmi les premières préoccupations qui ont été soulevées, mentionnons le fait de croire que le vaccin a été mis au point trop rapidement, les effets secondaires à court et à long terme, l'infertilité et la sécurité pendant la grossesse, et le désir d'attendre de voir comment le vaccin fonctionne pour les autres. • Une fois les premières préoccupations réglées, d'autres préoccupations qui revenaient souvent portaient sur le fait de croire que le vaccin cause la

Décembre et janvier 2021	Sujets des questions : 1) Hésitation par rapport à la vaccination	COVID-19, la paralysie de Bell, le fait qu'un vaccin de rappel soit requis, le fait qu'il est inefficace contre les nouveaux variants et un résultat positif à un test antérieur. • Parmi les préoccupations qui ont été soulevées plus tard dans la discussion, mentionnons l'incertitude à savoir si le fait de recevoir le vaccin aura un effet sur les mesures de précaution à respecter (port d'un couvre-visage, distanciation sociale, etc.), la peur des micropuces et la sécurité chez les personnes atteintes de maladies chroniques. •
Grumbach (2021) (112) Étude transversale É.-U. Novembre 2020 à janvier 2021	Une enquête en ligne a été menée auprès de 3 161 adultes de la communauté et de 1803 membres du personnel soignant de trois centres médicaux de la baie de San Francisco pour évaluer les intentions de vaccination et les raisons de l'acceptation et de l'hésitation. Sujets des questions : 1) Intentions de se faire vacciner 2) Hésitation à se faire vacciner Outils d'enquête disponibles? Non Des recherches formatives ont-elles été menées? Oui Enquête prétestée? Non	• Les travailleurs de la santé avaient davantage l'intention de se faire vacciner que la population générale (83,6 % contre 65,5 %, P < 0,001). • Chez les travailleurs de la santé, les Noirs (RR ajusté 0,24, IC 95 % : 0,10 % à 0,60 %), les Latinos (RR ajusté 0,50, IC 95 % : 0,31 % à 0,79 %), les Asiatique (RR ajusté 0,37, IC 95 % : 0,27 % à 0,51 %), les communautés multiraciales (RR ajusté 0,49, IC 95 % : 0,29 % à 0,82 %) et les personnes d'autres races (RR ajusté 0,28, IC 95 % : 0,15 % à 0,53 %) avaient moins l'intention de se faire vacciner que les travailleurs de la santé blancs. • Les raisons pour lesquelles les répondants noirs, latino-américains et asiatiques avaient l'intention de ne pas se faire vacciner comprenaient le manque de confiance dans la capacité du vaccin à prévenir la COVID-19 (RR ajusté 2,39, IC 95 % : 1,58 % à 3,61 %; RR ajusté 2,04, IC 95 % : 1,58 % à 2,64 %; RR ajusté 1,85, IC 95 % : 1,51 % à 2,27 %, respectivement), le manque de confiance dans les fabricants de vaccins (RR ajusté 3,08, IC 95 % : 2,00 % à 4,73 %; RR ajusté 1,85, IC 95 % : 1,38 % à 2,48 %; RR ajusté 1,34, IC 95 % : 1,04 % à 1,72 %, respectivement), et les préoccupations concernant l'approbation précipitée du vaccin (RR ajusté 2,10, IC 95 % : 1,44 % à 3,05 %; RR ajusté 1,68, IC 95 % :

		1,34 % à 2,10 %, RR ajusté 1,81, IC 95 % : 1,53 % à 2,15 %, respectivement).
Weng (2021) *préimpression* (119) Étude transversale États-Unis Novembre 2020 à janvier 2021	Les différences raciales ethniques dans les intentions de vaccination contre la COVID-19 ont été examinées au moyen d'un sondage en ligne effectué auprès de 3 161 adultes de la population générale et de 1 803 travailleurs de la santé en Californie. Sujets des questions : 1) Intentions en ce qui concerne la vaccination 2) Hésitation par rapport à la vaccination Outils d'enquête disponibles? Non Recherches formatives effectuées? Oui Enquête prétestée? Non	• Les travailleurs de la santé étaient plus susceptibles que le grand public d'avoir l'intention de se faire vacciner (83,6 % comparativement à 65,5 %). • Chez les travailleurs de la santé, l'intention de se faire vacciner était la plus élevée chez les Blancs (89 %), suivis des Latins ou des Hispaniques (78 %), des Asiatiques (75 %), des autres races (66 %) et des Noirs ou des Afro-Américains (65 %). • Les répondants latinx et asiatiques étaient beaucoup plus susceptibles que les répondants blancs de dire que la recommandation d'un médecin était une raison importante pour se faire vacciner. • Comparativement aux Blancs, environ 15 % de plus de Noirs, de Latins et d'Asiatiques ont indiqué que le risque d'une mauvaise réaction au vaccin et le fait que le gouvernement précipite le processus d'approbation étaient des raisons majeures de ne pas se faire vacciner. Ils étaient aussi beaucoup plus susceptibles de déclarer des préoccupations au sujet du vaccin qui leur donnait la COVID-19.
Woodhead (2021) (226) *nouveau* Étude qualitative R.-U. Oct.-janv. 2021	Des entrevues en ligne semi-structurées ont été menées auprès de 17 travailleurs de la santé et de huit cadres supérieurs afin d'étudier comment sont prises les décisions concernant l'adoption du vaccin contre la COVID-19 et si le racisme et la discrimination entrent en ligne de compte dans la décision. Sujets des questions : 1) Intentions de se faire vacciner	• Les personnes interrogées se situent dans un continuum allant de celles qui accepteraient immédiatement de se faire vacciner (un peu plus de la moitié) à une minorité qui serait plus sûre de le refuser, un tiers exprimant des opinions hésitantes. • Les personnes interrogées ont tendance à peser activement les avantages et les risques, les personnes réticentes voyant les avantages et les risques de manière égale et les personnes refusant de se faire vacciner se concentrant sur les risques pour elles-mêmes. • Les personnes acceptant de se faire vacciner étaient plus susceptibles de déclarer qu'elles

	2) Réticence à se faire vacciner 3) Attitudes envers les vaccins	considéraient le retour à la normale comme un élément positif dans la prise de décision. • Les risques étaient caractérisés par des inquiétudes concernant les effets secondaires en lien avec des vulnérabilités préexistantes. • Les expériences passées avec les vaccins étaient liées à des points de vue sur la normalisation (par rapport au vaccin contre la grippe) pour les personnes acceptant de se faire vacciner, tandis que les personnes réticentes et refusant de se faire vacciner l'associaient à de grands événements néfastes comme la tragédie de la thalidomide. • Les personnes qui ont exprimé des opinions hésitantes ou opposées ont cité l'absence de renseignements fiables qui pourraient permettre la manipulation et la désinformation. • Tous les groupes se doutaient qu'ils recevraient des messages directs et indirects les incitant à se faire vacciner, mais les personnes refusant de se faire vacciner et les personnes réticentes craignaient davantage d'être forcées à se faire vacciner par leurs institutions.
Harrison (2021) (130) *nouveau* Étude qualitative É.-U. Déc. 2020	Cinq groupes de discussion réalisés par vidéoconférence (Zoom) avec 54 participants ont été organisés avec le personnel d'établissements de soins spécialisés afin de mieux comprendre les réticences. La localisation aux États-Unis n'a pas été indiquée. Sujets des questions : 1) Réticence à se faire vacciner 2) Attitudes envers les vaccins	• Parmi les personnes qui sont réticentes à se faire vacciner, on retrouve quatre thèmes : (1) préoccupations générales et personnelles concernant l'innocuité et l'efficacité du vaccin, (2) manque de confiance dans l'effort de vaccination, (3) désinformation sur le vaccin et (4) augmentation de l'adoption du vaccin. • Les préoccupations générales portaient sur la courte période de développement et d'essai, la nouveauté, les effets à long terme, l'impact sur les conditions sous-jacentes ou le fait que la COVID-19 ne serait pas grave si elles tombaient malades. • Certains répondants ont cru à tort que le vaccin contiendrait un virus vivant ou atténué. Les rumeurs de désinformation portaient sur les micropuces, les virus vivants et l'infertilité.

		• Le manque de confiance a été ressenti à la fois pour l'affiliation politique ou le scepticisme historique pour les personnes de couleur. • Lorsqu'on leur a demandé comment augmenter le taux d'adoption, les répondants ont souhaité voir des renseignements faciles à comprendre et faire venir des représentants pour discuter (groupes religieux) ou être vus en train de recevoir le vaccin.
Abuown (2021) (227) Étude transversale ROYAUME-UNI Décembre 2020	Un sondage en ligne effectué auprès de 514 adultes à Londres a évalué l'intention de se faire vacciner. Sujets des questions : 1) Intentions en ce qui concerne la vaccination 2) Hésitation par rapport à la vaccination Outils d'enquête disponibles? Non Recherches formatives effectuées? Non Enquête prétestée? Oui	• 59 % étaient prêts à se faire vacciner contre la COVID-19, 24 % ont dit ne pas l'être alors que 17 % étaient indécis. • Les médecins étaient plus susceptibles d'accepter un vaccin que les infirmières (P < 0,001), les auxiliaires de santé (P < 0,001), les pharmaciens (P < 0,001), les professionnels paramédicaux (P < 0,01) et le personnel administratif (P < 0,01). Les membres du personnel de gestion de l'hôpital étaient plus susceptibles d'accepter cette option que les infirmières, les aides-soignants et les pharmaciens (P < 0,01). • Ceux qui ont accepté de recevoir un vaccin antigrippal étaient moins susceptibles de refuser un vaccin contre la COVID-19 (RC 0,45, IC à 95 % : 0,031 à 0,96) et ceux qui ont refusé un vaccin contre la grippe étaient plus susceptibles de refuser le vaccin contre la COVID-19 (RC 8,32, IC à 95 % : 5,36 à 12,91, P < 0,001). • Les travailleurs de la santé plus âgés (61 ans et plus) étaient beaucoup plus susceptibles d'avoir l'intention de se faire vacciner (P < 0,01). • Le rapport de probabilité de refus du vaccin était de 0,51 pour les hommes (IC à 95 % : 0,34 à 0,77) et de 1,26 pour les femmes (IC à 95 % : 1,12 à 1,42, P < 0,001). • L'intention de se faire vacciner était beaucoup plus faible chez les travailleurs de la santé noirs que chez les Blancs (P < 0,01), les Indiens (P < 0,001) ou les autres personnes d'origine asiatique (P < 0,01).

		• Les préoccupations en matière de sécurité étaient le motif de réticence le plus courant.
Meyer (2021) (228) Étude transversale ÉTATS-UNIS Décembre 2020	Un sondage en ligne effectué en Pennsylvanie visait à évaluer les intentions de se faire vacciner et les raisons de l'hésitation chez 16 158 travailleurs de la santé. Sujets des questions : 1) Intentions en ce qui concerne les vaccins 2) Hésitation par rapport à la vaccination Outils d'enquête disponibles? Non Recherches formatives effectuées? Non Enquête prétestée? Non	• 55 % des répondants ont l'intention de se faire vacciner lorsque le vaccin sera disponible, 16,4 % n'accepteraient pas de faire vacciner et 28,5 % étaient indécis. • Les patients qui sont en contact avec les travailleurs de la santé ont déclaré des intentions de vaccination plus élevées que ceux qui n'en ont pas (56,8 % comparativement à 51,4 %, p < 0,005). • Dans les zones dans les hôpitaux, ceux qui travaillaient à l'urgence étaient ceux qui voulaient le moins se faire vacciner (51,9 %), tandis que ceux qui travaillaient aux soins intensifs (63,1 %) et aux soins aux personnes hospitalisées (60,9 %) étaient ceux qui voulaient le plus recevoir le vaccin. • Les principales raisons qui poussaient les gens à hésiter étaient les préoccupations au sujet des risques inconnus du vaccin (90,3 %), les préoccupations au sujet des effets secondaires connus (57,4 %) et le désir d'attendre pour voir les répercussions du vaccin sur les autres (44,4 %). • Parmi les autres raisons associées à l'hésitation, mentionnons un manque de confiance à l'égard du processus ou des résultats de la FDA (21,1 %), des préoccupations au sujet du suivi par l'État ou le réseau hospitalier (13,9 %), des préoccupations au sujet de la technologie de l'ARNm (11,4 %) et la croyance qu'ils ne présentent pas un risque élevé d'être atteints d'une maladie grave (10,4 %). • La division des réponses reçues avant le vote sur l'approbation du vaccin Pfizer (92,8 % des réponses) et après (7,2 % des réponses) révèle que 79 % des répondants ont déclaré qu'ils recevraient le vaccin, comparativement à 53,2 % qui avaient dit avoir l'intention de se faire vacciner avant le vote.
Piltch-Loeb (2021) (229)	L'effet des médias sur l'acceptation des vaccins a été évalué à l'aide d'un sondage en ligne effectué	• 39,9 % ont déclaré qu'ils étaient susceptibles de se faire vacciner dans les deux mois, 47,3 % avaient

Étude transversale ÉTATS-UNIS Décembre 2020	auprès de 2 650 adultes appartenant aux groupes prioritaires pour la vaccination, y compris les travailleurs de la santé. 61,4 % des participants travaillaient dans le secteur des soins de santé. Sujets des questions : 1) Intentions en ce qui concerne les vaccins 2) Hésitation par rapport à la vaccination 3) Perception des vaccins Outils d'enquête disponibles? Non Recherches formatives effectuées? Non Enquête prétestée? Oui	un certain degré d'hésitation et 12,8 % étaient peu susceptibles d'accepter le vaccin. • 61 % ont obtenu de l'information sur le vaccin contre la COVID-19 de la télévision locale et 37,8 % de Facebook. • Les répondants ont indiqué que les nouvelles sur le vaccin étaient positives (53,6 %), neutres (25,3 %), surtout négatives (16,3 %) ou qu'ils n'avaient pas vu l'information sur le vaccin (4,8 %). • Dans l'ensemble, la confiance dans les sources d'information sur les vaccins était de modérée à faible, 23 % déclarant une confiance élevée, 40,5 % une confiance modérée et 36,3 % un bas niveau de confiance. • Dans l'analyse à variables multiples, les prédicteurs positifs de l'intention de se faire vacciner comprenaient le fait de connaître une personne décédée de la COVID-19 (RR = 1,47, IC à 95 % : 1,08 à 1,99), d'avoir une certaine confiance dans l'information sur les vaccins (RR = 2,01, IC à 95 % : 1,61 à 2,51), d'avoir une grande confiance dans l'information sur les vaccins (RR = 15,6, IC à 95 % : 11,69 à 20,81), et d'obtenir des renseignements sur les vaccins par la télévision nationale (RR = 1,75, IC à 95 % : 1,02 à 1,53), la télévision locale (RR = 1,75, IC à 95 % : 1,40 à 2,19), ou des journaux nationaux (RR = 1,81, IC à 95 % : 1,45 à 2,24). • Un faible niveau quant à l'intention de se faire vacciner a été associé aux répondants qui n'utilisaient que les médias sociaux (RC = 0,45, IC à 95 % : 0,32 à 0,64) ou ont utilisé à la fois les médias sociaux et les canaux médiatiques traditionnels (RC = 0,81, IC à 95 % : 0,66 à 1,00) par rapport à ceux qui n'ont utilisé que les médias traditionnels pour obtenir des renseignements sur les vaccins.
Kuter (2021) (109)	Pour évaluer l'intention de se faire vacciner, un sondage en ligne a été mené dans deux grands hôpitaux	• 63,7 % des participants ont dit avoir l'intention de se faire vacciner contre la COVID-19 lorsque le vaccin sera disponible, 26,3 % se sont dits

