Produits thérapeutiques émergentes pour la COVID-19

Groupe de travail FPT sur les pénuries de médicaments

6 avril 2021

PROTECTING AND EMPOWERING CANADIANS TO IMPROVE THEIR HEALTH

Objectif

- Présenter au groupe de travail FPT sur les pénuries de médicaments une mise à jour sur les thérapies émergentes pour la COVID-19 :
  - *Essais cliniques en cours;*
  - *Résultats cliniques récemment rapportés.*
- Une attention particulière est accordée aux médicaments antiviraux et à certains médicaments actuellement à l'étude à Santé Canada

Produits thérapeutiques émergentes et autorisées pour la COVID-19

Médicaments Antiviraux

- **Remdesivir***
- **Favipiravir****
- **Molnupiravir**
- **PF-07321332**

Monoclonaux neutralisants

- Bamlanivimab en monothérapie*
- Bamlanivmab + Etesevimab**
- Casirivimab + Imdevimab**
- VIR-7831
- AZD-7442
- CT-P59

Médicaments immunomodulateurs

- Dexaméthasone/ Glucocorticoïdes
- Tocilizumab
- Sarilumab
- Anakinra
- Baricitinib
- Otilimab
- **Colchicine****
- **Leronlimab****
- Fumarate de diméthyle (DMF)

Autre

- Aspirine
- Ivermectine
- Fluvoxamine
- Oxyde nitrique

**Homologué par Santé Canada*
***En cours d'examen à Santé Canada*

Cibles pharmacologiques pour la COVID-19

Médicaments anti-inflammatoires à cibles multiples

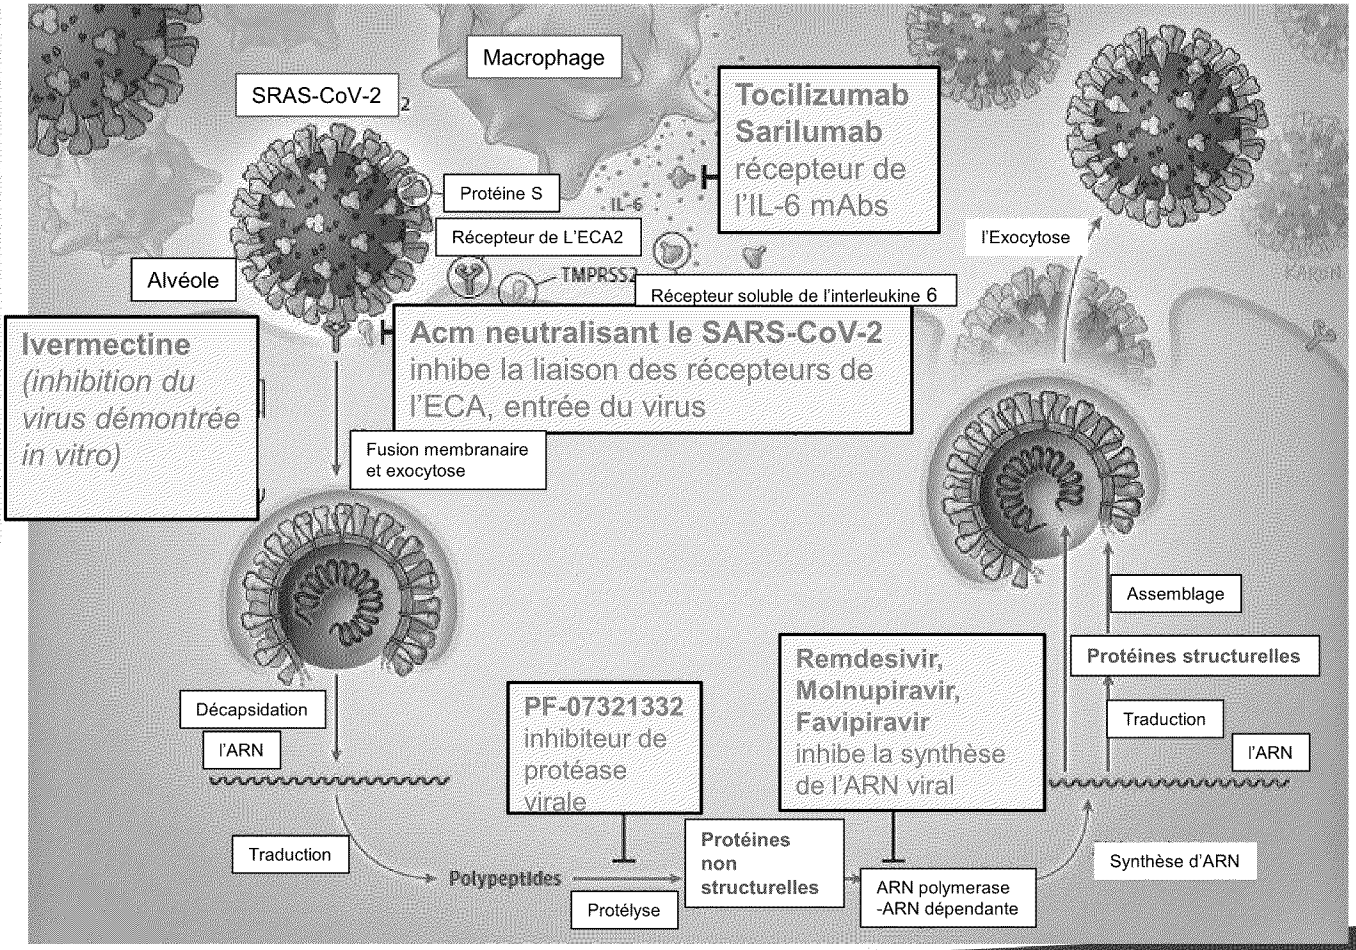
Dexaméthasone/ glucocorticoïdes de nombreux effets; antagoniste du NFkB

Colchicine, DMF de nombreux effets; inhibe l'inflammasome NLRP3

Autres thérapeutiques

Aspirine antiplaquettaire

Oxyde nitrique antiviral, immunomodulateur



Autres médicaments anti-inflammatoires ayant des cibles cellulaires spécifiques

Anakinra
Antagoniste de l'IL-1

Leronlimab
(*AcM* anti-CCR5)

Baricitinib
(inhibiteur de JAK1/2)

Otilimab
AcM anti-GM-CSF

Fluvoxamine
Active le récepteur sigma-1

AcM = anticorps monoclonal

Adapté de Sanders, JM, et coll. *Pharmacologic Treatments for Coronavirus Disease 2019 (COVID-19)*. Examen, JAMA, 2020, vol.18, nº 323, p.1824-1836

Médicaments antiviraux du SRAS-CoV-2

- Potentiels pour les thérapies combinées (par exemple le régime antiviral combiné du VIH);
- Ciblent la reproduction active du virus;
- Phase aiguë (avant ou début de la phase symptomatique);
- COVID de longue durée (excrétion virale prolongée).

Médicaments antiviraux autorisés et expérimentaux contre le SRAS-CoV-2

	Remdesivir *(Veklury®)*	Favipiravir *(Avigan®, Reeqonus®)*	Molnupiravir *(MK-4482)*	PF-07321332
Fabricant (Cible originale)	Gilead (Ebola; médicament expérimental)	Appili; Dr Reddy; Global Response Aid; FujiFilm (grippe pandémique).	Merck; Ridgeback Pharmaceuticals (grippe).	Pfizer (SRAS-CoV-1)
Cible	analogue de nucléotide.	enzyme virale (ARN polymérase ARN dépendante)	prodrogue d'analogue nucléosidique.	Protéase virale (3CL)
Mécanisme d' action	Inhibe la synthèse de l'ARN viral.	Inhibe la synthèse de l'ARN viral.	Inhibe la synthèse de l'ARN viral.	Inhibe la réplication viral
Administration	IV (forme inhalée dans les essais).	Oral	Oral	Oral
Statut	Autorisé par Santé Canada dans le cadre d'une ordonnance provisoire pour les adultes et les adolescents âgés de 12 ans et plus souffrant d'une COVID-19 grave et nécessitant un supplément d'O2.	Examen en cours par Santé Canada pour la COVID-19 légère à modérée chez les adultes	Essais de phase 2 et de phase 2 et 3 adaptatifs en cours, tant en milieu hospitalier qu'en milieu ambulatoire.	Début des essais de phas 1 en mars 2021
Essais en cours	Essai de phase 1/2 sous **par voie inhalée** (traitement ambulatoire	Autorisé en Russie, en Indonésie et en Inde pour la COVID-19.	Données de phase 2 positives pour la réduction de la charge virale.	

CM1

Slide 6

CM1 Données sur l'efficacité et l'innocuité de la phase 2 prévues au printemps 2021

Cheryl Marinsky, 2021-04-12

Favipiravir c. soins standard pour la gravité légère/modérée/non spécifiée de la COVID-19 : *Méta-analyse de réseau à partir de 7 essais contrôlés randomisés*

Résultats	Effets absolus anticipés (IC 95 %)		Risque relatif (IC 95 %)	Nombre de participants (études)	Certitude de la preuve (GRADE)	Commentaires

COLCHICINE -
EMPLOI NON CONFORME POUR LA COVID-19

Colchicine: Profil pharmaceutique et statut d'authorisation

- Autorisé par le Santé Canada pour le traitement de la goutte aiguë, la prophylaxie des crises de goutte récurrentes, et la prévention des crises aiguës de fièvre méditerranéenne familiale (FMF) chez les adultes; son utilisation n'est autorisée pour aucune indication chez les patients de moins de 16 ans.

- Commercialisé sous forme de comprimés de 0,6 mg par plusieurs fournisseurs.

- De nombreuses emplois courants non conforme à l'étiquette, notamment la prévention de la péricardite aiguë ou récurrente, le traitement du syndrome de Behçet, la prophylaxie et le traitement de la chondrocalcinose articulaire.

- Utilisation non-approuvée au Canada pour la prévention ou le traitement de la COVID-19.

- Santé Canada a reçu une soumission en vertu de l'ordonnance provisoire le 25 janvier 2021 pour des comprimés de colchicine, formulation de 0,5 mg (PendoPharm; PharmaScience) comme traitement contre la COVID-19 légère à modérée (examen en cours).

Colchicine:preuves clinique de premier ordre

Essai COLCORONA (prépublication; *non examinée pas les pairs*):

- Les investigateurs ont issu une prépublication de l'ECR COLCORONA multinationale, sans contact, en double aveugle le 27 janvier, 2021.
- L'essai a pris fin prématurément; les données cliniques préimprimées ont été analysées chez 4 488 adultes âgés de 40 ans et plus ayant reçu un diagnostic de COVID-19 probable ou confirmé dans les 24 heures précédant l'inscription, avec au moins un facteur de risque de complications liées à la COVID-19.
- Les facteurs de risque comprenaient l'âge (70 ans), l'obésité (IMC 30), les comorbidités cardiovasculaires, le diabète sucré, l'hypertension non contrôlée, la bicytopénie/pancytopénie, ainsi que les symptômes de la COVID-19 (fièvre 38,4 au cours des 48h précédentes et/ou combinaison d'un taux élevé de neutrophiles/d'un faible nombre de lymphocytes et/ou de dyspnée).
- Une dose de 0.5mg de colchicine administrée deux fois par jour pendant trois jours, puis une fois par jour pendant 27 jours (comprimés; PharmaScience, Québec; (n=2,235) ; ou placebo (n=2,253)), lancé dans les 48h suivant les résultats des tests / diagnostic positifs.

https://www.medrxiv.org/content/10.1101/2021.01.26.21250494v1

Colchicine: preuves clinique de premier ordre

Essai COLCORONA (prépublication; *non examinée pas les pairs*):

- L'essai n'a pas atteint son critère composite primaires de réduction des hospitalisations ou de la mortalité à 30 jours (4,7 % pour la colchicine contre 5,8 % pour le placebo).
- Aucune différence significative entre les deux groupes en ce qui concerne l'incidence des décès ou des hospitalisations, ni en ce qui concerne la ventilation mécanique, qui a été évaluée en tant que résultat secondaire.
- Dans une analyse de sous-groupe sur des patients confirmés par ACP (n=4159) : Incidence réduite des hospitalisations ou de la mortalité à 30 jours de la COVID-19, (4,6 % de colchicine [n=2075] contre 6,0 % de placebo [n=2084]; RC 0,75; IC à 95 % 0,57 à 0,99).
- Dans ce sous-groupe, le rapport de cotes pour la réduction des hospitalisations était de 0,75; (IC de 95 %, 0,57 à 0,99), mais aucune différence n'a été observée pour le décès seul (0,56 ; IC de 95 %, 0,19 à 1,66) ou la ventilation mécanique (0,50 ; IC de 95 %, 0,23 à 1,07).
- Des EI graves ont été signalés chez 4,9 % des participants du groupe colchicine [n=2 195] contre 6,3 % dans le groupe placebo [n=2 217] (p=0,05), notamment une pneumonie 2,9 % contre 4,1 % (p=0,02), une embolie pulmonaire 0,5 % contre 0,1 % (p=0,01) et une diarrhée 13,7 % contre 7,3 % (p<0,0001), respectivement.

Colchicine : Preuves cliniques de premier ordre

Essai RECOVERY (communiqué de presse; *non évalué par les pairs*) *:*

- Essai randomisé ouvert basé au Royaume-Uni chez des patients hospitalisés pour la COVID-19.
- Décision du Comité indépendant de surveillance de données, rendue le 4 mars, de fermer le volet de traitement à la colchicine en raison de la futilité
- Analyse préliminaire fondée sur 2 178 décès signalés parmi 11 162 patients randomisés (94 % également traités par un corticostéroïde).
- Aucune différence significative dans le critère principal de mortalité à 28 jours
  - 20 % colchicine contre 19 % soins habituels seuls; (p=0,63)
- Le suivi des patients est en cours; la publication de l'analyse finale est prévue prochainement.
  https://www.recoverytrial.net/news/recovery-trial-closes-recruitment-to-colchicine-treatment-for-patients-hospitalised-with-covid-19
- Preuves diverses de l'avantage clinique provenant de nombreux petits essais insuffisamment puissants chez les patients hospitalisés atteints de COVID-19

Colchicine pour le traitement de la COVID-19: L'OPINION D'EXPERTS

Le groupe de travail ad hoc sur la pharmacologie clinique de la COVID-19 (GTPC)**:** *10 Février, 2021*
Recommendation

Le Groupe de travail sur la pharmacologie clinique recommande que l'utilisation de la colchicine (d'un dose de 0.6mg) comme traitement pour les patients non hospitalisés atteints de COVID-19- pour un emploi non-conforme- soit limitée à des essais contrôlés aléatoires. Des preuves cliniques supplémentaires sont nécessaires pour déterminer si les bénéfices potentiels de la colchicine l'emportent sur les risques connus et potentiels. Cette orientation sera mise à jour au fur et à mesure que des preuves évaluées par des pairs apparaîtront, en particulier à partir d'essais cliniques bien étayés qui peuvent fournir des preuves supplémentaires des risques et des bénéfices dans des sous-groupes de patients spécifiques (comorbidités, populations âgées/pédiatriques, ethnicité ou sexe).

https://www.canada.ca/en/public-health/corporate/mandate/about-agency/external-advisory-bodies/list/covid-19-clinical-pharmacology-task-group/statement-colchicine.html

COVID-19 directives de traitement pour la colchicine dans les provinces et territoires

- Comité thérapeutique du BC COVID-19 : Le CTC ne recommande pas l'utilisation systématique de la colchicine à en ce moment. Chez les patients âgés de 40 ans ou plus atteints de COVID-19 confirmé par ACR, qui présentent au moins un facteur de risque (selon l'essai COLCORONA) et aucune contre-indication [spécifiée dans les directives], l'administration de colchicine à raison de 0,6 mg PO BID x 3 jours, puis 0,6 mg par jour x 27 jours peut être envisagée au cas par cas en discussion avec le patient en soulignant clairement l'incertitude quant au bénéfice du traitement, ainsi que les risques et les effets indésirables potentiels. Le consentement éclairé doit être obtenu et le traitement doit être initié dès que possible. La colchicine pour le traitement des patients gravement ou gravement malades atteints de COVID-19 n'est pas recommandée en dehors des essais cliniques approuvés.

- Groupe consultatif scientifique COVID-19 des services de santé de l'Alberta : Pour l'instant, la colchicine ne doit pas être prescrite ou administrée pour traiter la COVID-19. Les cliniciens et les chercheurs de l'Alberta devraient soutenir des essais cliniques de haute qualité en Alberta ou dans le cadre d'une étude multicentrique bien conçue pour aider à découvrir si la colchicine présente un avantage pour le traitement de la COVID-19.

- INESSS : L'état actuel des connaissances scientifiques et l'incertitude sur les avantages et les risques potentiels de l'administration de colchicine chez les personnes non hospitalisées ayant un diagnostic de COVID-19 confirmé ou non par un test RT-PCR, et qui répondent aux critères de sélection de l'étude COLCORONA (plus de 40 ans avec au moins un facteur de risque), ne permettent pas de soutenir l'utilisation de la colchicine pour cette population en dehors d'un protocole de recherche. SRAS-CoV-2 confirmé, traitement en milieu hospitalier.

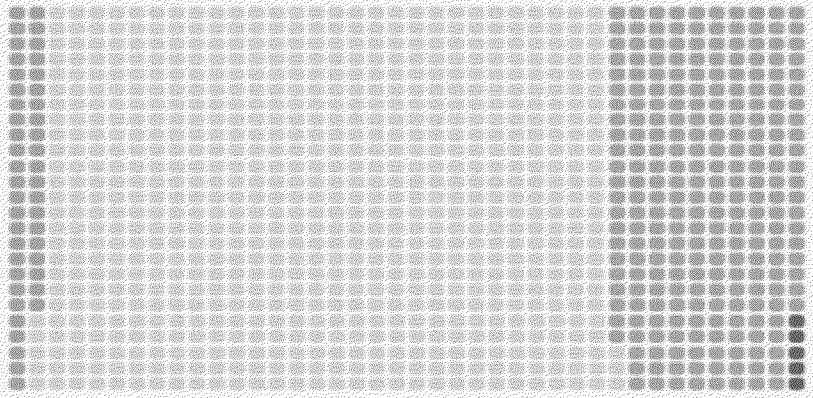
REPRÉSENTATION GRAPHIQUE DES EFFETS POTENTIELS DU TRAITEMENT

La figure ci-dessous illustre les effets potentiels de la colchicine sur les hospitalisations et les évènements indésirables chez des personnes qui correspondent aux critères de l'étude et qui ont un obtenu un test RT-PCR positif.

⚠ Les causes qui ont mené aux hospitalisations, la durée réelle du séjour au-delà des 24 heures prédéfinies et la nécessité d'un transfert aux soins intensifs sont non documentées dans la prépublication.

Traitement de 30 jours avec colchicine

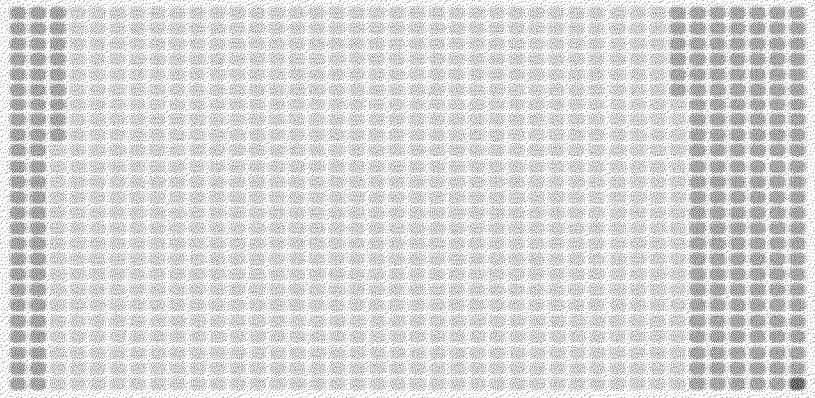
1000 personnes ayant résultat par RT-PCR positif pour la COVID-19
Non hospitalisées | 40 ans et plus | ≥ 1 Facteur de risque



- 45 auraient été hospitalisées en raison de la COVID-19
- 242 auraient subi des événements indésirables (surtout gastro-intestinal)
- 5 auraient subi une embolie pulmonaire

Traitement de 30 jours avec placébo

1000 personnes ayant résultat par RT-PCR positif pour la COVID-19
Non hospitalisées | 40 ans et plus | ≥ 1 Facteur de risque



- 59 auraient été hospitalisées en raison de la COVID-19
- 155 auraient subi des événements indésirables (surtout gastro-intestinal)
- 1 aurait subi une embolie pulmonaire

https://www.inesss.qc.ca/fileadmin/doc/INESSS/COVID-19/INESSS_COVID-19_Colcorona_outil_analyse_donnees.pdf

LERONLIMAB - *MÉDICAMENT EXPÉRIMENTAL POUR LES PATIENTS ATTEINTS DE COVID-19 CRITIQUE*

Leronlimab : Profil du médicament

- Anticorps monoclonal humanisé anti-CCR5 (récepteur de la chimiokine C-C de type 5); bloque le co-récepteur CCR5 présent sur les cellules T et d'autres cellules immunitaires.

- L'activation de CCR5 par l'intermédiaire de ligands immuno-stimulateurs (CCL5 (RANTES), CCL3 (MIP-1α) et CCL4 (MIP-1β)) entraîne une infiltration des cellules immunitaires.

- L'état hyper-inflammatoire caractérisé par la COVID-19 grave et critique peut être en partie attribuable à une infiltration accrue de cellules immunitaires.

Leronlimab : Statut de l'autorisation

- Non approuvé pour utilisation au Canada pour toute indication.

- Le 23 mars 2021, Santé Canada a reçu une demande dans le cadre de l'ordinance provisoire pour le leronlimab (CytoDyn, Inc.; Amarex) comme traitement de la COVID-19 légère à modérée (examen en cours).

- L'Administration des États-Unis chargée des aliments et des médicaments a accordé à **CytoDyn Inc.** le statut de médicament nouveau expérimental d'urgence (EIND) pour le leronlimab dans le cadre de la COVID-19.

Leronlimab : Preuves cliniques de premier ordre

- Un communiqué de presse portant sur une étude multicentre, randomisée, à double insu, contrôlée par placebo, de phase IIb/III, parrainée par une société pharmaceutique, à deux volets, randomisée, à double insu, contrôlée par placebo, chez des patients adultes hospitalisés atteints de la COVID-19 grave ou critique.

- Les patients ont été randomisés pour recevoir soit des doses hebdomadaires de 700 mg de leronlimab, soit un placebo, par voie sous-cutanée.

- Le critère de jugement principal est la mortalité toutes causes confondues à 28 jours.

- Les résultats basés sur 309 patients de la population en intention de traiter modifiée, rapportés dans un communiqué de presse le 30 mars 2021, ont indiqué une réduction du risque absolu de décès le 28^{e} jour de 6,5 % pour les patients ayant reçu le leronlimab par rapport au placebo, en plus des autres traitements de la COVID-19 (P = 0,0319).

- Aucune étude ou prépublication par les pairs n'a été effectuée sur des études contrôlées randomisées démontrant l'efficacité et l'innocuité clinique en tant que traitement pour la COVID-19

Subject: Daily MCM Therapeutic Titles for Thursday January 28, 2021

Good afternoon,

Here are the Daily MCM Therapeutics Titles for Thursday January 28th, 2021:
Please note this email and any assessments contained within are intended for your situational awareness of emerging clinical evidence of COVID-19 therapeutics; it is not intended as a complete systematic review.

Colchicine

- **PREPRINT** Tardif et al. Efficacy of Colchicine in Non-Hospitalized Patients with COVID-19. medRxiv. January 27, 2021.
- DESCRIPTION: COLCORONA is a contactless, randomized, double-blind, placebo-controlled trial conducted in 6 countries from March 2020 to January 2021. Participants enrolled over a telephone assessment and drug was couriered to their home within 4h of enrollment
- ***Population***: Non-hospitalized patients diagnosed with COVID-19 disease and have at least one risk factor for severe disease (N=4,488); [Mean age 54.7 years; 53.9% women; and 19.9% had diabetes]
- Eligible patients were at least 40 years of age, received a diagnosis of COVID-19 within 24 hours of enrollment, not currently hospitalized or under consideration for hospitalization, and presented with at least one of high-risk criteria.

- ***High risk criteria:*** ≥70 years of age, BMI ≥30, diabetes, uncontrolled hypertension (systolic blood pressure ≥150 mm Hg), known respiratory disease, known heart failure, known coronary disease, fever of at least 38.4°C within the last 48 hours, dyspnea at the time of presentation, bicytopenia, pancytopenia, or the combination of high neutrophil and low lymphocyte counts.
- ***Exclusion criteria:*** Inflammatory bowel disease, chronic diarrhea/maladsorption, pre-existent progressive neuromuscular disease; estimated glomerular filtration rate less than 30 ml/minute/1.73 m2; severe liver disease; current treatment with colchicine; current chemotherapy for cancer; or a history of significant sensitivity to colchicine.
- ***Intervention***: 2,192 patients received colchicine (0.5mg twice daily for the first 3 days and then once daily for 27 days thereafter) so treatment would commence within 48h of COVID-19.
- ***Comparator***: 2,189 patients received a placebo
- ***Key Results:***
- Primary outcome***:*** composite of death or hospitalization due to COVID-19 infection within 30 days
    - Composite endpoint of death or hospitalization due to COVID-19 occurred in 4.7% (104/2,235) of patients in the colchicine group and 5.8% (131/2,253) of patients in the placebo group (OR 0.79 [95% CI 0.61 to 1.03; p=0.08]).
- Secondary outcomes:
    - Death occurred in 0.2% (5/2,235) of patients in the colchicine group and 0.4% (9/2,253) died in the placebo group (OR 0.56 [95% CI 0.19 to 1.67]).
    - Hospitalizations due to COVID-19 occurred in 4.5% (101/2,235) of patients in the colchicine group and 5.7% (128/2,253) in the placebo group (OR 0.79 [95% CI 0.60 to 1.03]).
    - Mechanical ventilation was required for 0.5% (11/2,235) of the patients in the colchicine group and 0.9% (21/2,253) in the placebo group (OR 0.53 [95% CI 0.25 to 1.09]).
- Pre-specified analysis of patients with RT-PCR confirmed COVID-19 (N=4,159):

  Primary outcomes:
    - The rate of death or hospitalization due to COVID-19 were 4.6% (96/2,075) in the colchicine group and 6.0% (126/2,084) in the placebo group (OR 0.75 [95% CI 0.57 to 0.99; p=0.04]).
    - Death occurred in 0.2% (5/2,075) of patients in the colchicine group and 0.4% (9/2,084) in the placebo group (OR 0.56 [95% CI, 0.19 to 1.66]).
    - Hospitalization due to COVID-19 occurred in 4.5% (93/2,075) patients in the colchicine group and 5.9% (123/2,084) in the placebo group (OR 0.75 [95% CI 0.57 to 0.99]).
    - Mechanical ventilation was required for 0.5% (10/2,075) of patients in the colchicine group and 1.0% (20/2,084) in the placebo group (OR 0.50 [95% CI 0.23 to 1.07]).

  Secondary outcomes:
    - The secondary efficacy endpoint of the need for mechanical ventilation occurred in 0.5% (11/2,235) of the patients in the colchicine group and 0.9% (21/2,253) in the placebo group (OR 0.50 [95% CI 0.23 to 1.07]).
- Treatment effect for the primary outcome in a pre-specified subgroup based on sex: The rate of death or hospitalization due to COVID-19 was maintained in men (0R 0.67; 95% CI 0.48-0.95) but no treatment effect was observed in women (OR 1.07; 95% CI 0.70-1.65).
- ***Safety Signals:***
    - The rate of serious adverse events were 4.9% in the colchicine group and 6.3% in the placebo group (p=0.05).
    - The number of pulmonary embolism and pneumonia SAE was higher in patients in the colchicine group compared to placebo (0.5% versus 0.1%).
    - The most common adverse events were gastrointestinal events. Diarrhea was reported in 13.7% and 7.3% of patients in the two trial groups (P<0.0001).