Étude transversale ÉTATS-UNIS Novembre et décembre 2020	universitaires de Philadelphie auprès de 12 034 employés. Sujets des questions : 1) Intentions en ce qui concerne les vaccins 2) Hésitation par rapport à la vaccination Outils d'enquête disponibles? Non Recherches formatives effectuées? Oui Enquête prétestée? Oui	incertains et 10,0 % ont dit ne pas être disposés à se faire vacciner. • Parmi ceux qui ont l'intention de se faire vacciner, 79,1 % ont dit qu'ils recevraient le vaccin le plus tôt possible, 19,1 % aimeraient attendre de 3 à 6 mois une fois qu'il aura été administré à d'autres, et 1,8 % l'auraient fait une fois que 12 mois se seront écoulés après l'administration à d'autres personnes. • Les deux caractéristiques les plus importantes du vaccin pour les répondants étaient l'innocuité (94,4 %) et l'efficacité (82,8 %). • Si un vaccin devait comporter des effets secondaires tels qu'une forte fièvre, des douleurs musculaires, des frissons et des maux de tête entraînant une perte de deux jours de travail, seulement 28,3 % des répondants ont déclaré qu'ils seraient disposés à le recevoir. 33,2 % se sont dits incertains. • L'intention de se faire vacciner a augmenté à mesure que l'efficacité du vaccin augmentait (35,8 % se sont dits prêts à recevoir un vaccin dont l'efficacité était de 50 %, 61,1 % s'il était efficace à 70 % et 85,6 % s'il était efficace à 90 %). • Les facteurs associés de façon significative à l'intention de se faire vacciner étaient le sexe masculin (RC = 2,41, IC à 95 % : 2,12 à 2,75), l'âge plus avancé (> 65 ans : RC = 3,50, IC à 95 % : 2,50 à 4,90; 40 à 64 ans : RC = 1,41, IC à 95 % : 1,26 à 1,56) et un plus grand niveau de scolarité (diplôme d'études supérieures : RC = 4,59, IC à 95 % : 3,83 à 5,50, baccalauréat ou maîtrise : RC = 1,84, IC à 95 % : 1,59 à 2,13). • Comparativement à l'origine ethnique blanche, l'intention de se faire vacciner était considérablement plus faible chez les Noirs (RC = 0,23, IC à 95 % : 0,19 à 0,27), les Hispaniques (RC = 0,51, IC à 95 % : 0,39 à 0,67) et ceux qui ont

		déclaré des races multiples/autres (RC = 0,58, IC à 95 % : 0,47 à 0,73). • Les résidents des régions urbaines étaient beaucoup plus susceptibles d'avoir l'intention de se faire vacciner que les résidents des banlieues (RC = 0,71, IC à 95 % : 0,65 à 0,79) et des régions rurales (RC = 0,41, IC à 95 % : 0,30 à 0,54). • L'intention de se faire vacciner était plus faible chez les personnes dont la santé était mauvaise ou passable (RC = 0,73, IC à 95 %, 0,56 à 0,95) et chez celles qui n'étaient pas à jour avec leur vaccination (RC = 0,36, IC à 95 %, 0,18 à 0,71) que chez leurs homologues. • Les raisons les plus courantes pour accepter de se faire vacciner étaient la protection de la famille (86,7 %), le fait de se protéger soi-même (82,9 %), la protection de la communauté (68,8 %) et le retour à la vie normale (59,4 %). • Les raisons les plus fréquentes pour hésiter à se faire vacciner ou refuser le vaccin étaient la préoccupation au sujet des effets secondaires (89,1 %), le fait que le vaccin était trop nouveau (84,0 %) et le manque de connaissances sur le vaccin (77,9 %).
Shaw (2021) (110) Étude transversale ÉTATS-UNIS Novembre et décembre 2020	Un sondage en ligne a permis d'évaluer la volonté de se faire vacciner de 5 287 travailleurs de la santé d'un grand centre médical universitaire de New York. Sujets des questions : 1) Intentions en ce qui concerne les vaccins 2) Hésitation par rapport à la vaccination Outils d'enquête disponibles? Non	• 57,5 % des répondants étaient prêts à accepter un vaccin offert gratuitement, 26,4 % étaient incertains et 15,9 % ont dit qu'ils le refuserait. • Les hommes étaient plus susceptibles d'avoir l'intention de se faire vacciner (72,5 %) que les femmes (52,4 %) ou les personnes non binaires ou non déclarées (41,0 %), P < 0,001. • Ceux qui se sont déclarés asiatiques (73,8 %) ou blancs (58,4 %) étaient plus enclins à se faire vacciner que les autres répondants (47,6 %), les Indiens d'Amérique ou les Autochtones de l'Alaska (39,3 %) ou les Noirs (30,8 %), P < 0,001. • Les scientifiques et les médecins (80,4 %), ainsi que les employés œuvrant en sécurité publique et dans les soins spirituels (77,8 %) étaient les plus

	Recherches formatives effectuées? Oui Enquête prétestée? Non	susceptibles d'avoir l'intention de se faire vacciner. Les infirmières autorisées (41,2 %), les membres des services auxiliaires (46,4 %) et les professionnels paramédicaux (51,4 %) étaient les moins susceptibles de se faire vacciner (P < 0,001). • Ceux qui étaient plus âgés et ceux qui ne donnaient pas de soins directs aux patients étaient plus susceptibles d'avoir l'intention de se faire vacciner. • Les répondants blancs étaient d'accord pour dire qu'un vaccin contre la COVID-19 serait sécuritaire lorsqu'il est approuvé (45,9 %) plus fréquemment que les répondants noirs (26,2 %), P < 0,001). • Les préoccupations les plus courantes au sujet du vaccin sont l'innocuité, les effets secondaires, l'efficacité et la rapidité du développement du vaccin.
Jain (2021) *préimpression* (111) Étude transversale ÉTATS-UNIS Novembre et décembre 2020	Les motivations, les préoccupations et les intentions concernant les vaccins contre la COVID-19 ont été évaluées dans un sondage en ligne mené auprès de 2 135 travailleurs de la santé (âgés de 18 ans et plus) de trois centres médicaux en Californie. Sujets des questions : 1) Intentions en ce qui concerne les vaccins 2) Hésitation par rapport à la vaccination 3) Connaissance des vaccins Outils d'enquête disponibles? Non Recherches formatives effectuées? Non Enquête prétestée? Non	• 69 % des travailleurs de la santé se feraient vacciner si la FDA l'approuvait officiellement, 22 % étaient incertains et 10 % le refuseraient. En revanche, seulement 35 % se feraient vacciner si ce vaccin était approuvé pour une utilisation d'urgence seulement. • 25 % voulaient être parmi les premiers à recevoir un vaccin, 36 % préféraient se faire vacciner après le premier cycle et 18 % voulaient attendre plus de deux mois. • Les principaux facteurs qui motivaient la vaccination comprenaient le risque perçu associé à la COVID-19 pour soi-même (65 %) et pour les membres de sa famille/ses amis (63 %). • Les principales préoccupations en ce qui concerne le vaccin étaient les effets secondaires (28 %), la participation politique au processus d'approbation de la FDA (21 %), la méfiance à l'égard des sociétés pharmaceutiques (16 %) et l'efficacité (12 %). • 19 % des répondants ont déclaré être très informés ou bien informés au sujet des vaccins candidats contre la COVID-19, tandis que 66 % ont

		déclaré qu'ils étaient quelque peu informés, alors que 16 % n'étaient pas du tout informés.
O'Brien (2021) *préimpression* (107) Étude longitudinale ÉTATS-UNIS Octobre à décembre 2020	Un sondage en ligne a été réalisé en octobre auprès de 2 070 travailleurs de la santé aux États-Unis pour déterminer leur intention de se faire vacciner en vertu d'une autorisation d'utilisation d'urgence. Ce sondage a été répété chez 1 541 travailleurs de la santé en décembre. 998 participants ont répondu aux deux sondages. Sujets des questions : 1) Intentions en ce qui concerne les vaccins Outils d'enquête disponibles? Non Recherches formatives effectuées? Non Enquête prétestée? Non	• L'intention de se faire vacciner est passée de 54,2 % en octobre à 76,2 % en décembre. Pendant cette période, l'intention de se faire vacciner a augmenté de 64,0 % à 90,5 % chez les médecins, de 68,9 % à 75 % chez les ambulanciers paramédicaux et de 46,6 % à 66,9 % chez les infirmières. • En ce qui concerne les 998 personnes qui ont pris part aux deux sondages, 69 % étaient disposées à se faire vacciner les deux fois, 15 % étaient hésitantes les deux fois, 13 % étaient hésitantes en octobre, mais étaient disposées à se faire vacciner en décembre, et 2,9 % étaient disposées à se faire vacciner en octobre, mais hésitaient en décembre.
Keleker (2021) (129) *nouveau* Étude transversale É.-U. Sept.-déc. 2020	248 étudiants en médecine dentaire (DS) et 167 étudiants en médecine (MS) de trois écoles dentaires et d'une école de médecine ont été interrogés en ligne sur leur comportement vaccinal passé et leur réticence actuelle envers le vaccin contre la COVID-19. Sujets des questions : 1) Intentions de se faire vacciner 2) Réticence à se faire vacciner 3) Attitudes envers les vaccins	• 23 % des étudiants en médecine et 45 % des étudiants en médecine dentaire ont déclaré qu'ils étaient réticents à se faire vacciner contre la COVID-19, ce qui indique que les étudiants en médecine étaient 2,7 fois plus susceptibles de se faire vacciner. • Les attitudes générales envers les vaccins étaient positives parmi les MS, 99,4 % d'entre eux étant d'accord pour dire que les vaccins sont importants pour rester en bonne santé en tant qu'un travailleur de la santé et 99,4 % croyant qu'ils ont un rôle à jouer pour en apprendre au sujet des vaccins pour leurs patients. • Les étudiants en MS étaient significativement plus susceptibles de soutenir la vaccination obligatoire pour le grand public (OR= 3,12, IC à 95 % : de 2,06

	Outils de sondage disponibles? Non Des recherches formatives ont-elles été menées? Oui Sondage prétesté? Non	à 4,76) et pour les travailleurs de la santé (OR= 5,18, IC à 95 % : de 3,15 à 8,76). • Les étudiants en MS étaient significativement plus susceptibles de faire confiance aux renseignements reçus sur les vaccins contre la COVID-19 que les étudiants en DS (OR= 3,51, IC à 95 % : de 2,09 à 6,08), mais étaient également plus susceptibles d'avoir des inquiétudes quant à l'efficacité du vaccin (OR= 2,78, IC à 95 % : de 1,80 à 4,36). • Il était plus improbable pour les MS que les DS de dire qu'ils ne se feraient vacciner que si cela était imposé par les systèmes scolaires ou de santé (OR= 0,38, IC à 95 % : de 0,22 à 0,62) ainsi que de déclarer qu'à l'âge adulte, ils ont refusé de se faire vacciner pour une raison autre qu'une maladie ou une allergie (OR= 0,41, IC à 95 % : de 0,23 à 0,73). • Dans l'analyse logistique, le fait d'appartenir à une minorité sous-représentée, de croire que la vaccination contre la COVID-19 devrait être obligatoire pour le public, de croire que la vaccination contre la COVID-19 est importante pour soi en tant que travailleur de la santé, de faire confiance aux renseignements sur le vaccin contre la COVID-19 était associé de manière significative à la volonté de recevoir un vaccin, tandis que la crainte d'avoir des effets indésirables et le fait de ne recevoir un vaccin que si nécessaire étaient associés au refus d'accepter de se faire vacciner.
Unroe (2020) (121) Étude transversale ÉTATS-UNIS Novembre 2020	Un sondage en ligne a été effectué auprès de 8 243 employés de maison de soins infirmiers et de personnes qui offrent des soins à domicile en Indiana afin d'évaluer leur volonté de se faire vacciner. Sujets des questions : 4) Intentions en ce qui concerne les vaccins	• 45 % des répondants seraient prêts à recevoir un vaccin approuvé par la FDA dès qu'il sera disponible. • Parmi ceux qui ne seraient pas prêts à recevoir le vaccin immédiatement, 44 % seraient prêts à le recevoir à une date ultérieure. • Les raisons les plus courantes de l'hésitation à se faire vacciner comprennent les effets secondaires potentiels (70 %), les préoccupations relatives à la santé (34 %), les préoccupations relatives à l'efficacité (20 %) et les motifs religieux (12 %).

	5) Hésitation par rapport à la vaccination Outils d'enquête disponibles? Non Recherches formatives effectuées? Non Enquête prétestée? Non	• Comparativement à leurs homologues, les personnes âgées de plus de 60 ans, les hommes et ceux qui se déclarent d'origine blanche étaient plus disposés à se faire vacciner (p < 0,0001). • Les travailleurs de la santé noirs étaient 12 % (IC à 95 % : 8,6 à 15,7 %) moins disposés à accepter le vaccin que les travailleurs de la santé blancs. • Le personnel responsable de l'alimentation, de l'entretien ménager et de l'administration était plus susceptible d'avoir l'intention de se faire vacciner que le personnel de soins cliniques, y compris les infirmières auxiliaires et les infirmières (p < 0,0001).
Shekhar (2021) (123) Étude transversale ÉTATS-UNIS Octobre et novembre 2020	Un sondage en ligne a évalué l'intention de se faire vacciner chez 3 479 travailleurs de la santé (âgés de 18 ans et plus). Sujets des questions : 1) Intentions en ce qui concerne les vaccins 2) Perception des vaccins Outils d'enquête disponibles? Non Recherches formatives effectuées? Non Enquête prétestée? Non	• 36 % des répondants ont dit être prêts à se faire vacciner dès que le vaccin serait disponible, 56 % ont dit ne pas être certains et voulaient examiner les données sur l'innocuité avant de se faire vacciner, et 8 % ont dit qu'ils refuseraient le vaccin. • L'intention de se faire vacciner a augmenté avec l'âge (34 % dans le groupe des 18 à 30 ans contre 47 % dans le groupe des plus de 70 ans). • Le sexe masculin, le niveau de scolarité supérieur, les niveaux de revenu plus élevés, le fait de vivre dans le Sud, dans une région urbaine et de s'identifier comme libéral ou démocrate étaient associés à une plus grande intention de se faire vacciner dès qu'il est disponible par rapport à leurs homologues. • Les travailleurs de la santé noirs (19 %) et amérindiens/autochtones de l'Alaska (10 %) étaient moins susceptibles que les travailleurs blancs (37 %) et asiatiques (44 %) (p < 0,001) d'avoir l'intention de se faire vacciner dès que les vaccins seraient disponibles. La majorité des travailleurs de la santé noirs (65 %), amérindiens (80 %) et tous les travailleurs de la santé hawaïens/autres insulaires du Pacifique (100 %) ont choisi d'attendre d'examiner les données avant de recevoir le vaccin.