- SUMMARY + CONTEXT: **In this randomized, double-blind, placebo-controlled trial (COLCORONA) of 4,488 non-hospitalized patients with COVID-19 and at least one risk factor, colchicine treatment failed to meet statistical significance in the primary endpoint of composite of death or hospitalization due to COVID-19 infection within 30 days. In a pre-specified subgroup analysis in patients with PCR confirmed COVID-19 (N=4,159), colchicine treatment reduced the risk of death or hospitalization, as well as the risk of hospitalization alone, compared to placebo. The most common adverse events related to colchicine were gastrointestinal events and diarrhea.**
- Considerations:
  - The trial was stopped when 75% of the planned patients were recruited and had completed the 30-day follow-up. Reasons given for early termination were logistical issues related to maintaining the central study call centre and a perceived need to disseminate the study results rapidly.
  - The composite outcomes of death or hospitalizations show significance; however, when the outcomes were analyzed individually, no significant differences in the outcomes were observed, with the exception of hospitalization in the RT-PCR confirmed COVID-19 patients.
  - COVID-19 diagnosis was defined as positive PCR by naso-pharyngeal swab or by a clinical algorithm in a symptomatic patient without an obvious alternative cause, or by epidemiological link to a SARS-CoV-2 positive household member.

Ivermectin

- Chachar et al, 2020. Effectiveness of ivermectin in SARSCoV-2/COVID-19 patients. International Journal of Sciences, September 2020.
- *Taken from Abstract:*

Background: The first case of Infection with severe acute respiratory syndrome coronavirus 2 (SARSCoV-2) were diagnosed in Wuhan, China in 2019. In the first half of 2020, this disease has already converted into a global pandemic. Objectives, to assess the efficacy of Ivermectin in mild cases of COVID-19 patients on the basis of predefined assessment criteria.
Methods: Study setting Fatima Memorial Hospital, Lahore open label randomized control trial. Duration of study, from 1st May, 2020 to 30th June, 2020. Sample size and technique: Sample size was 50 patients; 25 patients were kept in control group and 25 patients were kept in experimental group.
Results: There were total 50 patients, divided into two groups case and control group. The mean
age of the participants was 40.60 ± 17 and out of those 31 (62%) were male and 19 (38%) were females. Cough was observed more in case group (p= 0.049). Fever, myalgias and dyspnea were the commonest symptoms in both the groups (p= 1.000). Diarrhea and vomiting were more common in control group (p=0.0001, p= 0.042 respectively). On follow up at day 7, patients were stratified as asymptomatic and symptomatic. Amongst the case group, out of 25 patients, 16 (64%) patients were asymptomatic and rest of the 9 (36%) patients were symptomatic. In control group, out of 25 patients, 15 (60%) patients were asymptomatic and rest of the 10 (40%) patients was symptomatic p-value (0.500). Statistically there was no significant difference between case group who were given ivermectin along with symptomatic treatment and control group who were only given symptomatic treatment without ivermectin, being asymptomatic on day 7 at follow up. p-value (0.500)

Conclusions: Our study didn't show statistically any significant difference between case and control group. In Ivermectin's (case group) recovery was almost equal to control group who received only conventional symptomatic treatment, so this is the need of the day that we need to conduct more randomized controlled trials across our country involving major tertiary care health care facilities with larger sample size to assess its efficacy for validating the use of Ivermectin against SARS-CoV-2.

- SUMMARY + CONTEXT: **This open label randomized controlled trial in a single centre of 50 adult outpatients with mild COVID-19 disease compared the efficacy of ivermectin treatment + symptomatic care versus symptomatic care alone in symptom resolution. No difference was reported between groups on symptom resolution by day 7 follow-up.**

Note- As of October 23, 2020, clinical data on lopinavir/ritonavir and hydroxychloroquine/chloroquine are no longer included in this listing due to overwhelming evidence of little to no clinical benefit. However, these titles are still being retained in our cloud based database.
Feedback and discussion on this daily email is always welcome.

Have a good evening,

Subject: QF for Feb. 4

Hi Jennifer,

Please see below QFs for today.

February 4, 2021: The NIH updated COVID-19 treatment guidelines on the use of tocilizumab and sarilumab.

NIH updated their guidelines following preprint of the REMAP-CAP trial, citing **insufficient data to recommend** either for or against the use of tocilizumab or sarilumab for the treatment of COVID-19 patients who are at high risk of ICU admission and mechanical ventilation, and that, consistent with previous recommendations from the NIH, these treatments should be used in the context of a clinical trial.

The guidelines notes that **some NIH Panel members would recommend** the use of tocilizumab, but not sarilumab, in addition to dexamethasone, to patients who meet the above criteria and are at risk of respiratory failure.

For patients who are not in the ICU or who are in the ICU but do not require mechanical ventilation the **Panel recommends against** the use of tocilizumab or sarilumab for the treatment of COVID-19, except in a clinical trial.

February 4, 2021: Merck & Co Inc. statement against the use of ivermectin for the treatment of COVID-19.

- The company announced that its analysis of existing and emerging preclinical and clinical data does not support the efficacy of its anti-parasite drug, ivermectin, for the treatment of COVID-19.
- The company also cites a concerning lack of safety data in the majority of studies evaluating ivermectin for COVID-19 and cautioned against the use of the drug beyond its indication as an anti-parasitic.
- Ivermectin is not approved for use in Canada or in the USA for the prevention or treatment of COVID-19.

Have a good evening,
Elaha

Subject: Daily MCM Therapeutics Titles for Friday February 26, 2021

Good afternoon,

Here are the Daily MCM Therapeutics Titles for Friday February 26, 2021:
Please note this email and any assessments contained within are intended for your situational awareness of emerging clinical evidence of COVID-19 therapeutics; it is not intended as a complete systematic review.

Interleukin-6 Inhibitors

- Gordon et al., Interleukin-6 Receptor Antagonists in Critically Ill Patients with Covid-19 - Preliminary report. **New England Journal of Medicine.** February 25, 2021.
  Taken directly from the abstract:
  BACKGROUND: The efficacy of interleukin-6 receptor antagonists in critically ill patients with coronavirus disease 2019 (Covid-19) is unclear.
  METHODS: We evaluated tocilizumab and sarilumab in an ongoing international, multifactorial, adaptive platform trial. Adult patients with Covid-19, within 24 hours after starting organ support in the intensive care unit (ICU), were randomly assigned to receive tocilizumab (8 mg per kilogram of body weight), sarilumab (400 mg), or standard care (control). The primary outcome was respiratory and cardiovascular organ support–free days, on an ordinal scale combining in-hospital death (assigned a value of −1) and days free of organ support to day 21. The trial uses a Bayesian statistical model with predefined criteria for superiority, efficacy, equivalence, or futility. An odds ratio greater than 1 represented improved survival, more organ support–free days, or both.
  RESULTS: Both tocilizumab and sarilumab met the predefined criteria for efficacy. At that time, 353 patients had been assigned to tocilizumab, 48 to sarilumab, and 402 to control. The median number of organ support–free days was 10 (interquartile range, −1 to 16) in the tocilizumab group, 11 (interquartile range, 0 to 16) in the sarilumab group, and 0 (interquartile range, −1 to 15) in the control group. The median adjusted cumulative odds ratios were 1.64 (95% credible interval, 1.25 to 2.14) for tocilizumab and 1.76 (95% credible interval, 1.17 to 2.91) for sarilumab as compared with control, yielding posterior probabilities of superiority to control of more than 99.9% and of 99.5%, respectively. An analysis of 90-day survival showed improved survival in the pooled interleukin-6 receptor antagonist

groups, yielding a hazard ratio for the comparison with the control group of 1.61 (95% credible interval, 1.25 to 2.08) and a posterior probability of superiority of more than 99.9%. All secondary analyses supported efficacy of these interleukin-6 receptor antagonists.
CONCLUSIONS: In critically ill patients with Covid-19 receiving organ support in ICUs, treatment with the interleukin-6 receptor antagonists tocilizumab and sarilumab improved outcomes, including survival. (REMAP-CAP ClinicalTrials.gov number, **NCT02735707**).

- SUMMARY + CONTEXT: **This international, ongoing, adaptive, single-blinded randomized controlled trial showed that in critically ill patients with Covid-19 the IL-6 receptor antagonists, tocilizumab and sarilumab, are both effective compared with current standard of care, which included corticosteroids in the majority of patients (>80%). Specifically, tocilizumab and sarilumab compared to standard of care lead to reduced mortality and higher median organ-support-free days in this patient population, compared to the standard of care. Clinical benefits was consistent across primary and secondary outcomes, and across subgroups and secondary analyses. Some serious adverse events were reported in the tocilizumab group, but not in the sarilumab.**
  - This trial was previously summarized and reported in the daily titles as a preprint on January 7, 2021: **PREPRINT:** Gordon et al., Interleukin-6 Receptor Antagonists in Critically Ill Patients with Covid-19 - Preliminary report. January 7, 2021.
  - No major updates to results were report between the preprint and this publication, except with additional information on the estimated interaction between interleukin-6 receptor antagonists and glucocorticoids being additive and slightly in the direction of synergistic, but with substantial variability in the estimate (Tables S5 and S6).
  - Methods section contained additional information on primary analysis being conducted by the statistical analysis committee
  - The results of the analysis reported by the statistical analysis committee and the international trial steering committee were consistent with the primary analysis.

Corticosteroids

- Ma et al., Efficacy and safety of systemic corticosteroids among severe COVID-19 patients: a systematic review and meta-analysis of randomized controlled trials. Signal Transduction and Targeted Therapy. February 21, 2021.
  Taken directly from Abstract:
  Background: The benefits and harms of corticosteroids for patients with severe coronavirus disease 2019 (COVID-19) remain unclear.
  Methods: We systematically searched PubMed, Embase, and Cochrane Central Register of Controlled Trials from December 31, 2019 to October 1, 2020 to identify randomized controlled trials (RCTs) that evaluated corticosteroids in severe COVID-19 patients. The primary outcome was all-cause mortality at the longest follow-up. Secondary outcomes included a composite disease progression (progression to intubation, ventilation, extracorporeal membrane oxygenation, ICU transfer, or death among those not ventilated at enrollment) and incidence of serious adverse events. A random-effects model was applied to calculate risk ratio (RR) with 95% confidence intervals (CIs). We used the Grading of Recommendations Assessment, Development, and Evaluation approach to evaluate the certainty of the evidence.
  Results: Seven RCTs involving 6250 patients were included, of which the Randomized Evaluation of COVID-19 Therapy (RECOVERY) trial comprised nearly 78% of all included subjects. Results showed that corticosteroids were associated with a decreased all-cause mortality (27.3 vs. 31.1%; RR: 0.85; 95% CI: 0.73–0.99; $P = 0.04$; low-certainty evidence). Trial sequential analysis suggested that more trials were still required to confirm the results. However, such survival benefit was absent if RECOVERY trial was excluded (RR: 0.83; 95% CI: 0.65–1.06; $P = 0.13$). Furthermore, corticosteroids decreased the occurrence of composite disease progression (30.6 vs. 33.3%; RR: 0.77; 95% CI: 0.64–0.92; $P = 0.005$), but not increased the incidence of serious adverse events (3.5 vs. 3.4%; RR: 1.16; 95% CI: 0.39–3.43; $P = 0.79$).
- SUMMARY + CONTEXT: **The findings from this systematic review and meta-analysis of randomized control trials (n=7) demonstrate that in hospitalized patients with severe COVID-19, corticosteroids treatment was associated with reduced mortality and disease progression, and no increase in serious adverse events. However, results only show survival benefit if RECOVERY trial, which account for 78% of patients, is included in pooled analysis. Based on AMSTAR-2 criteria, the overall confidence in the results from this study is rated as moderate. Therefore, the systematic review may provide an accurate summary of the results of the available studies that were included in the review.**

Ivermectin

- **PREPRINT**: Okumus et al, 2021. Evaluation of the Effectiveness and Safety of Adding Ivermectin to Treatment in Severe COVID-19 Patients. BMC Infectious Diseases. February 24,2021.
  Taken directly from Abstract:
  Background: An effective treatment option is not yet available for SARS-CoV2, which causes the COVID-19 pandemic and whose effects are felt more and more every day. Ivermectin is among the drugs whose effectiveness in treatment has been investigated. In this study; it was aimed to investigate the presence of gene mutations that alter ivermectin metabolism and cause toxic effects in patients with severe COVID-19 pneumonia, and to evaluate the effectiveness and safety of ivermectin use in the treatment of patients without mutation.
  Methods: Patients with severe COVID19 pneumonia were included in the study, which was planned as a prospective, randomized, controlled, single-blind phase 3 study. Two groups, the study group and the control group, took part in the study. Ivermectin 200 mcg/kg/day for five days in the form of a solution prepared for enteral use added to the reference treatment protocol -hydroxychloroquine + favipiravir + azithromycin- of patients included in the study group. Patients in the control group were given only reference treatment with 3 other drugs without ivermectin. The presence of mutations was investigated by performing sequence analysis in the mdr1/abcab1 gene with the Sanger method in patients included in the study group according to randomization. Patients with mutations were excluded from the study and ivermectin treatment was not continued. Patients were followed for 5 days after treatment. At the end of the treatment and follow-up period, clinical response and changes in laboratory parameters were evaluated.
  Results: A total of 66 patients, 36 in the study group and 30 in the control group were included in the study. Mutations affecting ivermectin metabolism was detected in genetic tests of six (16.7%) patients in the study group and they were excluded from the study. At the end of the 5-day follow-up period, the clinical improvement rate was higher in the study group [22/30 (73.3%)] compared to the control group [16/30 (53.3%)] (p=0.10). At the end of the study, mortality developed in 6 patients (20%) in the study group and in 9 (30%) patients in the control group (p=0.37). At the end of the follow-up period, the average peripheral capillary oxygen saturation (SpO2) values of the study and control groups were found to be 93.5% and 93.0%, respectively. Partial pressure of oxygen (PaO2)/FiO2 ratios were determined as 236.3 ± 85.7 and 220.8 ± 127.3 in the study and control groups, respectively. While the blood lymphocyte count was higher in the study group compared to the control group (1698±1438 and 1256±710, respectively) at the end of the follow-up period (p=0.24); reduction in serum C-reactive protein (CRP), ferritin and D-dimer levels was more pronounced in the study group (p=0.02, p=0.005 and p=0.03, respectively).
  Conclusions: According to the findings obtained, ivermectin can provide an increase in clinical recovery, improvement in prognostic laboratory parameters and a decrease in mortality rates even when used in patients with severe COVID-19. Consequently, ivermectin should be considered as an important alternative to the treatment of COVID-19 disease or as an additional option to existing protocols.
- SUMMARY + CONTEXT**: This prospective, randomized, controlled, single-blind multicenter Phase 3 clinical trial assessed the effectiveness of ivermectin treatment compared with standard of care (hydroxychloroquine + favipiravir + azithromycin) among 66 hospitalized, adult male patients with severe COVID-19 pneumonia. No statistically significant differences between groups on the rate of clinical improvement, mortality and SOFA scores at 5-day follow-up and/or by the end of the study was reported. Improved peripheral capillary oxygen saturation and reductions in various blood markers (C - reactive protein, ferritin and D-dimer) were reported for the ivermectin group vs the standard of care group by the end of the follow-up period.**

Notes:
As of January 28, 2021, systematic review and meta-analysis studies of low/very low quality (based on AMSTAR 2 criteria) and those on therapeutics that the CPTG has approved statements will be included in the daily titles as an abstract with a rapid critical appraisal.

As of October 23, 2020, clinical data on lopinavir/ritonavir and hydroxychloroquine/chloroquine are no longer included in this listing due to overwhelming evidence of little to no clinical benefit. However, these titles are still being retained in our cloud based database.
Feedback and discussion on this daily email is always welcome.

Have a good evening,

The MCM Daily Titles (Therapeutics) Team

(Yung-En Chung, Jaahnavi Dave, Nicole Forbes, Ramya Krishnan, Shalane Ha, Cheryl Marinsky, Elaha Sarwar, and Karen Timmerman)

Correspondence on Colchicine and Ivermectin and Vitamin D

Dear [redacted]

I am writing in response to your correspondence of April 21, 2021, addressed to Dr. Tam, alerting us to the use of Ivermectin, vitamin D, and Colchicine, to support Canada's response to COVID-19. The honourable Minister of Health, Patty Hajdu, has asked that I reply on her behalf. I sincerely regret the delay in responding.

The Government of Canada is closely tracking all potential therapeutic treatments, vaccines, diagnostic tests, medical devices, and disinfectants currently available and in development in Canada and abroad. The Public Health Agency of Canada (PHAC) conducts a thorough analysis and synthesis of the emerging evidence of promising therapeutics to treat COVID-19. This work informs decisions around procurement of therapeutics proven to be safe, effective, and authorized for COVID-19 indication by Health Canada.

Currently there is no clear evidence from any clinical trial to suggest that Vitamin D supplementation has any clinical benefit for the treatment or prevention of COVID-19, particularly in the Canadian context. Although some studies observed an association between vitamin D deficiency and higher COVID-19 incidence, this does not establish a causal link between low vitamin D levels and COVID-19 infection, nor does it serve as proof that supplementing with vitamin D could treat or prevent COVID-19.

Ivermectin is a broad-spectrum anti-parasitic agent authorized and approved by Health Canada for human and veterinary applications. Although ivermectin is used in humans to treat parasitic infections, Health Canada has **not** authorized its use for the treatment of COVID-19. The first of many steps in the authorization process includes the provision of promising results documented and obtained from high quality study designs and clinical trials demonstrating safety and efficacy followed by submission of an application by the manufacturer to Health Canada, which follows a well-defined channel to qualify for approval for a particular indication.

In laboratory studies ivermectin prevented the virus causing COVID-19 from replicating, raising the possibility that ivermectin may have a role in COVID-19 prophylaxis or treatment; however, many drugs that show promise in laboratory studies are not found to be effective in patients. To address the increased international attention on ivermectin as a potential treatment for COVID-19, the World Health Organization (WHO) convened an independent, international panel of clinical care experts from multiple specialties, patient partners and ethicists to review the evidence. Following a review of the existing data, the panel concluded that there was little proof of ivermectin's effectiveness on several important clinical measures such as reducing mortality, need for mechanical ventilation and time to clinical improvement. Consequently, on March 31st 2021, The WHO issued a statement on ivermectin advising against its use outside of clinical trials, stating the current evidence was inconclusive.

Colchicine is an anti-inflammatory drug authorized by Health Canada for the treatment of gout, and other inflammatory diseases, for short courses of treatment and is used off-label for other conditions at the discretion of the primary heath care provider. Use of this drug for therapeutic purposes is limited by side effects such as fatigue, nausea, vomiting, and diarrhea. Interest in this drug originates from its anti-inflammatory activity and potential use to prevent the "cytokine storm" characteristic of severe COVID-19. A review of available clinical trial results, evaluating the effectiveness of colchicine as a treatment for COVID-19 was independently conducted by

PHAC, the Canadian Agency for Drugs and Technologies in Health, l'Institut national d'excellence en santé et services sociaux and Alberta Health Services. All of whom concluded that there was no clear benefit to colchicine treatment and some concerning harms (e.g. a small number of patients treated with colchicine in the trials developed blood clots in the lungs, a serious complication that could lead to death). There are a number of ongoing clinical trials of colchicine, as these results become available; PHAC will assess if there is a benefit to treating COVID-19 patients with this repurposed drug. At this time, Canadian expert groups do not recommend prescribing colchicine to treat COVID-19.

In summary, currently there is no clear evidence to suggest that either ivermectin, colchicine, or Vitamin D supplementation provides clinical benefit for the treatment or prevention of COVID-19, particularly in the Canadian context. Health Canada, the regulator in Canada, will review clinical data once submitted from the manufacturer and determine the benefits and risks of potential therapeutics and provide regulatory approval for COVID-19 accordingly. PHAC is actively monitoring emerging evidence of clinical efficacy and safety on novel and repurposed therapeutics for COVID-19, including ivermectin, colchicine, and vitamin D; and makes recommendation based on findings from emerging high quality evidence on an ongoing basis.

Thank you. I apologize for the email I just sent. I had not read this response yet.

Can you recommend what agency or person I might correspond with in Alberta? I have been told it was Health Canada's jurisdiction to recommend Covid 19 treatments so I would like to confirm. Thanks.

On Fri, Jun 4, 2021 at 2:59 PM, Ephrem, Bersabel (PHAC/ASPC) <bersabel.ephrem@canada.ca> wrote:

Thank you [redacted] for your follow up questions. I would like to offer some points of clarification in my response.

One of the Public Health Agency of Canada's (PHAC) roles to support Canada's COVID-19 response is to acquire medications to treat COVID-19. This is to ensure that Canadians will have access to safe and effective treatments in the context of substantial global demand. PHAC monitors the emerging evidence around therapeutics to inform the decisions around procurement. Please note that PHAC does not issue recommendations as such, for or against the use of medications for COVID-19.

A manufacturer seeking market authorization will submit safety and efficacy data to Health Canada (HC). As the regulator, HC grants market authorization when it is satisfied that the benefits outweigh the potential risks. The list of applications received for drugs and vaccines for COVID-19 is available online.

The provinces and territories have primary responsibility for decisions around choice and use of therapeutics - including for COVID-19 – within their jurisdictions. In Canada, a health care professional's decision to prescribe or use a particular drug for a labelled or off-label indication is part of the practice of medicine, which falls under the jurisdiction of provincial and territorial professional regulatory authorities.

With best regards,

Bersabel

Subject: RE: I-Mask+ Protocol for early treatment of Covid-19

Good morning

Thank you for your prompt response to my inquiry. If I may, I urge you to reconsider Canada's stance on this extremely important matter. Have you, personally, read the research studies? Have you been following new developments as more and more respected scientists and researchers become convinced of the efficacy of this treatment for Covid-19? I implore you and your committee to do your own research and that you be be willing to step out of the accepted norms. Would you consider even allowing it on a person by person basis with informed consent? I know many people who are considering self treatment with veterinary quality ivermectin which concerns me greatly. I believe that it's in the best interest of Canadian for Canada to reconsider.

Respectfully,

[redacted]

On Thu, Jun 3, 2021 at 3:23 PM, Ephrem, Bersabel (PHAC/ASPC) <bersabel.ephrem@canada.ca> wrote:

>
> The Public Health Agency of Canada (PHAC) conducts a thorough analysis of the emerging scientific evidence regarding promising therapeutics to treat COVID-19, and Health Canada (HC) formally reviews these drugs to assess their safety, efficacy and quality before authorizing their sale in Canada. Many drugs that show promise in laboratory studies are found to be ineffective in patients.
>
> I-MASK+ Protocol is a prevention and early outpatient treatment protocol for COVID-19. While it includes a number of medications and supplements, it is centred on ivermectin, a broad-spectrum anti-parasitic agent authorized and approved by HC for human and veterinary applications to treat parasitic infections. At this time, HC has not authorized its use for the treatment of COVID-19.
>
> Independent reviews of available clinical trial results that evaluate the effectiveness of ivermectin as a treatment for COVID-19 have been conducted by: the Canadian Agency for Drugs and Technologies in Health (CADTH); Alberta Health Services; British Columbia's COVID-19 Therapeutics Committee/COVID-19 Therapeutics Review and Advisory Working Group; and Ontario's COVID-19 Science Advisory table. These bodies of scientific experts all concluded that there is no clear benefit to ivermectin treatment among patients with COVID-19.
>
> On March 31, 2021, the World Health Organization (WHO) issued a statement on ivermectin advising against its use outside of clinical trials, stating the current evidence was inconclusive. Further, the manufacturer - Merck - has also issued a statement against the use of ivermectin for the treatment of COVID-19.

https://www.merck.com/news/merck-statement-on-ivermectin-use-during-the-covid-19-pandemic/

In summary, there is currently no robust evidence (i.e., from high quality, well-designed clinical trials) to suggest that the I-MASK+ Protocol provides clinical benefit for the treatment or prevention of COVID-19, particularly in the Canadian context. Please be assured that PHAC continues to monitor the emerging evidence of clinical efficacy and safety from high quality trials on novel and repurposed therapeutics for COVID-19. The provinces and territories have primary responsibility for decisions around choice and use of therapeutics - including for COVID-19 – within their jurisdictions.

Thank you for writing to the Public Health Agency of Canada. I hope this information is helpful.

With best regards,

Bersabel

Subject: I-Mask+ Protocol for early treatment of Covid-19

Good morning Ms. Levesque:

I am writing to ask for your assistance. I have been following a growing body of research on the use of the I-Mask Protocol for early treatment and prophylaxis for Covid-19. Early in the pandemic, this protocol was not well understood and had only anecdotal evidence of its efficacy. Recently, however, I've been encouraged to see multiple studies showing good evidence of efficacy. I am puzzled as to why this treatment is not being studied in Canada as we are still in a situation across the country where people are being hospitalized for Covid-19. I am not a medical professional, but I wonder if it is not prudent and compassionate to open the door to other treatment possibilities which could prevent further deterioration of newly diagnosed victims of this virus? I do not know if you are the right person to send this email to, but I do know that you believe that we should be doing absolutely everything to try to treat this disease. My sincere hope is that you and your Task Force are seeking to include the use of existing medicines that we know are not harmful in and of themselves, such as Ivermectin, which is one of the components in the I-Mask Protocol. While we all look forward to the day when vaccinations take effect Canada-wide, in the meantime there are still many people who are falling ill and require medical treatment for this disease.

I respectfully submit to you this link to the growing body of knowledge and research studies around the I-Mask+ Protocol and I beg you to use your considerable influence to bring it to the attention of the Covid 19 Task Force and study it with all due diligence. If there is merit in this treatment, and your committee agrees to try it on a limited study basis, perhaps many Canadian lives could be saved and/or at the very least, saved from the longevity of hospitalizations for Covid 19 which they may be facing under the current treatment protocols. I believe that your committee has a moral and ethical obligation to fairly and diligently consider all possible treatments, irrespective of WHO or any other body who may be telling you otherwise. We are Canadians, first and foremost. We are responsible for one another.

Thank you so very much for your time. I ask you to please respectfully consider my request, and I very much look forward to your reply.

Sincerely,

[redacted]

Subject: COVID-19 Ontario Science Table webinar debrief: Treatment of outpatients with COVID-19.

As discussed at our division meeting, we didn't hear anything new at the Ontario webinar last night. It was designed to help primary care practitioners respond to questions from their patients about available treatments.

Ontario's science table does not recommend any current products available for outpatient use to treat COVID-19. They presented information on budesonide, dexamethasone, colchicine, vitamin D, ivermectin, bamlanivimab, hydroxychloroquine, and antibiotics.

Key take aways:
- no drugs or biologics recommended for outpatient use. Lack of strong evidence, weak studies.
- patient related outcomes very important when looking at clinical trial results (most trials so far are of poor quality)
    - critical appraisal lens very important when reviewing clinical trial results;
    - analysis of impact on vulnerable populations important as not all populations represented in clinical trials.
- for outpatients, emphasis should be placed on getting vaccinated, and other public health measures such as masking, physical distancing, hand washing, etc.

The Ontario science table did highlight a few drugs they are watching and I have asked Mina to take a look at the first 3 below:
- Camostat mesylate (protease inhibitor)
- Interferon beta (immune modulator)
- BMS-986414/BMS-986414
- Molnupiravir – we are already watching this one so good to see it on their list as well.

Mina, just looking for a quick summary of each so that we know a bit about them.

Thanks,
Jackie

Subject: Follow up request

Dear Mr. Ephrem,

As a final follow up, I am asking for your gracious indulgence. The link below will take you to a two hour interview with Dr.Peter McCullough from Dallas, Texas. Dr. McCullough has successfully submitted and published peer reviewed papers on the use of various protocols to treat outpatients with Covid-19, in The Lancet. Please make time in your busy schedule to listen to Dr. McCullough explain his perspective on the successful use of many existing drugs and neutraceuticals to treat early onset Covid 19 patients.

I am heartened and encouraged by your willingness to be open and to actively seek alternative treatments for Covid 19. May God grant you extraordinary insight, wisdom and courage.

I look forward to hearing from you and to your feedback on this interview.

I have copied my MP, Mr. Blaine Calkins on this correspondence. I hope you won't mind.

Kind Regards

ISSUE NOTE v2
Ivermectin; STROMECTOL® (Merck & Co.)
15 December 2021

Essential Facts

- **About the Product:** Ivermectin (Stromectol®, Mectizan®; Merck & Co.) is a broad-spectrum antiparasitic and belongs to a class of drugs called anthelmintics.
- **Method of administration:** Ivermectin is administered intravenously (I.V.) and orally in studies for the treatment of COVID-19. It is also being evaluated as a prophylaxis in oral tablet form.
- **Approved use in Canada**:
    - Ivermectin is not authorized for any COVID-19 indication in Canada.
    - Health Canada has authorized ivermectin for the treatment of parasitic infections in humans and animals. In humans, ivermectin is indicated for the treatment of intestinal strongyloidiasis and onchoceriasis, or rosacea.
- **Approved use for COVID-19 internationally**
    - In May 2020, the Peruvian Ministry of Health recommended ivermectin for the treatment of mild and severe COVID-19. The recommendation was removed in June 2020.
    - Ivermectin has not been authorized for the prevention or treatment of COVID-19 in any other jurisdiction worldwide.
- **Key benefits:** Orally administered. In small RCTs, ivermectin may reduce viral load in patients with mild-to-moderate COVID-19. However,
    - Ivermectin is generally well tolerated for its approved indications.
- **Key challenges:**
    - More robust clinical trials with larger sample sizes are needed to determine its efficacy for COVID-19. The majority of trials on ivermectin in COVID-19 were limited to small sample sizes and mixed evidence on clinical benefits.

Status of Agreements

- **Current procurement status**: Nil
- **Current distribution status**: Nil

Considerations (optional)

- In June 2020, the Pan American Health Organization (PAHO) released a statement for ivermectin to be used only in the context of clinical trials.
- On January 14 2021, the National Institutes of Health (NIH) issued a statement on the lack of clear benefit or harm in the use of ivermectin for the treatment of COVID-19 due to the insufficient evidence.
- On February 4 2021, Merck and Co. announced they do not support the safety and efficacy of ivermectin for the treatment of COVID-19 based on an analysis of the available data and emerging studies. Their analysis identified no scientific basis for ivermectin as a potential therapeutic from

pre-clinical studies; no meaningful evidence for clinical activity or clinical efficacy in patients with COVID-19 disease; and the lack of safety data in the majority of studies.

Positions

CPTG Position: The CPTG is monitoring emerging evidence of ivermectin as a treatment for COVID-19 and will conduct a detailed review once more evidence becomes available.

TTF Position: Nil

P/T Position: As of February 2021, the British Columbia COVID-19 Therapeutics Committee and the Alberta COVID-19 Scientific Advisory Group do not recommend ivermectin for the treatment or prophylaxis of COVID-19 outside of approved RCTs.

ANNEX

Key Findings (RCTs, Studies)

Ongoing RCTs:

- There are several ongoing randomized controlled trials (RCTs) evaluating the safety and efficacy of ivermectin for the prevention or treatment of COVID-19. The majority of trials are small with less than 100 participants.
    - NCT04527211: This RCT aims to determine the effectiveness and safety of ivermectin (200mcg/kg once a week for 7 days) as prophylactic treatment against SARS-CoV-2 infection in Columbian health workers with negative RT-PCR for SARS-CoV-2 infection (N=550). **Completion date: December 16, 2020.**
    - NCT04405843: The EPIC Trial is a Ph2/Ph3 RCT that aims to evaluate the efficacy of ivermectin treatment in adult patients with mild/moderate COVID-19 (N=476). **Completion date: December 21, 2020.**
    - NCT04529525: The IVERCORCOVID19 study is a single-center RCT that aims to evaluate the use of ivermectin in adults with mild/moderate COVID-19 disease (N=500) on incidence of hospitalizations. **Estimated completion date: January 31, 2021.**

Why is there no advise for use of Vitamin D3 for prevention of covid? It does prevent respiratory infections?
Why are ivermectin and HCQ not approved in Canada for use as prevention and treatment of covid? It's used in many countries with great success.

One of the Public Health Agency of Canada's (PHAC) roles to support Canada's COVID-19 response is to acquire medications to treat COVID-19. This is to ensure that Canadians will have access to safe and effective treatments in the context of substantial global demand. PHAC monitors the emerging evidence around therapeutics to inform the decisions around procurement.

Please note that PHAC does not issue recommendations as such, for or against the use of medications (including *vitamin D*) for COVID-19. Currently there is no clear evidence from any clinical trial to suggest that vitamin D supplementation has any clinical benefit for the treatment or prevention of COVID-19. Although some studies observed an association between vitamin D deficiency and higher COVID-19 incidence, this does not establish a causal link that vitamin D supplements could treat or prevent COVID-19.

Regarding your question about "approval" of ivermectin and HCQ for use as prevention and treatment of COVID: A manufacturer seeking market authorization (what you refer to as "*approval*") will submit safety and efficacy data to Health Canada (HC). As the regulator, HC grants market authorization when it is satisfied that the benefits outweigh the potential risks. The list of applications received for drugs and vaccines for COVID-19 is available online.

The provinces and territories have primary responsibility for decisions around choice and use of therapeutics - including for COVID-19 – within their jurisdictions. In Canada, a health care professional's decision to prescribe or use a particular drug for a labelled or off-label indication is part of the practice of medicine, which falls under the jurisdiction of provincial and territorial professional regulatory authorities.

Additional info from recent response, but I think the above is sufficient.

Ivermectin is a broad-spectrum anti-parasitic agent authorized and approved by Health Canada for human and veterinary applications to treat parasitic infections; Health Canada has not authorized its use for the treatment of COVID-19.

The World Health Organization (WHO) convened an independent, international panel of clinical care experts from multiple specialties, patient partners and ethicists to review the evidence. On March 31st 2021, the WHO issued a statement on ivermectin advising against its use outside of clinical trials, stating the current evidence was inconclusive. The manufacturer also issued the following statement against the use of ivermectin for the treatment of COVID-19:
https://www.merck.com/news/merck-statement-on-ivermectin-use-during-the-covid-19-pandemic/

Subject: RE: looping in Jane FW: For Action 21-110716-914 Correspondence Info Please COVID Therapies

Hi,

These are the only portions that I see us providing input for, There are many areas that the writer wants info on, but the others mainly concern public health measures and risks associated with vaccines.

1) We don't (CCDIC) provide guidance/recommendations for therapeutics (clinical management of COVID) though there is guidance on the PHAC website.
2) This is really under HC's jurisdiction though we could indicate that it is up to the manufacturer/sponsor to apply and submit data in support of a particular indication.

I will see what info we have provided in the past and send you a draft outline/response tomorrow.

Margaret

Hi,
Please review the new Incoming Correspondence attached. We are being asked to provide input only for the areas for which your section is responsible for. IDPB has the opinion that COVID Therapeutics may have some input. Please provide your Director approved input in the Mulit Branch template attached to me by **June 25, 2021** .
Thank you, Laura

Hello Aida
I am not sure how to proceed and more precisely, I do not understand what IDPCB means as 'suggest that Corporate could turn this correspondence and treat as a multi branch'. Would this be webmail requesting input for the applicable programs ?

Subject: FW: info please

Good morning. There are numerous areas that would need to be involved in providing input for this request, HC, VRAT, Stats Can, IDPB to name a few.

I would suggest that Corporate could change this into correspondence and treat as a multi branch where Corporate would request input from all pertinent areas and roll up the input. In the past I have seen the Director of Corporate sign correspondence. Perhaps they could be the signatory for this.

Pls let me know if you have any questions. Thank you, Nicky

Hello:

I was wondering if you could provide answers and links to the following questions:

Statistics on 2020 causes of death by month for Canada
Statistics on 2016-2019 causes of death by month for Canada
Statistics on monthly hospital admissions Canada 2016 to 2020

What are the conditions under which the covid vaccines are authorized for emergency use?
When does the emergency use of covid vaccines expire?
Why is there no advise for use of Vitamin D3 for prevention of covid? It does prevent respiratory infections?
Why are ivermectin and HCQ not approved in Canada for use as prevention and treatment of covid? It's used in many countries with great success.
Why are there still restrictions on people such as mask wearing and 'social distancing' which have zero effect on transmission as there's zero science behind such measures? Isolation and loneliness creates more harms and majority of people recover from covid quite fine and would recover better if therapeutics were used, such as ivermectin and HCQ, which have FDA and Health Canada approval?
Who is going to be responsible for deaths and injuries resulting from covid vaccines?
If people can't sue the drug companies, can they sue the pharmacists and/or health authorities administering experimental drugs?
What can be the long term adverse effects of these gene therapies injected for a virus that has very high recovery rate? If you don't know this, how can you promote this as 'safe' and how can you be telling people they save lives if:
1) you don't care about saving lives as lockdowns killed people
2) you don't care about saving lives as you're not allowing therapeutics which save people's lives and are used in other countries
3) majority of people recover from covid quite fine
4) natural immunity is long-lasting with no side effects of untested experimental injections
5) people who get covid and recover are helping others therefore locking people up prevents people from developing natural immunity
What type of informed consent are people being injected with this experimental gene therapy given? Are they advised of risk of injury and death following injection of this? Are they advised they're given experimental treatment which is more risky for majority of people than covid?
Why are there emergency orders? In real pandemics we would have around 20% of population at risk, hospitalized and dying, those are real pandemics when huge amount of population is at risk of dying.
Can you provide the link for vaccine adverse effects monitoring?
What % of vaccine injuries are usually reported (I gather it can be as low as 6% or less)?

thanks,

[redacted]

Subject: RE: Question re: ivermectin SR results: FYI ONLY: LOVE notifications

Hi Margaret,

Me and Serena provided some updates regarding Ivermectin and reviewed the publications that have become available since June 8th. We sent the summary to Joe. I've copy/pasted it here as well for your consideration. Bryant et al., was reviewed as well. We'll make sure to update the issue note today.

Best,
Mina

Two studies examining the efficacy of ivermectin in the treatment of covid-19 patients have been published since June 7th, 2021. Bryant et al. is kindly reviewed by Serena (please see below). Krolewiecki et al. did not include a large population size in their trial (n=45).

Although few observational studies and clinical trials have assessed ivermectin for the treatment and prevention of COVID-19 in humans, most had inadequate information and methodological limitations, according to another study (Lind et al.).

Bryant et al.:
A systematic review and meta-analysis of 24 randomized controlled trials assessed the efficacy of ivermectin treatment in reducing mortality, in several secondary outcomes such as time to PCR negativity, clinical recover, length of hospital stay..etc. All-cause mortality was assessed in 15 trials and found that ivermectin reduced the risk of mortality by 62% compared to no ivermectin treatment. For secondary outcomes, the evidence was less certain, rated low to very low certainty. They also assessed prophylaxis use of ivermectin, although only 3 studies were included in these analyses.

Subject: Question re: ivermectin SR results: FYI ONLY: LOVE notifications

Hi,

Could you please advise how the results of this study “align” with what is in our most recent version (June 8) of the issue sheet? As an aside, the issue sheet is entitled Feb. 23 so not sure if that should be revised/updated.

Thank you,

Margaret

- **Key benefits:** Orally administered. In small RCTs, ivermectin may reduce viral load in patients with mild-to-moderate COVID-19. However,
  - Ivermectin is generally well tolerated for its approved indications.
- **Key challenges:**
  - More robust clinical trials with larger sample sizes are needed to determine its efficacy for COVID-19. The majority of trials on ivermectin in COVID-19 were limited to small sample sizes and mixed evidence on clinical benefits.

Question: Ivermectin for COVID-19

Systematic reviews 1

1. Bryant A, Lawrie TA, Dowswell T, Fordham EJ, Mitchell S, Hill SR, Tham TC. Ivermectin for Prevention and Treatment of COVID-19 Infection: A Systematic Review, Meta-analysis, and Trial Sequential Analysis to Inform Clinical Guidelines. American journal of therapeutics. 2021; | Epistemonikos | DOI

CONCLUSIONS:

Moderate-certainty evidence finds that large reductions in COVID-19 deaths are possible using ivermectin. Using ivermectin early in the clinical course may reduce numbers progressing to severe disease. The apparent safety and low cost suggest that ivermectin is likely to have a significant impact on the SARS-CoV-2 pandemic globally.

Subject: Ivermectin and mAbs: FYI ONLY: LOVE notifications

DATA SYNTHESIS:

The collective search retrieved 3818 citations. Eight trials relating to 9 pharmacological interventions were identified. No evidence for nonpharmacological interventions was identified. Low certainty evidence of effectiveness in preventing severe disease was found for fluvoxamine (absolute difference: -8.7%; 95% CI.: -1.8% to -16.4%) and bamlanivimab plus etesevimab (absolute difference: -4.9%; 95% CI.: -0.8% to -8.9%). Both trials were limited by small sample sizes and short durations of follow-up. In addition, very low certainty evidence of effect was found for ivermectin plus doxycycline and sulodexide. Based on published data, insufficient evidence of effect was found for bamlanivimab (monotherapy), casirivimab plus imdevimab, ivermectin (monotherapy), nitazoxanide, and peginterferon lambda.

Subject: RE: Could we revise/remove the notes : Daily Therapeutics Titles for Wednesday, June 30th

Hi Margaret,

I made a few changes. We are primarily focusing on abstracts at this point, and if a title comes up that is particularly intriguing to us (both in terms of quality and the importance of the therapeutic), we will consider it for a summary.
For ivermectin, we reviewed recent studies and were unable to come up with any promising results (Joe, am I correct? Could you please confirm that this is the case?)

Notes:
As of June 30, 2021, systematic review and meta-analysis studies of Moderate and high quality (based on AMSTAR 2 criteria) and those on therapeutics that the CPTG has approved statements will be included in the daily titles as an abstract with a rapid critical appraisal. The summary format will be provided only for the high-impact studies containing critical data on closely monitored therapeutics.

As of October 23, 2020, clinical data on lopinavir/ritonavir and hydroxychloroquine/chloroquine, and as of May 13th, 2021, clinical data on ivermectin, are no longer included in this listing due to overwhelming evidence of little to no clinical benefit. However, these titles are still being retained in our cloud-based database.

Feedback and discussion on this daily email are always welcome.

Sent: 2021-06-30 3:31 PM
To: Arthur, Jacqueline (PHAC/ASPC) <jacqueline.arthur@canada.ca>; Djiometio, Joseph (PHAC/ASPC) <joseph.djiometio@canada.ca>; Azad, Mina (PHAC/ASPC) <mina.azad@canada.ca>
Subject: Could we revise/remove the notes : Daily Therapeutics Titles for Wednesday, June 30th

Some parts are out of date (reference to CPTG statements) and is it still accurate to say there's overwhelming evidence of no benefit to ivermectin?

Margaret

Notes:
As of January 28, 2021, systematic review and meta-analysis studies of low/very low quality (based on AMSTAR 2 criteria) and those on therapeutics that the CPTG has approved statements will be included in the daily titles as an abstract with a rapid critical appraisal.

As of October 23, 2020, clinical data on lopinavir/ritonavir and hydroxychloroquine/chloroquine, and as of May 13th, 2021, clinical data on ivermectin, are no longer included in this listing due to overwhelming evidence of little to no clinical benefit. However, these titles are still being retained in our cloud based database.

Feedback and discussion on this daily email is always welcome.

Docket #21-110716-914
Note: ***Please note Health Canada will also be providing input.***

Subject: **Correspondent looking for info re data, vaccines, Vitamin D, etc.**

From: **IDPB-CCDIC-COVID-19 Therapeutics Team**

Date: **June 22, 2021**

The following paragraphs are suggested for inclusion in the above-mentioned docket:

We are providing input to the following questions taken from the incoming.

Why is there no advice for use of Vitamin D3 for prevention of Covid-19? It does prevent respiratory infections.
Why are ivermectin and Hydroxychloroquine not approved in Canada for use as prevention and treatment of Covid-19? It is used in many countries with great success.

One of the Public Health Agency of Canada's (PHAC) roles to support Canada's COVID-19 response is to acquire medications to treat COVID-19. This is to ensure that Canadians will have access to safe and effective treatments in the context of substantial global demand. PHAC monitors the emerging evidence around therapeutics to inform the decisions around procurement.

PHAC does not issue recommendations as such, for or against the use of medications (including *vitamin D*) for COVID-19.

Regarding the question about "approval" of ivermectin and hydroxychloroquine (HCQ) for use as prevention and treatment of COVID-19: Before drug products are authorized for sale in Canada, Health Canada (HC) reviews them to assess their safety, efficacy and quality. A manufacturer seeking market authorization must present scientific evidence of a product's safety, efficacy and quality to HC. As the regulator, HC grants market authorization when it is satisfied that the benefits outweigh the potential risks. The list of applications received for drugs and vaccines for COVID-19 is available at: https://www.canada.ca/en/health-canada/services/drugs-health-products/covid19-industry/drugs-vaccines-treatments/authorization/applications.html.

Commented [JA1]: HC will need to review our suggested input.

The provinces and territories have primary responsibility for decisions around choice and use of therapeutics - including for COVID-19 – within their jurisdictions. In Canada, a health care professional's decision to prescribe or use a particular drug for a labelled or off-label indication is part of the practice of medicine, which falls under the jurisdiction of provincial and territorial professional regulatory authorities.

Subject: FYI Medscape Editorial FW: Ivermectin for COVID: How Do We Know What to Believe?

Hi,

You may or may not have seen this already via Medscape. It's a fairly quick read about a meta-analysis of trials looking at ivermectin to treat COVID.

Margaret

This transcript has been edited for clarity.
Welcome to *Impact Factor*, your weekly dose of commentary on a new medical study. I'm Dr F. Perry Wilson of the Yale School of Medicine.
This week, it's time we talk about ivermectin.
Since the first days of the COVID-19 pandemic, various existing drugs have been touted as near miracle cures for the disease. Often, the discussion of agents like hydroxychloroquine, lopinavir, and their ilk veered into the conspiratorial, squelching reasonable scientific discussion. Boosters would accuse detractors of hiding the truth of a safe and effective treatment at the behest of big pharma or the deep state. Detractors would accuse boosters of bad data analysis and wishful thinking.

Enter ivermectin and this meta-analysis of randomized trials by Andrew Hill and his colleagues in *Open Forum Infectious Diseases* that seems to show that the drug has pretty remarkable efficacy against COVID-19.

But before we dig in, let's put the mechanistic cards on the table.

Ivermectin is an antiparasitic agent that has been used to treat scabies, river blindness, and filariasis, among others. You may give it to your dog to prevent heartworm.
Discovered in 1975, the drug has been in worldwide use for nearly five decades and appears on the WHO list of essential medicines.
Ivermectin binds to certain chloride channels on nerve and muscle cells, paralyzing the creature exposed to it. These channels are present in worm and insect nervous systems, which is why the drug works.

Humans have the channels too, but only in our brains and spinal columns. Since ivermectin can't cross the blood-brain barrier, we are spared from its effects.
But you will note that SARS-CoV-2 has no muscles or nerves. So why the interest in this drug for this virus?
A lot of the enthusiasm comes from this study, by a group that has done nice work showing that the drug may have antiviral properties by affecting a protein called importin that a lot of viruses hijack for their own nefarious uses.
Researchers infected a cell culture with SARS-CoV-2 and added various concentrations of ivermectin. They then measured viral replication and found that the drug — in a petri dish, at least — could dramatically inhibit the ability of the virus to reproduce.
<< OLE Object: Picture (Device Independent Bitmap) >>
Caly L, et al. *Antiviral Res*. 2020;178:104787. https://doi.org/10.1016/j.antiviral.2020.104787

But there's a problem. The inhibitory concentration of the drug, around 2.5 micromolar, is not achievable in real live humans. In fact, standard ivermectin dosing achieves blood concentrations of about 25 nanomolar, 100-fold less than what was needed in vitro. Lung concentrations are a bit higher than blood concentrations but still 50-fold less than what is needed to inhibit the virus in cells in culture.

So, if ivermectin is going to work in humans with COVID-19, it has to be via some other mechanism — anti-inflammation or something. But as a starting point, biological plausibility here is not high.
But that never stopped us before. Multiple clinical trials at this point have evaluated the drug in COVID-19, and according to this meta-analysis at least, the results are compelling.

The authors combined data from 24 randomized trials of ivermectin — a total of 3328 patients — to examine a variety of outcomes ranging from resolution of symptoms to death. I'm going to focus on mortality because it's a pretty important endpoint, but the results for other outcomes are broadly similar.
Eleven trials with about 2000 patients total had death data available. Combining them gave a death rate of 3% in the ivermectin arm and 8.7% in the comparator arm, a statistically significant result.
<< OLE Object: Picture (Device Independent Bitmap) >>
Hill A, et al. *Open Forum Infect Dis*. 2021. https://doi.org/10.1093/ofid/ofab358
These forest plots can be a bit tough to read, but basically, each bar represents the effect of a single study and the diamond is the overall effect. Anything that crosses the line at 1 is not statistically significant. So, you have several studies trending toward significance that, when combined, give you that overall final result. This is how meta-analyses work.
But there is a bit of a problem here.
Remember that the data you get out of a meta-analysis are only as good as the data you put in. And there are some things to criticize about these data.
The authors aggregated data from studies that were peer-reviewed, those that were hosted on preprint servers, and those whose results they obtained through a network of researchers interested in ivermectin — even if the studies hadn't been published elsewhere. I broke down the mortality results by publication status here.
<< OLE Object: Picture (Device Independent Bitmap) >>
Hill A, et al. *Open Forum Infect Dis*. 2021. https://doi.org/10.1093/ofid/ofab358. Color-key modifications made by F. Perry Wilson, MD, MSCE.

I'm worried about a few things here. First, inclusion of completely unpublished studies is really problematic, since there is no way for anyone to vet the results. It's possible that those people running trials with promising data are even more likely to provide that to the meta-analyzers than those whose trials turned up nothing.
I do get why you might want to include preprints in your meta-analysis; peer-review is slow and the pandemic is happening fast. But peer review really does have a purpose. Some of these studies will probably never get published, and not because dark forces are conspiring against ivermectin; they just have some real problems.
One study driving the mortality benefit is this one, out of Iran, hosted on a preprint server.
It's a six-arm randomized trial of patients hospitalized with COVID-19. But it's weird. According to Table 1, 29% of them were PCR-negative for SARS-CoV-2. What's worse, this percentage is much higher in the two control groups (47%) compared with the ivermectin groups (20%). My math suggests that such a discrepancy would only occur 2 out of 10,000 times if randomization was, well, random.
<< OLE Object: Picture (Device Independent Bitmap) >>

I'm not saying this is fake or anything, but this is exactly the sort of thing that peer review would pick up on and give the authors a chance to correct. And yet here, this trial is given equal weight to all the others.
The other trial that seems to drive these results, also not yet peer-reviewed, is the Elgazzar trial out of Egypt.
Here, ivermectin was compared with hydroxychloroquine in 400 individuals with COVID-19. The results were pretty stark, in terms of death. In the moderately ill group, there were no deaths in the ivermectin group, four in the hydroxychloroquine group. In the severely ill group, two deaths in the ivermectin group, 20 in the hydroxychloroquine group.
<< OLE Object: Picture (Device Independent Bitmap) >>

Now, you'll note that hydroxychloroquine is not placebo, so there is some chance that what we are seeing is a sign that hydroxychloroquine is bad, not that ivermectin is good. But, inspired by the Iran paper, I went ahead and looked at Table 1 again. There were multiple statistically significant imbalances across baseline characteristics. Again, this is very unlikely if there wasn't some failure of randomization.

<< OLE Object: Picture (Device Independent Bitmap) >>

Elgazzar A, et al. https://www.researchsquare.com/article/rs-100956/v3

All I'm doing is some peer review of a study that has not yet been peer-reviewed. I'm not saying it's wrong, but review would allow the authors to provide an explanation, or maybe even reanalyze their results. Mistakes get made all the time in research; it helps to have a critical eye.

Others have noted that if you remove the Iran and Elgazzar papers, the protective effect of ivermectin in this meta-analysis disappears:

Which doesn't mean ivermectin isn't useful. What it means is we still don't know. We don't have ironclad evidence. The meta-analysis authors note that there are multiple large clinical trials going on right now that should seal the deal one way or the other. But what do we do until then?

Well, the easy answer is to say just cut the Gordian knot and get vaccinated; then you won't even need ivermectin. But there are plenty of places around the world where vaccines are not available and ivermectin is.

So, here's my pitch. All of these trialists should, in the interest of public health, release not just their results but their analytic datasets in a de-identified format to a site like datadryad.org so the community can review them directly. Instead of trying to parse what the authors mean in this or that sentence in the manuscript, just share the data. We'll know right away if we should believe it or not. This is easy, transparent, and perfectly legal. All of us — ivermectin boosters or ivermectin detractors — should speak with one voice on this: We are in a public health emergency. Release the data so we can know, for sure, what to believe.

Hi,

I know several people are working on this, but just sharing an earlier response we sent to someone who wrote about a treatment protocol. Some of the content might be useful, wrt our role etc.

I will see if I can find the word document as it is saved to our files as a pdf.

Margaret

Hi Joe,

I also included some zinc information. I'm assuming you'll remove the majority of the details, so please accept my apologies for having too much text.
This is the version that includes all of the comments and changes. As soon as I receive new comments, I will create a clean version for you to share with Cheryl and Jane.
I've also copied Margaret here in case she's willing to share her valuable inputs ☺

Best,
Mina

Hi Mina,

I just had a look at this doc., thank you for your prompt work!

Although I appreciate all the details that you have provided, the response that we will be crafting is limited to ¾ of page to one page. I would suggest summarizing this information in 2 bullets for our use. Briefly explaining the study parameters, findings and limitations- i.e. why this therapeutic is not suggested for use as a COVID-19 treatment. I suggest the same approach for zinc. I hope this helps. If you have any additional questions. Please reach out to me if you have any questions don't hesitate to ask ☺

Cheryl

Hello everyone,

I've attached a report for fluvoxamine. Although a paper was published in December 2020, it was not reviewed in our daily titles at the time. However, I was able to locate some information from a retrospective, observational cohort study in our daily title email from February 2021.

I was going to begin work on the other product (zinc), but I wanted to share this one with you first to ensure that I'm on the right track and that this is what you actually require. I would be grateful for your feedback.

Best,

Mina

Subject: RE: I-Mask+ Protocol for early treatment of Covid-19

Dear [redacted]

Thank you for your correspondence concerning the use of the I-Mask Protocol for early treatment and prophylaxis for COVID-19 to support Canada's response to COVID-19.

The Public Health Agency of Canada (PHAC) conducts a thorough analysis of the emerging scientific evidence regarding promising therapeutics to treat COVID-19, and Health Canada (HC) formally reviews these drugs to assess their safety, efficacy and quality before authorizing their sale in Canada. Many drugs that show promise in laboratory studies are found to be ineffective in patients.

I-MASK+ Protocol is a prevention and early outpatient treatment protocol for COVID-19. While it includes a number of medications and supplements, it is centred on ivermectin, a broad-spectrum anti-parasitic agent authorized and approved by HC for human and veterinary applications to treat parasitic infections. At this time, HC has not authorized its use for the treatment of COVID-19.

Independent reviews of available clinical trial results that evaluate the effectiveness of ivermectin as a treatment for COVID-19 have been conducted by: the Canadian Agency for Drugs and Technologies in Health (CADTH); Alberta Health Services; British Columbia's COVID-19 Therapeutics Committee/COVID-19 Therapeutics Review and Advisory Working Group; and Ontario's COVID-19 Science Advisory table. These bodies of scientific experts all concluded that there is no clear benefit to ivermectin treatment among patients with COVID-19.

On March 31, 2021, the World Health Organization (WHO) issued a statement on ivermectin advising against its use outside of clinical trials, stating the current evidence was inconclusive. Further, the manufacturer - Merck - has also issued a statement against the use of ivermectin for the treatment of COVID-19. https://www.merck.com/news/merck-statement-on-ivermectin-use-during-the-covid-19-pandemic/

In summary, there is currently no robust evidence (i.e., from high quality, well-designed clinical trials) to suggest that the I-MASK+ Protocol provides clinical benefit for the treatment or prevention of COVID-19, particularly in the Canadian context. Please be assured that PHAC continues to monitor the emerging evidence of clinical efficacy and safety from high quality trials on novel and repurposed therapeutics for COVID-19. The provinces and territories have primary responsibility for decisions around choice and use of therapeutics - including for COVID-19 – within their jurisdictions.

Thank you for writing to the Public Health Agency of Canada. I hope this information is helpful.