		• L'intention de se faire vacciner dès qu'un vaccin serait disponible était plus faible chez ceux qui s'identifiaient comme hispaniques ou latino-américains (30 %) que chez ceux qui ne s'identifiaient pas à cette origine ethnique (37 %). • Les travailleurs qui croient être immunisés contre la COVID-19 (22 %), qui sont sûrs de ne pas être infectés (27 %), et ceux qui n'ont pas pris soin de patients atteints du COVID-19 (9,2 %) affichaient les taux les plus élevés d'intention de refuser un vaccin. • Les principales préoccupations exprimées au sujet de la vaccination comprennent la sécurité et les effets indésirables (69 %), l'efficacité (69 %) et la rapidité du développement et de l'approbation (74 %). • La majorité des travailleurs de la santé font confiance à leurs médecins et aux professionnels de la santé qui recommandent le vaccin (73 %), mais 46 % ne font pas confiance aux renseignements fournis par le gouvernement au sujet du vaccin et de sa gravité et 34 % ne font pas confiance aux organismes de réglementation (p. ex., CDC ou FDA) pour superviser la mise au point et l'innocuité des vaccins.
Caban-Martinez (2021) (133) Étude transversale États-Unis Octobre 2020	Aux États-Unis, un sondage en ligne a été mené auprès de 3 169 travailleurs des services médicaux d'urgence et pompiers afin d'évaluer leur intention de se faire vacciner. Sujets des questions : 1) Intentions en ce qui concerne la vaccination Outils d'enquête disponibles? Non	• 48,2 % étaient disposés à se faire vacciner lorsque le vaccin sera disponible, 27,6 % étaient moyennement disposés à le recevoir et 24,2 % étaient incertains. • Les personnes les plus susceptibles de ne pas accepter le vaccin étaient âgées de 30 à 39 ans (RCa 3,62, IC à 95 % : 2,00 à 6,55), de race noire (RCa 3,60, IC à 95 % : 1,12 à 11,53), de race multiple (RCa 2,98, IC à 95 % : 1,61 à 5,51), d'origine hispanique ou latine (RCa 2,39, IC à 95 % : 1,45 à 3,92), avaient un plus faible niveau d'éducation (RCa 2,06, IC à 95 % : 1,29 à 3,27), étaient ou non mariées (RCa 1,65, IC à 95 % : 1,03 à 2,65) et cette probabilité d'accepter ou non le

	Recherches formatives effectuées? Oui Enquête prétestée? Non	vaccin variait selon le grade actuel du pompier ou du travailleur des services médicaux d'urgence (RCa 2,21, IC à 95 % : 1,60 à 3,08).
Gadoth (2021) (120) Étude transversale ÉTATS-UNIS Septembre et octobre 2020	Pour comprendre l'intention des travailleurs de la santé de se faire vacciner et les attitudes à l'égard de l'innocuité, de l'efficacité et de l'acceptabilité des vaccins dans le contexte de la pandémie de COVID-19, un sondage en ligne a été mené auprès de 609 travailleurs de la santé. Sujets des questions : 1) Intentions en ce qui concerne les vaccins 2) Perception des vaccins 3) Hésitation par rapport à la vaccination Outils d'enquête disponibles? Non Recherches formatives effectuées? Oui Enquête prétestée? Non	• 47,8 % des participants ont déclaré qu'ils ne prendraient pas part à un essai de vaccin contre la COVID-19. • 65,5 % ont l'intention de retarder la vaccination et de ce nombre, 49,4 % préféreraient attendre et voir d'abord comment le vaccin affecte les autres. Comparativement aux médecins, le pourcentage corrigé de personnes qui ont déclaré leur intention de retarder la vaccination ou de refuser de se faire vacciner était de 0,52, de 0,54 et de 0,59 fois plus élevée chez les infirmières, les autres membres du personnel ayant des contacts avec les patients et ceux qui n'ont aucun contact avec les patients, respectivement. • Les répondants s'entendent pour dire que les vaccins sont utiles pour se protéger contre la maladie (score moyen de Likert de 4,69 IC à 95 % : 4,64 à 4,73) et pour protéger la santé de la collectivité (score moyen de Likert de 4,69 IC à 95 % : 4,65 à 4,74). Les médecins avaient toutefois une telle attitude plus souvent que les infirmières. • Les avis étaient partagés en ce qui concerne l'énoncé selon lequel les nouveaux vaccins comportent plus de risques que les vaccins plus anciens (score moyen de Likert de 3,23 IC à 95 % : 3,14 à 3,32). • Moins de la moitié des répondants (46,9 %) étaient d'avis qu'un vaccin les protégerait contre la COVID-19 et 34,8 % étaient confiants quant au processus de contrôle scientifique. • Les femmes et les minorités raciales ou ethniques ont exprimé des attitudes plus hésitantes à l'égard des vaccins que leurs homologues. • Les principales variables qui ont eu une incidence sur ceux qui prévoyaient retarder la prise du vaccin ou refuser de se faire vacciner étaient des

		préoccupations au sujet de la nature accélérée du développement du vaccin et du manque de transparence ou d'information publique à propos du vaccin.
Robbins (2021) (230) Étude transversale ROYAUME-UNI Septembre 2020	Un sondage en ligne a été mené auprès de 593 travailleurs de la santé dans un grand hôpital de référence tertiaire afin d'évaluer leur intention de se faire vacciner. Sujets des questions : 1) Intentions en ce qui concerne les vaccins 2) Perception des vaccins Outils d'enquête disponibles? Non Recherches formatives effectuées? Non Enquête prétestée? Non	• Si un vaccin était disponible et distribué gratuitement par l'entremise de leur employeur, et qu'il comportait des données appropriées sur l'innocuité et l'efficacité, 83,4 % des répondants seraient susceptibles de se faire vacciner. • 58,9 % seraient disposés à se faire vacciner en dehors de leurs heures normales de travail (p. ex., la fin de semaine) et 53,1 % seraient disposés à se rendre à un autre endroit pour se faire vacciner. • 68,5 % seraient prêts à se faire vacciner dans leur voiture et 76,6 % ne verraient pas d'inconvénient à attendre dans une file d'attente en respectant la distanciation physique pour se faire vacciner. • 77,8 % croient que les travailleurs de la santé devraient avoir la priorité pour recevoir un vaccin et 82,8 % croient que le personnel en première ligne qui traite directement les patients devrait avoir la priorité sur les gens qui n'ont aucun contact avec les patients.
Manning (2021) (124) Étude transversale ÉTATS-UNIS Août et septembre 2020	Les facteurs associés à l'intention de se faire vacciner ont été évalués dans un sondage en ligne effectué auprès de 78 membres à temps plein de la faculté des sciences infirmières, de 105 membres auxiliaires du corps professoral en soins infirmiers et de 1 029 élèves infirmiers. Sujets des questions : 1) Intentions en ce qui concerne les vaccins 2) Perception des vaccins	• L'intention de se faire vacciner était la plus élevée chez les membres à temps plein de la faculté (60,3 %), suivis des étudiantes (45,3 %) et des membres auxiliaires du corps professoral. • Les hommes étaient plus susceptibles que les femmes d'avoir l'intention de se faire vacciner (60,3 % comparativement à 44,9 %, P = 0,002). • Les personnes de 60 ans et plus avaient la plus forte intention de se faire vacciner (85,7 %, P = 0,004). • Les raisons les plus courantes pour lesquelles ces personnes voulaient se faire vacciner comprenaient le désir de protéger sa famille, soi-même, les patients et la collectivité, et la conviction que ce serait la meilleure façon d'éviter

	3) Hésitation par rapport à la vaccination Outils d'enquête disponibles? Non Recherches formatives effectuées? Oui Enquête prétestée? Oui	de tomber gravement malade à cause de la COVID-19. • Les raisons les plus fréquentes de ne pas vouloir se faire vacciner étaient le fait de croire que le vaccin avait été mis au point trop rapidement pour être sécuritaire, et les effets secondaires. Ces préoccupations ont été plus fréquemment signalées par les étudiants et le corps professoral clinique auxiliaire que par le corps professoral à temps plein ($P < 0,05$). • La vaccination obligatoire comme condition d'emploi était soutenue par 52 % du corps professoral à temps plein, 39 % du corps professoral auxiliaire et 35 % des étudiants.
Parente (2021) (126) *nouveau* Étude transversale É.-U. Août 2020	Les associations à l'adoption des vaccins ont été évaluées en ligne pour un vaccin hypothétique en tenant compte des périodes de retard (de 1 à plus de 12 mois après l'approbation) chez 3 347 travailleurs de la santé du Kentucky. Sujets des questions : 1) Intentions de se faire vacciner 2) Réticence à se faire vacciner Outils de sondage disponibles? Non Des recherches formatives ont-elles été menées? Oui Sondage prétesté? Oui	• 37,2 % des répondants ont accepté tôt de se faire vacciner, souhaitant être vaccinés dans le premier mois de l'approbation. • 22,3 % souhaitaient être vaccinés dans les 1 à 3 mois, 11,4 % dans les 4 à 6 mois, 6,9 % dans les 7 à 12 mois et 12,3 % plus de 12 mois après l'approbation. • 9,9 % déclarent qu'ils n'ont jamais l'intention de se faire vacciner. • Les raisons invoquées pour retarder ou refuser la vaccination étaient les effets secondaires à long terme (57,1 %), l'innocuité du vaccin (55,0 %), l'efficacité du vaccin (37,1 %), les risques par rapport aux avantages du vaccin (31,0 %), le coût du vaccin (12,2 %) et les allergies possibles (11,2 %). • Les répondants asiatiques étaient 1,53 fois plus susceptibles de déclarer vouloir se faire vacciner dans les trois mois comparativement aux répondants blancs. En revanche, les répondants noirs étaient significativement moins enclins à se faire vacciner au cours de la même période (OR 0,16, IC à 95 % : de 0,10 à 0,25). • L'adoption précoce d'un vaccin (dans les 3 mois) était significativement associée aux hommes (RCa

		2,43, IC à 95 % : de 2,00 à 2,95), ceux qui ont été vaccinés contre la grippe en 2019-2020 (RCa 2,35, IC à 95 % : de 1,75 à 3,18), une plus grande inquiétude concernant la COVID-19 (RCa 2,40, IC à 95 % : de 2,07 à 2,79), et des niveaux d'éducation plus élevés (RCa 1,41, IC à 95 % : de 1,21 à 1,65).
Hoke (2021) (132) Étude transversale ÉTATS-UNIS Mai 2020	Un sondage a été effectué en ligne auprès de 350 infirmières des écoles de soins infirmiers de Pennsylvanie (âgés de 18 ans et plus) pour évaluer l'intention de se faire vacciner et les perceptions à l'égard du vaccin. Sujets des questions : 3) Intentions en ce qui concerne les vaccins 4) Perception des vaccins Outils d'enquête disponibles? Non Recherches formatives effectuées? Non Enquête prétestée? Non	• 84,9 % des infirmières étaient disposées à se faire vacciner lorsqu'un vaccin sera disponible, 14,5 % ont dit qu'il était peu probable qu'elles se fassent vacciner et 0,6 % n'ont pas répondu. • 63,7 % appuyaient le retour à l'école même si les personnes n'avaient pas été vaccinées. • Comparativement aux infirmières en milieu rural, les infirmières en milieu urbain étaient plus disposées à recevoir un vaccin lorsqu'il serait disponible (RC = 2,21, IC à 95 % : 1,41 à 3,46) et étaient plus préoccupées par le retour à l'école sans avoir été vacciné (RC = 1,58, IC à 95 % : 1,05 à 2,38).
Sathianathan (2020) (231) Étude transversale ÉTATS-UNIS Mars 2020	Un sondage en ligne a été utilisé pour comparer les connaissances sur le vaccin contre la COVID-19 entre 4 966 travailleurs de la santé et 854 personnes qui travaillaient dans un secteur autre en Pennsylvanie. Sujets des questions : 1) Connaissance des vaccins Outils d'enquête disponibles? Oui	• Lorsqu'on leur a demandé si un vaccin contre la COVID-19 serait disponible dans un délai de trois mois, les travailleurs de la santé étaient plus susceptibles de répondre correctement (faux) que les personnes qui travaillent dans un autre domaine.

	Recherches formatives effectuées? Oui Enquête prétestée? Oui	

RCa = rapport des cotes ajustées, IC = intervalle de confiance

POPULATIONS À RISQUE ÉLEVÉ

ÉTUDE	MÉTHODES ET OUTILS D'ENQUÊTE	RÉSULTATS CLÉS RELATIFS AUX CONNAISSANCES, ATTITUDES ET COMPORTEMENTS
ENCEINTE OU QUI ALLAITENT		
Woolf (2021) *préimpression* (114) Étude transversale et étude qualitative ROYAUME-UNI Décembre 2020 à mars 2021	Pour évaluer l'hésitation à se faire vacciner contre la COVID-19 et les prédicteurs à cette hésitation, une enquête en ligne a été menée auprès de 11 584 travailleurs de la santé (16 et +). Les données qualitatives ont été recueillies par le biais d'entretiens (n = 24), de groupes de discussion (n = 17) et de réponses à des enquêtes ouvertes (n = 58). Tous les résultats concernant les travailleurs de la santé se trouvent dans la section TRAVAILLEURS DE LA SANTÉ. Sujets des questions : 1) Hésitation à se faire vacciner Outils d'enquête disponibles? Oui Des recherches formatives ont-elles été menées? Oui Enquête prétestée? Non	• Les travailleuses de la santé enceintes étaient 7,12 fois plus susceptibles d'être hésitantes que les travailleuses de la santé non enceintes (RR ajusté 7,12, IC 95 % : 4,74 % à 10,70 %).

Skjefte (2021) (135) Étude transversale 16 pays : Australie, Afrique, Argentine, Brésil, Chili, Colombie, Inde, Italie, Mexique, Nouvelle-Zélande, Pérou, Philippines, Russie, Espagne, Royaume-Uni, États-Unis. Octobre et novembre 2020	Un sondage en ligne a été utilisé pour évaluer le niveau d'acceptation de la vaccination contre la COVID-19 chez 5 294 femmes enceintes et 12 562 mères d'enfants de moins de 18 ans. Sujets des questions : 1) Intentions en ce qui concerne les vaccins 2) Hésitation par rapport à la vaccination Outils d'enquête disponibles? Non Recherches formatives effectuées? Non Enquête prétestée? Non	• Pour un vaccin efficace à 90 %, 52,0 % des femmes enceintes et 73,4 % des femmes non enceintes ont indiqué leur intention de se faire vacciner. • 69,2 % de toutes les femmes avaient l'intention de faire vacciner leurs enfants. Les niveaux d'acceptation étaient supérieurs à 85 % en Inde, au Mexique, au Brésil et en Colombie et inférieurs à 52 % aux États-Unis, en Australie et en Russie. • L'intention de se faire vacciner des femmes enceintes variait selon le pays avec des taux d'acceptation supérieurs à 80 % au Mexique et en Inde, et inférieurs à 45 % aux États-Unis, en Australie et en Russie. • La réticence à se faire vacciner était associée à un âge plus jeune, à un revenu plus faible, à un niveau de scolarité plus faible, au fait de ne pas être marié et à l'absence d'assurance-maladie. • Les prédicteurs les plus solides de l'intention de se faire vacciner étaient la confiance dans l'innocuité et l'efficacité du vaccin, le faire de croire à l'importance des vaccins pour leur propre pays, la confiance dans les vaccins de routine donnés pendant l'enfance, l'inquiétude au sujet de la COVID-19, la confiance dans les organismes de santé publique ou la science de la santé, et la conformité aux lignes directrices sur les couvre-visage. • 53,0 % des répondants étaient convaincus qu'un vaccin contre la COVID-19 approuvé à l'échelle nationale serait sans danger alors que 60,4 % étaient convaincus qu'il serait efficace. • Chez les femmes enceintes, les raisons les plus courantes de refuser un vaccin étaient les effets secondaires potentiels pour leur bébé (65,9 %), la crainte que l'approbation du vaccin soit précipitée pour des raisons politiques (44,9 %) et le manque de données sur l'innocuité et l'efficacité chez les femmes enceintes (48,8 %).

		• Pour les mères, les raisons les plus courantes de refuser un vaccin étaient la crainte que l'approbation du vaccin soit précipitée pour des raisons politiques (39,8 %), le manque de données sur l'innocuité et l'efficacité chez les enfants (32,7 %) et les préoccupations au sujet de l'innocuité et des effets secondaires (28,4 %). • Une recommandation d'un fournisseur de soins de santé a eu une incidence limitée sur l'intention de se faire vacciner. 45,9 % des femmes enceintes et 54,6 % des femmes non enceintes seraient plus susceptibles de se faire vacciner ou de faire vacciner leurs enfants si les fournisseurs de soins de santé le recommandaient.
Skirrow (2021) *préimpression* (19) Étude de prévalence et qualitative ROYAUME-UNI Août à octobre 2020	Un sondage en ligne et des entrevues semi-structurées ont été menés auprès d'un groupe de 1 181 femmes enceintes (âgées de 16 ans et plus) afin de déterminer leurs points de vue sur l'acceptabilité du vaccin contre la COVID-19 pour elles-mêmes lorsqu'elles sont enceintes ou non enceintes, ainsi que pour leur bébé. Sujets des questions : 1) Intentions en ce qui concerne la vaccination 2) Hésitation par rapport à la vaccination Outils d'enquête disponibles? Non Recherches formatives effectuées? Oui Enquête prétestée? Non	• 81,2 % des femmes ont déclaré qu'elles accepteraient certainement un vaccin ou auraient tendance à le faire si elles n'étaient pas enceintes. L'acceptation du vaccin était beaucoup plus faible pendant la grossesse (62,1 %, P < 0,005), ainsi que pour leurs bébés (69,9 %, p < 0,005). • Comparativement aux femmes de race blanche, les femmes de minorités ethniques étaient deux fois plus susceptibles de refuser un vaccin pour elles-mêmes lorsqu'elles n'étaient pas enceintes, étaient enceintes et pour leur bébé (P > 0,005). • Les personnes de ménages à faible revenu, âgées de moins de 25 ans et provenant de certaines régions géographiques étaient plus susceptibles de refuser un vaccin lorsqu'elles n'étaient pas enceintes, enceintes et pour leurs bébés. • Les femmes non vaccinées contre la coqueluche pendant la grossesse étaient plus de quatre fois plus susceptibles de refuser un vaccin lorsqu'elles n'étaient pas enceintes, enceintes et pour leur bébé. • L'analyse thématique a révélé que les raisons les plus courantes de réticence étaient l'innocuité du vaccin et une méfiance plus grande à l'égard des vaccins en général.

Battarbee (2021) *préimpression* (136) Étude transversale ÉTATS-UNIS Juillet à octobre 2020	915 femmes enceintes de l'Utah, de l'Alabama et de l'État de New York ont été interrogées au téléphone ou lors de visites en personne afin de mesurer leurs attitudes à l'égard du vaccin contre la COVID-19 et de l'acceptabilité de ce dernier. Sujets des questions : 1) Intentions en ce qui concerne les vaccins 2) Attitudes à l'égard des vaccins Outils d'enquête disponibles? Non Recherches formatives effectuées? Non Enquête prétestée? Non	• 41 % des femmes ont dit qu'elles accepteraient un vaccin, et cette donnée n'a pas varié en fonction du mois d'inscription à l'étude. • Les femmes disposées à accepter un vaccin ont cité des raisons comme le désir de protéger leur grossesse (95 %), de se protéger (85 %), de protéger les membres de leur famille (79 %) et de protéger leur communauté (68 %). • Celles qui ne sont pas disposées à se faire vacciner pendant leur grossesse ont dit qu'elles le refuseraient en raison de préoccupations au sujet de l'innocuité du vaccin pendant la grossesse (82 %), de l'innocuité pour elles-mêmes (68 %), de l'efficacité du vaccin (52 %) et de la croyance qu'elles n'ont pas besoin du vaccin (22 %). • Le fait d'avoir un diplôme d'études supérieures a multiplié par 2,4 la probabilité d'accepter un vaccin par rapport à celles qui n'avaient pas de diplôme d'études secondaires (IC à 95 % : 1,3 à 4,7). • Dans la modélisation multivariée, le fait de n'avoir reçu qu'un vaccin contre la grippe au cours de la dernière année (RCa = 2,1, IC à 95 % : 1,5 à 3,0) a permis d'augmenter le niveau d'acceptation du vaccin. À l'inverse, seule l'origine ethnique (répondantes hispaniques et noires) était associée au refus d'accepter un vaccin (RCa = 0,4, IC à 95 % : 0,2 à 0,6 chacun).
PERSONNES EN SITUATION D'ITINÉRANCE		
Kuhn (2021) *préimpression* (41) Étude transversale ÉTATS-UNIS	Le niveau d'adoption du vaccin et d'hésitation chez 90 personnes sans abri de Los Angeles (âgées de 18 ans et plus) a été évalué à l'aide d'un sondage effectué par téléphone cellulaire. Sujets des questions : 1) Adoption du vaccin	• Parmi les 90 participants, 17 se sont vus offrir un vaccin et de ce nombre, 10 ont accepté et 7 ont refusé. • Parmi les 73 participants à qui le vaccin n'a pas été offert, 51 % ont dit qu'ils le prendraient s'il leur était offert, 32 % ont dit qu'ils ne se feraient pas vacciner et 17 % ont refusé de répondre. • Dans l'ensemble, 48 % des personnes ont refusé un vaccin lorsqu'il leur était offert, ont dit qu'elles le refuseraient s'il leur était offert ou ont refusé de

Décembre 2020 à février 2021	2) Hésitation par rapport à la vaccination 3) Intentions en ce qui concerne les vaccins Outils d'enquête disponibles? Non Recherches formatives effectuées? Non Enquête prétestée? Non	répondre et ont donc été jugées « hésitantes face à la vaccination ». • Parmi les participants qui hésitaient à se faire vacciner, les raisons les plus souvent mentionnées étaient la peur des effets secondaires (37 %), le désir d'avoir plus d'information (30 %) et le fait qu'ils ne veulent pas recevoir de vaccin (27 %). • Selon une analyse multivariée, les personnes qui ont une perception élevée de la menace que représente la COVID-19 (RC = 0,25, P = 0,02) et celles qui faisaient confiance à des sources officielles (RC = 0,37, P = 0,08) étaient beaucoup moins susceptibles d'hésiter à se faire vacciner. Celles qui avaient un comportement hautement protecteur (RC = 3,63, P = 0,02) et celles qui faisaient confiance à leurs contacts personnels (RC = 2,70, P = 0,07) étaient plus susceptibles d'hésiter.
Knight (2021) *préimpression* (137) Étude qualitative ÉTATS-UNIS Juillet à octobre 2020	Pour comprendre les facteurs et les obstacles à l'acceptabilité du vaccin chez les adultes sans abri (âgés de 20 à 71 ans), une étude qualitative a été effectuée auprès deux échantillons de gens : 1) une cohorte longitudinale de 37 adultes âgés sans abri à Oakland, en Californie, et 2) un échantillon de proximité comprenant 57 personnes pendant une activité de dépistage mobile de la COVID-19 à San Francisco, en Californie. Sujets des questions : 1) Intentions en ce qui concerne les vaccins 2) Hésitation par rapport à la vaccination	• De nombreux participants ont indiqué qu'ils étaient disposés à recevoir un vaccin lorsqu'il serait disponible. Ils ont cité le désir de retourner à la vie de tous les jours et la responsabilité civique comme raisons pour se faire vacciner. • Quatre thèmes se sont dégagés en ce qui concerne la réticence à l'égard de la vaccination, notamment : 1) le désir d'obtenir plus de données sur les essais, l'innocuité et l'approbation du vaccin, 2) des préoccupations associées au fait que les vaccins rendaient les gens malades, 3) le désir d'attendre que d'autres aient reçu le vaccin avant d'accepter de se faire vacciner, et 4) la méfiance à l'égard du gouvernement. Certains ont fait un lien entre cette méfiance et des expériences antérieures de racisme. • En dépit de l'exclusion sociale et du manque d'accès à la technologie, les participants ont suivi les reportages sur le vaccin et l'information souhaitée sur l'efficacité et l'innocuité du vaccin.
ADULTES PLUS ÂGÉS		

Horizon Research (2021) *non publiée* (15, 195, 232) Étude longitudinale Nouvelle-Zélande Mars à mai 2021	Un sondage effectué en ligne auprès d'adultes (âgés de 16 ans et plus) visait à évaluer l'adoption du vaccin. Mars et avril, n = 1 350 Avril et mai, n = 1 387 Mai, n=1,234 *nouvelle* Sujets des questions : 1) Intentions en ce qui concerne la vaccination Outils d'enquête disponibles? Oui Recherches formatives effectuées? Non Enquête prétestée? Non	**Mai** • 9 % des 65 à 74 ans et 14 % des 75 ans et plus étaient peu susceptibles de se faire vacciner. • Les principales préoccupations des personnes âgées de 65 à 74 ans étaient les effets secondaires (30 %), les effets à long terme (28 %) et la crainte de ce qui se produirait si elles avaient une réaction indésirable (26 %). On a observé des préoccupations semblables chez les plus de 75 ans. **Avr-mai** • 81 % des 65 à 74 ans et 88 % des personnes âgées de 75 ans et plus ont dit qu'elles se feraient probablement vacciner.
Australia Bureau of Statistics (2021) *Non publié* (141) *nouveau* Étude longitudinale Australie Avril 2020-mai 2 021	Le sondage sur les impacts sur les ménages est un sondage mensuel qui recueille des données en ligne et par téléphone auprès d'un groupe d'adultes (18 ans et plus) sur des sujets liés à la COVID-19, y compris les attitudes envers les vaccins. Mai : n=3371 Sujets des questions : 1) Intentions de se faire vacciner Outils de sondage disponibles? Non	• 7.6 % des personnes âgées de plus de 70 ans ne se feraient certainement pas vacciner si on leur proposait et 9,4 % ne se feraient probablement pas vacciner si on leur proposait. • La recommandation du médecin généraliste était le facteur le plus important dans la décision de se faire vacciner chez 41,1 % des personnes âgées de 70 ans et plus.

	Des recherches formatives ont-elles été menées? Non Sondage prétesté? Non	
Office for National Statistics (2021) *non publiée* (140) Étude transversale ROYAUME-UNI Février et mars 2021	17 201 réponses provenant de quatre vagues de résultats recueillis dans le cadre du sondage en ligne Opinions and Lifestyle Survey (126) ont été mises en commun pour mettre l'accent sur les associations démographiques spécifiques et la réticence à se faire vacciner. Sujets des questions : 1) Intentions en ce qui concerne les vaccins 2) Hésitation par rapport à la vaccination Outils d'enquête disponibles? Oui Recherches formatives effectuées? Oui Enquête prétestée? Oui	• 3 % des 65 à 69 ans et 5 % des 60 à 64 ans ont dit hésiter à se faire vacciner. 4 % des 55 à 59 ans aussi étaient hésitants. • Parmi les personnes âgées de 75 à 79 ans qui étaient très ou assez peu susceptibles de se faire vacciner, 49 % ont déclaré être contre les vaccins en général, 46 % ont mentionné des préoccupations au sujet d'une condition préexistante et 31 % avaient d'autres raisons. • Les inquiétudes chez les 65 à 79 ans étaient plus variées et incluaient notamment les préoccupations concernant les effets secondaires, les effets à long terme, les inquiétudes au sujet des problèmes de santé existants, le fait de ne pas croire que le vaccin est dangereux et le désir de voir si le vaccin fonctionne. • Les personnes âgées de 55 à 64 ans avaient d'autres croyances selon lesquelles elles n'étaient pas à risque ou croyaient déjà avoir eu la COVID-19.
Nikolovski (2021) (139) Étude transversale ÉTATS-UNIS Novembre 2020	Un sondage a été effectué auprès de 7 402 adultes âgés (de 65 ans et plus) à l'aide d'une application mobile sur la santé pour déterminer les facteurs associés aux intentions de se faire vacciner de cette population. Sujets des questions : 1) Intentions en ce qui concerne les vaccins 2) Hésitation par rapport à la vaccination	• 91,3 % des participants ont déclaré qu'ils étaient disposés ou plutôt disposés à se faire vacciner alors que 8,7 % n'étaient pas disposés à se faire vacciner ou étaient quelque peu réticents à le faire. • L'hésitation était la plus forte chez les femmes (RC = 0,49, IC à 95 % : 0,45 à 0,54) et les Afro-Américaines ou les Noires (RC = 0,24, IC à 95 % : 0,18 à 0,31). • Les participants qui ont déclaré un revenu plus élevé (RC = 2,60, IC à 95 % : 1,98 -3,42) ou un niveau de scolarité plus élevé (RC = 2,31, IC à 95 % : 1,84 à 2,94) étaient plus susceptibles d'avoir l'intention de se faire vacciner.

	Outils d'enquête disponibles? Oui Recherches formatives effectuées? Non Enquête prétestée? Non	• Les croyances fortement associées à l'intention de se vacciner étaient la protection de soi et des autres (RC = 38,6, IC à 95 % : 32,4 à 46,1), un vaccin sûr et efficace (RC = 21,6, IC à 95 % : 18,9 à 24,7) et le confort avec des effets secondaires à court terme (RC = 10,9, IC à 95 % : 9,1 à 13,1). • La majorité des répondants voulaient parler à un fournisseur de soins de santé avant de prendre la décision de se faire vacciner. Cela comprend tant ceux qui sont prêts à se faire vacciner (91,4 % des femmes et 88,9 % des hommes) que ceux qui ne le sont pas (68,4 % des femmes et 62,3 % des hommes). • Les nouvelles positives concernant le vaccin étaient associées à une augmentation des intentions de se faire vacciner. Après la diffusion des résultats de l'essai clinique de phase 3 de Pfizer, l'intention de se faire vacciner a augmenté (RC = 1,46, IC à 95 % : 1,28 à 1,69).
Luo (2021) (150) *nouveau* Étude transversale É.-U. Oct.-nov. 2020	En utilisant le Medicare Current Beneficiary Survey, 6 715 bénéficiaires de Medicare (âgés de 65 ans et plus) ont été interrogés par téléphone sur leurs intentions de se faire vacciner contre la COVID-19. Sujets des questions : 1) Intentions de se faire vacciner 2) Réticence à se faire vacciner Outils de sondage disponibles? Non Des recherches formatives ont-elles été menées? Non Sondage prétesté? Non	• 61,0 % (IC à 95 % : de 59,1 à 63,0) seraient disposés à se faire vacciner lorsque les vaccins seront disponibles et 39,0 % (IC à 95 % : de 37,0 à 40,9) étaient réticents à se faire vacciner. • 59,6 % des personnes âgées de 65 à 74 ans ont déclaré être prêtes à se faire vacciner, contre 63,5 % des personnes âgées de 75 ans et plus. • Les répondants âgés de 65 à 74 ans (RCa 0,83, IC à 95 % : de 0,74 à 0,92), les Noirs non hispaniques (RCa 0,33, IC à 95 % : de 0,24 à 0,44), hispanique (RCa 0,60, IC à 95 % : de 0,47 à 0,77), les femmes (RCa 0,56, IC à 95 % : de 0,48 à 0,64), les personnes ayant un revenu inférieur à 25 000 dollars (RCa 0,71, IC à 95 % : de 0,62 à 0,81), et celles qui ne pensaient pas que la COVID-19 était plus contagieuse (RCa 0,53, IC à 95 % : de 0,41 à 0,69) ou plus mortelle (RCa 0,51, IC à 95 % : de 0,41 à 0,65) étaient significativement moins susceptibles de se faire vacciner.