With best regards,

Bersabel

Subject: I-Mask+ Protocol for early treatment of Covid-19

Good morning Ms. Levesque:

I am writing to ask for your assistance. I have been following a growing body of research on the use of the I-Mask Protocol for early treatment and prophylaxis for Covid-19. Early in the pandemic, this protocol was not well understood and had only anecdotal evidence of its efficacy. Recently, however, I've been encouraged to see multiple studies showing good evidence of efficacy. I am puzzled as to why this treatment is not being studied in Canada as we are still in a situation across the country where people are being hospitalized for Covid-19. I am not a medical professional, but I wonder if it is not prudent and compassionate to open the door to other treatment possibilities which could prevent further deterioration of newly diagnosed victims of this virus? I do not know if you are the right person to send this email to, but I do know that you believe that we should be doing absolutely everything to try to treat this disease. My sincere hope is that you and your Task Force are seeking to include the use of existing medicines that we know are not harmful in and of themselves, such as Ivermectin, which is one of the components in the I-Mask Protocol. While we all look forward to the day when vaccinations take effect Canada-wide, in the meantime there are still many people who are falling ill and require medical treatment for this disease.

I respectfully submit to you this link to the growing body of knowledge and research studies around the I-Mask+ Protocol and I beg you to use your considerable influence to bring it to the attention of the Covid 19 Task Force and study it with all due diligence. If there is merit in this treatment, and your committee agrees to try it on a limited study basis, perhaps many Canadian lives could be saved and/or at the very least, saved from the longevity of hospitalizations for Covid 19 which they may be facing under the current treatment protocols. I believe that your committee has a moral and ethical obligation to fairly and diligently consider all possible treatments, irrespective of WHO or any other body who may be telling you otherwise. We are Canadians, first and foremost. We are responsible for one another.

Thank you so very much for your time. I ask you to please respectfully consider my request, and I very much look forward to your reply.

Sincerely,

[redacted]

Hi everyone,

Just thought I would share the Cochrane review on Ivermectin just issued! Not surprisingly, ivermectin is not recommended for the treatment and prevention of COVID-19. Their confidence in the reviewed evidence was low, have a look at the explanation in the summary of findings table, very interesting. Here is a link to the full report:

https://www.cochranelibrary.com/cdsr/doi/10.1002/14651858.CD015017.pub2/full

Thanks, please share with anyone else who might be interested!

Hi Cheryl,

Interesting! This is the second retraction of an Ivermectin article!!

Thank you so much for sharing them with us ☺

Best,
Mina

Subject: Ivermectin Study Retraction

Hi everyone,

Not sure if you have seen this, came up in my alerts from last week that I am just getting through now!

There was a claim made that a study included in the following meta-analysis was retracted over concerns of scientific fraud:

Meta-analysis of randomized trials of ivermectin to treat SARS-CoV-2 infection | Open Forum Infectious Diseases | Oxford Academic (oup.com)

A revised version of this study is underway.

Here is in interesting read from the same journal:

Ivermectin for the treatment of COVID-19 disease: Too good to pass up or too good to be true? | Open Forum Infectious Diseases | Oxford Academic (oup.com)

Thanks,

Cheryl

Subject: GPHIN Daily Report (24 August 2021)

Good morning,

Please find below the daily Summary and articles collected by GPHIN for your review and risk assessment.

GPHIN Daily Report
August 24, 2021

The Highlight of the Day

- **Burkina Faso:** The Ministry of Health announced on August 22, 2021 the detection of a suspected case of Ebola hemorrhagic fever at the Bogodogo University Hospital Center in Ouagadougou. According to officials, the 22-year-old patient arrived two days ago from Côte d'Ivoire. (AA, Africa Times)

Updates on COVID-19 (Media & Officials)

COVID-19 Variants

As of August 24, 2021:

- Countries with confirmed Alpha (B.1.1.7) variant: (171 countries)
- Countries with confirmed Beta (B.1.351) variant: (128 countries)
- Countries with confirmed Gamma (P.1) variant: (71 countries)
- Countries with Confirmed Delta (B.1.617.2) and Delta* (B.1.617 of unspecified lineage): **New** Egypt (138 countries)

***Please, note that countries may have reported directly to WHO and may not have been captured yet in our counts if no source was found. Both open source and WHO weekly Epi Update has been used to confirm the countries/ territories that have officially reported a variant. As of August 17, 2021, the WHO weekly Epi update has stated that the Alpha (B.1.1.7) variant has been reported in 190 countries, the Beta (B.1.351) variant in 138 countries and the Gamma (P.1) variant has been reported in 82 countries. As of August 10, Delta (B.1.617.2) has been detected in 148 countries. There have also been reports of Delta + (B.1.617 in 2 countries that did not identify the sub-lineage). No official source has yet been found for those countries that are not captured in our counts. Discrepancies between WHO and GPHIN's counts can also be attributed to geopolitics considerations, with WHO map not labelling Taiwan and Hong Kong SAR and therefore likely not including them in their list of countries. Variants of Interest (VOI) Eta (B.1.525) and Lambda (C.37) are being tracked on the spreadsheet.*

Immunization & Adverse events

- As of August 23, there were 52,441,903 doses of COVID-19 vaccine administered in Canada. For further information and breakdowns by province and territories, please view the link. (PHAC)
- As of August 23, 2021, 4,619,976,274 vaccine doses have been administered. For further information on country breakdown, please view the link. (WHO)
- **Canada:** Saskatchewan announced on Aug 20 that some 11-year-olds who turn 12 this year are allowed to get COVID-19 vaccination. This follows similar policy in Manitoba, British Columbia, Alberta and Ontario. Meanwhile, Health Canada has not approved any vaccines for children under 12. (National Post)
- **Cuba:** The Center for State Control of Medicines, Equipment and Medical Devices has granted emergency approval for its homegrown Soberana 2 vaccine which has an efficacy rate of 91.2%, and has already been used in areas with high rates of transmission. (Reuters)
- **United States:** On Aug 23, the U.S. FDA approved the first COVID-19 vaccine. The vaccine which has been known as the Pfizer-BioNTech COVID-19 Vaccine, and will now be marketed as Comirnaty, for the prevention of COVID-19 disease in individuals 16 years of age and older. The vaccine also continues to be available under emergency use authorization (EUA), including for individuals 12-15 years of age and for the administration of a third dose in certain immunocompromised individuals. (FDA)
- **South Africa**: Health Products Regulatory Authority received 1,473 reports of Covid-19 vaccine side-effects over a period of almost three months, but investigations showed no link between the drugs and people dying. The side-effect cases account for only 0.02% of the almost 7.1-million doses of vaccines administered in South Africa between the start of the nationwide vaccination roll-out on 17 May until 31 July. (Mail & Guardian)

Canada

- As of August 23, 2021 at 19:00 EST, there were 1,473,624 cases of COVID-19 recorded in Canada including 26,814 deaths. For further information and breakdowns by province and territories, please view the link. (PHAC)

- **Ontario**: Potentially 7,000 people need to get tested for COVID-19 after a basketball tournament, attended by teams from all over Ontario and other provinces, resulted in an outbreak. Durham Region Health Department is urging anyone who attended the 43rd Annual Jane and Finch Classic basketball tournament, which was held at Playground Global facility in Oshawa from Aug. 3 to 8, to get tested "immediately." (CTV)

International

- Globally, as of August 23, 2021, 5:09 pm CEST, there have been 211,730,035 confirmed cases of COVID-19, including 4,430,697 deaths. (WHO)
- **International:** FDA warns against the use of Ivermectin for use in treating or preventing COVID-19 in humans. The National Institutes of Health UK reviewed studies of the drug to treat COVID-19 patients and found insufficient evidence to recommend for or against use of the drug. (FDA, Daily Mail UK)
- **Niger:** A research, co-funded by European Union and ECOWAS Commission conducted in Niger, aimed at understanding the socio-economic impact of COVID-19 on free movement, migrant remittances and the well-being of migrant households, families, and communities in Niger has released their results. (Relief Web)
- **WHO:** On Aug 23th, WHO called for a two-month moratorium on administering booster shots of COVID-19 vaccines as a means of reducing global vaccine inequality and preventing the emergence of new coronavirus variants. Priority should be given to raising vaccination rates in countries where only 1 percent or 2 percent of the population has been inoculated (City News)

Studies Related to COVID -19

- **Canada:** The Wellesley Institute and Ontario Health released a report on race-based data collected between June 26, 2020, and April 21, 2021. The Institute found that racialized populations were much more likely to get COVID and to have negative impacts from COVID than the White population in Ontario. The Latino, Middle Eastern, Southeast Asian, South Asian and Black populations were five to seven times more likely to get COVID than the White population. Hospitalizations, ICU stays and deaths were also much higher. (*The Wellesley Institute*)
- **United States:**
    - Only 21 percent of patients with severe pneumonia caused by SARS-CoV-2 have a documented bacterial superinfection at the time of intubation, resulting in potential overuse of antibiotics, according to new research. (Outbreak News Today, *Journal of Respiratory and Critical Care Medicines*)
    - The majority of individuals who experience mild or moderate COVID-19 infection also experience long COVID-19, or persistent symptoms more than 30 days after they test positive, according to data from the longitudinal CoVHORT study at the University of Arizona Health Sciences. (Arizona,edu, *PLOS*)
- **China:** Inactivated COVID-19 vaccines developed by China curbed the spread of the Delta variant during a May outbreak in Guangzhou city in south China, a study has shown. Researchers from the Guangzhou Center for Disease Control and Prevention found that two shots of the vaccines provided an efficacy of 59 percent against COVID-19 caused by the Delta variant, 70.2 percent against moderate form of the disease, and 100 percent against severe cases. (ECNS, *Emerging Microbes and Infections*)

Domestic Events (Media & Officials)

- **Alberta:** Accidental opioid poisonings were increasingly reported in the emergency department at the Royal Alexandra Hospital in central Edmonton. Between January and May of this year, 624 Albertans died from accidental drug poisonings, a 41 per cent increase over the same time period in 2020. (Edmonton Journal)

- **Saskatchewan**: A study by University of Calgary showed higher rates of Kennedy's Disease among Indigenous people in Saskatchewan. The rate is 14.7 per 100,000 — way above the average rate of one to two per 100,000. Eighty-three per cent of the study's participants self-identified as Indigenous. (The Leader Post)

International Events (Media & Officials)

- **Hong Kong:** For the third time in a week, Hong Kong health officials report monitoring a human case of avian influenza A (H5N6) on the Chinese mainland. The latest case involves a 55-year-old man living in Liuzhou, Guangxi. He is a farmer and had contact with live poultry. He developed symptoms on August 17th and was admitted for treatment on the same day. The patient is in critical condition. (Outbreak News Today)

- **Sierra Leone:** Ebola booster vaccination kicks off following administration of the prime dose of Johnson & Johnson Ebola vaccine in May 2021 (Relief Web)

- **India:** There has been a spike in viral fever cases in rural areas of western UP. More than 70% of patients coming to the out-patient departments of government hospitals over the past week have complained of suffering from fever, cough, cold, dehydration and body ache. Health department has issued an alert at all the community health centres in the rural areas following the death of six people, including five children, in Mathura's Konh village in Farah due to a "mysterious" fever. The cause of death is still not clear but investigations are underway to test samples for malaria, dengue and COVID-19. (Times of India)

Research, policies, and guidelines (Media & Officials)

- **Study: Vaping damages blood vessels, much like cigarettes, study finds**
  Aerosol from vaping devices may impact human blood vessels to the same extent as smoke from cigarettes, according to an analysis presented on August 23rd. In experiments involving rats, the function of the endothelium, a layer of cells that help control blood clotting, blood pressure levels and immune function and keep blood vessels healthy was significantly impaired after a five-minute exposure to vaping aerosols, the data showed. Canada

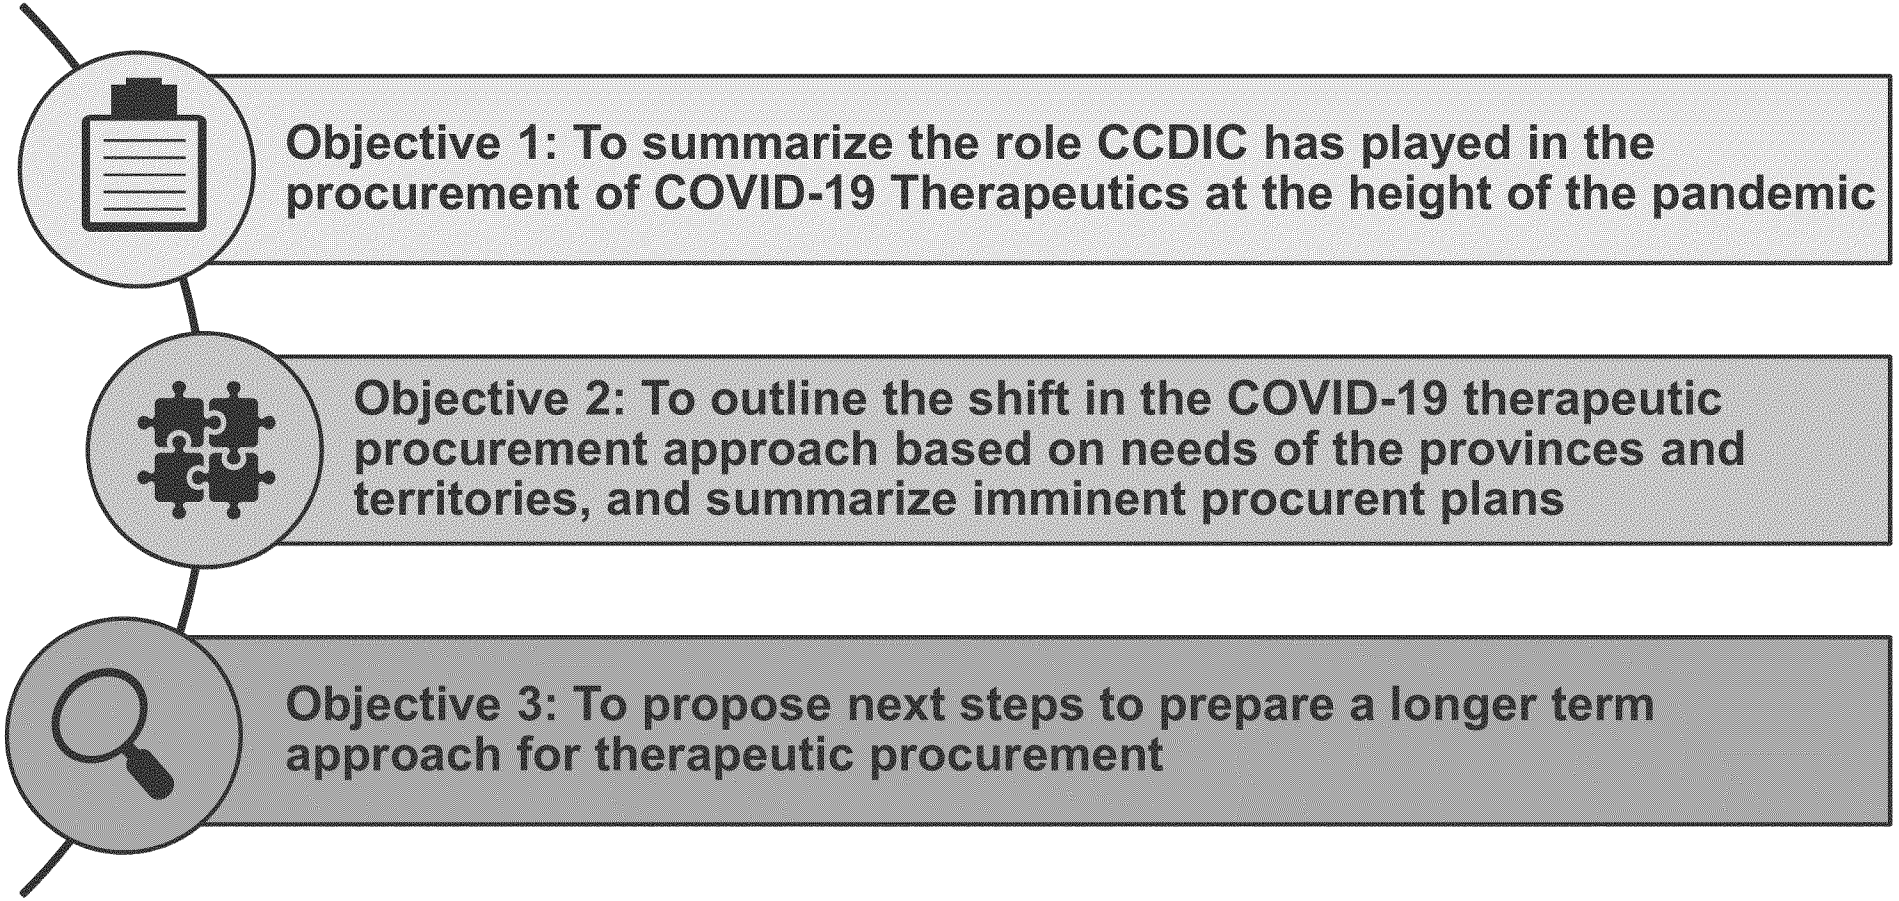
Update on COVID-19 Therapeutics and Next Steps

Briefing to the President

September 2, 2021

PROTECTING AND EMPOWERING CANADIANS
TO IMPROVE THEIR HEALTH

Objectives



The COVID-19 Therapeutics Procurement Landscape During the Height of the Pandemic

- Canada's ***health care system*** was at risk of being ***overwhelmed:***
  - Absence of safe and effective vaccines
  - Absence of prophylaxis to prevent and treat COVID-19
  - Shortage of novel therapeutics in development and fierce global competition for those that were
  - Uneven provincial and territorial capacity to urgently procure, and manage warehousing and logistics

- Therapeutic procurement is traditionally the ***responsibility of provinces and territories*** **(PTs)**, however during the unpresented global pandemic, the Government of Canada took responsibility for COVID-19 therapeutic procurement.
  - PHAC, with the support of Public Services and Procurement Canada (PSPC), assumed federal responsibility to urgently procure COVID-19 therapeutics to support timely access to (and equitable distribution of) critical COVID-19 therapies for the country.
    - PHAC received $200 million for the procurement of COVID-19 treatments through the Medical Countermeasures Wave 3a (MCM3a) budget. In September 2020, MCM3b secured an additional $300 million. (Approximately $338 million remains).

Governance

- Health Canada ***expedited the review of COVID-19 treatments*** while ensuring the products met safety, effectiveness and quality standards, and established the ***Critical Drug Reserve*** to help ensure that Canadians had access to the non-COVID-19 drugs they needed (divestment of the CDR is planned for March 31, 2022),

- The Deputy Minister Vaccine and Therapeutic Procurement Committee (DMPC) was established to integrate advice from different sources and make ***strategic decisions on the procurement of therapeutics***, vaccines and related supplies on behalf of Canada.

- PHAC's Infectious Diseases Programs Branch led the implementation of this ***new role*** to procure COVID-19 therapeutics that included identifying and building skills and expertise. *(see Appendix 1: Org Chart)*

- While PHAC made these products available free of charge for use by PTs, jurisdictions continued to execute their authorities to decide whether and how to use the novel COVID-19 therapeutics procured (i.e. adding new products to their formularies).

COVID-19 Therapeutic Procurements Completed to Date

Manufacturer	Type	Product Name	Number of Doses Procured	Remaining Doses	Source of External Advice (*see notes for details*)
Mint Pharmaceutical	Anti-malarial	Hydroxychloroquine Sulphate	[redacted]		N/A
Apotex	Anti-malarial	Hydroxychloroquine Sulphate			N/A
Gilead Sciences	Antiviral (Hospital use)	Remdesivir (Veklury)			COVID-19 Therapeutics Task Force (CTTF) recommendation COVID-19 Clinical Pharmacology Task Group (CPTG) limit use in clinical trials
Eli Lilly/AbCellera	Monoclonal Antibody (Outpatient use)	Bamlanivimab (LY-CoV555)			CTTF recommendation CPTG limit use in clinical trials
Hoffman La Roche	Monoclonal antibody (Hospital use)	Tocilizumab (Actemra)			CPTG and CTTF recommendations
Hoffman La Roche	Monoclonal Antibodies Cocktail (Outpatient use)	REGEN-COV			CTTF recommendation P/T clinical experts interest

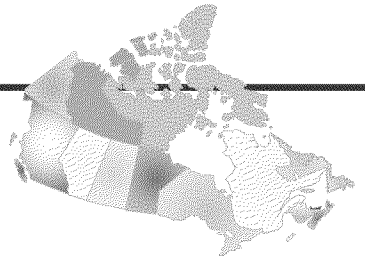
Provincial and Territorial Perspectives

Product Demand and Use

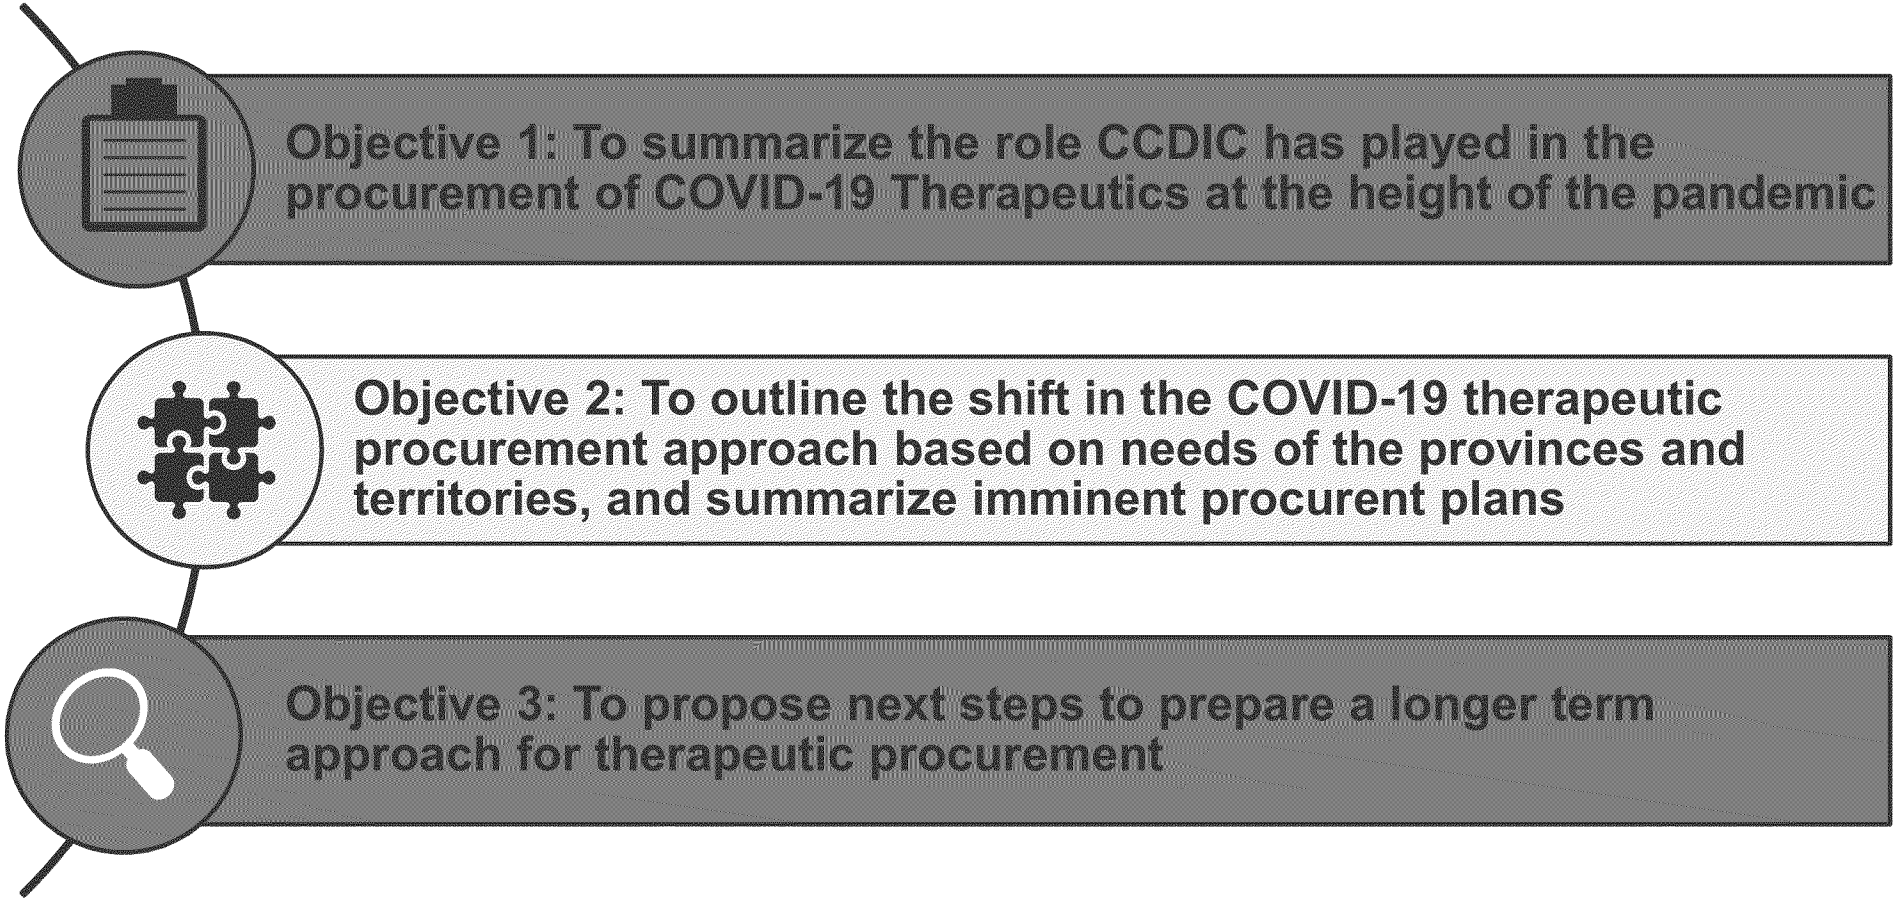
Tocilizumab	Distributed to PTs; used extensively
Bamlanivimab	Uptake has been limited; however, it has been used in some scenarios (immunocompromised patients)
Remdesivir	High demand by some PTs in the 3rd wave
REGN-COV	Several PTs have expressed interest and are requesting

Feedback From Provinces and Territories

- A desire for **early engagement** (prior to procurement) to assess the need for implementing new therapies in their jurisdiction.
- A need for **clinical guidance** from the Agency for Drugs and Technologies in Health (CADTH) and l'Institut national d'excellence en santé et services sociaux (INESSS).
- More **control** over what drugs enter into their Formulary.
- Concerns about future **costs** of novel COVID-19 drugs.



TACTICS



Section 2: Tactics - Fall 2021 COVID-19 Therapeutics Procurement Plans

Type of Drug & Mechanism of action	Immunomodulating drug (blocks the inflammatory cascade and improves survival in severe COVID-19)	Neutralizing monoclonal antibody (binds to and neutralizes the virus)	Broad spectrum antiviral (inhibits replication of SARS-CoV-2 to prevent disease progression and transmission) in mild or moderate COVID-19
Route of Administration	Intravenous (administered directly into a vein in a hospital setting that requires special equipment and trained personnel)	Intravenous (administered directly into a vein in a hospital setting that requires special equipment and trained personnel)	Oral (taken through the mouth in an “at home” setting)
Status in Canada	Off-label use for COVID-19 patients (authorized in Canada for the treatment of rheumatoid arthritis)	Authorized under the IO for the treatment of mild to moderate COVID-19	Submission to Health Canada anticipated in late 2021
International Regulatory Status	Authorized for treatment of rheumatoid arthritis, but not for treatment of COVID-19; use is “off-label”	May 26th 2021: FDA issued an EUA May 21, 2021 the EMA concluded that sotrovimab can be used to treat confirmed COVID-19	June 9th, 2021: U.S. government commits to purchase 1.7 million courses upon issuance of EUA by FDA
Key Product Benefits	- Similar to tocilizumab (purchased and used extensively) - Supplier of tocilizumab has been unable to meet demand, hence sarilumab would serve as a back-up	- Laboratory studies suggest superior performance against Variants of Concern (VOC) - Studies underway to determine if it can be provided through intramuscular injection, making it easy to administer in non-specialized settings (providing implementation benefit to PTs)	- There is no currently authorized oral antiviral for outpatient treatment of COVID-19 - Ease of administration makes it very suitable for use in the context of a pandemic

Fall 2021: COVID-19 Therapeutics Procurement Plans, con't:

- Additional quantity of ***tocilizumab*** (Hoffman La Roche) is being procured as part of current contract; used extensively by PTs.