		• Les principales raisons citées pour la réticence à se faire vacciner sont la faible confiance dans le gouvernement (42,1 %), la crainte des effets secondaires (41,3 %) et l'incertitude quant à l'efficacité du vaccin (11,3 %). • L'intention de se faire vacciner était significativement plus élevée chez les personnes ayant un accès à Internet à domicile que chez celles n'en ayant pas (RCa 1,22, IC à 95 % : de 1,01 à 1,49).
Callow (2021) (233) Étude transversale États-Unis Août 2020	Pour examiner l'impact des attitudes, des normes subjectives et du contrôle comportemental perçu sur les attitudes à l'égard de la vaccination, on a effectué un sondage en ligne auprès de 583 adultes (âgés de 60 ans et plus) du Delaware, du Maryland, de Washington DC et de Virginie. Sujets des questions : 1) Attitudes à l'égard des vaccins Outils d'enquête disponibles? Non Recherches formatives effectuées? Oui Enquête prétestée? Non	• On a observé des attitudes plus favorables à l'égard des vaccins contre la COVID-19 chez les hommes (β = 0,10, P < 0,01), chez les personnes qui avaient déjà reçu le vaccin contre la grippe (β = 0,15, P < 0,001), chez celles qui percevaient la maladie comme étant plus grave (β = 0,11, P < 0,01) et chez celles qui avaient une attitude positive à l'égard des vaccins en général (β = 0,48, P < 0,001). • Comparativement à ceux qui se sont identifiés comme des démocrates forts, les scores d'attitude face au vaccin étaient moins favorables chez les démocrates modérés (β = 0,08, P < 0,05), les indépendants (β = 0,26, P < 0,001), les républicains modérés (β = 0,16, P < 0,001) et les républicains forts (β = 0,44, P < 0,001).
Waite (2021) (92) Étude transversale Canada Mai 2020	Un sondage en ligne a été effectué auprès de 1 001 Canadiens âgés de 50 à 64 ans et auprès de 3 500 Canadiens âgés de 65 ans et plus afin d'évaluer les intentions de se faire vacciner contre la COVID-19. Sujets des questions :	• Parmi les 50 à 64 ans, 69,1 % ont dit avoir l'intention de se faire vacciner lorsque les vaccins seront disponibles, 11,3 % ne se feront pas vacciner et 19,6 % étaient incertains. • 79,5 % des 65 ans et plus ont l'intention de se faire vacciner lorsque le vaccin sera disponible, 5,6 % refuseront de le faire et 14,9 % ont dit être incertains. • Dans les deux groupes d'âge, les personnes qui acceptaient de se faire vacciner étaient beaucoup

	1) Intentions en ce qui concerne la vaccination 2) Attitudes à l'égard des vaccins Outils d'enquête disponibles? Non Recherches formatives effectuées? Oui Enquête prétestée? Non	plus susceptibles d'être de sexe masculin et d'avoir au moins un problème de santé chronique (P < 0,05). • L'endroit privilégié pour recevoir un vaccin chez ces deux groupes était le bureau du médecin de famille, suivi de la pharmacie, du lieu de travail (pour les 50 à 64 ans) et des cliniques de santé publique.
Williams (2020) (138) Étude transversale ROYAUME-UNI Avril 2020	Un sondage en ligne effectué auprès de 311 adultes âgés (65 ans et plus) et de 216 patients atteints d'une maladie respiratoire chronique (âgés de 18 à 64 ans) a été utilisé pour évaluer l'intention de se faire vacciner et les perceptions à l'égard du vaccin. Sujets des questions : 1) Intentions en ce qui concerne les vaccins Outils d'enquête disponibles? Oui Recherches formatives effectuées? Oui Enquête prétestée? Non	• Dans la population totale (n = 527), 58 % et 27 % des participants ont dit qu'ils voudraient certainement ou probablement se faire vacciner une fois que le vaccin sera disponible. Il n'y avait pas de différence entre le groupe des adultes plus âgés et le groupe des personnes ayant une maladie respiratoire chronique (p = 0,78). • La volonté de se faire vacciner contre la COVID-19 était associée positivement à la croyance que l'éclosion de la COVID-19 allait se poursuivre pendant longtemps (0,09, p < 0,05) et associée négativement à la croyance que les médias ont exagéré les risques d'attraper la COVID-19 (-0,122, p < 0,05). • Une analyse thématique des commentaires associés au sondage a révélé que la « santé personnelle » (n = 176), la « gravité de la COVID-19 » (n = 85) et les « conséquences pour la santé des autres » (n = 36) étaient vues comme des facteurs qui facilitaient la vaccination, alors que les « préoccupations au sujet de l'innocuité du vaccin » (n = 158) constituent plutôt un obstacle à l'adoption du vaccin.
CONSOMMATION DE DROGUES ET D'ALCOOL		
Yang (2021) (147) Étude transversale	L'intention de se faire vacciner et la réticence à se faire vacciner de 387 adultes (âgés de 18 ans et plus) aux États-Unis qui ont déjà utilisé des produits du tabac ou de la	• 49,1 % étaient prêts à se faire vacciner, 26,0 % ont dit ne pas l'être alors que 24,9 % étaient indécis. • La consommation de cigarettes, de cigarettes électroniques, de marijuana et de boissons

États-Unis Décembre 2020 à janvier 2021	marijuana ont été évaluées au moyen d'un sondage en ligne. Sujets des questions : 1) Intentions en ce qui concerne la vaccination 2) Hésitation par rapport à la vaccination Outils d'enquête disponibles? Non Recherches formatives effectuées? Non Enquête prétestée? Non	alcoolisées n'était pas associée à la réticence à se faire vacciner. • Ceux qui étaient Noirs, qui vivaient en banlieue ou en milieu rural, qui vivaient seuls ou avec une famille de cinq membres ou plus, et ceux qui n'étaient pas stressés à cause de la pandémie de COVID-19 étaient plus susceptibles de ne pas accepter un vaccin lorsqu'il serait offert. • Comparativement à ceux qui avaient reçu un vaccin contre la grippe chaque année ou presque, ceux qui n'avaient jamais reçu de vaccin contre la grippe, une seule fois ou certaines années étaient 7,0, 6,2 et 5,2 fois plus susceptibles de ne pas accepter de vaccin.
Spechler (2021) *préimpression* (146) Étude transversale É.-U. Décembre 2020 à janvier 2021	Un groupe de 45 consommateurs de cannabis (déclarant avoir consommé plus de 10 fois du cannabis au cours de leur vie) a été apparié à 45 personnes ayant déclaré avoir consommé moins de 10 fois du cannabis au cours de leur vie afin d'évaluer la volonté de recevoir un vaccin contre la COVID-19 à l'aide d'une enquête en ligne. Sujets des questions : 1) Intentions de se faire vacciner Outils d'enquête disponibles? Non Des recherches formatives ont-elles été menées? Non Enquête prétestée? Non	• La volonté de recevoir un vaccin ne diffère pas significativement entre les consommateurs de cannabis et les témoins *(t88* = 0,33, P = 0,74; BF_{01} = 4,3). • Parmi les consommateurs de cannabis, l'augmentation de la consommation de cannabis au cours de la vie était corrélée à une volonté moindre de se faire vacciner *(r43*= -0,33, P = 0,03).
Masson (2021) (234) *nouveau*	258 Californiens souffrant de troubles liés à l'abus de substances ont reçu des sondages sur papier dans des programmes de	• 11,2 % des participants font totalement confiance, 28,3 % font plutôt confiance et 28,3 % font légèrement confiance au fait que le vaccin contre la COVID-19 serait sûr et efficace. 32,2 % ne

Étude transversale É.-U. Août-déc. 2020	traitement des toxicomanies et ont été interrogés sur leur confiance dans les vaccins contre la COVID-19. Sujets des questions : 1) Perception des vaccins Outils de sondage disponibles? Non Des recherches formatives ont-elles été menées? Non Sondage prétesté? Non	croient pas qu'un vaccin contre la COVID-19 soit sûr et efficace. • Dans la modélisation multivariée, seuls l'âge (RCa 1.03, IC à 95 % = de 1,02 à 1,05) et le port régulier du masque par rapport au port moins fréquent (RCa 2.48, IC à 95 % = de 1,86 à 3,31) étaient significativement associés à la confiance dans les vaccins, alors que les Afro-Américains étaient moins susceptibles de faire confiance aux vaccins que les Blancs non hispaniques (RCa 0,41, IC à 95 % = de 0,23 à 0,70).
Jackson (2020) *préimpression* (145) Étude transversale ROYAUME-UNI Sep à Oct 2020	Dans le cadre de l'étude sociale sur la COVID-19, un sondage en ligne a été mené auprès de 29 148 fumeurs actuels, anciens fumeurs et personnes n'ayant jamais fumé, afin de déterminer les attitudes générales envers le vaccin et les intentions de se faire vacciner contre la COVID-19. Sujets des questions : 1) Intentions en ce qui concerne les vaccins 2) Hésitation par rapport à la vaccination Outils d'enquête disponibles? Non Recherches formatives effectuées? Oui Enquête prétestée? Non	• L'intention de se faire vacciner était de 66 % (IC à 95 % : de 64,9 à 67,1 %) chez les anciens fumeurs, de 65,8 % (IC à 95 % : de 65.1 à 66,4 %) chez les personnes n'ayant jamais fumé, et de 50,9 % (IC à 95 % : de 49,3 à 52,6 %) chez les fumeurs actuels. • Les fumeurs actuels étaient à la fois les plus indécis (27,6 %, IC à 95 % : de 26.1 à 29,1 %) et réticents (21,5 %, IC à 95 % : de 20,2 à 22,9 %) à avoir l'intention de se faire vacciner une fois le vaccin disponible. • Les attitudes négatives envers les vaccins étaient les plus élevées chez les fumeurs actuels (de 10,6 à 24,0 %), puis chez les anciens fumeurs (de 8,8 à 19,4 %), et les plus faibles chez les personnes n'ayant jamais fumé (de 5,9 à 17,7 %). • Les fumeurs actuels étaient les plus préoccupés par les effets futurs imprévus, avaient une méfiance envers les avantages des vaccins et la recherche de profits excessifs, et avaient une préférence plus marquée pour l'immunité naturelle.
Mellis (2021) (144)	Des entrevues téléphoniques et par vidéo structurées ont été effectuées auprès de 87 personnes qui consomment actuellement des	• 45 % des répondants ont dit qu'ils étaient immédiatement prêts à se faire vacciner, 8 % étaient prêts à se faire vacciner après un certain

Étude transversale ÉTATS-UNIS Septembre 2020	substances, suivent un traitement ou sont en cure de désintoxication pour déterminer leur confiance et leur état de préparation à la vaccination contre la COVID-19. Sujets des questions : 3) Intentions en ce qui concerne les vaccins 4) Hésitation par rapport à la vaccination Outils d'enquête disponibles? Non Recherches formatives effectuées? Non Enquête prétestée? Non	temps, 23 % étaient incertains et 25 % n'étaient pas prêts. • Les répondants ont déclaré hésiter en raison de la rapidité du développement du vaccin, des effets secondaires potentiels, du fait qu'ils ne croyaient pas être à risque élevé et de leurs inquiétudes au sujet des interactions avec des problèmes préexistants. • Les sources de confiance pour les décisions en matière de soins de santé incluaient le médecin (y compris ceux qui étaient hésitants), les membres de la famille, les médias sociaux, la télévision/les journaux, la radio, les sites Web officiels, les NIH/CDC, la famille, les données de recherche/revues médicales et Internet. • La possibilité qu'un vaccin nécessite des doses multiples n'a pas modifié l'intention de se faire vacciner, mais les répondants ont mentionné des obstacles potentiels comme l'accès aux cliniques et la prise de rendez-vous.
COMMUNAUTÉS VULNÉRABLES		
Marquez (2021) *préimpression* (3) *nouveau* Étude transversale É.-U. Février-mai 2021	Un site de vaccination communautaire (Unidos en Salud UeS) a été déployé en février pour surmonter les obstacles à la vaccination contre la COVID-19 auxquels sont confrontés les LatinsX à San Francisco. Le site communautaire a été évalué grâce à 997 réponses à des sondages en personne (du 2 au 19 mai) auprès des personnes âgées de plus de 16 ans et aux données de surveillance sur la COVID-19 de la ville. Sujets des questions : 1) Perception des vaccins	• 36,1 % des répondants ont découvert le site par l'intermédiaire d'un ami, d'un membre de la famille ou d'un collègue, 21 % par message texte, 17,8 % en voyant le site et 11,4 % par recommandation directe. Les répondants latinsX étaient plus susceptibles de déclarer avoir vu le site que d'avoir reçu une invitation directe. • La raison la plus souvent citée pour le choix du site communautaire est l'emplacement (28,6 %), la commodité des horaires (26,9 %) et une recommandation fiable (18,1 %). • 99 % des personnes se rendant sur le site communautaire ont déclaré avoir vécu une expérience positive. • 58,4 % des répondants déclarent s'être fait vacciner plus tôt grâce au site (56,1 % des LatinsX et 63,2 % des non-LatinsX).

	Outils de sondage disponibles? Non Des recherches formatives ont-elles été menées? Oui Sondage prétesté? Non	• 90,1 % des répondants ont estimé qu'ils étaient plus susceptibles de recommander de se faire vacciner après avoir été vaccinés à l'UeS. • 65,3 % des clients latinsX ont contacté trois personnes ou plus pour recommander la vaccination (55,9 % des clients non latinsX).
Berenson (2021) (235) *nouveau* Étude transversale É.-U. Nov-Déc 2020	342 femmes à faibles revenus (âgées de 18 à 45 ans) ont été recrutées dans trois cliniques de reproduction du Texas pour répondre anonymement à un sondage papier en anglais ou en espagnol concernant les intentions de se faire vacciner contre la COVID-19. Sujets des questions : 1) Intentions de se faire vacciner 2) Perception des vaccins Outils de sondage disponibles? Non Des recherches formatives ont-elles été menées? Non Sondage prétesté? Non	• 33,5 % des répondants se feraient vacciner dès que possible, mais cette proportion augmente si le vaccin est recommandé par l'employeur (33,9 %), par des amis ou des membres de la famille (36,7 %), s'il est offert gratuitement (41,8 %) ou s'il est recommandé par leur médecin (49,5 %). • L'adoption d'un vaccin contre la COVID-19 recommandé par un médecin était associée au fait d'avoir reçu un vaccin annuel contre la grippe, d'avoir reçu le vaccin contre le VPH, d'avoir peur d'attraper la COVID-19 et que leurs sentiments étaient liés à des renseignements puisés dans les médias sociaux. • Dans l'analyse multivariée seule, le fait d'avoir été vacciné contre le VPH et d'avoir été vacciné contre la grippe chaque année était significativement associé à une probabilité accrue d'accepter un vaccin s'il était recommandé par un médecin (RCa 2,26 IC à 95 % : de 1,07 à 4,79 et un RCa 2,78 (IC à 95 %) : de 1,39 à 5,58 respectivement). • La plupart des répondants ont déclaré avoir besoin de plus de renseignements sur l'innocuité des vaccins (69,2 %) et de preuves de leur efficacité (48,1 %).
Gehlbach (2021) *préimpression* (236) *nouveau* Étude qualitative É.-U.	Des groupes de discussion semi-structurés menés sur la plateforme de vidéoconférence Zoom avec 55 travailleurs agricoles latinsX/autochtones en Californie visaient à éclaircir les thèmes communs liés aux attitudes et aux comportements envers la COVID-19.	• Les thèmes englobent la désinformation et les obstacles à l'accès à l'information (accès à Internet, information dans la langue de leur choix, connaissance des sources d'information appropriées/correctes concernant la COVID-19). • La méfiance politique/institutionnelle (gouvernement et santé publique) a joué dans les mythes liés au vaccin comme méthode de contrôle ou dans le désir exprimé de ne pas être un cobaye.