- Continue to monitor the emerging evidence for COVID-19 treatments, including oral antivirals under development by ***Pfizer*** and monoclonal antibody by ***AstraZeneca*** . PHAC is in discussions with these companies for information exchange.

- Continue to monitor emerging scientific data from clinical trials as well as media to inform FPT discussions:
  - Casirivimab/imdevimab (REGN-COV) [HC authorized; PHAC procured]
    - Both the US and the UK have given emergency/conditional authorization for use for post-exposure prophylaxis, given intravenously (IV) or subcutaneously (SC)
  - Ivermectin [not authorized; not-procured]
    - High media interest due to US increasing use of veterinary drug; not supported by rigorous, scientific evidence.

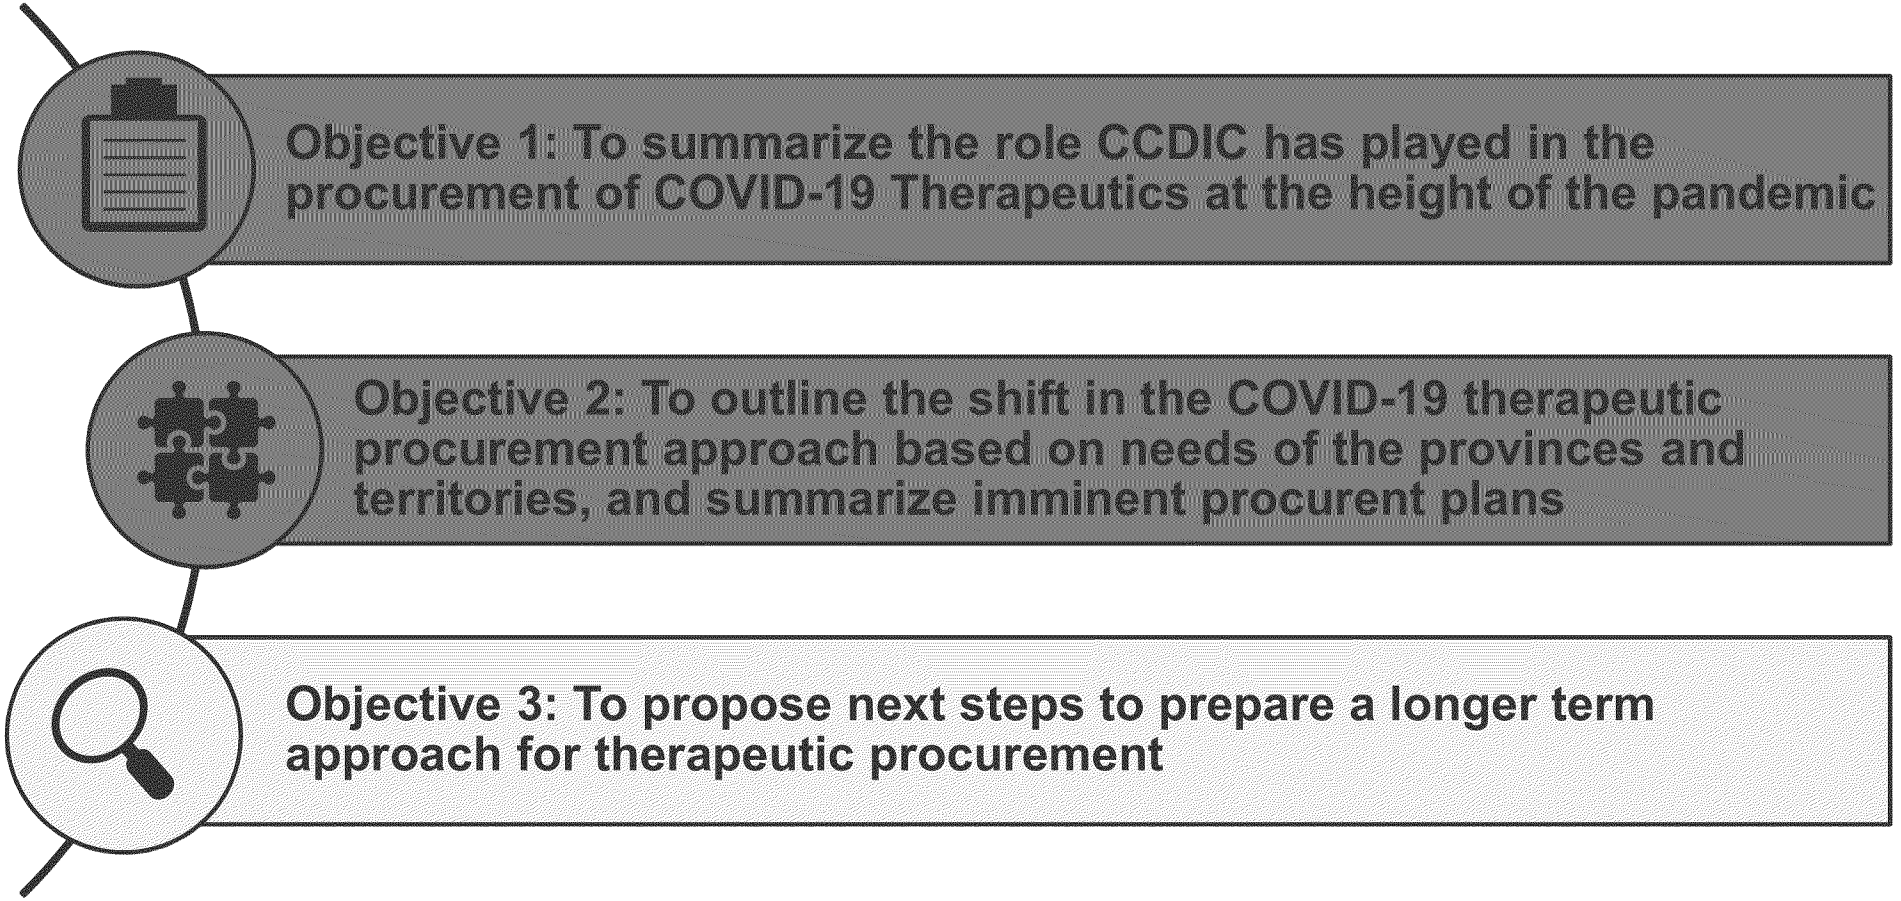
COVID-19 Lessons Learned at the Height of the Pandemic

- Federal procurement was initially ***more nimble*** than PT or FPT procurement, and ***removed barriers*** related to costs for PTs (if 100% covered by federal government). Drug companies ***preferred a single-window*** approach into the Canadian market in the context of a pandemic.
- Central buying power ensured that ***Canadians had equitable access*** to COVID-19 therapies, but required a high degree of ***interdepartmental coordination*** and ***collaboration.***
- The decision-making process to procure a COVID-19 therapeutic needs to be grounded in a consultative, science-based approach and is dependent on (*refer to Appendix 2: Decision-Making Process):*
  - A ***coherent approach*** among FPT governments with ***common understanding*** of roles and responsibilities;
  - Health Canada's independent ***regulatory review and authorization;***
  - The interest and needs of ***provinces and territories;***
  - Close collaboration with the FPT Drug Shortages tables responsible for PT procurement of drugs;
    - Input and advice through clinical expert discussions and feedback
  - ***Advice*** from CADTH and INESSS to guide PT decision-making about uptake and use of novel therapeutics.

Key Considerations in the Procurement Process and Engagement with Industry

- **Assessment of epidemiology and risk population:**
  - Does the new/repurposed therapeutic fill a treatment gap for COVID-19?
- **Impact of vaccines and alternative therapies:**
  - Does an alternative therapy already sufficiently address a COVID-19 treatment gap?
- **Urgency to act during global pandemic:**
  - Will Canada need to act quickly to secure access to the therapeutic so that it is available to clinicians and Canadians if needed?
- **PT interest and need:**
  - What is the evidence, feasibility and cost for implementation?
- **International partners actions/decisions:**
  - Has the therapy been authorized and implemented in similar healthcare systems?

NEXT STEPS



Therapeutics Procurement – COVID-19 and beyond

- Based on lessons learned, need to ***determine a FPT approach for decision-making*** in the acquisition and stockpiling of therapeutics in preparation for, and during future emergency situations.
  - With engagement of CADTH, INESSS and other key players

- Different branches/centres within PHAC (i.e., NESS, CIRID) and Health Canada (i.e., HPFB, SPB, ROEB) will need to be engaged to develop a coordinated approach for the future therapeutic procurement.

- A health portfolio-wide working group has been formed to explore options for moving forward on COVID-19 therapeutics (including divestment of inventory) for pandemic response by March 2022 .
  - Aligns with the Health Canada's Critical Drug Reserve set to end March 31, 2022
  - Considers changes to Health Canada's Interim Order as it extends beyond September 16, 2021.
  - Implications for PT formulary (costs) will need to be an important consideration.

- Further engagement of portfolio partners, provinces and territories, CADTH, INESSS and other government departments (e.g., PSPC, ISED) will help inform a transition approach for therapeutics procurement for COVID-19 and beyond.

Section 3: Next Steps

Next Steps: Longer Term Approach to Therapeutics – COVID-19 and beyond

- IDPB to come to Executive Committee in collaboration with the Emergency Preparedness and Response Branch and the Policy, Liaison and Coordination Branch (Vaccines) to discuss future PHAC role in therapeutics as well as the management of the COVID-19 therapeutics inventory.
- Bring forward a longer term approach to therapeutics procurement and use for discussion within the Health Portfolio.

Subject: RE: The Globe and Mail: The ivermectin mess: People are embracing a dangerous livestock drug, while rejecting vaccines

Not to rain on the parade, but there have been at least a couple of instances in the US of judges ORDERING a hospital to provide ivermectin to a patient. I read about that yesterday on Medscape. Horrifying to think of medical care being decided that way. No one on the hospital staff (physician) would administer it, so a physician who is sympathetic to the (ivermectin) cause was granted temporary privileges.

https://www.nbcnews.com/news/us-news/judge-orders-ohio-hospital-treat-covid-patient-ivermectin-n1278267

What a crazy, crazy place.

Subject: RE: The Globe and Mail: The ivermectin mess: People are embracing a dangerous livestock drug, while rejecting vaccines

Not to rain on the parade, but there have been at least a couple of instances in the US of judges ORDERING a hospital to provide ivermectin to a patient. I read about that yesterday on Medscape. Horrifying to think of medical care being decided that way. No one on the hospital staff (physician) would administer it, so a physician who is sympathetic to the (ivermectin) cause was granted temporary privileges.

What a crazy, crazy place.

Margaret

Hi Holly,

Thanks for the update.

Bersabel just replied with feedback. I would definitely make sure that we include Bersabel's proposed revision.

Margaret and Jane can look at it, but Bersabel mentioned that she wanted it to go up within the next few minutes.

Thanks,

Niyi

Hi Niyi,

I've sent an updated draft of the MLs to the group just now, which will need to be approved by Margaret and Bersabel, then I can try to expedite the rest of the approvals for it and get a copy of the updated MLs to OCPHO.

I think Dr. Tam is doing a press conference today on modelling at noon, so she may be looking for the lines ASAP this morning. I will give her office the old approved MLs in the mean time and we will do our best to get them the updated ones this morning.

But I think we need to take our discussion yesterday and turn it into an action plan to

- partner with CADTH as discussed now
- procure the new therapies now
- work with CADTH to provide use guidance in coming weeks

With milestones and target in use for Canadians date

Howard can you and Bersebel flesh this plan out so we

- can engage our partners?
- brief DM vaccines procurement committee (Simon's committee) week after next (sept 14) with a simple 1-page or so outline document we have pre discussed with HC regulator, PSPC?

Kaili can you work with Howard to get this on simon's agenda week after next?

Iain

The COVID super treatment Canadians can't get

The case for monoclonal antibody treatments

by: Sharon Kirkey

Florida and other American states seeing record-setting surges in COVID-19 cases are ordering truckloads of labmade antibodies Canadian doctors say are being underused in Canada.

Data suggest monoclonal antibody therapies, one of the formulations famously used to rid then-U.S.

President Donald Trump of COVID, can keep people with mild to moderate symptoms from ending up in hospital, or dead. Most recently, an early analysis of a Canadian-led study, a preprint not yet peer-reviewed, found a single dose of an antibody treatment developed by GlaxoSmithKline and Vir Biotechnology reduced the risk of COVID progressing from mild to serious illness in high-risk people by 85 per cent compared with a placebo.

"Importantly, in the test tube, this antibody retains activity against multiple variants," Dr. Anthony Fauci, U.S. President Joe Biden's top infectious diseases doctor told a recent White House briefing. GSK's antibody is a lab-engineered version of an antibody isolated from the blood of a survivor of the SARS outbreak two decades ago.

Vaccines offer the best hope of ultimately conquering COVID, but treatments are still needed to prevent severe disease in the infected, especially as the virus evolves. Ontario and other models are forecasting a "substantial" fall wave and while "we do not expect to see the same proportion of severely ill cases in the vaccinated," Ontario's COVID-19 science advisory table reported this week, not so for the unvaccinated. "Among the unvaccinated, we do expect to see a rapid increase in the number of seriously ill people needing hospital care as workplaces and education reopen in September."

Despite the pricey costs attached (typically $2,000 per dose) and logistical challenges (the drugs, for the most part, are administered via intravenous infusion) when given within five to 10 days of testing positive for COVID, monoclonal antibodies can slow the disease by blocking the virus, once inside the body, from invading new cells and replicating.

"These are valuable tools not being used in Canada, and should be," Dr. Andrew Morris, an infectious diseases specialist at Toronto's Mount Sinai Health System said on social media.

In Florida, state-run monoclonal antibody infusion clinics have been swamped with unvaccinated COVID patients seeking the free treatments.

In the U.S., the drugs have also been authorized as a "post-exposure" prophylaxis for close contacts of people infected with COVID who don't yet have symptoms, but who are at risk of getting infected, especially if they aren't fully vaccinated or might not have mounted a strong immune response to the vaccine.

But the prophylactic question hasn't been well studied. "Let's say you're at work and you find out that Bob down the hall is COVID positive and he's been talking to everybody at the coffee break," said infectious diseases specialist Dr. Donald Vinh, of McGill University Health Centre. Hypothetical Bob has symptoms, like sore throat and a fever. "In theory, you could say everybody who was talking to Bob is at high risk," Vinh said. "Those people might benefit from prophylaxis. But those studies are hard and expensive to do." It might make sense in principle, Vinh said, but the data are lacking.

GSK's sotrovimab was granted Health Canada authorization in July. The company is now "in active discussions with the federal government to secure supply of sotrovimab by early fall 2021," GSK said in an email to the National Post. The intent is that appropriate people will have access to it, with no out-of-pocket cost.

"Before somebody gets hospitalized with COVID, there isn't all that much," said Dr. Anil Gupta, a family doctor at William Osler Health System and lead investigator of the sotrovimab trial. By treating early, "we're preventing the cascade of events that includes viral replication and the body's inflammatory response. We're attacking before we get to that inflammatory response stage."

In the U.S. demand for sotrovimab has spiked almost 300 per cent over the past month, the Washington Post reported. Eli Lilly and Roche Canada also have been granted interim authorization for antibody cocktails.

The federal Liberals secured 26,000 doses of Lilly's bamlanivimab last November. Five months later, the government issued a "failure" warning that the drug may not be effective against certain variants. It's not known how many doses were used before the alert, but doctors say most of it sat on shelves, partly because there was no system to coordinate its use.

Bamlanivimab, Lilly said in an email this week, is not effective "against the variants currently at play in Canada." The company has another monoclonal combination currently under review by Health Canada that is effective at neutralizing Delta.

What hasn't proven effective against Delta are cow-sized doses of the dewormer ivermectin. In an Instagram video Wednesday, COVID-positive Joe Rogan said he threw "all kinds of meds" at the infection, including ivermectin, which conspiracy ideologues have been pushing as a "cure" for COVID. Health Canada issued an alert this week warning ivermectin, in livestock or human doses, has not been proven to treat COVID and that Canadians "should never consume health products intended for animals."

"Honestly, it's mind-boggling," Morris said in an interview. "In a variety of settings people have so-called 'drunk the Kool-Aid.'Ivermectin is the 2021 Kool-Aid."

Monoclonal antibodies aren't a magic bullet that will treat all. While the drugs seem well-tolerated, they can cause side effects like diarrhea and rash, though in fairly small numbers. What's more, bringing someone who has tested positive for COVID into a medical space that has adequate ventilation, personal protective equipment and skilled staff to infuse the drug and watch people for possible reactions requires a lot of infrastructure in an already stretched system, said Dr. Zain Chagla, an infectious diseases specialist and associate professor of medicine at McMaster University. "But the payoff is huge. There is probably a big cost benefit here, in preventing ventilator days and ICU days and hospitalization, to really scale this up as much as possible to mitigate the spread of the fourth wave, especially among people that are unvaccinated."

"This therapy is being used in the United States. It's being used in places in Europe," Chagla said. "It definitely can be done - I don't think there's anything to say we can't do this."

But with no national system, it's very possible that each province will land in different places in terms of who gets a monoclonal antibody and who doesn't, said Morris, a member of Ontario's COVID-19 science advisory table. "Across the provinces, they're looking at where and when to use them," he said.

"How do you figure out who's eligible and who is not? What are the criteria? How do you identify and notify them? We don't really have great systems in place for that."

Monoclonal antibodies shouldn't be seen as a substitute for vaccination, he and others stressed. "Are there going to be some people who avoid vaccination and just get this? I anticipate there will be. It's a shame," Morris said. "It's like the difference between quitting smoking and saying if I get lung cancer, I'll get an operation."

"The truth is that everyone who has forgone vaccination by now, the majority of them have no plans to get vaccinated in the near future. I'm not sure that they're banking on a monoclonal as a way to avoid future vaccination."

Still, experiences south of the border suggest some are unwisely putting their money on the treatments instead of the shots. "That is not a good thing," said Vinh.

Monoclonal antibodies have proven beneficial for high-risk people (including those with obesity, asthma, heart failure or chronic kidney disease and people over age 55) who have mild to moderate disease. "If you have more than that - you start requiring oxygen or hospitalization - not only is there no benefit in terms of survival from these monoclonal antibodies, there may even be a signal of increased risk of death, though it's hard to know if that's simply because those people were already too sick to begin with," Vinh said.

There's also a finite treatment window. The antibodies have to be given within 10 days after symptoms begin. "The thing about COVID is that it can progress rapidly," Vinh said. "You can literally go from sitting in your bed eating to, an hour or two later, requiring high amounts of oxygen. If you have to transport yourself to a setting where you have to wait in line and get triaged and get a monoclonal antibody, that window can close quickly."

Meeting Summary
Therapeutics Briefing: CPHO
Sept 2, 2021
5:30 – 6:00 pm

Attendees: Dr. Theresa Tam, Ian Stewart, Howard Njoo, Bersabel Ephrem, Jacqueline Arthur, Pamela Ponic, Jennifer Rendall, Vicki Wiseman,

Observers: Jane Kolbe

Summary of Action Items:

- Document COVID-19 therapeutics procured
  - Create a shared folder with OCFO to house folders supporting decision-making
- Raising the profile of COVID-19 therapeutics
  - Raise awareness, and enhance communication (including with SAC, and PT Chief Medical Officers)
- International comparison
  - Provide President with the international comparison
- Partnership with CADTH/INESSS
  - Engage CADTH to seek their support for the development of clinical guidance as part of the procurement decision-making process

KEY DISCUSSION POINTS

- ~~CPHO noted that we have to focus more on treatments~~
- An overview of GoC measures taken, and achievements to date, including COVID-19 therapeutics procured to date.~~Howard noted that therapeutic procurement is traditionally the responsibility of provinces and territories (PTs)~~
- ~~PHAC, (with PSPC) assumed responsibility to procure COVID-19 therapeutics and received $500 million under through the Medical Countermeasures budget~~.
- There is a need to communicate more about the role of COVID-19 therapeutics and the Federal Government contribution in the procurement of COVID-19 Therapeutics therapeutics.
  - ~~o~~

Current State of COVID-19 Therapeutics Procurements

- Howard noted that therapeutic procurement is traditionally the responsibility of provinces and territories (PTs)
- PHAC, (with PSPC) assumed responsibility to procure COVID-19 therapeutics and received $500 million under through the Medical Countermeasures budget ~~Howard gave an overview of GoC measures taken, and achievements to date, including COVID-19 therapeutics procured to date.~~
- Lessons/learnings were integrated into future decision-making processes - continually strengthened the procurement decision-making process.
  - Hydroxychloroquine was used as an example of early decisions taken at the beginning of the pandemic.
  - Future procurement decisions were later, better informed by advisory groups, and made by the Deputy Minister Procurement Committee.

Formatted

Formatted: Indent: Left: 0.63 cm, No bullets or numbering

- Discussion ensued regarding the role that the advisory groups that provided input to the decision-making. Specifically,
    - COVID-19 Therapeutics Task Force (CTTF)
    - COVID-19 Clinical Pharmacology Task Group (CPTG)
- Strengthening the process that documents procurement decisions requires attention and will enable PHAC to more expeditiously respond to an audit.
- CPHO – recognized that at the beginning, we needed to urgently invest, and now we need a different process.
    - Data from clinical trials are more informative at this stage of the pandemic, as opposed to early days
    - The UK was noted to be a useful jurisdiction to compare against in terms of procurements.

Action Item:

- *Document the decision-making process for the various COVID-19 therapeutics procured to date.*
- *Collect a complete record (Briefing Note, package, etc.).*
- *Work with the office of the Chief Financial Officer to ensure documents from IDPB and CFO documents are in a shared file.*

Shifting Needs of the PTs & Fall/2021 Procurement Plans

- Feedback from PTs was briefly discussed, including their desire for earlier engagement prior to procurement, a need for clinical guidance from CADTH and INESSS, more control over what drugs enter into their Formularies, and implementation costs and logistics.
- Howard noted our early thinking about the need to shift our procurement approach, collectively towards an FPT collective approach based on the needs of what PTs are telling us – and integrate this into our procurement plans.
- CPHO noted the important role that mAbs play – specifically in terms of having domestic capacity, "having mAb capacity is very important for an emerging pathogen".
- COVID-19 therapeutics currently under consideration for Fall/2021 procurement was discussed, including mAbs, and tocilizumab (as it was used extensively in previous waves)
    - The state of safety and efficacy data for oral antivirals was noted to be evolving.
    - PHAC is in the process of information exchanges with the drug makers, but until sufficient scientific data is available to assess safety and efficacy, procurement negotiations for oral anti-virals are premature.
- Ivermectin was discussed – The US FDA put out a tweet, and PHAC also issued a statement against the use of this drug for treatment of COVID-19

4th Wave Planning and the Role of COVID-19 Therapeutics

- CPHO noted that treatment is critical in the process of 4th wave/future wave planning.
    - She noted that treatment does not appear enough in 4th wave planning placemats, etc..
- CPHO brought this key consideration forward to DM – Health Canada
- Treatment must be a key aspect, as people will become ill and end up in the ICU
    - They can survive with an improvement in their treatment, or perhaps stay for a shorter time, which relieves the pressure on the health system
- There is a need to ensure we have a process, and if we don't, we have to make sure that we quickly have a plan to determine whether we have to procure any more
- We do not have a regularized process in for COVID-19 therapeutics as it exists for vaccine procurements (every-other day)

Commented [EB(1]: Don't recall this? When and what did she bring up to the DM?

Commented [EB(2]: I don't know if we can say that we do not have a regularized process. Do not have a long-standing and know process?

- Vaccine procurement was noted to differ from therapeutics in that it is less complex in that it does not require physician intervention, making bulk procurement of vaccines a more direct path
- The COVID-19 therapeutics landscape was noted to be more complex because of it requiring a physician prescription, and the role of formularies.

- How we communicate how we manage COVID has also been relatively silent in terms of therapeutics

Action Item:

- *CPHO signaled a desire for more regular executive involvement/communication – raising the profile of therapeutics*
  - *Governance work was noted to be important to the CPHO*
  - *CPHO interested in going to SAC to describe the role of therapeutics, and to more actively communicate PHAC's role in therapeutics*
  - *CPHO noted that COVID-19 therapeutics is not in the MTP process and tracker*

Discussion on Supply Issues of Specific COVID-19 Therapeutics

- Tocilizumab (was in high demand by PTs in wave 3) and sarilumab were noted to have excellent Clinical Trial results in terms of efficacy data
  - Both drugs are used for rheumatoid arthritis, high efficacy, and well established
  - PHAC was noted to be advancing contract negotiations to procure sarilumab as a result of the global shortage of tocilizumab, given it can be used as a back-up treatment in lieu of tocilizumab
- PSPC is in the process of advancing this negotiation with sarilumab

Action Item:

- *Send the Memo to President for the procurement of Sarilumab*
- *VP to check in with PHAC's – to ensure that funding is available for sarilumab*

Discussion on Next Steps:

- Howard introduced the need to take the lessons learned with COVID-19 procurement processes to date, and integrate this into longer term thinking
  - COVID-19 therapeutics is a complex process
  - Involving several Branches within PHAC
- Next steps would involve looking at a more fulsome FPT approach
- To build a sustainable model, beyond COVID-19 – for therapeutics in general for infectious diseases.
- Howard proposed the following process:
  - Commence internal discussions commence with VPs within PHAC to discuss the future role of therapeutic procurement within PHAC
  - Engage EC with a proposed approach for discussion
  - Roll out the discussion to the Health Portfolio
- The discussion of PHAC's public health role vs Health Canada's regulatory role regarding therapeutic procurement was also noted to be important to discern and articulate.
- Ian asked that we map out the needs/steps in the process of COVID-19 therapeutic procurement and perform an international comparison to visually demonstrate the public health role in therapeutics in other countries

Action Item:

- *Provide the President with the international comparison - mapping.*
- *Initiate engagement with PHAC VPs to discuss PHAC's future role in therapeutics with the view to developing a proposed approach for consideration at EC – with the eventual goal of consulting with the rest of the health portfolio partners to integrate their*
    - *Need a meeting of the minds of the VPs*

Discussion on the Use of FPT feedback to Inform procurement Decisions

- The Drug Shortages Table was noted to be a key existing mechanism that is being leveraged to inform PHAC's procurement recommendations.
- Current processes are ensuring that CCDIC is receiving PT endorsement before a procurement recommendation is rendered - to ascertain PT demand and likelihood of usage.
- CPHO noted that CCDIC has addressed the need for early engagement of PTs regarding COVID-19 therapeutic procurement recommendations.
- CPHO signaled her interest in ensuring broad awareness within PTs so that the Chief Medical Officers within the PTs are aware of the treatments procured and available
- CPHO also recognized that clinicians are needing clinical guidance – Either PHAC or HC to ensure that CADTH and INESS are engaged
    - Bersabel noted that we are pushing as far as we could to engage with CADTH to ensure that PTs have the guidance that they need. Conversations with CADTH are slow, but moving in the right direction.
    - CADTH may have resource limitations – which may influence the rate that they may be able to provide clinical guidance
- A request for top-up funding was requested prior to the writ dropping
    - 3 billion was given for vaccines, President advised that it could be repurposed for therapeutics, if necessary.
- CPHO – reiterated – the important role of therapeutics.
    - As we may see a variant of concern escaping the vaccine, and the vaccines being re-tooled, therapeutics plays a key role.

Action Item:

- *President suggested to consider partnering with CADTH to request that they provide guidance prior to PHAC doing large scale procurement*
- *CPHO would like to ascertain how many patients are being helped with the treatments that we have - to ensure that we are mapping out that what we have is aligned with the trajectory of the 4th wave modelling – with an assumption built in by clinicians who are indicating how they would be using the product.*

Bersabel and Niyi;
As requested please find attached the Word document on international comparisons that was prepared by the OPSM and submitted in April 2021 to Roman Szumski, VP at the time. Also is the list prepared by Jane of the “action items” from the most recent President briefing – there may be a more recent version but I have been out of the loop so Jane please circulate any updates.
Thanks,
Jackie

Subject: follow up from President briefing

Hi Jane;
Bersabel has asked for the “to do” list we had discussed at our debrief last week after the President’s briefing. She wants to send it to Howard so could you circulate it by email for us to look at today please?
Thanks,
Jackie

Meeting Summary
Therapeutics Briefing: CPHO
Sept 2, 2021
5:30 – 6:00 pm

Attendees: Dr. Theresa Tam, Ian Stewart, Howard Njoo, Bersabel Ephrem, Jacqueline Arthur, Pamela Ponic, Jennifer Rendall, Vicki Wiseman,

Observers: Jane Kolbe

Summary of Action Items:

- Document COVID-19 therapeutics procured
  - Create a shared folder with OCFO to house folders supporting decision-making
- Raising the profile of COVID-19 therapeutics
  - Raise awareness, and enhance communication (including with SAC, and PT Chief Medical Officers)
- International comparison
  - Provide President with the international comparison
- Partnership with CADTH/INESSS
  - Engage CADTH to seek their support for the development of clinical guidance as part of the procurement decision-making process

KEY DISCUSSION POINTS

- CPHO noted that we have to focus more on treatments
- Howard noted that therapeutic procurement is traditionally the responsibility of provinces and territories (PTs)
  - PHAC, (with PSPC) assumed responsibility to procure COVID-19 therapeutics and received $500 million under through the Medical Countermeasures budget.

Current State of COVID-19 Therapeutics Procurements

- Howard gave an overview of GoC measures taken, and achievements to date, including COVID-19 therapeutics procured to date.
- Lessons/learnings were integrated into future decision-making processes - continually strengthened the procurement decision-making process.
  - Hydroxychloroquine was used as an example of early decisions taken at the beginning of the pandemic.
  - Future procurement decisions were later, better informed by advisory groups, and made by the Deputy Minister Procurement Committee.
- Discussion ensued regarding the role that the advisory groups that provided input to the decision-making. Specifically,
  - COVID-19 Therapeutics Task Force (CTTF)
  - COVID-19 Clinical Pharmacology Task Group (CPTG)
- Strengthening the process that documents procurement decisions requires attention and will enable PHAC to more expeditiously respond to an audit.

- CPHO – recognized that at the beginning, we needed to urgently invest, and now we need a different process.
    - Data from clinical trials are more informative at this stage of the pandemic, as opposed to early days
    - The UK was noted to be a useful jurisdiction to compare against in terms of procurements.

Action Item:

- *Document the decision-making process for the various COVID-19 therapeutics procured to date.*
- *Collect a complete record (Briefing Note, package, etc.).*
- *Work with the office of the Chief Financial Officer to ensure documents from IDPB and CFO documents are in a shared file.*

Shifting Needs of the PTs & Fall/2021 Procurement Plans

- Feedback from PTs was briefly discussed, including their desire for earlier engagement prior to procurement, a need for clinical guidance from CADTH and INESSS, more control over what drugs enter into their Formularies, and implementation costs and logistics.
- Howard noted our early thinking about the need to shift our procurement approach, collectively towards an FPT collective approach based on the needs of what PTs are telling us – and integrate this into our procurement plans.
- CPHO noted the important role that mAbs play – specifically in terms of having domestic capacity, "having mAb capacity is very important for an emerging pathogen".
- COVID-19 therapeutics currently under consideration for Fall/2021 procurement was discussed, including mAbs, and tocilizumab (as it was used extensively in previous waves)
    - The state of safety and efficacy data for oral antivirals was noted to be evolving.
    - PHAC is in the process of information exchanges with the drug makers, but until sufficient scientific data is available to assess safety and efficacy, procurement negotiations for oral anti-virals are premature.
- Ivermectin was discussed – The US FDA put out a tweet, and PHAC also issued a statement against the use of this drug for treatment of COVID-19

4th Wave Planning and the Role of COVID-19 Therapeutics

- CPHO noted that treatment is critical in the process of 4th wave/future wave planning.
    - She noted that treatment does not appear enough in 4th wave planning placemats, etc..
- CPHO brought this key consideration forward to DM – Health Canada
- Treatment must be a key aspect, as people will become ill and end up in the ICU
    - They can survive with an improvement in their treatment, or perhaps stay for a shorter time, which relieves the pressure on the health system
- There is a need to ensure we have a process, and if we don't, we have to make sure that we quickly have a plan to determine whether we have to procure any more
- We do not have a regularized process in for COVID-19 therapeutics as it exists for vaccine procurements (every-other day)
    - Vaccine procurement was noted to differ from therapeutics in that it is less complex in that it does not require physician intervention, making bulk procurement of vaccines a more direct path
    - The COVID-19 therapeutics landscape was noted to be more complex because of it requiring a physician prescription, and the role of formularies.

- How we communicate how we manage COVID has also been relatively silent in terms of therapeutics

Action Item:

- *CPHO signaled a desire for more regular executive involvement/communication – raising the profile of therapeutics*
    - *Governance work was noted to be important to the CPHO*
    - *CPHO interested in going to SAC to describe the role of therapeutics, and to more actively communicate PHAC's role in therapeutics*
    - *CPHO noted that COVID-19 therapeutics is not in the MTP process and tracker*

Discussion on Supply Issues of Specific COVID-19 Therapeutics

- Tocilizumab (was in high demand by PTs in wave 3) and sarilumab were noted to have excellent Clinical Trial results in terms of efficacy data
    - Both drugs are used for rheumatoid arthritis, high efficacy, and well established
    - PHAC was noted to be advancing contract negotiations to procure sarilumab as a result of the global shortage of tocilizumab, given it can be used as a back-up treatment in lieu of tocilizumab
- PSPC is in the process of advancing this negotiation with sarilumab

Action Item:

- *Send the Memo to President for the procurement of Sarilumab*
- *VP to check in with PHAC's – to ensure that funding is available for sarilumab*

Discussion on Next Steps:

- Howard introduced the need to take the lessons learned with COVID-19 procurement processes to date, and integrate this into longer term thinking
    - COVID-19 therapeutics is a complex process
    - Involving several Branches within PHAC
- Next steps would involve looking at a more fulsome FPT approach
- To build a sustainable model, beyond COVID-19 – for therapeutics in general for infectious diseases.
- Howard proposed the following process:
    - Commence internal discussions commence with VPs within PHAC to discuss the future role of therapeutic procurement within PHAC
    - Engage EC with a proposed approach for discussion
    - Roll out the discussion to the Health Portfolio
- The discussion of PHAC's public health role vs Health Canada's regulatory role regarding therapeutic procurement was also noted to be important to discern and articulate.
- Ian asked that we map out the needs/steps in the process of COVID-19 therapeutic procurement and perform an international comparison to visually demonstrate the public health role in therapeutics in other countries

Action Item:

- *Provide the President with the international comparison - mapping.*
- *Initiate engagement with PHAC VPs to discuss PHAC's future role in therapeutics with the view to developing a proposed approach for consideration at EC – with the eventual goal of consulting with the rest of the health portfolio partners to integrate their*

- *Need a meeting of the minds of the VPs*

Discussion on the Use of FPT feedback to Inform procurement Decisions

- The Drug Shortages Table was noted to be a key existing mechanism that is being leveraged to inform PHAC's procurement recommendations.
- Current processes are ensuring that CCDIC is receiving PT endorsement before a procurement recommendation is rendered - to ascertain PT demand and likelihood of usage.
- CPHO noted that CCDIC has addressed the need for early engagement of PTs regarding COVID-19 therapeutic procurement recommendations.
- CPHO signaled her interest in ensuring broad awareness within PTs so that the Chief Medical Officers within the PTs are aware of the treatments procured and available
- CPHO also recognized that clinicians are needing clinical guidance – Either PHAC or HC to ensure that CADTH and INESS are engaged
    - Bersabel noted that we are pushing as far as we could to engage with CADTH to ensure that PTs have the guidance that they need. Conversations with CADTH are slow, but moving in the right direction.
    - CADTH may have resource limitations – which may influence the rate that they may be able to provide clinical guidance
- A request for top-up funding was requested prior to the writ dropping
    - 3 billion was given for vaccines, President advised that it could be repurposed for therapeutics, if necessary.
- CPHO – reiterated – the important role of therapeutics.
    - As we may see a variant of concern escaping the vaccine, and the vaccines being re-tooled, therapeutics plays a key role.

Action Item:

- *President suggested to consider partnering with CADTH to request that they provide guidance prior to PHAC doing large scale procurement*
- *CPHO would like to ascertain how many patients are being helped with the treatments that we have - to ensure that we are mapping out that what we have is aligned with the trajectory of the 4th wave modelling – with an assumption built in by clinicians who are indicating how they would be using the product.*

Subject: international comparison on therapeutics decision-making and "action items" from President briefing

Bersabel and Niyi;
As requested please find attached the Word document on international comparisons that was prepared by the OPSM and submitted in April 2021 to Roman Szumski, VP at the time. Also is the list prepared by Jane of the “action items” from the most recent President briefing – there may be a more recent version but I have been out of the loop so Jane please circulate any updates.
Thanks,
Jackie

Jacqueline Arthur, BScN, RN
(she | elle)
A/Executive Director | Directrice Exécutive par intérim
Strategic Issues and Integrated Management Division | Division des enjeux stratégiques et de la gestion intégrée
Centre for Communicable Diseases and Infection Control | Centre de la lutte contre les maladies transmissibles et les infections

Public Health Agency of Canada | Agence de la santé publique du Canada
t. (613) 889-8455

Action Items

- Document the decision-making process for the various COVID-19 therapeutics procured to date.
    - Development of SOPs

- Create an inventory and collect a complete record of information and communication materials related to procurement (issue notes, briefing notes, memos, etc.).

- Work with the office of the Chief Financial Officer to ensure documents from IDPB and OCFO documents are in a shared file.

- Preparation of briefing materials to support increased regularity and frequency of meetings between Therapeutics, the CPHO and with executives to increase awareness, relevance and visibility of therapeutics
    - e.g. Therapeutics presence at SAC meetings and briefings with provincial Chief Medical officers to clarify and convey PHAC's role in therapeutics

- Continue work to improve governance of Therapeutics

- Preparation of documents and information materials that support inclusion of Therapeutics in medium term planning policy (MTP) for pandemic response and addition to MTP tracker

- Development of mechanisms/strategies that facilitate and expedite decision making related to the need to procure additional therapeutics and a policy process to fast track purchases

- Send the Memo to the President for the procurement of Sotrovimab and Sarilumab

- VP to check in with PHAC – to ensure that funding is available for Sarilumab

- Provide the President with a map comparing international public health approaches, actions and roles in therapeutics

- Initiate engagement with PHAC VPs to discuss and consider a future role for PHAC in Therapeutics and preparation of associated briefing materials for internal discussions and dissemination to health portfolio partners to solicit feedback

- Initiate discussions with CADTH to explore partnering with them to provide PHAC with guidance prior to large scale procurements

- Provide CPHO with metrics related to the number of patients treated with federally procured therapeutics.
    - Use these metrics to verify that aligns the trajectory of 4th wave modelling with assumptions that include how these products are being used by clinicians

Meeting Summary
Therapeutics Briefing: CPHO
September 2, 2021
5:30 – 6:00 pm

Attendees: Dr. Theresa Tam, Ian Stewart, Howard Njoo, Bersabel Ephrem, Jacqueline Arthur, Pamela Ponic, Jennifer Rendall, Vicki Wiseman,

Observers: Jane Kolbe

SUMMARY OF ACTION ITEMS

Document COVID-19 therapeutics procured

- *Collect a complete record (Briefing Note, contract, legal review, etc.).*
- *Work with the office of the Chief Financial Officer to ensure documents from IDPB and OCFO documents are in a shared file.*

Raise the profile of COVID-19 therapeutics

- Increase awareness of PHAC's role and actions in COVID-19 therapeutic procurement, and enhance communication (including with SAC, and PT Chief Medical Officers)
- *Ensure that PHAC is able to determine whether we have to procure any more therapeutics during the 4th wave, and has an enabling process to accomplish this.*

Procurements underway

- *Send the Memo to President for the procurement of Sotrovimab and Sarilumab*
- *VP to check in with PHAC – to ensure that funding is available for sarilumab*
- *Ascertain/quantify how many patients are being helped with the treatments procured to date*

Ascertaining PHAC's future role in therapeutic procurement

- *Provide the President with the international comparison regarding the roles and responsibilities of public health in therapeutic procurement - mapping.*
- *Initiate engagement with PHAC VPs to discuss PHAC's future role in therapeutics*

Partnership with CADTH/INESSS

- Engage CADTH to seek their support for the development of clinical guidance as part of the procurement decision-making process

Current State of COVID-19 Therapeutics Procurements

- An overview of GoC measures taken with respect to COVID-19 therapeutics procured was provided.
    - Howard noted that therapeutic procurement is traditionally the responsibility of provinces and territories (PTs).
    - PHAC, (with PSPC) assumed responsibility to procure COVID-19 therapeutics to respond to the pandemic - received $500 million under the Medical Countermeasures budget.
- Hydroxychloroquine was used as an example of early decisions taken at the height of the pandemic.
    - Lessons/learned were integrated into future decision-making processes with respect to procurement of emerging COVID-19 therapies.
        - Continuous learning –strengthened the procurement decision-making process, including the approval chain via Deputy Minister Procurement Committee.
- Discussion ensued regarding the role that external advisory groups have played in the procurement decision-making process. Specifically,
    - COVID-19 Therapeutics Task Force (CTTF)
    - COVID-19 Clinical Pharmacology Task Group (CPTG).
- Strengthening the process that documents procurement decisions was mentioned and requires attention to support PHAC in an expeditious response to an audit.
- CPHO – recognized that at the beginning, we needed to urgently invest, and now we need a different process.
    - Data from clinical trials are more informative at this stage of the pandemic versus early days.
    - The UK was noted to be a useful jurisdiction to compare with in terms of procurements and processes.
- CPHO expressed a desire to communicate more about PHAC's role in COVID-19 therapeutics procurement.

Action Item:

- *Document the decision-making process for the various COVID-19 therapeutics procured to date.*
- *Collect a complete record (Briefing Note, package, etc.).*
- *Work with the office of the Chief Financial Officer to ensure documents from IDPB and OCFO documents are in a shared file.*

Shifting Needs of the PTs & Fall/2021 Procurement Plans

- Feedback from PTs was briefly discussed, including their desire for earlier engagement prior to procurement, a need for clinical guidance from CADTH and INESSS, more control over what drugs enter into their Formularies, implementation costs, and logistics.
- Howard noted our early thinking about the need to shift the existing GoC procurement approach towards an FPT collective approach - based on the expressed needs of the PTs – and integrate this into our current and future procurement plans.
- CPHO noted the important role that mAbs play - specifically in terms of having domestic capacity, "having mAb capacity is very important for an emerging pathogen".
- COVID-19 therapeutics currently under consideration for Fall/2021 procurement was discussed, including mAbs. Tocilizumab was noted to have been extensively used by PTs in previous waves.
    - The state of safety and efficacy data for oral antivirals was noted to be evolving.
    - PHAC is in the process of information exchanges with the drug makers, but until sufficient scientific data is available to assess safety and efficacy, procurement negotiations for oral anti-virals are premature.
- Ivermectin was discussed – The US FDA put out a tweet, and PHAC and Health Canada issued a joint tweet against the use of this drug for treatment of COVID-19.

4th Wave Planning and the Role of COVID-19 Therapeutics

- CPHO noted that treatment is critical in the process of 4th wave/future wave planning.
    - She noted that treatment is not prominently featured in 4th wave planning.
        - CPHO identified the need for including treatment in 4th wave planning and communicated this to DM-HC (Steve), however it does not appear in the placemat.
- Treatment must be a key aspect, as people will become ill and end up in the ICU – they can survive with an improvement in their treatment, or perhaps stay for a shorter time, which also relieves the pressure on the health system.
- Given treatment as a key element of 4th wave planning, it is necessary to ensure the establishment of an enabling process that expedites procurement of additional therapeutics based on emerging needs.
- Regarding Executive briefings, it was noted that while vaccine procurement had frequent executive/Sr. Management touch-points (every other day) and a regularized process, a similar approach needs to be established for COVID-19 therapeutics.

- Vaccine procurement differs from therapeutics and is less complex since it does not require physician intervention, making bulk procurement of vaccines a more direct path.
- The COVID-19 therapeutics landscape was noted to be more complex because it requires a physician prescription, involves the role of formularies, and includes the enmeshed intra and inter-departmental nature of the procurement process/considerations for emerging COVID-19 therapies.

- How/what we communicate is also different from vaccine procurement communication – and we have been relatively silent in terms of measures taken in the space of COVID-19 therapeutic procurement.

Action Item:

- *CPHO signaled a desire for more regular executive involvement/communication – raising the profile of therapeutics*
  - *Governance work was noted to be important to the CPHO*
  - *CPHO interested in going to SAC, and Provincial Chief Medical Officers to more actively communicate PHAC's role in therapeutics*
  - *CPHO noted that COVID-19 therapeutics is not in the MTP process and tracker*
- *Ensuring that PHAC has the tools and enabling processes necessary to quickly determine the need to procure any additional therapeutics during the 4th wave*

Discussion on Supply Issues of Specific COVID-19 Therapeutics

- Tocilizumab (was in high demand by PTs in wave 3) and sarilumab were noted to have excellent efficacy data in clinical trial results.
  - Both drugs are used for rheumatoid arthritis, have high efficacy, and are well established.
  - There is a global shortage of tocilizumab, consequently it was reported that PHAC was advancing contract negotiations to procure sarilumab since it can be used as a back-up treatment in lieu of tocilizumab.
- PSPC is in the process of advancing this negotiation with sarilumab.

Action Item:

- *Send the Memo to the President for the procurement of sotrovimab and sarilumab*
- *VP to check in with PHAC – to ensure that funding is available for sarilumab*

Discussion on Next Steps:

- Howard introduced the need to take the lessons learned with COVID-19 procurement processes to date, and integrate this into longer-term thinking.
    - COVID-19 therapeutics is a complex process involving several Branches within PHAC.
    - Next steps would involve looking at a more fulsome FPT approach.
- To build a sustainable model, beyond COVID-19 for therapeutics in general, for infectious disease preparedness Howard proposed the following process:
    - Commence internal discourse with VPs within PHAC to examine and deliberate on a future role for therapeutic procurement within PHAC
    - Engage EC with a proposed approach for discussion
    - Roll out the discussion to the Health Portfolio
- A discussion drawing attention to PHAC's public health role vs Health Canada's regulatory role in the therapeutic procurement sphere/space was also mentioned along with the importance of discerning and articulating these distinct roles.
- Ian asked that we map out the requisite steps and needs in the COVID-19 therapeutic procurement process and perform an international comparison to visually demonstrate the public health role in therapeutics in other countries.

Action Item:

- *Provide the President with the international comparison - mapping.*
- *Initiate engagement with PHAC VPs to discuss PHAC's future role in therapeutics with the view to developing a proposed strategy for consideration at EC – with the eventual goal of consulting with all other health portfolio partners to integrate their feedback, predicated on a meeting of the minds of PHAC VPs*

Discussion on the Use of FPT feedback to Inform procurement Decisions

- The Drug Shortages Table was noted to be a key existing mechanism that is being leveraged to inform PHAC's procurement recommendations.
- Current processes are ensuring that CCDIC is receiving PT endorsement before a procurement recommendation is rendered - to ascertain PT demand and likelihood of usage.
- CPHO noted that CCDIC has addressed the need for early engagement of PTs regarding COVID-19 therapeutic procurement recommendations.
- CPHO signaled her interest in ensuring broad awareness within PTs so that the Chief Medical Officers within the PTs are aware of the treatments procured and available.
- CPHO also recognized that clinicians need clinical guidance – Either PHAC or HC to ensure that CADTH and INESS are engaged.
    - Bersabel noted that we are pushing as much as possible to engage with CADTH to ensure that PTs have the guidance that they need. Conversations with CADTH are slow, but moving in the right direction.
    - CADTH may have resource limitations – which may influence the rate that they may be able to provide clinical guidance.
- A request for top-up funding was provided prior to the writ dropping.
    - 3 billion was given for vaccines; President advised that it could be repurposed for therapeutics, if necessary.
- CPHO – reiterated – the important role of therapeutics.
    - As we may see a variant of concern escaping the vaccine and the vaccines being re-tooled, therapeutics have a key role to play.

Action Item:

- *President suggested consideration be given to partnering with CADTH to facilitate requests for guidance in advance of any large scale procurements on behalf of PHAC.*
- *CPHO would like to ascertain how many patients are being helped with the treatments that we have procured - to ensure that we are tracking how procured treatments to date align with 4th wave modelling trajectories and the inclusion of assumptions related to how clinicians would be using this product.*

Hi Team,

Please see below correspondence into Dr. Tam.

Kaili can you please as your team/the HC team to do a roll up of what the TTF has done in this space?

Howard, Bersabel and Roman – can you please prepare advice for Dr. Tam and the President to consider in this area.

Thank you
Jen

Subject: Fwd: Ivermectin

There is an upsurge in emails on Ivermectin. Could we get the therapeutics task force to look at this?

Other research networks may also be able to review/summarize if this is not in line with what the therapeutic task force does.

Subject: Ivermectin

Get Outlook for iOSI've compiled a list of the email addresses for the Federal Minister of Health, all Provincial Ministers of Health, Canada's Chief Public Health Officer (Dr. Tam), and all the Provincial Health Officers. I've also written a letter imploring them to introduce Ivermectin as the front-line treatment to stop Covid-19 and the never-ending pandemic and it's restrictions. I will be sending it to all of them, as often as I can.

I am posting my letter below to make it easier for others to do the same. Since they are refusing to openly acknowledge it, the only way to be sure they know is for us to flood them with our demands. They are, after all, public servants, and unless we no longer live in a democratic society then they are "our" public servants, not the other way around. As I say in my closing statement, they owe it to their constituents, those they are sworn to protect, and all Canadians, to do everything in their power to stop this pandemic. This is entirely within their power to change, and they are obligated by their oath of office to do so…

URGENT ATTENTION:

With the Covid-19 crisis showing no signs of slowing, and current treatment options proving to have little success in the elderly and those with pre-existing life-limiting conditions, the saving of those lives is of paramount importance.

Reducing the spread of the Cov-2 virus from person to person and limiting community spread is crucial for protecting those most susceptible to the virus's respiratory effects. The WHO and manufacturers of the vaccines that are being promoted and given to Canadians have stated that there is no data showing they will reduce infection or the transmission of Cov-2, and so one must ask, "Why is this the only option being used?"

There seems to be a tunnel-vision mindset that is blinding public health authorities from considering any other alternatives, operating with single mindedness, and ignoring any information that challenges this approach. This does not follow the principles of scientific methodology and excludes any hope of discovering a control mechanism to stop Cov-2 and the devastation it is reaping on our country's health, both physical and mental, and our economy, which is in ruins.

Seeing no mention of it in any national media, or in the public health messages being provided, it is obvious you are ignoring the latest clinical research on Covid-19, that being the work done by the doctors of the Front Line COVID-19 Critical Care Alliance (FLCCC) and their ground-breaking exploration in using Ivermectin as a phenomenally successful front-line treatment for Covid-19.

The doctors that make up the FLCCC are leaders in critical care with expertise in therapies directed at severe infections and have spent all of 2020 treating patients with an Ivermectin protocol, believing it to have vast potential as an off-label drug with anti-viral properties.

Their research, and the peer-reviewed empirical data derived from it, has proven Ivermectin to be immensely effective in both the prophylaxis and treatment of all phases of COVID-19. Here are the highlights of their findings:

1) Ivermectin inhibits the replication of many viruses, including SARS-CoV-2, influenza, and others;
2) Ivermectin has potent anti-inflammatory properties with multiple mechanisms of inhibition;
3) Ivermectin diminishes viral load and protects against organ damage in animal models;
4) Ivermectin prevents transmission of COVID-19 when taken either pre- or post-exposure;
5) Ivermectin hastens recovery and decreases hospitalization and mortality in patients with COVID-19;
6) Ivermectin leads to far lower case-fatality rates in regions with widespread use.

https://covid19criticalcare.com/wp-content/uploads/2020/11/FLCCC-Ivermectin-in-the-prophylaxis-and-treatment-of-COVID-19.pdf

Every day that this information is ignored more people die that could have been saved using the Ivermectin protocol. It could be an unknown soul dying alone, or a member of your own family. Every day, battle-weary health care workers are forced to watch helplessly in a vain attempt to save yet another casualty of Covid-19. Every day, more businesses are forced to close forever under the restrictive public health guidelines. With utmost urgency, I implore you to review the data and

make this a front-line treatment in the fight against Covid-19. You owe it to your constituents, those you are sworn to protect, and all Canadians, to do everything in your power to stop this pandemic. This is entirely within your power to change, and you are obligated by your oath of office to do so…

Most Sincerely,

[redacted]

Bradley, Kevin (HC/SC)

Subject: FW: TAC Weekly Evidence Tracker - August 23, 2021
Attachments: Weekly COVID-19 Evidence Review Tracker_23AUG2021.pdf

Dear TAC members,

Please see attached for the CSO approved Weekly COVID-19 Evidence Review Tracker for August 23, 2021.

This week's tracker includes two new non-PHAC reviews:

- McMaster Health Forum (funded by PHAC OCSO): What is the efficacy and effectiveness of available COVID-19 vaccines in general and specifically for variants of concern? (Version 17)
- McMaster Health Forum/SPOR EA: Canadian provincial and territorial public health response to SARS-CoV-2 and variants of concern: A jurisdictional scan including select European countries

McMaster Health Forum (funded by PHAC OCSO) Canadian and Global Evidence Spotlights are also included for interest.

Thanks,

Mette

1. New Evidence Reviews and Findings[1]

[1] Findings presented in this tracker are subject to PHAC's final review before publication. Please note that PHAC-ESG reviews presented in Table 1 are approved for distribution to public health partners to inform timely decision-making, and that the linked documents are not for public distribution at this time.

Weekly COVID-19 Evidence Review – August 23, 2021

Version 66

Contents

1. New Evidence Reviews and Findings[1]

Summary information from recently released reviews produced by PHAC and public health partners. Knowledge mobilization by the Office of the Chief Science Officer. The full evidence reviews are accessible via the provided hyperlinks.

Title of review	Overview of the evidence	Key findings
MHF: What is the efficacy and effectiveness of available COVID-19 vaccines in general and specifically for variants of concern? (Version 17) Full Review	This evidence product was funded by PHAC OCSO. This LES is updated weekly and includes 68 studies identified up to August 25, 2021. New studies this week include data on Alpha [B.1.1.7] (3), Delta [B.1.617.2] (3) and Beta [B.1.351] (1). A visual summary of the evidence is presented in Table 1, with details in Table 2. Full details are available in the review.	Additional details available in the full review. Pfizer: • Moderate certainty evidence that 2 doses of BNT162b2 [Pfizer] prevented infection (range of mean estimates (ROME): 70-97%), prevented severe disease (ROME: 92-98%), prevented death (ROME: 91-98%), and reduced transmission of Alpha to close contacts ROME: 65-80%). • Moderate certainty evidence that 2 doses of BNT162b2 prevented symptomatic infection from Beta (ROME: 84-88%). Moderna: • Moderate certainty evidence that 2 doses of mRNA-1273 [Moderna] prevented infection from Alpha (ROME: 86-100%) and low certainty evidence it prevented infection from Beta (96.4% – 1 Obs). We have low certainty evidence that it prevented severe, critical, or fatal disease from Alpha (combined with Beta) (95.7% – 1 Obs). • Moderate certainty evidence that 2 doses of mRNA-1273 prevented infection from Delta (ROME: 76-86%) and low certainty evidence that it prevented severe, critical, or fatal disease (ROME: 93-100%). AstraZeneca: • Moderate certainty evidence that 2 doses of ChAdOx1 [AstraZeneca] prevented infection from Alpha (ROME: 62-79%) and moderate certainty evidence that it provided limited protection from infection by Beta (10.4% - 1 RCT). Combinations of vaccines: • Low certainty evidence that 1 dose of ChAdOx1 [AstraZeneca] followed by 1 dose of BNT162b2 [Pfizer] or mRNA-1273 [Moderna] prevented infection by Alpha (88% – 1 Obs).

[1] Findings presented in this tracker are subject to PHAC's final review before publication. Please note that PHAC-ESG reviews presented in Table 1 are approved for distribution to public health partners to inform timely decision-making, and that the linked documents are not for public distribution at this time.