Nov-déc. 2021	Sujets des questions : 1) Perception des vaccins 3) Attitudes à envers les vaccins	• L'inquiétude quant à l'état de leur documentation était un facteur clé tant pour le dépistage que pour le comportement de vaccination anticipée.
Ekezie (2020) (237) Étude qualitative ROYAUME-UNI Juin et juillet 2020	Trois groupes de discussion et 47 entrevues semi-structurées ont été utilisés pour évaluer les perceptions des minorités ethniques et des communautés vulnérables à l'égard de la participation aux essais des vaccins. Parmi les 70 participants, on comptait des Sud-Asiatiques, des Africains et des Afro-Caraïbes, des Polonais blancs, des Britanniques blancs et des représentants d'autres groupes vulnérables, y compris des personnes ayant des problèmes de santé mentale, des sans-abri et des membres des communautés Tzigane, Rom et Traveller.	• L'appréhension générale, le scepticisme et le faible niveau de confiance ont été observés dans tous les groupes. Ces attitudes ont été influencées par le manque d'information et par la spéculation en ce qui concerne les intentions cachées possibles des concepteurs de vaccins et du gouvernement. • La plupart des participants ont déclaré qu'ils étaient anxieux et effrayés à l'idée de prendre part à des essais de vaccins ou qu'ils ne voulaient tout simplement pas y participer. • Bien qu'hésitants, la plupart des participants sud-asiatiques étaient ouverts à participer à des recherches, mais pas nécessairement à des recherches effectuées en milieu hospitalier. Ce groupe était préoccupé par le fait que le vaccin pourrait contenir des produits animaux interdits dans diverses religions. Ils ont également fortement recommandé que la recherche ne tombe pas pendant le ramadan ou les périodes de jeûne. • Les participants africains et caribéens étaient les plus méfiants quant à la rapidité du développement du vaccin et aux intentions des entreprises qui y prennent part. On se méfiait beaucoup de ce qu'on ferait de leur ADN, et certains croyaient que le vaccin avait été mis au point pour éradiquer les Noirs. • Les personnes ayant des problèmes de santé mentale se sont dites préoccupées par la divulgation de renseignements sur la santé mentale et la perte de confidentialité. • Les sans-abri hésitaient à se rendre dans les hôpitaux, sauf en cas d'urgence. Il est souvent difficile de maintenir le contact avec ce groupe, de

		sorte qu'il peut avoir besoin d'une plus grande participation en personne dans des lieux communautaires comme les banques alimentaires. • Les participants membres des communautés tziganes, rom et traveller avaient un intérêt très limité pour les vaccins et avaient tendance à avoir une approche fataliste des problèmes de santé, croyant « ce qui doit arriver va arriver ».
Scott (2021) (142) Étude transversale ÉTATS-UNIS Avril 2020	Un sondage a été envoyé par la poste à 391 familles amish en Ohio pour déterminer les intentions de se faire vacciner contre la COVID-19. Sujets des questions : 1) Intentions en ce qui concerne les vaccins 2) Hésitation par rapport à la vaccination Outils d'enquête disponibles? Non Recherches formatives effectuées? Oui Enquête prétestée? Non	• 75,7 % n'avaient pas l'intention de faire vacciner leurs enfants contre la COVID-19. • Aucune différence significative dans l'intention de se faire vacciner contre la COVID-19 n'a été observée entre les personnes avec et sans enfants ayant des besoins spéciaux (14,8 % c. 7,6 %, P = 0,053). • Les Swartzentruber Amish étaient beaucoup moins susceptibles d'avoir l'intention de se faire vacciner que les autres membres des Amish (0,0 % contre 11,7 %, P < 0,001). • Les principales raisons génériques pour refuser le vaccin comprenaient un trop grand nombre d'effets secondaires (83,9 %), le fait qu'ils contiennent des produits chimiques/agents de conservation dangereux (46,0 %), le fait que se faire vacciner signifie ne pas faire confiance à Dieu pour protéger leurs enfants (13,0 %), le fait que la vaccination introduit des germes (9,6 %), le fait que d'autres familles ne se feront pas vacciner (7,0 %) et que les maladies pour lesquelles ils sont vaccinés ne sont pas un problème dans leur communauté (6,1 %). • Les personnes qui citent les médecins ou les infirmières comme étant la personne la plus influente dans la décision de se faire vacciner étaient plus susceptibles de recevoir tous les vaccins recommandés que celles qui n'ont reçu aucun vaccin (52,2 % c. 2,6 % P < 0,001). Toutefois, les familles qui ont refusé tous les vaccins recommandés étaient plus susceptibles de déclarer

		que leur évêque ou leur ministre était la personne la plus influente dans la décision de se faire vacciner comparativement aux familles qui ont reçu tous les vaccins (4,4 % comparativement à 0,0 %, P = 0,003).
GENERAL		
Horizon Research (2021) *non publiée* (15, 195) Étude longitudinale Nouvelle-Zélande Mars à mai 2021	Une enquête en ligne a été menée auprès des adultes (16 ans et plus) pour mesurer le taux d'utilisation du vaccin. Mar-Avr, n=1,350 Avr-Mai, n=1,387 Sujets des questions : 1) Prise du vaccin Outils d'enquête disponibles? Oui Des recherches formatives ont-elles été menées? Non Enquête prétestée? Non	• 83 % des personnes qui présentaient un risque élevé de tomber très malades avaient l'intention de se faire vacciner ou étaient déjà vaccinées, alors que 5 % ont déclaré qu'elles ne se feraient certainement pas vacciner.

CCPM = Centres pour contrôle et la prévention des maladies, NIH = Instituts nationaux de la santé

PERSONNES AYANT DES COMORBIDITÉS OU DES INCAPACITÉS

Tableau 6. Éléments de preuve des personnes atteintes de comorbidités sur les attitudes à l'égard du vaccin (n = 23)

ÉTUDE	MÉTHODES ET OUTILS D'ENQUÊTE	RÉSULTATS CLÉS RELATIFS AUX CONNAISSANCES, ATTITUDES ET COMPORTEMENTS
CANADA		
Vallis (2021) (164)	Les attitudes et les préoccupations à l'égard de la vaccination contre la COVID-19 chez les personnes en	

Étude transversale Canada Juin à octobre 2020	surpoids et atteintes d'obésité ont été évaluées par un sondage en ligne. Deux échantillons ont été utilisés : 1) un échantillon représentatif de 1 089 personnes en surpoids et atteintes d'obésité, et 2) un échantillon de proximité de 980 personnes recrutées auprès de services cliniques ou d'organisations de patients en obésité partout au Canada. Sujets des questions : 1) Intentions en ce qui concerne les vaccins 2) Hésitation par rapport à la vaccination Outils d'enquête disponibles? Non Recherches formatives effectuées? Oui Enquête prétestée? Non	• 64,6 % des personnes atteintes d'obésité se sentaient à l'aise de recevoir un vaccin alors que 35,4 % hésitaient. • Les personnes étaient moins à l'aise avec le fait que leurs enfants se fassent vacciner (58,5 % étaient à l'aise alors que 41,6 % hésitaient, P < 0,001). • Le score moyen sur la sous-échelle de la confiance dans l'échelle de l'hésitation à se faire vacciner était considérablement inférieur à toute autre mesure (moyenne = 2,26). • La peur de la COVID-19 était un prédicteur des attitudes à l'égard du vaccin pour toutes les mesures dépendantes. • On a établi un lien positif entre le degré d'acceptation du vaccin et le sexe masculin, le fait d'avoir un plus grand nombre de comorbidités, des niveaux de dépression plus faibles, le fait de ne pas pratiquer la distanciation sociale et le fait d'avoir déjà reçu un vaccin contre la grippe.
AUSTRALIE ET NOUVELLE-ZELANDE		
Horizon Research (2021) *non publiée* (15, 195, 232) Étude longitudinale Nouvelle-Zélande Mars – Mai 2021	Une enquête en ligne a été menée auprès des adultes (16 ans et plus) pour mesurer le taux d'utilisation du vaccin. Mar-Avr, n=1,350 Avr-Mai, n=1,387 Mai, n=1,234 *nouvelle* Sujets des questions : 1) Prise du vaccin Outils d'enquête disponibles? Oui	**Mai** • 13 % des personnes interrogées qui se sont identifiées comme handicapées ou souffrant de maladies chroniques ont déclaré qu'il était peu probable qu'elles se fassent vacciner. • Parmi les raisons de ne pas se faire vacciner, on trouve des préoccupations liées à l'innocuité (49 %), la conviction qu'un vaccin n'est pas nécessaire (21 %) et une méfiance envers les vaccins en général (18 %). **Avril-mai** • 77 % des personnes vivant avec des déficiences ou des problèmes de santé à long terme étaient susceptibles d'accepter un vaccin ou avaient été

	Des recherches formatives ont-elles été menées? Non Enquête prétestée? Non	vaccinées alors que 5 % des personnes ont déclaré qu'elles ne se feraient certainement pas vacciner. • 70 % des personnes qui se sont dites invalides étaient susceptibles d'accepter de se faire vacciner ou avaient été vaccinées alors que 5 % d'entre elles ont dit qu'elles ne se feraient certainement pas vacciner.
Australia Bureau of Statistics (2021) *non publiée* (141) *nouvelle* Étude longitudinale Australie Apr 2020-May 2021	L'enquête sur les répercussions sur les ménages est une enquête mensuelle qui recueille des données en ligne et par téléphone auprès d'un groupe d'adultes (18 ans et plus) sur des sujets liés à la COVID-19, y compris les attitudes à l'égard des vaccins. Mai: n=3,371 Sujets des questions : 1) Intentions en ce qui concerne les vaccins 2) Hésitation par rapport à la vaccination Outils d'enquête disponibles? Non Recherches formatives effectuées? Non Enquête prétestée? Non	• Les personnes handicapées ou souffrant d'un problème de santé de longue durée étaient légèrement plus susceptibles d'avoir l'intention de se faire vacciner que les autres (68,6 % pour les personnes handicapées contre 68,1 % pour les personnes non handicapées et 70,1 % pour les personnes souffrant d'un problème de santé de longue durée contre 66,5 % pour les personnes sans problème de santé de longue durée). • Le facteur principal de la décision de se faire vacciner est une recommandation de leur médecin généraliste (33,7 % et 31,0 % respectivement pour l'invalidité et les maladies chroniques). • Les inquiétudes concernant les effets secondaires ont dominé les raisons de ne pas vouloir se faire vacciner (62,7 % pour les personnes handicapées et 62,1 % pour les personnes souffrant de maladies chroniques).
Bonner (2020) *préimpression* (152) Étude longitudinale Australie	Les personnes qui ont dit souffrir d'hypertension (n = 466) ont été comparées à des témoins sains (n = 466) pendant le confinement afin de déterminer si elles ont des perceptions du risque plus élevé et souffrent d'anxiété, ainsi que pour connaître leurs intentions en matière de prévention. Un sondage en ligne a été utilisé pour évaluer	• Au départ, 87 % des personnes souffrant d'hypertension et 85 % des témoins sains ont déclaré qu'ils recevraient le vaccin contre la COVID-19. • Il n'y avait pas de différences significatives dans la volonté de se faire vacciner contre la COVID-19 entre les personnes souffrant d'hypertension et les témoins sains.

Avril et juin 2020	l'intention de se faire vacciner pendant le confinement, puis de nouveau, deux mois après l'assouplissement des restrictions. Sujets des questions : 1) Intentions en ce qui concerne les vaccins Outils d'enquête disponibles? Non Recherches formatives effectuées? Non Enquête prétestée? Non	• Malgré une diminution de la gravité perçue et de l'anxiété deux mois après la levée des restrictions après le confinement, l'intention de se faire vacciner contre la COVID-19 était toujours ferme (plus de 80 %) au moment du suivi.
ÉTATS-UNIS		
Ricotta (2021) *préimpression* (153) Étude transversale ÉTATS-UNIS Février 2021	Afin d'évaluer l'acceptation du vaccin chez les personnes atteintes de maladies respiratoires chroniques ou de maladies auto-immunes, un sondage en ligne a été mené auprès de 1 232 personnes ayant une maladie respiratoire chronique ou auto-immune autodéclarée et de 1 303 témoins sains aux États-Unis. Sujets des questions : 3) Intentions en ce qui concerne les vaccins 4) Hésitation par rapport à la vaccination Outils d'enquête disponibles? Non Recherches formatives effectuées? Oui Enquête prétestée? Non	• Comparativement aux témoins en santé, les personnes qui ont dit être atteintes de maladies respiratoires chroniques étaient 5,7 % plus disposées à se faire vacciner (IC à 95 % : 0,05 à 0,09). • Lorsqu'on leur a demandé pourquoi elles avaient l'intention de se faire vacciner, les personnes atteintes de maladies respiratoires chroniques (RC = 1,08, IC à 95 % : 1,03 à 1,13) et de maladies auto-immunes (RC = 1,06, IC à 95 % : 1,01 à 1,11) étaient plus susceptibles de se faire vacciner pour se protéger contre la COVID-19 que le groupe-témoin. Les personnes atteintes de maladies respiratoires chroniques étaient également plus susceptibles de vouloir retourner au travail en toute sécurité (RC = 1,08, IC : 1,03 à 1,14). • Parmi celles qui n'ont pas l'intention de se faire vacciner, les personnes atteintes de maladies auto-immunes étaient le seul groupe à avoir une association significative avec une cause particulière d'hésitation. En fait, elles étaient plus susceptibles de dire que la crainte d'une mauvaise réaction au

		vaccin était la raison de leur hésitation (RC = 1,22, IC à 95 % : 1,06 à 1,41).
Garcia (2021) (156) Étude transversale États-Unis Janvier et février 2021	Un sondage en ligne a été mené dans 150 centres de dialyse choisis au hasard aux États-Unis afin d'évaluer les intentions en ce qui concerne la vaccination et la réticence des 1 515 patients en hémodialyse. Sujets des questions : 1) Intentions en ce qui concerne la vaccination 2) Hésitation par rapport à la vaccination Outils d'enquête disponibles? Oui Recherches formatives effectuées? Oui Enquête prétestée? Oui	• 20 % des patients hésitaient à accepter un vaccin même s'il était considéré sans danger pour la population en général. Si le vaccin était offert au centre de dialyse, cette hésitation diminuait à 18 %. • La réticence à se faire vacciner était la plus élevée chez les patients de 18 à 44 ans (RCa 1,5, IC à 95 %, 1,0 à 2,3), les femmes (RCa 1,6, IC à 95 %, 1,2 à 2,0), les patients noirs (RCa 1,9, IC à 95 %, 1,3 à 2,7) et les patients qui s'identifiaient comme étant d'autres races ou ethnies (RCa 2,0, IC à 95 %, 1,1 à 3,7). • La réticence à se faire vacciner était plus faible chez les patients de 80 ans et plus (RCa 0,4, IC à 95 % : 0,3 à 0,7), chez ceux qui avaient fait certaines études collégiales (RCa 0,4, IC à 95 % : 0,2 à 0,6) et chez ceux qui avaient reçu le vaccin contre la grippe (RCa 0,2, IC à 95 % : 0,1 à 0,3). • 53 % des personnes hésitant à se faire vacciner se sont dites préoccupées par les effets secondaires.
Tsai (2021) *préimpression* (160) Étude transversale É.-U. Janvier à février 2021	Une enquête internationale en ligne a été menée pour mesurer l'hésitation à se faire vacciner chez 21 943 personnes présentant des conditions à risque élevé telles que le cancer, les maladies auto-immunes et d'autres conditions de comorbidités. 74 % des participants étaient originaires des États-Unis et 4 % du Canada. Sujets des questions : 1) Intentions de se faire vacciner 2) Hésitation à se faire vacciner	• 25 % des personnes interrogées avaient reçu au moins un vaccin, tandis que 7 % avaient essayé de se faire vacciner sans y parvenir. • 43 % prévoient de se faire vacciner, 5 % le feront probablement, 5 % sont incertains, 4 % ne se feront probablement pas vacciner et 10 % ne l'accepteront certainement pas. • En fonction des conditions, les fumeurs actuels étaient les plus hésitants (29 %), suivis des personnes souffrant d'obésité (20 %), de diabète de type 2 (19 %), d'hypertension (18 %) et de maladies pulmonaires chroniques (18 %). • Les personnes ayant subi un traitement anticancéreux dans le passé étaient plus hésitantes que celles qui subissent actuellement un traitement anticancéreux (13 % contre 11 %).