MHF/SPOR EA: Canadian provincial and territorial public health response to SARS-CoV-2 and variants of concern: A jurisdictional scan including select European countries Full Text	This jurisdictional scan compiles Canadian provincial and territorial public health guidance relating to COVID-19 and the VOC between August 8 and 18, 2021, as well as guidance from Belgium and Germany from the same time-period. This snapshot provides an overview of each region's vaccine rollout, proof of vaccination requirements, isolation and quarantine requirements, travel restrictions, and gathering limits, as well as whether or not any of this guidance has been influenced by VOC. Full details are available in the document.	• Very little guidance mentions VOC explicitly. It may be assumed that the prevalence of VOC in a region at any given time has an implicit impact on public health measures. • Vaccination is now available to everyone aged 12+ in every province and territory, and in Germany and Belgium. All provinces/territories are on the penultimate or final step of their reopening plans. • Some provinces/territories such as Manitoba and Nova Scotia have vaccination strategies/campaigns to support Indigenous populations. • Ontario is the only Canadian province offering third doses. Belgium and Germany are planning to offer third doses in the coming weeks. • Quebec will require proof of vaccination for non-essential activities starting in September, while Manitoba allows businesses to ask for proof at their own discretion. • Ontario requires long-term care workers to be vaccinated. No other province/territory requires proof for activities within the province. • No changes have been made to hand washing, masking, or physical distancing requirements due to VOC. • For confirmed COVID-19 cases, 10-14 days of isolation is required in most provinces/territories, while some consider length of isolation on a case-by-case basis. Alberta will be lifting this requirement in September. Belgium and Germany require 10 days of isolation. • 14 days of quarantine for close contacts is required in most provinces/territories and Germany and Belgium, with some exceptions for fully vaccinated individuals. Alberta no longer requires quarantine of close contacts. • No quarantine is required after entering Alberta, British Columbia, New Brunswick, Ontario, Quebec, Saskatchewan, or Yukon from within Canada. In all other provinces/territories and Belgium and Germany, exemptions from/modifications to quarantine apply to partially or fully vaccinated individuals. • Attendance limits on private and public gatherings vary widely between regions.

MHF: Evidence Spotlights
 	
Canadian Spotlight
 	
Global Spotlight
	This evidence product was funded by PHAC OCSO.
	
	Canadian and Global spotlights are each published twice a month, and horizon scans are published monthly.
		• Canadian spotlight 8.2: Key additions from the second half of August 2021:
		  ○ In the second half of August, contributing Canadian evidence-synthesis teams have shared with us 13 newly completed evidence syntheses which are listed in the table below. Two of these syntheses provide insights across all domains of the COVID-END taxonomy (public-health measures, clinical management, health-system arrangements, and economic and social response) and the remaining focus on public-health measures (n=8), and clinical management (n=3).
		• Global spotlight 8.2: Key additions from the second half of August 2021:
		  ○ There are two newly added syntheses and one update to a living evidence synthesis that is already included in the public-health measures part of the COVID-END inventory of 'best' evidence syntheses, six newly added syntheses and 20 updates to living evidence syntheses that are already included in the clinical management parts of the inventory, and one newly added synthesis in the health-system arrangements part of the inventory.

2. Previous PHAC Reviews[2]

Summary information from previously shared evidence products, beginning with the most recent reviews. The titles are hyperlinked to the original review at the time of distribution. Please note, if a review has been updated, only the most recent version of the review is included in this table with previous versions available upon request.

Emerging Evidence on COVID-19

COVID-19 Summary of Face Shields to Prevent Transmission of SARS-CoV-2

Introduction

How effective are face shields at preventing SARS-CoV-2 virus transmission, with and without additional mask wearing?

This evidence brief summarizes the relevant research on face shields in preventing the transmission of respiratory droplets and aerosols from infected individuals to susceptible individuals, published until July 7, 2020. Eye protection and goggle use are not captured in this review.

Key Points

- Face shields are a form of personal protective equipment that has been used in healthcare settings (e.g., surgical/medical, dental, veterinary) to cover the face and mucosal membranes (eyes, nose, mouth) and prevent infectious particle exposure from aerosols and body fluid spatter. A face shield is often used when performing medical procedures that increase the risk of aerosols or patient body fluid splashes, sprays or splatter and is worn with other personal protective equipment (e.g., medical masks, respirators, medical gowns) (Roberge, 2016).
- All studies included in this review are experiments conducted under controlled conditions. With the exception of one study which used influenza (Lindsley et al., 2014), the studies in this review did not use virus contaminated fluids.
- Studies on face shield use by healthcare workers report a protective effect particularly from patient generated splatter during specific medical procedures when used in combination with other protective equipment such as a surgical mask (Table 1 and Table 2) (Mansour et al., 2009; Mostaghimi et al., 2020; Shoham et al., 2016). Face shields have also been designed for the patient to wear when undergoing an aerosol generating procedure to contain the aerosols and protect the health care workers doing the procedure from exposure (Anon, Denne, & Rees, 2020;)
- Two simulation studies reported on droplet inhalation and exposure when wearing face shields as the only protective equipment (Table 1). Both studies report 90% of the large droplets were blocked by a cough aimed at the middle of the face shield (Lindsley et al., 2014; Ronen et al., 2020), however the protective effects decreased when the direction of the cough was varied (higher/lower/side). Over time (30 minutes) inhalation of small droplets was only reduced by 23% by the face shield (Lindsley et al., 2014).
- Three studies simulated coughing in an individual wearing the face shield and reported the level of contamination resulting from respiratory particles released (Table 1 and Table 2). Two studies report

the release of droplets and aerosols from around the openings in the face shield (Anon et al., 2020; Viola et al., 2020), while the third reports that the face shield provided a good forward barrier as no droplets reached a simulator 60 cm away (Ronen et al., 2020).

- The design of the face mask is reported to be important. Face shields that wrap further around the face, fully shielding the cheek area, wrap under the chin and any enhancements that minimize bioaerosol leakage/entry around the edges of the mask were more protective (Viola et al., 2020; Anon et al., 2020; Mostaghimi et al., 2020).

Overview of the Evidence

Few studies examine and report on the protective effects of face shields with or without masks. All identified studies report findings from simulation studies conducted in controlled laboratory settings, and do not necessarily account for real-world parameters (e.g., height differences among individuals, temperatures, humidity, wind velocities etc.) or the infectious dose. None of the studies used SARS-CoV-2 in the simulation. Variation across studies in their design, how and what outcomes were measured and what face shields were used meant the findings are not directly comparable. Although the available body of evidence does support the use of face shields alongside medical masks in health care settings, results of face shields alone were less consistently protective.

CONTENTS

EFFECTIVENESS OF FACE SHIELDS

There were no studies identified that evaluated the efficacy of face shield use in the field to prevent respiratory infection transmission.

In health care settings, two simulation studies evaluating various medical procedures find face shields, usually worn with a medical mask, protect healthcare workers' faces from fluid splatters by providing a physical barrier, and some protection from the inhalation of small aerosols and droplet nuclei (Table 1) (Mansour et al., 2009; Shoham et al., 2016). One study found the combination of a face cover and face shield to be more effective than either alone (Mansour et al., 2009), while the other found a full face shield provided better protection than the combination of an eye shield and a surgical mask (Shoham et al., 2016).

Two studies reporting on the effectiveness of face shields used as the only protective equipment compared face shields to other face covers report face shields are effective barriers for the short term blockage of droplets (Lindsley et al., 2014; Ronen et al., 2020). The study by Ronan et al., describes the short term protective effects of a face shield blocking 90% of splatter from a cough 60 cm away directed at the center of

the face shield. A face mask in the same simulation blocked half the droplets. The protective effect of the face shield decreased significantly when the direction of the cough (higher/lower/side) was varied. (Ronen et al., 2020). Similarly, Lindsley et al., reported face shields reduce inhalation of large droplets by 90% and small droplets by over 60% immediately following a cough. However, the inhalation of smaller droplets was only reduced by 23% as the time since coughing (i.e. aerosol generation event) increased to 30 min. This increase in aerosol and small droplet inhalation risk is attributed to the formation of smaller droplet nuclei over time that can leak in from the face shield edges (Lindsley et al., 2014).

The three simulation studies evaluating the level of contamination by respiratory particles from an individual wearing a face shield reported a good forward barrier to projecting respiratory droplets (Ronen et al., 2020), however powerful backward and downward bioaerosol leakage jets were measured (Viola et al., 2020; Anon et al., 2020). Gross droplet splatter and contamination below the neck and chest area took place when a patient wearing a standard face shield underwent a simulated aerosol generating procedure, like flexible endoscopy (Anon et al., 2020). Observations of airflow and bioaerosol ejection while wearing different types of face shields find front airflow generated from breathing, loud speaking and coughing to be largely reduced, but substantial aerosol leakage to still take place. Powerful leakage jets of bioaerosols were identified near the wearer's brow region and in the downward direction (Viola et al., 2020). However, despite the leakage measured in two studies, the third reported a good forward barrier based on experimental results from a breathing simulator positioned 60 cm from a coughing simulator wearing a face shield that did not inhale or detect splatter droplets (Ronen et al., 2020). Thus, bioaerosols escape into the environment when an individual wears a face shield.

Table 1: Literature on face shield performance

Publication Title	Key Outcomes	Reference
Experimental and Simulation Studies		
Efficacy of Face Shields Against Cough Aerosol Droplets from a Cough Simulator	Simulation experiment (face shields only): Effectiveness of face shields in blocking the transmission of aerosols is measured using a breathing simulator intended to mimic a healthcare worker, and a cough aerosol simulator loaded with Influenza virus. The study finds more than a 90% reduction in larger aerosol (mean diameter of 8.5 µm) inhalation risk from face shield use, and an over 60% reduction in the risk of inhaling smaller aerosols (size of 3.4 µm) immediately after coughing. Face shields led to only a 23% reduction in smaller aerosol inhalation risk when the coughs generating the aerosols occurred within the previous 30 min, the increase in risk was due to smaller particles staying airborne longer and floating around the face shield to be inhaled.	(Lindsley et al., 2014)
Face Coverings, Aerosol Dispersion	Simulation and human experiment (face shield vs. surgical mask, homemade mask, and respirator)	(Viola et al., 2020)

and Mitigation of Virus Transmission Risk	Researchers use a background oriented schlieren technique to investigate airflow ejection by individual volunteers and manikins using different face coverings during breathing, coughing and aerosol generating procedures. Bioaerosol leakage with different face covers (i.e. homemade and surgical masks, filtering facepiece respirators (FFP1, FFP2), N95 respirators, and light and heavy weight face shields) was visualized. Overall, the study finds all face covers substantially reduced the front flow of bioaerosols. Only the tested FFP diminished backward and downward leakage jets, whereas the tested surgical masks, homemade masks, N95 respirators and face shields demonstrated backwards and downward jets to various degrees. Specific to face shields, bioaerosol containing airflow was found to leak through the seams and joints of the tested face shields and be minimally displaced horizontally (a distance of few centimetres). Face shields also generated upward (brow region), downward, sideway, and strong backward leakage jets. Backward jets occur when air escapes from the side of face covers and are projected backwards at high speed, potentially resulting in a significant displacement. Powerful downward leakage jets were noted for face shields that did not curve below the chin, which allowed for unobstructed air flow in and out.	
Examining the Protection Efficacy of Face Shields Against Cough Aerosol Droplets Using Water Sensitive Papers	Simulation experiment (face shield only vs. mask, respirator or no equipment) This simulation experiment reported on the effectiveness of face shields used as the only protective equipment, with the objective of this study informing use of face shields by the general population outside of a health care setting. The study used a cough simulator that was carefully tuned to replicate human cough in terms of droplet size distribution and outlet velocity. The tested personal protective equipment were placed on a manikin head simulating human breathing. An Aerodynamic Particle Sizer (APS) and water sensitive paper were used to analyze the concentration and size distribution of particles that reach the manikin head. The study reports face shields are as effective as face masks in successfully blocking respiratory droplets (3µm in diameter) from a cough, and blocked fine particles (0.3µm) better than medical masks in the short term. In other words, while the medical mask	(Ronen et al., 2020)

	reduced the number of inhaled particles by roughly a factor of two, the face shield provided superior protection by blocking more than 90% of the otherwise inhaled particles when a simulated cough was directly at the face shield. These blocking effects were reduced when contamination of areas beyond the middle of the face (i.e. cheeks and neck) were considered. Furthermore, in experiments where the vertical distance between the cough and breathing manikin simulators were varied, droplet deposits on the face was no different from droplets deposited over the shield, and blocking efficacy was as low as 45% in some instances. No respiratory contamination of the surroundings was noted when the cough simulator was covered by a face shield (simulating an infected person wearing the face shield).	
Eye Protection in Orthopaedic Surgery	Simulation Experiment (face shield with a mask): Mannequin heads outfitted with different personal protective equipment and sprayed with fluorescent dye sprays find face shields that cover the eyes worn in combination with facemasks to be effective barriers. This combination of personal protective equipment reduced contamination by macroscopic droplets and/or debris by 64% during simulated femoral osteotomies.	(Mansour et al., 2009)
Comparison of Protection Against Ocular Contamination with Disposable Eyewear Products	Poster Presentation - 2016 (Face shield vs. eye protection with a mask) A simulation study of manikin heads outfitted with eye shields or face shields, with and without face masks and N95 respirators. Using a Glogerm fluorescent dye system, eye contamination from micro droplet occurred with combination surgical mask and eye shield, but no face contamination (i.e. eyes, nose or mouth) occurred when a full face shield was used.	(Shoham et al., 2016)
Review Literature		
Face Shields for Infection Control: A Review	A literature review on face shields as a form of personal protective equipment for healthcare workers, and discusses various face shield designs. All outlined evidence predates the emergence of COVID-19.	(Roberge, 2016)
Facial Protection for Healthcare Workers During Pandemics: A Scoping Review	A scoping review of face protection for healthcare workers. The review identified one study on efficacy of face shields (Lindsley et al., 2014) and concluded that face shields should not be used by health care workers as the primary protection for preventing	(Godoy et al., 2020)

	transmission of respiratory diseases, but they can be used with other facial protection.	

NOVEL FACE SHIELD SYSTEMS

Alternative face shield systems are presented as physical barriers that provide better protection from patient generated body fluid splatter.

Table 2: Novel face shield systems

Publication Title	Key Outcomes	Reference
Patient-Worn Enhanced Protection Face Shield for Flexible Endoscopy	Simulation experiment (face shield vs. enhanced face shield) A simulation proof of concept study compares aerosolized dye exposure and contamination when a patient wears a standard face shield vs. face shield of enhanced design with a tab closure system (covering the space under the chin) during endoscopy procedures. The enhanced design is reported to have contained simulated respiratory splatter within the confines of the enclosed space around the patients face and prevented bioaerosol escape under the neck/chin area.	(Anon et al., 2020)
Rapid Prototyping and Clinical Testing of a Reusable Face Shield for Health Care Workers Responding to the COVID-19 Pandemic	Development/evaluation of enhanced face shields The clinical utility and user comfort of 3 face shield prototypes among healthcare workers are surveyed. The effectiveness of each design in preventing droplet splatter was not investigated.	(Mostaghimi et al., 2020)

Methods:

A daily scan of the literature (published and pre-published) is conducted by the Emerging Science Group, PHAC. The scan has compiled COVID-19 literature since the beginning of the outbreak and is updated daily. Searches to retrieve relevant COVID-19 literature are conducted in Pubmed, Scopus, BioRxiv, MedRxiv, ArXiv, SSRN, Research Square and cross-referenced with the literature on the WHO COVID literature list, and COVID-19 information centers run by Lancet, BMJ, Elsevier and Wiley. The daily summary and full scan results are maintained in a Refworks database and an Excel list that can be searched. Targeted keyword searching is conducted within these databases to identify relevant citations on COVID-19 and SARS-CoV-2. Search terms used included: (Face and Shield). An additional search was conducted in PubMed to identify older, non-COVID-19 research on face shields using: (face and shield and (virus or respiratory)).

Each potentially relevant reference was examined to confirm it had relevant data and relevant data is extracted into the review. This review contains research published up to July 7, 2020.

Emerging Evidence on COVID-19

COVID-19 Summary of SARS-CoV-2 Transmission and Singing/Wind Instruments

Introduction

What is the risk of SARS-CoV-2 virus transmission from singing or playing a wind instrument in a choir, orchestra and or practice setting with other people?

This evidence brief summarizes what is known on aerodynamic transmission of respiratory droplets and aerosols from activities that involve deep breathing and singing; the epidemiological evidence around music-related activities that resulted in transmission of SARS-CoV-2; and risk assessments, mitigation strategies or other decision analyses that may be relevant to creating music in groups. This evidence brief highlights specific literature on possible infection transmission linked to singing published until June 26, 2020.

Key Points

- The available evidence suggests the activity of singing in indoor settings can contribute to amplified infection transmission of SARS-CoV-2 if an infected person is participating. Epidemiological reports of COVID-19 clusters with high attack rates linked to choir practice in the US, Singapore, and the Netherlands, as well as a karaoke bar in South Korea provide evidence that transmission has occurred during activities that involve singing (Tables 2 and 3).
- Primary evidence on wind and brass instrument use and SARS-CoV-2 transmission could not be identified. However, one descriptive risk assessment and one grey literature study of wind instruments indicate more research should be done on the risk of SARS-CoV-2 transmission from wind instrument aerosols (Table 3). One protocol to study wind instruments and safe playing was identified (Miller, Vance, Hertzberg, & Toohey, 2020).
- No evidence on mitigation strategies for musicians was identified.
- Experimental evidence and modelled scenarios on droplet dispersion and aerosolization of SARS-CoV-2:
    - Infectious particles are commonly expelled into the surrounding air by an infected person (e.g., breathing, speaking, sneezing, singing and coughing) and these particles may transmit SARS-CoV-2 to another person when inhaled (Table 1).
    - Airborne SARS-CoV-2 particles can exist in the form of aerosols, droplets, droplet nuclei or other small particles containing viral RNA. One study reports SARS-CoV-2 virus can remain viable within aerosols for longer than three hours (van Doremalen et al., 2020).

- No simulation studies have examined particle generation during singing or wind instrument use, but studies do report on speaking and coughing. For example, 1000s of virus containing particles are estimated to be produced during a minute of loud speaking and remain airborne for longer than eight minutes (Table 1) (Stadnytskyi, Bax, Bax, & Anfinrud, 2020).
- Mathematical models informed by particle physics and aerodynamics predict respiratory and saliva particles can remain suspended in air for long enough to be inhaled by another individual, and has the potential to be dispersed some distance away from the infectious source (Vuorinen et al., 2020) (Guerrero, Brito, & Cornejo, 2020; Zhao, Qi, Luzzatto-Fegiz, Cui, & Zhu, 2020) (Feng, Marchal, Sperry, & Yi, 2020). According to mathematical models, droplet size, humidity, temperature, airflow and air turbulence all impact the movement and decay of virus containing airborne particles (Table 1).

Overview of the Evidence

The available empirical body of evidence on SARS-CoV-2 transmission during singing is linked to a few choir clusters from early in the SARS-CoV-2 outbreak. These studies are retrospective outbreak investigations that are considered to be at high risk of bias and low quality evidence.

Laboratory simulations and modelled scenarios also provide theoretical evidence to support increased transmission of SARS-CoV-2 from activities such as speaking loudly. These studies appear to have been conducted without obvious flaws in their methodology and are considered moderate to high quality evidence.

Major knowledge gaps were identified in examining the evidence underpinning the review question, additional research is needed to assess the transmission risk associated with singing or playing instruments in a group setting. There is a lack of experimental evidence that fully characterize the risk and the circumstances that lead to transmission. The risk of transmission events from singing and playing wind instruments in a choir, orchestra and/or practice setting with other people is unknown, but theoretical evidence and recorded clusters attributed to this activity indicate that there is a risk.

CONTENTS

SARS-COV-2 DROPLETS AND AEROSOLS

Six experiments and five models investigate aerosolization of SARS-CoV-2 and characterize some of the circumstances under which aerosolization or droplet dispersions occur. Infectious particles are commonly expelled into the surrounding air by an infected person (e.g., breathing, speaking, sneezing, singing or coughing) and these particles may transmit SARS-CoV-2 to another person when inhaled (Table 1). Risk of transmission likely depends on the characteristics of the environment, the activity, the distance from and duration of time spent with an infected person. Airborne SARS-CoV-2 particles can exist in the form of aerosols, droplets, droplet nuclei or other small particles containing viral RNA. van Doremalen provides primary evidence to support the viability of SARS-CoV-2 virus particles in aerosols. The study reports SARS-CoV-2 virus can remain viable within aerosols for longer than three hours (van Doremalen et al., 2020).

No simulation studies have examined particle generation during singing or wind instrument use, but studies reported on speaking and coughing. Simulations have successfully visualized thousands of minute respiratory droplets and aerosols that are generated during normal speech, and remain suspended in air for longer than eight minutes (Anfinrud, Bax, Stadnytskyi, & Bax, 2020; Chanpong, Tang, Rosenczweig, Lok, & Tang, 2020; Stadnytskyi et al., 2020). Additionally, 1,000s of virus containing particles are estimated to be produced during a minute of loud speaking, and remain airborne for longer than eight minutes (Stadnytskyi et al., 2020). Coughing also generated respiratory droplets and aerosol that traveled average distances of two and a half meters and a maximum of four meters, as well as substantial droplet splatter on nearby healthcare workers (Chanpong et al., 2020; Loh et al., 2020). As such it is likely singing can also lead to the dispersion of infectious particles.

Mathematical models informed by particle physics and aerodynamics predict respiratory and saliva particles can remain suspended in air for long enough to be inhaled by another individual. And have the potential to be dispersed some distance away from the infectious source (Vuorinen et al., 2020) (Guerrero et al., 2020; Zhao et al., 2020) (Feng et al., 2020). According to mathematical models, droplet size, humidity, temperature, air flow, and air turbulence all impact the movement and decay of virus containing airborne particles (Table 1).

Table 1: Primary literature on SARS-CoV-2 aerosol and droplets

Publication Title	Key Outcomes	Reference
Experimental and Simulation Studies		
Aerosol and surface stability of SARS-CoV-2 as compared with SARS-CoV-1	The stability and decay of SARS-CoV-2 and SARS-CoV-1 in aerosols was estimated using a Bayesian regression model SARS-CoV-2 virus remained viable in aerosols up to three hours hrs (duration of the experiment), with a reduction in infectious titer from $10^{3.5}$ to $10^{2.7}$ $TCID_{50}$ per liter of air.	(van Doremalen et al., 2020)
The impact of high-flow nasal cannula (HFNC) on coughing	A simulation study using healthy volunteers (n=5) found cough-generated droplets spread a mean distance of 2.48 meters (1.03 standard deviation) at baseline, maximum of 3.90 meters.	(Loh et al., 2020)

distance: implications on its use during the novel coronavirus disease outbreak	When wearing well-fitting High Flow Nasal Cannula, mean cough generated droplet spread was 2.91 meters (1.09) with a maximum distance of 4.50 meters.	
Aerosol-generating procedures and simulated cough in dental anesthesia	Aerosol and droplet splatter was visualized using a Glo Germ system. Simulated cough was found to produce more extensive splatter than test aerosol generating dental procedures.	(Chanpong et al., 2020)
Could SARS-CoV-2 be transmitted via speech droplets?	A planar beam of laser light passing through a dust-free enclosure is used to detect saliva droplets emitted while speaking. The investigation provides visual evidence that infection transmission from droplets and aerosols is possible. Preliminary observations find thousands of respiratory and saliva droplets emitted while speaking are much smaller than those emitted during coughing, and simple phrases such as "stay healthy" can generate thousands of small droplets with the potential to transmit infection. Researchers state additional studies are necessary to assess the viral titre present in speech-induced droplets based on COVID-19 severity.	(Anfinrud et al., 2020)
The airborne lifetime of small speech droplets and their potential importance in SARS-CoV-2 transmission	Sensitive planar beam laser light scattering observations and aerodynamic particle sizer (APS) measurements are used to visualize droplet dispersion and decay. The experiments find droplets generated during normal speech to decay within 8-14 minutes in close stagnant environments (similar to indoor environments, particularly with poor ventilation), and the longest decay times were observed for droplets with a diameter ≥12 µm when exiting the mouth. The researchers estimate 1 minute of loud speaking can generate a minimum of 1,000 virion containing droplet nuclei that remain airborne for more than 8 minutes. The findings suggest air suspended virus containing particles could be inhaled by others.	(Stadnytskyi et al., 2020)
Mathematical Models		
Publication Title	**Key Outcomes**	**Reference**
COVID-19: Effects of weather conditions on the propagation	A comprehensive mathematical model was established to explore speech generated droplet evaporation, heat transfer and kinematics under different conditions (e.g., temperature, humidity and ventilation). Low temperature and high humidity	(Zhao et al., 2020)

of respiratory droplets	facilitate droplet transmission and dispersion, but supresses the formation of aerosols. On the other hand, high temperature and low humidity promotes rapid loss of respiratory droplet mass (from evaporation) and reduce droplet travel distance, but these conditions increase transmission risk from aerosol particles. The study concludes current social distancing recommendations may not be sufficient to diminish airborne transmission risks as droplets can travel distances up to 6 meters.	
COVID-19. Transport of respiratory droplets in a microclimatologic urban scenario	Examined the spread of respiratory droplets in outdoor environments by applying a computational model of a sneezing person in an urban scenario under a medium intensity climatological wind. The spread of respiratory droplets is characterized by the dynamics of droplet size: larger droplets (400 – 900 μm) are spread between two to five meters during 2.3 seconds while smaller droplets (100 – 200 μm) are transported between eight and eleven meters in 14.1 seconds when influenced by turbulent wind.	(Guerrero et al., 2020)
Influence of wind and relative humidity on the social distancing effectiveness to prevent COVID-19 airborne transmission: A numerical study	Air transmission of cough droplets with condensation and evaporation effects are modeled between 2 virtual humans under different environments and wind velocities. Micro-droplets follow airflow streamlines and can be deposited on virtual human bodies (including head regions) at greater than 3.05 meter (10 feet) distances. High Relative humidity (99.5%) also leads to larger droplet sizes and greater deposition of cough droplets on surfaces (due to hygroscopic growth effects). Suspended micro droplets could be transmitted between the 2 virtual humans in less than 5 seconds. The study concludes due to environmental wind, convection effects, and relative humidity on respiratory particles emitted by humans, the frequently recommended 1.83 meters (six feet) of social distancing may not be sufficient to prevent inter-person aerosol transmission.	(Feng et al., 2020)
Modelling aerosol transport and virus exposure with numerical simulations in relation to SARS-CoV-2 transmission	Available evidence on aerosol transport in air is combined with 0D-3D simulations in physics-based models and theoretical calculations. Monte Carlo simulations indicate droplets produced by speech and cough (diameter < 20 μm) can become airborne and linger in the air from 20 minutes up to 1 hour, and be inhaled by others. The exposure time to inhale 100 aerosols (assumed to be an adequate infectious dose) is variable based on	(Vuorinen et al., 2020)

by inhalation indoors	the situation and can range from one second, to 1 minute, to 1 hour. 3D computational fluid dynamic (CFD) simulations suggest aerosols (dp <20 µm) can be transported over 10 meter distances in generic environments, dependent on relative humidity and airflow. Finally the rapid drying of expelled mucus droplets would yield droplet nuclei and aerosols which could potentially carry airborne virus particles. Such droplets (initial particle diameter of 50 µm to 100 µm) could remain airborne for approximately 20 seconds to 3 minutes.	

COVID-19 CLUSTERS ATTRIBUTED TO SINGING

Five published articles were identified that document outbreaks of COVID-19 related to singing and/or playing instruments. One outbreak of Skagit Valley, WA choir COVID-19 cluster with a secondary attack rate of 53-87% (Hamner et al., 2020) and a mathematical model based estimation of emissions generated in this scenario (Miller et al., 2020) suggest infection transmission in this cluster primarily occurred from sharing an indoor space with a single infectious individual who was singing. Multiple case cluster summaries highlight singing class, karaoke, music concerts and choir practice clusters from Japan, and Singapore (Furuse et al., 2020; Dalton, Katelaris, & Wilson, 2020., Wei et al., 2020). Risk of transmission depends on the characteristics of the environment, the activity, the distance from and duration of time spent with an infected person (Waddell., 2020).