	Outils d'enquête disponibles? Non Des recherches formatives ont-elles été menées? Non Enquête prétestée? Non	• L'hésitation à se faire vacciner était associée à un âge plus jeune, au sexe féminin, à l'appartenance ethnique des Noirs-Pacifiques-Islandais-Amérindiens, à un faible niveau d'éducation, à des tendances politiques conservatrices, à une résistance aux masques ou aux vaccinations de routine contre la grippe et à une méfiance à l'égard de la couverture médiatique. • Ceux qui ont répondu avec un certain niveau d'hésitation ont indiqué que le vaccin était trop nouveau (53 %), qu'ils s'inquiétaient des effets secondaires ou de l'inconfort (44 %), qu'ils avaient le sentiment que le processus avait été impliqué dans la politique (39 %) et qu'ils voulaient attendre que d'autres l'aient pris (33 %). • 21 % ont déclaré ne pas faire confiance aux vaccins en général, mais étaient plus négatifs à l'égard du vaccin COVID-19 en particulier (40 %).
Iadarola (2021) *préimpression* (157) Étude transversale ÉTATS-UNIS Janvier et février 2021	L'intention de se faire vacciner a été évaluée dans un sondage en ligne effectué auprès de 825 personnes ayant des déficiences intellectuelles et développementales, ainsi que des membres de leur famille et du personnel soignant dans l'État de New York. Sujets des questions : 1) Intentions en ce qui concerne les vaccins 2) Hésitation par rapport à la vaccination Outils d'enquête disponibles? Non Recherches formatives effectuées? Oui Enquête prétestée? Non	• 62 % des répondants ont dit qu'ils se feraient certainement ou probablement vacciner contre la COVID-19 alors que 13,9 % avaient déjà reçu le vaccin. • L'hésitation à se faire vacciner était plus grande chez les personnes plus jeunes et celles qui prenaient des décisions au nom d'une personne atteinte de la maladie. • Les répondants noirs de plus de 50 ans étaient plus susceptibles d'avoir l'intention de se faire vacciner ou d'avoir déjà reçu un vaccin comparativement aux répondants plus jeunes (RC = 3,72, IC à 95 % : 1,73 à 8,00) et aux répondants blancs âgés de plus de 50 ans (RC = 2,39, IC à 95 % : 1,36 à 4,17). • Les motifs d'hésitation les plus courants étaient les préoccupations au sujet des effets secondaires (16 %), la croyance que le vaccin était trop nouveau (15 %), le désir de ne pas être un

		« cobaye » du vaccin (14 %) et la méfiance à l'égard du gouvernement (14 %). • Les répondants hispaniques et noirs (96 % et 91 % respectivement) se sont dits plus souvent préoccupés par le fait d'être utilisés comme « cobayes » que les répondants blancs ou asiatiques (76 % et 67 % respectivement). • Les professionnels de la santé (92 %) étaient la source la plus fiable d'information sur le vaccin, suivis des amis et de la famille (74 %).
McCabe (2021) *préimpression* (166) Étude transversale É.-U. Décembre 2020 à février 2021	Une enquête nationale distribuée par voie électronique a été menée auprès de 34 470 travailleurs de la santé et d'adultes de la population générale afin de mesurer l'intention de recevoir un vaccin et les facteurs liés à l'acceptation et au refus. Le nombre de travailleurs de la santé n'a pas été indiqué. Sujets des questions : 1) Intentions de se faire vacciner 2) Hésitation à se faire vacciner Outils d'enquête disponibles? Oui Des recherches formatives ont-elles été menées? Non Enquête prétestée? Oui	• Les personnes présentant trois pathologies préexistantes ou plus étaient 1,19 fois plus susceptibles que les autres d'hésiter à se faire vacciner (RR ajusté 1,19, IC 95 %) : 1,06 % à 1,34, P = 0,004 5).
Xiang (2021) (162) *nouveau* Enquête transversale	Un sondage en ligne a été mené auprès de 401 patients atteints de sclérose en plaques aux États-Unis (la majorité dans l'Oregon, l'État de Washington et la Californie) afin d'évaluer les intentions de se faire vacciner.	• 70,1 % étaient prêts à se faire vacciner, 7,2 % ne le seraient pas et 22,7 % étaient incertains. • La plupart des répondants étaient motivés par la volonté de se protéger (77,6 %) ou de protéger leurs proches (58,7 %), et de réduire les risques de maladie grave (53,4 %).

É.-U. Déc. 2020-janv. 2021	Sujets des questions : 1) Intentions de se faire vacciner 2) Réticence à se faire vacciner 3) Perception des vaccins Outils de sondage disponibles? Oui Des recherches formatives ont-elles été menées? Non Sondage prétesté? Non	• Parmi les personnes qui ont l'intention de refuser un vaccin, les principales raisons sont l'inquiétude quant aux effets secondaires potentiels (55,2 %), la rapidité du développement du vaccin (55,2 %) et le désir d'obtenir davantage de preuves d'innocuité en raison du développement précipité (44,8 %). • Les répondants indécis ont exprimé le désir d'obtenir des renseignements sur la sécurité de la population (57,1 %). Les indécis croyaient également que les pressions politiques influaient sur les essais de vaccins (37,4 %) et souhaitaient que les personnes non atteintes de SP reçoivent le vaccin en raison de problèmes d'innocuité (29,7 %). • L'analyse multivariée a révélé que l'intention de se faire vacciner était plus élevée chez les personnes qui avaient parlé ou prévoyaient de parler du vaccin à leur médecin spécialiste de la SP (RCa 2,93, IC à 95 % : de 1,32 à 6,49 et 2,57, IC à 95 % : de 1,38 à 4,80, respectivement), une vaccination antérieure contre la grippe (la plupart des années RCa 5,59, IC à 95 % : de 2,44 à 12,77 et chaque année RCa 8,96, IC à 95 % : de 4,39 à 18,31), tout niveau d'inquiétude concernant la COVID-19, tout niveau d'inquiétude concernant leur risque d'hospitalisation ou de décès, et le fait de ne pas pouvoir socialiser en public, mais à la maison (RCa 14,07, IC à 95 % : de 1,43 à 138,33) ou de n'avoir que des relations sociales virtuelles (RCa 17,53, IC à 95 % : de 1,80 à 170,60).
Kelkar (2021) (154) Étude avant/après États-Unis	Cette étude visait à déterminer si un webinaire améliorerait les connaissances sur les vaccins contre la COVID-19 et aurait une incidence sur l'intention de se faire vacciner. 264 personnes atteintes de cancer ou leurs soignants en Floride ont participé au webinaire, puis se sont inscrits pour répondre à au moins un sondage en ligne	• Avant le webinaire, 71 % des personnes avaient l'intention de se faire vacciner, 5 % ont précisé qu'elles ne se feraient pas vacciner et 24 % étaient incertaines. • 97 personnes sur 105 ont répondu à la question précise portant sur l'intention en ce qui concerne la vaccination dans les sondages avant et après le webinaire. Après le webinaire, 82,5 % des personnes avaient l'intention de se faire vacciner,

Décembre 2020 à janvier 2021	(avant et après le webinaire). De ce nombre, 105 ont répondu aux deux sondages. Sujets des questions : 4) Intentions en ce qui concerne la vaccination 5) Hésitation par rapport à la vaccination Outils d'enquête disponibles? Oui Recherches formatives effectuées? Non Enquête prétestée? Non	2,1 % ont précisé qu'elles ne se feraient pas vacciner et 15,5 % étaient incertaines. • Les raisons les plus courantes pour hésiter à se faire vacciner étaient les préoccupations au sujet des effets secondaires du vaccin (30 %), le manque d'information sur l'efficacité du vaccin (14 %) et le manque de confiance quant à l'innocuité du vaccin pour les patients atteints de cancer (8 %).
Dalal (2021) (149) Étude transversale ÉTATS-UNIS Décembre 2020 à janvier 2021	Un sondage en ligne a été effectué auprès de 906 adultes atteints d'une maladie du côlon irritable dans un hôpital de Boston ou dans les médias sociaux associés au côlon irritable avant d'évaluer leurs intentions de se faire vacciner et de cerner les préoccupations possibles. Sujets des questions : 1) Intentions en ce qui concerne les vaccins 2) Hésitation par rapport à la vaccination Outils d'enquête disponibles? Non Recherches formatives effectuées? Non Enquête prétestée? Non	• L'intention de se faire vacciner était élevée chez les répondants recrutés localement (80,9 %) comparativement à 60,0 % de ceux recrutés sur les médias sociaux. • Les motifs de réticence les plus courants dans les deux groupes comprenaient les inquiétudes au sujet des effets à long terme et des effets indésirables, le désir de voir comment les autres tolèrent le vaccin, l'inquiétude que le vaccin n'ait pas fait l'objet de vérifications d'innocuité régulières, l'inquiétude associée au fait que le vaccin nuise à l'efficacité des médicaments contre le côlon irritable et des antécédents personnels de réactions allergiques. • Une recommandation d'un de leurs fournisseurs de soins de santé en lien avec le côlon irritable a été jugée être un élément important, tant chez les répondants acquis localement (92 %) que dans les médias sociaux (80,6 %). • De leur fournisseur de soins, les répondants voulaient notamment en savoir plus sur les risques et les avantages, recevoir des documents écrits, obtenir de l'information sur l'innocuité et

		l'efficacité des médicaments contre le côlon irritable et d'autres maladies auto-immunes. • On a établi un lien positif entre l'intention de se faire vacciner et l'âge (RC = 2,21, IC à 95 % : 1,07 à 4,54), le fait d'être titulaire d'un baccalauréat ou d'un autre diplôme d'études supérieures (RC = 3,31, IC à 95 % : 1,36 à 8,06), d'être blanc (RC = 2,13, IC à 95 % : 1,17 à 3,85), d'avoir eu la COVID-19 (RC = 2,02, IC à 95 % : 1,09 à 3,73) ou de prendre actuellement un produit biochimique (RC = 1,52 IC à 95 % : 1,07 à 2,16).
Serper (2021) (159) Étude transversale É.-U. Décembre 2020	Pour évaluer les attitudes et les intentions concernant les vaccins contre la COVID-19, une enquête en ligne a été menée auprès de 1 215 patients soignés pour des affections gastro-intestinales et hépatiques chroniques (syndrome du côlon irritable, cirrhose ou transplantation hépatique) au sein d'un grand système de santé du sud-est de la Pennsylvanie. Sujets des questions : 1) Intentions de se faire vacciner 2) Attitudes à l'égard des vaccins 3) Hésitation à se faire vacciner Outils d'enquête disponibles? Oui Des recherches formatives ont-elles été menées? Oui Enquête prétestée? Non	• 85 % étaient tout à fait ou plutôt d'accord avec le fait qu'ils se feraient vacciner si le vaccin était disponible, 7 % étaient neutres et 8 % étaient tout à fait ou plutôt en désaccord. • Les préoccupations signalées à l'égard des vaccins comprenaient la sécurité (54 %), l'efficacité (26,7 %), le fait de ne pas être prioritaire pour le vaccin (39 %), le coût (17,4 %) et les inconvénients (10,3 %). • Les personnes interrogées étaient plus susceptibles d'accepter un vaccin contre la COVID-19 dans un cabinet médical ou une pharmacie, par rapport aux sites avec service au volant, aux lieux de travail ou aux sites communautaires (par exemple, église, école). • Plus de 75 % suivraient la recommandation de leur gouvernement ou de leur médecin concernant le vaccin contre la COVID-19, 91 % suivraient la recommandation de leur gastro-entérologue ou de leur spécialiste du foie et 56 % suivraient la recommandation de leur employeur. • Femmes (RR ajusté 2,02, IC 95 % : 1,40 % à 2,92 %, P < 0,001) et ceux dont les revenus sont plus faibles (RR ajusté 2,17, IC 95 % : 1,26 % à 3,74 %, P = 0,005) étaient plus susceptibles d'hésiter à se faire vacciner et les personnes âgées de 65 ans et plus (RR ajusté 0,52, IC 95 % : 0,30 % à 0,92 %, P =

		0,024) et avec la réception préalable d'un vaccin annuel contre la grippe (RR ajusté 0,11, IC 95 % : 0,07 % à 0,10 %, p < 0,000 1) étaient moins hésitants.
Ou (2021) (165) *nouveau* Étude transversale É.-U. Nov.-déc. 2020	Les attitudes envers un éventuel vaccin contre la COVID-19 ont été évaluées chez 1 308 transplantés d'organes solides (TOS) et 1 617 non-transplantés d'organes solides par l'intermédiaire d'un sondage en ligne. Sujets des questions : 1) Intentions de se faire vacciner 2) Attitudes envers les vaccins Outils de sondage disponibles? Non Des recherches formatives ont-elles été menées? Oui Sondage prétesté? Oui	• 50,5 % des TOS et 60,7 % des non-TOS avaient l'intention de se faire vacciner. • 49,5 % des TOS et 39,3 % des non-TOS n'avaient pas l'intention de se faire vacciner. • Chez les TOS, les personnes peu enclines ou réticentes étaient plus susceptibles d'être âgées de 30 à 49 ans, d'être des femmes, d'être de race noire, de ne pas résider aux États-Unis, d'avoir un diplôme d'études secondaires ou moins, de ne pas être mariées, d'avoir un revenu familial inférieur à 30 000 dollars, de ne pas avoir été vaccinées contre la grippe au cours de l'année écoulée, de ne pas prévoir de se faire vacciner contre la grippe cette année, de penser que les patients transplantés courent un plus grand risque de contracter une maladie à cause du vaccin, de penser que le vaccin contre la COVID-19 pourrait entraîner un rejet et de ne pas croire que les vaccins sont sûrs pour les patients transplantés. • 80,0 % des TOS ont déclaré avoir besoin d'information de la part de leur médecin ou d'une assurance que leur santé personnelle soit compatible avec le vaccin (75,4 %). Ils étaient 86,8 % à être recommandés par leur chirurgien transplanteur, 71,9 % par un autre membre de l'équipe de transplantation et 64,1 % par leur médecin traitant. • Les TOS étaient plus susceptibles de percevoir le vaccin comme nécessaire et que les vaccins fonctionnent, d'exprimer leur niveau de confort envers les vaccins, de ne pas craindre les vaccins, de faire confiance aux entreprises pharmaceutiques, aux CDC et aux vaccins en général, par rapport aux non-TOS.

		• Les non-TOS qui vivent avec un TOS sont moins nombreux que ceux qui ne vivent pas avec un TOS à déclarer avoir l'intention de se faire vacciner (57,6 % contre 61,3 %). Cela restait vrai si le vaccin était recommandé par un médecin (73,9 % contre 76,7 %), mais pas s'ils estimaient que les TOS devaient se faire vacciner (52,2 % contre 52,0 %). • L'annonce de l'efficacité de Moderna a légèrement augmenté l'intention de se faire vacciner, de 53,5 % à 57,8 % après l'annonce.
Rodriguez (2021) (238) *nouveau* Étude transversale É.-U. Mai-déc. 2020	Un échantillon de 175 personnes séropositives âgées de plus de 18 ans a été interrogé en ligne afin de valider l'échelle de réticence à se faire vacciner (ERV), dans le but de comprendre les attitudes envers le vaccin contre la COVID-19 et la volonté de se faire vacciner. Sujets des questions : 1) Intentions de se faire vacciner 2) Attitudes envers les vaccins 3) Réticence à se faire vacciner Outils de sondage disponibles? Oui Des recherches formatives ont-elles été menées? Non Sondage prétesté? Non	• Le manque de confiance et les risques expliquent respectivement 45,55 % et 12,31 % de la variance des réponses quant à la réticence à se faire vacciner. • Les réponses moyennes révèlent que les niveaux de réticence à se faire vacciner sont plus élevés chez les personnes qui ne croient pas à l'efficacité du vaccin, chez celles qui ne se laisseraient pas influencer par la recommandation d'un professionnel de la santé, chez celles qui ne pensent pas qu'il soit important de se faire vacciner en raison de leur état de santé et qui ne se feraient pas vacciner si cela était nécessaire pour reprendre une vie normale. • Les niveaux moyens de réticence à se faire vacciner étaient plus faibles chez les personnes qui ne pensaient pas que leur état de santé serait aggravé par le vaccin.
Jones (2021) (239) Étude transversale États-Unis	Un sondage en ligne effectué auprès de 94 adultes (âgés de 18 ans et plus) vivant avec le VIH à Miami, en Floride, appartenant à des groupes ethnoraciaux sous-représentés afin d'évaluer l'intention de se faire vacciner et les facteurs associés à la réticence. Les participants étaient des Noirs non	• Comparativement aux Latinx non noirs, les participants noirs non latins étaient moins susceptibles de dire que les vaccins sont importants pour leur santé (92 % comparativement à 68 %, P = 0,009), de croire que les vaccins sont efficaces pour prévenir les maladies (84 % comparativement à 68 % P = 0,029) et de croire que l'information sur le vaccin est fiable et

Août à novembre 2020	latinx (60 %) et des Latinx non noirs (40 %). Sujets des questions : 1) Intentions en ce qui concerne la vaccination 2) Hésitation par rapport à la vaccination 3) Attitudes à l'égard des vaccins Outils d'enquête disponibles? Oui Recherches formatives effectuées? Oui Enquête prétestée? Non	digne de foi (71 % comparativement à 36 %, P = 0,002). • L'intention de se faire vacciner a été associée positivement à la croyance selon laquelle les vaccins sont importants (RC 12,0, IC à 95 % : 3,22 à 44,8, P < 0,001) et efficaces (RC 5,71, IC à 95 % : 1,78 à 14,59, P = 0,001), au fait de reconnaître que l'information sur les vaccins est fiable et digne de confiance (RC 6,76, IC à 95 % : 2,71 à 16,88, P = 0,001), au fait de croire qu'ils devraient se conformer aux ordonnances du médecin (RC 5,28, IC à 95 % : 1,57 à 17,71, P = 0,001) et de croire qu'un vaccin est le meilleur moyen de se protéger contre la maladie (RC 7,07, IC à 95 % : 2,14 à 23,42, P < 0,001).
Bogart (2020) (158) Étude transversale ÉTATS-UNIS Mai à juillet 2020	101 personnes noires vivant avec le VIH ont été interrogées par téléphone afin d'évaluer les liens entre la méfiance médicale, les intentions quant à la vaccination et l'hésitation face à la vaccination. Sujets des questions : 1) Intentions en ce qui concerne les vaccins 2) Hésitation par rapport à la vaccination Outils d'enquête disponibles? Non Recherches formatives effectuées? Non Enquête prétestée? Non	• Les croyances les plus courantes au sujet du vaccin contre la COVID-19 étaient que le vaccin serait nocif (51 %), qu'ils n'y feraient pas confiance (34 %) et qu'ils ne voudraient pas se faire vacciner (32 %). • L'analyse multivariée a révélé qu'une plus grande méfiance liée à la COVID-19 était fortement associée à l'hésitation à se faire vacciner [b (SE) = 0,85 (0,14), P < 0,000]). • Les corrélations de Pearson indiquaient que les participants n'ayant pas terminé leurs études secondaires présentaient des niveaux plus élevés d'hésitation à se faire vacciner (r = 0,20, P = 0,04).
Ehde (2021) (148)	Un sondage en ligne a été utilisé pour évaluer les facteurs associés à l'intention de recevoir ou non un vaccin contre la COVID-19 chez	• 66,0 % des participants étaient disposés à se faire vacciner lorsque le vaccin sera disponible, 18,5 % étaient moyennement disposés à le recevoir et 15,5 % n'en voulaient pas.

Étude transversale ÉTATS-UNIS Avril et mai 2020	486 adultes (âgés de 18 ans et plus) atteints de sclérose en plaques. Sujets des questions : 4) Intentions en ce qui concerne les vaccins Outils d'enquête disponibles? Non Recherches formatives effectuées? Oui Enquête prétestée? Non	• Les prédicteurs statistiquement significatifs d'une volonté accrue de se faire vacciner comprennent l'enseignement supérieur (β = 0,20, P < 0,001) et la perception d'être plus à risque de contracter la COVID-19 (β = 0,18, P = 0,001). • Les participants étaient d'avis que les fournisseurs de soins de santé et la société de la sclérose en plaques avaient la plus grande fiabilité perçue pour l'information sur la COVID-19. La fiabilité perçue des sources d'information était fortement associée à l'intention de se faire vacciner.
Rungkitwattanakul (2021) (155) Étude transversale ÉTATS-UNIS Date n.d.	Pour évaluer les intentions en matière de vaccination, on a effectué un sondage en ligne auprès de 90 patients dans un centre de dialyse urbain de Washington DC. qui dessert une population de patients principalement afro-américains. Sujets des questions : 1) Intentions en ce qui concerne les vaccins 2) Hésitation par rapport à la vaccination Outils d'enquête disponibles? Non Recherches formatives effectuées? Non Enquête prétestée? Non	• 49 % des répondants ont indiqué qu'ils seraient disposés à recevoir un vaccin contre la COVID 19, 34 % n'étaient pas disposés à le recevoir et 17 % étaient incertains. • L'intention de se faire vacciner contre la COVID-19 était associée au fait d'avoir déjà reçu le antigrippal P < 0,001. • Les raisons les plus courantes de l'hésitation à se faire vacciner étaient le manque d'information adéquate sur l'innocuité et l'efficacité (46,8 %), le manque de confiance envers le gouvernement fédéral (36,4 %) et le manque de confiance envers les fabricants de vaccins (28,9 %).
ROYAUME-UNI		
Office for National Statistics (2021) & Office of National Statistics (2021)	Les réponses provenant de quatre vagues de résultats recueillis dans le cadre du sondage en ligne Opinions and Lifestyle Survey (167) ont été mises en commun pour mettre l'accent sur les associations	**Mars avril** • Les adultes handicapés avaient un peu moins d'hésitation à se faire vacciner que les adultes non handicapés (5 % contre 7 %). L'hésitation a diminué depuis le dernier rapport (8 % et 9 % respectivement).

non publiée (43, 140) Étude longitudinale Royaume-Uni Fev-Avr 2021	démographiques spécifiques et la réticence à se faire vacciner. Le nombre de personnes handicapées, de personnes extrêmement vulnérables sur le plan clinique et de parents n'a pas été déclaré. Fév.-Mar: 17 201 réponses ont été mises en commun Mar-Avr: 16 362 réponses ont été mises en commun Sujets des questions : 1) Intentions en ce qui concerne les vaccins 2) Hésitation par rapport à la vaccination Outils d'enquête disponibles? Oui Recherches formatives effectuées? Oui Enquête prétestée? Oui	• Les répondants cliniquement extrêmement vulnérables (RCE) ont eu beaucoup moins d'hésitation que les répondants non RCE (4 % contre 7 %). • Les répondants non RCE sont nettement plus nombreux à déclarer qu'il est probable qu'ils se fassent vacciner (31 %), alors que moins de 1 % des RCV ne le feront probablement pas. **Fév. à mars** • Les adultes handicapés étaient un peu moins réticents à se faire vacciner que les adultes non handicapés (8 % comparativement à 9 %). • Les motifs d'hésitation les plus courants chez les adultes handicapés étaient les préoccupations au sujet des problèmes de santé existants (48 %), suivies des préoccupations au sujet des effets secondaires (46 %) et de l'attente de voir si le vaccin fonctionne (43 %). • Les répondants extrêmement vulnérables sur le plan clinique avaient beaucoup moins d'hésitation que les autres répondants (4 % contre 9 %). • Les motifs d'hésitation les plus courants chez ces adultes extrêmement vulnérables étaient les préoccupations au sujet des effets secondaires (49 %), suivies des inquiétudes au sujet des effets à long terme (47 %) et des préoccupations au sujet des problèmes de santé existants (42 %). • Les répondants qui avaient des problèmes de santé sous-jacents étaient moins hésitants que ceux qui n'en avaient pas (6 % comparativement à 10 %). • Les préoccupations au sujet des effets à long terme (42 %), suivies des préoccupations au sujet des effets secondaires (37 %) et des effets sur les problèmes de santé existants (34 %) sont les raisons les plus courantes d'hésitation chez les personnes ayant des problèmes de santé sous-jacents.

Saunders (2021) (163) *nouvelle* Étude transversale Royaume-Uni Mars 2021	Les intentions de se faire vacciner et les attitudes à l'égard des risques associés à la COVID-19 ont été mesurées en ligne chez 964 personnes atteintes d'une néoplasie myéloprolifératives chronique (NMP). Sujets des questions : 1) Intentions en ce qui concerne les vaccins 2) Hésitation par rapport à la vaccination Outils d'enquête disponibles? Non Recherches formatives effectuées? Non Enquête prétestée? Non	• 91,5 % des répondants ont déclaré avoir été vaccinés (93,5 % d'entre eux ont reçu la première dose seulement). • 0,03 % (29 sur 964) avaient réservé leur rendez-vous pour la première dose, 0,05 % (53 sur 964) n'avaient pas pris de rendez-vous pour une dose et de ces personnes, 14 s'étaient vues offrir une dose de vaccin alors qu'aucune dose n'avait été offerte aux 38 autres. • 0,8 % (n = 8) ont refusé la vaccination pour des raisons comme les effets secondaires (n = 5), la mise au point rapide du vaccin (n = 4), l'innocuité (n = 3) et l'efficacité perçue en raison de la NMP (n = 2). Les réponses en texte libre mentionnaient un stress immunitaire possible en tenant compte de l'infection antérieure à la COVID-19, le fait que les dispensateurs de médecines douces ne l'aient pas recommandé et d'autres voulaient en discuter avec leur oncologue. • 16,7 % des personnes vaccinées ont exprimé des préoccupations au sujet de la vaccination en raison d'une réaction grave possible (30,6 %), de l'efficacité chez les patients atteints de NMP (15,4 %), de l'interférence du vaccin avec leur NMP (14,3 %) ou avec les médicaments qu'elles prennent pour leur NMP (10,2 %). • 82,9 % des répondants vaccinés n'avaient aucune préférence générale pour le vaccin, 65,2 % préféraient Pfizer, 30,4 % AstraZeneca, 2,9 % Moderna et 1,4 % un autre vaccin. • 89,0 % des répondants faisaient confiance à leur fournisseur de soins de santé pour les informer des risques et des avantages. • Pour les 97 répondants qui ont dit ne pas faire confiance à leur fournisseur de soins de santé, la principale raison est qu'ils ne connaissaient pas suffisamment le vaccin (34,0 %), les avantages (30,0 %) ou la connaissance de la NMP ou des

		vaccins chez les patients atteints de NMP (12,0 %) et la méfiance à l'égard de leur médecin principal.
Bateman (2021) (240) *nouveau* Étude quasi expérimentale R.-U. Déc. 2020	Une vidéo éducative de huit minutes a été envoyée par message texte à une cohorte de 661 patients en rhumatologie afin de mesurer l'incidence de la vidéo sur l'intention de se faire vacciner. Sujets des questions : 1) Intentions de se faire vacciner Outils de sondage disponibles? Non Des recherches formatives ont-elles été menées? Non Sondage prétesté? Non	• Sur les 8 886 patients ayant reçu le message texte avec le lien vidéo, 2 358 ont visionné la vidéo (27 %) et 661 ont répondu à l'évaluation. • Avant la vidéo, 36 % des patients âgés de 30 à 49 ans, 47 % de ceux âgés de 50 à 69 ans et 52 % de ceux âgés de 70 ans et plus ont déclaré qu'ils connaissaient les vaccins contre la COVID-19 et qu'ils leur étaient recommandés. Après le visionnement de la vidéo, ce pourcentage est passé à 88 %, à 92 % et à 94 % pour ces catégories d'âge respectives. • Sur une échelle de 1 (pas du tout d'accord) à 5 (tout à fait d'accord), les personnes interrogées se sont senties mieux informées (moyenne = 4,1), plus confiantes pour se faire vacciner (moyenne = 4,2), ont déclaré qu'elles se feraient vacciner (moyenne = 4,1) et que la vidéo était utile pour transmettre l'information (moyenne = 4,4). • Les patients plus âgés (50+) étaient plus susceptibles de déclarer qu'ils avaient appris davantage, qu'ils se sentaient plus confiants et qu'ils étaient plus enclins à se faire vacciner que ceux âgés de 30 à 49 ans.
ETATS-UNIS ET ROYAUME-UNI		
Felten (2021) (161) Étude transversale 56 pays Décembre 2020	L'intention de se faire vacciner et la réticence à se faire vacciner ont été évaluées chez 1 258 patients atteints d'une maladie auto-immune ou d'une maladie rhumatismale inflammatoire à l'aide d'un sondage en ligne auquel ont répondu 327 personnes au Royaume-Uni et 114 personnes aux États-Unis. Sujets des questions :	• Parmi les personnes atteintes d'une maladie auto-immune ou d'une maladie rhumatismale inflammatoire au Royaume-Uni, 39,4 % étaient prêtes à accepter de se faire vacciner, 31,3 % hésitaient et 10,5 % étaient méfiantes. • Aux États-Unis, 15,6 % d'entre elles étaient prêts à accepter un vaccin, 9,2 % étaient hésitantes et 5,9 % étaient méfiantes. • Les patients atteints d'une maladie auto-immune ou d'une maladie rhumatismale inflammatoire qui se méfiaient du vaccin étaient beaucoup plus préoccupées par la vaccination en général, pensaient qu'il était moins important de se faire

	1) Intentions en ce qui concerne la vaccination 2) Hésitation par rapport à la vaccination Outils d'enquête disponibles? Oui Recherches formatives effectuées? Oui Enquête prétestée? Non	vacciner, s'inquiétaient de l'utilisation d'une nouvelle technologie dans le vaccin, du manque de recul concernant la vaccination contre la COVID, et les liens financiers potentiels entre les gouvernements et les sociétés pharmaceutiques. • Les personnes hésitantes ou suspectes craignaient beaucoup plus que le vaccin ne provoque une flambée de leur maladie. • Les hommes étaient plus susceptibles d'avoir l'intention de se faire vacciner que les femmes (P < 0,0001) et les personnes plus jeunes étaient moins susceptibles de le faire que les personnes plus âgées (P < 0,0001).

AUTRES POPULATIONS D'INTÉRÊT

Tableau 7. Éléments de preuve sur les attitudes d'autres populations d'intérêt à l'égard des vaccins (n = 61)

ÉTUDE	MÉTHODES ET OUTILS D'ENQUÊTE	RÉSULTATS CLÉS RELATIFS AUX CONNAISSANCES, ATTITUDES ET COMPORTEMENTS
LGBTQ+		
CANADA		
Statistic Canada (2020) *non publiée* (78) Étude transversale Canada Septembre et octobre 2020	Un sondage téléphonique a été effectué auprès de 120 000 participants (âgés de 18 ans et plus) pour évaluer leur intention de se faire vacciner. Sujets des questions : 1) Intentions en ce qui concerne les vaccins Outils d'enquête disponibles? Oui Recherches formatives effectuées? Oui Enquête prétestée? Oui	• 87,6 % des membres de la communauté LGBTQ2+ étaient prêts à accepter un vaccin, comparativement à 76,4 % des personnes non membres de cette communauté.

Ogilvie (2021) (79) Étude transversale Canada Août et septembre 2020	On a évalué l'intention de se faire vacciner chez 4 058 adultes et travailleurs de la santé de la Colombie-Britannique (âgés de 25 à 69 ans). Sujets des questions : 1) Intentions en ce qui concerne les vaccins Outils d'enquête disponibles? Oui Recherches formatives effectuées? Oui Enquête prétestée? Oui	• Les personnes non binaires, allosexuelles, agentes, bispirituelles ou autres étaient plus susceptibles de recevoir un vaccin (RC = 3,04, IC à 95 % : 1,08 à 8,55, P < 0,04).
Statistics Canada (2020) & Statistics Canada (2021) *non publiée* (65, 80) Étude longitudinale Canada Septembre à décembre 2020	Un sondage en ligne mené par Statistique Canada dans le cadre de l'Enquête sur la santé dans les collectivités canadiennes (ESCC) a évalué les comportements des Canadiens pour protéger leur propre santé et celle des autres. Une question sur les intentions de vaccination a été ajoutée au sondage de septembre. Le plus récent rapport fait état de 20 000 réponses reçues de personnes âgées de 12 ans et plus. Sujets des questions : 1) Intentions en ce qui concerne les vaccins Outils d'enquête disponibles? Oui Recherches formatives effectuées? Oui Enquête prétestée? Oui	• Pendant la période d'échantillonnage, 77 % des personnes ont dit être prêtes à se faire vacciner. Cela représente une augmentation par rapport à septembre (75,5 %) à octobre (74,8 %) et à novembre-décembre (80,3 %). • Les membres de la communauté LGBTQ2+ étaient plus susceptibles de se faire vacciner (83,3 %).

ÉTATS-UNIS