Table 2: Literature on epidemiological investigations that (partially) attribute singing to transmission

Publication Title	Key Outcomes	Reference
High SARS-CoV-2 attack rate following exposure at a choir practice — Skagit County, Washington, March 2020	A choir practice in Washington, US involving 61 singers, including the symptomatic index case, led to 32 confirmed and 20 probable secondary COVID-19 cases (attack rate = 53.3% to 86.7%); 3 patients were hospitalized, and 2 died. Authors conclude transmission was likely facilitated by close proximity (within 6 feet) during singing practice and augmented by the act of singing.	(Hamner et al., 2020)
Transmission of SARS-CoV-2 by inhalation of respiratory aerosol in the Skagit Valley Chorale	Case study of the Skagit County choir outbreak that explores infection risk variability based on the rates of removal of respiratory aerosols by ventilation, deposition onto surfaces and viral decay. Due to the high secondary attack rate a common fomite and person to person transmission are assumed unlikely. Shared	(Shelly L. Miller et al., 2020)

superspreading event	indoor air at the practice site, and high emissions of respiratory aerosols during singing are assumed to be the dominant factors linked to infection transmission. Modeled airborne infection risk assessment infers an emission rate of E = 970 (± 390) quanta per hour in this scenario from the single infectious index case.	
Presymptomatic Transmission of SARS-CoV-2 — Singapore, January 23–March 16, 2020	Investigation of 7 COVID-19 clusters identified in Singapore find asymptomatic transmission to have occurred. In two independent clusters infection transmission is attributed to multiple women attending music class (Cluster B, Cluster F) with confirmed cases.	(Wei et al., 2020)
Clusters of Coronavirus disease in communities, Japan, January-April 2020	Investigation of 61 clusters of >5 cases in Japan Jan 15- Apr 4. 18 (30%) healthcare facilities; 10 (16%) care facilities of other types, such as nursing homes and day care centers; 10 (16%) restaurants or bars; 8 (13%) workplaces; 7 (11%) music-related events, such as live music concerts, chorus group rehearsals, and karaoke parties; 5 (8%) gymnasiums; 2 (3%) ceremonial functions; and 1 (2%) transportation-related incident in an airplane. The largest non–healthcare-related cluster was >30 persons who attended a live music concert, including performers, audience members, and event staff. Many COVID-19 clusters were associated with heavy breathing in close proximity, such as singing at karaoke parties, cheering at clubs, having conversations in bars, and exercising in gymnasiums.	(Furuse et al., 2020)
Open with care: minimising COVID-19 superspreading settings in Australia	Risk benefit evaluation Karaoke rooms and choir practice where singing is involved is viewed as possible amplification of transmission risk due to people congregated in closely and the action of singing. Churches and religious gathering outbreaks have been recorded in the USA, S. Korea and Singapore. Characteristics of religious gatherings may increase risk of transmission due to activities such as singing, hugging and handshakes during greetings and services, passing of sacramental objects, close seating arrangements and sharing of food and refreshments. The article warns, in the Australian context, lifting of restrictions should be done carefully. In conditions of very low community spread and high proportions of susceptible populations, these superspreading events may be very important sources of cases.	(Dalton, Katelaris, & Wilson, 2020)

GREY LITERATURE ON COVID-19 RISK AND SINGING AND WIND INSTRUMENTS

This table summarizes relevant grey literature. Two outbreaks, one in the Netherlands involving a large choir and orchestra and a second associated with a karaoke outbreak in South Korea. A risk assessment, an experiment and a protocol for future research on the risk of transmission due to playing wind instruments. As well as two previously conducted evidence summaries by Alberta (May 22) and Newfoundland (Jun 1), which also capture several guidance documents and position statements.

Table 3: Grey literature on infection transmission attributed to singing and wind instruments

Publication Title	Key Outcomes	Reference
Wind instrument aerosol in Covid Era - COVID-19 and horns, trumpets, trombones, euphoniums, tubas, recorders, flutes, oboes, clarinets, saxophones and bassoons	Risk Assessment This risk assessment provides an overview of the different activities involved in playing wind instruments that may result in aerosols or direct transmission. • There is no direct evidence, but indirect evidence suggests it may exceed normal background risk of transmission. • The authors describe common practices among musicians that have the potential to spread the virus. The practice of sharing or touching other musicians' reeds was described as high risk and there were no recommendations for disinfection of reeds. • The authors conclude there is insufficient evidence to properly assess the risk of SARS-CoV-2 transmission due to playing instruments with other people.	(Schwalje & Hoffman, 2020)
Aerosol generation from playing band instruments and risk of infectious disease transmission	This is a protocol for a study being conducted at University of Colorado. The goal of this project is to provide measurements and risk modelling estimates in a timely manner to better understand particle emissions from playing band instruments. Proposed four activities: 1. Flow imaging studies to qualitatively document the emission and particulate plume through photography and lasers 2. Chamber studies to measure particle generation rates from the following activities:	(Shelly L. Miller et al., 2020)

	a. 5 woodwinds – flute, clarinet, oboe, saxophone, bassoon b. 4 brass – french horn, trumpet, trombone, tuba c. The 4 vocal ranges – soprano, alto, tenor, bass d. Musical theatre – talking, monologue, singing, dancing (male and female actors) e. Elementary – male and female in grades 3-5 f. Aerobic simulation (marching band, show choir, dance, etc.) 3. Field rehearsal studies measuring concentrations in a rehearsal room with multiple players the University of Colorado Boulder (contingent upon IRB and campus approval) 4. Modelling of risk of transmission using the Wells-Riley Model	
Bamberg Symphony Orchestra: Scientists measure aerosol emissions	On-line publication (in German) Scientists at the Bamberg Symphony Orchestra use air currents to measure how many aerosols are emitted by a trombone, clarinet or horn. The emitted suspended matter is considered to represent the potential for air contaminated with SARS-CoV-2 to be expelled from the instrument if the musician was infected.	("Bamberg Symphony Orchestra: Scientists measure aerosol emissions," 2020)
(LEAD) Itaewon-tied cases rise to 153, karaoke facilities emerge as infection routes	Online newspaper article Infections in Seoul, South Korea linked to nightspots in the neighborhood of Itaewon, karaoke facilities are suspected infection transmission sites.	("(LEAD) Itaewon-tied cases rise to 153, karaoke facilities emerge as infection routes," 2020)
That one passion that did go on, with disastrous consequences.	Online newspaper article This outbreak involved 102 COVID-19 cases among 130 members of a choir and orchestra in Amsterdam, Netherlands. At the beginning of the outbreak, the group continued to practice despite members of the choir becoming ill. Based on the sequence of events and illnesses, there were potentially multiple transmission events.	(van der Lint, P., 2020)
COVID-19 quick response report: Choirs and COVID-19	Quick response report on the evidence with respect to choirs and COVID-19 up to June 3, 2020. The authors summarize many of the guidance documents, expert opinions and evidence on choirs and transmission of SARS-CoV-2.	(Williams, S and Navarro, P., 2020)

Singing as a risk for transmission of SARS-CoV-2 virus	Rapid review on the evidence and guidance around singing as a risk of transmission. It was last evaluated May 22, 2020. The review includes non-SARS-CoV-2 literature relevant to singing and the potential to spread pathogens. The report on choir related transmission events of influenza A, and tuberculosis.	(Kania-Richmond, A and Sharpe H., 2020)

Methods:

A daily scan of the literature (published and pre-published) is conducted by the Emerging Science Group, PHAC. The scan has compiled COVID-19 literature since the beginning of the outbreak and is updated daily. Searches to retrieve relevant COVID-19 literature are conducted in Pubmed, Scopus, BioRxiv, MedRxiv, ArXiv, SSRN, Research Square and cross-referenced with the literature on the WHO COVID literature list, and COVID-19 information centers run by Lancet, BMJ, Elsevier and Wiley. The daily summary and full scan results are maintained in a Refworks database and an Excel list that can be searched. Targeted keyword searching is conducted within these databases to identify relevant citations on COVID-19 and SARS-CoV-2. Search terms used included: sing, karaoke, choir, wind and instrument, music, singing, vocalize, religious, church. An additional search for grey literature was conducted using search strings (COVID-19 or SARS-CoV-2) AND (choir or music or (wind and instrument)) in google. Previously conducted reviews were sought from the NCCMT repository, CADTH, and SPOR evidence alliance.

Each potentially relevant reference was examined to confirm it had relevant data and relevant data is extracted into the review. This review contains research published up to June 26, 2020.

Prepared by: Lisa Waddell and Chatura Prematunge. Emerging Science Group, PHAC.

Emerging Evidence on COVID-19

Evidence Brief of Aerosol Generating Procedures in Dental Care Settings

Introduction

What is the existing evidence of SARS-CoV-2 transmission in dental settings, and the infection transmission from Aerosol Generating Procedures (AGP) use in dental care?

AGP can increase risk of infection transmission from an infected patient to a healthcare worker due to close proximity and generation of aerosols in large volumes. This evidence brief summarizes the available literature and guidance on aerosol generating procedures (AGP) in dental care settings as they relate to SARS-CoV-2 transmission and can be used with the evidence summary on aerodynamics of SARS-COV-2 dated May 28, 2020, which summarizes the evidence on aerosolization of SARS-COV-2 - available through the PHAC emerging sciences secretariat.

Key Points

- No published reports of COVID-19 transmission, clusters, or outbreaks in dental care settings could be identified.
- SARS-COV-2 aerosolization:
    - Air samples collected from hospital care settings treating COVID-19 cases have demonstrated SARS-COV-2 RNA contamination, likely from aerosols and small respiratory droplets (Guo et al., 2020; Liu et al., 2020; Santarpia et al., 2020). SARS-CoV-2 is found to remain viable in aerosols for up to 4 hours, but neither the infectiousness or the infectious dose of these particles has been established (van Doremalen et al., 2020).
    - Dental procedures can induce gag reflexes leading to increased saliva secretion and coughing in patients. High speed dental instruments can create high volumes of aerosols containing water, saliva, blood, microorganisms and other debris (Ather, Patel, Ruparel, Diogenes, & Hargreaves, 2020; Jamal et al., 2020; Sales, Sales, & Da Hora Sales, 2020).
    - A recent publication by Workman et al., reports on cadaver simulations where aerosolization risks linked to endonasal procedures were assessed (Workman et al., 2020). The study concludes high-speed surgical drill procedures resulted in substantial aerosol contamination in all tested conditions. These findings may be extended to dental drills and procedures that are considered aerosol generating.

- Guidance Documents:
    - Published guidance indicates confirmed and suspected COVID-19 patients should NOT be treated in routine dental practice settings, and only be managed in negative-pressure infection isolation rooms (AIIR). (Ather et al., 2020; Jamal et al., 2020)
    - Reviews of multiple COVID-19 dental guidance documents indicate that some procedures and equipment used are associated with increased risk of aerosol generation and should be either avoided or modified during the COVID-19 pandemic (Table 1). Specific guidance linked to aerosol generating procedures and instruments from these publications are summarized below.
        - Intraoral Radiographs should be avoided and replaced with extraoral imaging such as panoramic radiography or cone-beam computed tomographic imaging when intraoral imaging is unavoidable (Ather et al., 2020; Jamal et al., 2020; Meng, Hua, & Bian, 2020).
        - Use of a rubber dam to minimize splatter generation is the standard of care for nonsurgical endodontic treatment. Recommendations suggest it may be advantageous to place the rubber dam so that it covers the nose (Ather et al., 2020; Jamal et al., 2020; Sales, Sales, & Da Hora Sales, 220). Also, when the rubber dam is applied, extra high-volume suction for aerosol and spatter is recommended along with regular suction (Peng et al., 2020).
        - Ultrasonic instruments such as triplex syringes, high-speed hand pieces, ultrasonic scalers, air abrasion devices, and intra-oral sandblasters are identified to be associated with increased aerosolization risk that should be avoided or the use minimized (Ather et al., 2020; Jamal et al., 2020; Meng et al., 2020; Sales et al., 220). If the use of such equipment is unavoidable, the application of high volume saliva ejectors are recommended alongside applicable instruments (Ather et al., 2020; Jamal et al., 2020; Meng et al., 2020).
        - To minimize the risk of dental aerosols, it is recommended that hand instruments, low-speed hand pieces, instruments without water spray and hand piece with an anti-retraction valve or other anti-reflex technology are used where possible (Ather et al., 2020; Jamal et al., 2020).
        - Peng et al., suggest the use of dental hand pieces without anti-retraction function should be prohibited during the epidemic period of COVID-19. Instead, anti-retraction dental hand piece with specially designed anti-retractive valves or other anti-reflux designs are strongly recommended as an extra preventive measure for cross-infection. It is important to note these recommendations are based on previous evidence from Hepatitis B infection transmission in dental care settings (Peng et al., 2020).

Overview of the Evidence

Currently, there is no published reports of COVID-19 clusters or outbreaks linked to dental care settings. No published simulation studies have specifically assessed droplet dispersion or aerosol generation of any dental procedures since the emergence of COVID-19. The designation of AGP in dental setting is largely based on evidence from medical procedure based simulations or national guidance from various dental associations. The available body of evidence from medical procedures is small, largely theoretical, and does not consider the infectiousness of SARS-CoV-2 aerosols specifically, yet the evidence does not appear to be of low quality.

Aerosol Generating Procedures (AGP) and COVID-19 transmission in dental care are understudied topics with substantial knowledge gaps. These areas would benefit from additional research and reporting that focus on COVID-19 pandemic experiences in dentistry.

CONTENTS

COVID-19 GUIDANCE FOR DENTAL CARE SETTINGS

Table 1: Five reviews describe aerosol generating dental procedures, the underpinning evidence and available guidance on minimizing aerosols from dental procedures.

Reference	Key Features
Ather et al., 2020	Provides a brief overview of the epidemiology, symptoms, and routes of transmission of COVID-19, as well as specific recommendations for dental practice during the current pandemic. These recommendations are informed by the emerging evidence on SARS-CoV-2 and past experiences from SARS-CoV transmission in healthcare settings.
Jamal et al., 2020	Reviews and summarizes COVID-19 guidance published by multiple national dental associations, including guidelines from American Dental Association, Scottish Dental Clinical Effectiveness Programme, New Zealand Dental Association and International federation of Endodontic Association - Indian Endodontic Society joint statement, and American Association of Endodontics.
Meng et al., 2020	Discusses aerosol producing procedures and techniques that were avoided at a Hospital of Stomatology in Wuhan, China during the emergence of the COVID-19 pandemic in early 2020.
Peng et al., 2020	Provides an overview of the available evidence on COVID-19 infection transmission routes, and details COVID-19 infection prevention and guidance for dental settings. The authors strongly advocate for prohibited use of dental hand pieces without anti-retraction function during the pandemic. The evidence against the use of hand pieces without anti-retraction function is from studies investigating cross infection risk from Hepatitis B virus (not a respiratory virus).
Sales et al., 2020	Examines the available literature and provides recommendations for dental care in light of the COVID-19 pandemic. Recommends the avoidance of high-speed instruments and the use of rubber dams to mitigate aerosol risk.

Methods:

A daily scan of the literature (published and pre-published) is conducted by the emerging sciences group, PHAC. The scan has compiled COVID-19 literature since the beginning of the outbreak and is updated daily. Searches to retrieve relevant COVID-19 literature are conducted in Pubmed, Scopus, BioRxiv, MedRxiv, ArXiv, SSRN, Research Square and cross-referenced with the literature on the WHO COVID literature list, and COVID-19 information centers run by Lancet, BMJ, Elsevier and Wiley. The daily summary and full scan results are maintained in a refworks database and an excel list that can be searched. Targeted keyword searching is conducted within these databases to identify relevant citations on COVID-19 and SARS-COV-2. Search terms used included: aerosol, dental

This review contains research published up to June 9, 2020.

EEach potentially relevant reference was examined to confirm it had relevant data and relevant data was extracted into the review.

Emerging Evidence on COVID-19

Evidence Brief on Infection Risk from Eye Exposures to Inform Contact and Droplet Precautions

Introduction

This evidence brief summarizes the available evidence on whether the use of eye protection in addition to standard medical masks and respirators prevent infection transmission to Healthcare Workers (HCWs) caring for COVID-19 cases. Particularly pauci- or asymptomatic COVID-19 patients.

For the purposes of this review, COVID-19 is a respiratory infection that is primarily transmitted by droplets, and possibly aerosols, during close unprotected interactions [1]. Speaking, coughing, and sneezing by symptomatic patients can lead to infection transmission due to small virus-laden droplets (and possibly aerosols) being expelled into the healthcare environment [1-4]. Coughing is the most commonly reported symptom among COVID-19 cases in Canada [5].

Key Points

- No studies to date have specifically investigated or reported COVID-19 infection due to SARS-CoV-2 exposure of ocular surfaces due to interactions with asymptomatic and pre-symptomatic cases. Key evidence that support the use of eye protection by healthcare workers to minimize infection transmission of coronaviruses is outlined below (and in Table 1)
    - A systematic review and meta-analysis by Chu et al., examine the available evidence from observational studies on coronavirus (SARS-CoV-2, MERS-CoV, SARS) transmission risk from physical distancing, facemask and eye protection[13]. Based on the pooling of primary study data on SARS and MERS the reviewers conclude eye protection used in conjunction with surgical mask/ respirator further mitigates coronavirus infection transmission risk compared to face protection alone (risk difference and adjusted odds ratio between eye protection vs. no eye protection is estimated to be -10.6% 95% CI -12.5 to -7.7 and aOR 0·22, 95% CI 0·12 to 0·39 respectively).
    - ACE-2 receptors, a cellular receptor for SARS-CoV-2 virus attachment are found in human eye tissue. Numerous studies, including a systematic review, provide molecular biological evidence that SARS-CoV-2 can use optical tissues (i.e. the eye) as a portal of entry to infect human hosts [14-18].

- SARS-CoV-2 viral RNA has been identified from ocular swabs and during autopsy of COVID-19 cases with and without ocular manifestations [19].

- Exposure data from multiple hospitals during the SARS outbreak in Ontario, Canada provide observational data that reported eye protection reduced the incidence of SARS infections among responding healthcare workers [20].

- Available guidance for healthcare worker precautions indicate:

  - Infection prevention and control (IPAC) guidance recommend the use of contact AND droplet precautions (i.e. use of gloves, masks, face shields, and goggles) when healthcare workers 1) interact with symptomatic COVID-19 patients, or 2) are in proximity to any aerosol generating procedure - regardless of acute respiratory infection symptom presentation in the patient [6-8].

  - IPAC best practices specific to COVID-19 also recommend a point of care risk assessment be applied (based on the patient, the interaction, and the task) to determine additional precautions necessary for ALL patient and visitor at this time [6].

- Emerging evidence suggests the absolute risk of exposure of healthcare worker contact with a SARS-CoV-2 infected person increases with the prevalence in the community.

  - Serological testing of hospital workers in Italy revealed healthcare IgG positivity to be associated with the geographical prevalence of COVID-19 infections in the region [11].

  - COVID-19 outbreak data from Ontario's nursing homes also show associations between outbreaks and the incidence of COVID-19 infections in the surrounding health regions and nursing home bed-size [12].

Overview of the Evidence

A recent systematic review and meta-analysis presents the available evidence on eye protection and betacoronavirus (SARS, COVID-19/SARS-CoV-2, MERS) transmission, these estimates are considered to be of low certainty via the application of GRADE and do not include COVID-19 data. The review identified a single COVID-19 study [21] conducted in healthcare workers, however no SARS-COV-2 infections occurred among health care workers in either group.

Although observational study data on the protective effects of eye protection specific to COVID-19 transmission in healthcare is lacking, molecular biology data from other studies do provide evidence to support the plausibility of SARS-CoV-2 infection using the host eye as a portal of entry. The available evidence offers low certainty that the reported protective effects of wearing eye protection will not change with future research. There are knowledge gaps in the research that estimate infection transmission risks to healthcare workers, and under what circumstances that risk may be considered to increase or decrease.

CONTENTS

INFECTION VIA OCULAR EXPOSURE

COVID-19 is a respiratory infection that is primarily transmitted by droplets, and possibly aerosols, during close unprotected interactions [1]. Speaking, coughing, and sneezing by symptomatic patients can lead to infection transmission due to small virus-laden droplets (and possibly aerosols) being expelled into the healthcare environment [1-4]. Coughing is the most commonly reported symptom among COVID-19 cases in Canada [5].

Guidance for most high risk healthcare interactions during the ongoing pandemic would suggest droplet AND contact precautions. In instances where healthcare workers are required to interact with people of unknown COVID-19 status, IPAC best practices recommend a point of care risk assessment be applied as SARS-CoV-2 is a novel and emerging pathogen [6-8]. These risk assessments are intended to guide the use of appropriate additional precautions during potential COVID-19 patient interactions, and should be based on the patient, the specific interaction, and task to be performed by the healthcare worker. COVID-19 prevalence within the patient catchment areas should be considered when assessing transmission risk and use of additional precautions.

Table 1: Literature on infection transmission risk from ocular surface exposures.

Reference	Relevant Findings	Infection
Primary Literature		
Burke, RM et al [21]	The study reports on varied personal protection equipment (PPE) use among healthcare workers attending to the early travel related cluster of COVID-19 cases in the US. This is the only study (to date) to consider and provide data on selective personal protection equipment use among healthcare workers during COVID-19. Relative risk of COVID-19 infection based on eye protection vs. no eye protection can NOT be estimated as no secondary cases among healthcare workers were identified.	SARS-CoV-2
Ma, D et al [14] Lange, C et al [15] Zhang , L et al [16] Zhou, L et al [18]	Human eye tissue is found to express ACE-2 receptors, cellular receptors for SARS-CoV-2, thus confirming the ability of the virus to infect a host via the eye.	SARS-CoV-2
Raboud, J et al [20]	According to a multicenter investigation of a past SARS outbreak in Toronto, inconsistent goggle and eye protection when entering a patient room increased healthcare worker infection risk (n=624). A statistically significant association between eye protection and infection were identified, suggesting conjunctiva could have been a portal of pathogen entry.	SARS-CoV

Key Commentaries and Reviews		
Chu, D et al [13]	The review captures evidence available up to May 3rd, 2020 A systematic review and meta-analysis by Chu et al., examine the available evidence from observational studies on coronavirus (SARS-CoV-2, MERS-CoV, SARS) transmission risk based on eye protection. The review concludes eye protection alongside mask/respirator use is associated with a reduction in coronavirus infection transmission (Risk Difference of -10.6% (95% CI -12.5 to -7.7) and adjusted odds ratio 0·22, 95% CI 0·12 to 0·39 respectively with low certainty). SARS-CoV-2 are not considered in the eye protection risk estimates as this evidence does not presently exist. (Ref to Burk et al)	SARS-CoV-2 MERS-CoV SARS
Aiello, F et al [17]	A systematic review by Aiello summarizes the available information on the presence of SARS-CoV-2 in cornea, conjunctiva, lacrimal, sac and tears. The review confirms SARS-CoV-2 can be present and infect eye tissue, and therefore may use ocular structures as an additional transmission route.	SARS-CoV-2
Lu, C-W et al [22]	Commentary where authors refer to a media report (in Chinese) where infection transmission in a worker wearing an N95 mask but no eye protection was reported to have occurred.	SARS-CoV-2

Methods:

A daily scan of the literature (published and pre-published) is conducted by the emerging sciences group, PHAC. The scan has compiled COVID-19 literature since the beginning of the outbreak and is updated daily. Searches to retrieve relevant COVID-19 literature are conducted in Pubmed, Scopus, BioRxiv, MedRxiv, ArXiv, SSRN, Research Square and cross-referenced with the literature on the WHO COVID literature list, and COVID-19 information centers run by Lancet, BMJ, Elsevier and Wiley. The daily summary and full scan results are maintained in a RefWorks database and an excel list that can be searched. Targeted keyword searching was conducted within these databases to identify relevant citations on COVID-19 and SARS-COV-2. An additional target keyword search was conducted on Pubmed to identify relevant citation not specific to COVID-19 and SARS-COV-2. Search terms used included: ocular, eye, ACE2, contact precautions, and droplet precautions,
Each potentially relevant reference was examined to confirm it had relevant data and relevant data is extracted into the review.

This review contains research published up to June 2nd, 2020.

Emerging Evidence on COVID-19

Evidence Brief of De-escalation of Social Bubbles

Introduction

What evidence is available on the de-escalation of "household bubbles", is there suggestions for how we can decrease the network segmentation of communities to larger networks?

This review will examine the evidence on the concept of network segmentation. This has been implemented within the general public as "social bubbles". This concept refers to limitations on individual interactions with people outside of their closed network (e.g. immediate family). As we move to different phases of the epidemic, it is of interest to understand what impact increasing the social bubble size or segmented networks may have on the epidemic. This evidence brief includes literature up to June 15, 2020.

Key Points

- This evidence brief consists of four predictive models, three of which are recent preprints and have not undergone the peer-review process.
- One preprint was identified that directly models social bubbles and real world options using the UK as the case study. The study reports that single family bubbles are estimated to have reduced the number of cases by 17%. In their model they explore relaxing the single household bubble to different scenarios of multiple households using three different secondary attack rates and Ro as the outcome. Ro is shown to increase as restrictions are relaxed, but some of the limited options appear to have minimal increase in risk.
- Three social network models also provide some evidence to support that larger, but still closed and segmented networks offer a protective effect against introduction of SARS-CoV-2. The larger a segmented network and the more contacts outside of that network, the higher the risk of virus introduction.
- There are many studies that look at the impact of social distancing more generally and in combination with other interventions. They have not been summarized in this evidence brief, but are available upon request as they are collected within the Public Health Intervention evergreen review.
- One protocol for a systematic review on physical distancing interventions was also identified, but it will not be conducted until October 2020.

Overview of the Evidence

The concept of reducing transmission of SARS-CoV-2 by restricting close interactions to a very strict, small network (i.e.: a single family) is an effective intervention. Increasing the size of the network or de-escalation of the intervention is important to do carefully and not too quickly so control over the epidemic is maintained while slowly lifting restrictions. As there are few observations in the literature, the evidence is largely

contained in a few recent preprints that report on predictive models. These models are based on scenarios and are parameterized using observational data from the outbreak; caution should be exercised in using these findings, as the extent to which the results can be generalized to the local context is variable.

CONTENTS

SOCIAL BUBBLES

Four predictive models explored concepts of social bubbles using agent-based models and other network models to demonstrate the protective impact of having closed and limited contact networks during the COVID-19 epidemic (Block et al., 2020; Leng et al., 2020; Sneppen & Simonsen, 2020; St-Onge, Thibeault, Allard, Dube, & Hebert-Dufresne, 2020). One model directly explores a range of relaxing options for contact restrictions and explores the implications using Ro (Leng et al., 2020). These models explore and explain the concept of small-segmented community networks providing increased resistance to an introduction of the virus event into smaller networks. They also explore the activities that degrade the protection of a segmented network. This occurs when an individual from a closed network interacts with other networks and is particularly higher risk when the interaction is within a random gathering event where unknown people mix e.g. public transportation, commuting to a workplace outside of the segmented network, social places such as bars and restaurants, or sporting events. However, the extent that these estimates can be used is unknown as they were based on the epidemic dynamics in a specific place.

Table 1: Modelling studies on social bubbles or restricted social networks

Reference	Study Description	Relevant Outcomes
(Leng et al., 2020) *Preprint*	Individual-based model: Using the UK as a case study, a mathematical model was used to assess the effectiveness of various social bubble strategies as part of a gradual lockdown exit strategy. Using a base case where non-essential shops and schools are closed, the household attack rate is 20%, and R0=0.8, a number of social bubble strategies are simulated. Results demonstrate that in this base case scenario, social bubbles reduced cases and fatalities by 17% compared to an unclustered increase of contacts.	Keeping the secondary attack rate = 20% constant. The base scenario is single family bubbles Ro = 0.8 The following scenarios show how Ro would be expected to change with moderate relaxing of contact restrictions: 1. Allowing all households with primary school age children to pair up Ro= 0.85 2. Allowing all households with children of any age to pair up = 0.90 3. All single occupancy households to link up with other single occupancy households 0.85 4. All single occupancy households to

	Clustering contacts outside the household into exclusive social bubbles is an effective strategy of increasing contacts while limiting some of the associated increase in epidemic risk.	link up with any other household Ro=1.00 5. Scenarios 1 and 3 Ro=0.90 6. All households pair up Ro=1.11
(Block et al., 2020)	Stochastic Model: Adopting a social network approach, we evaluate the effectiveness of three distancing strategies designed to keep the curve flat and aid compliance in a post-lockdown world. We demonstrate that a strategic social network-based reduction of contact strongly enhances the effectiveness of social distancing measures while keeping risks lower.	3 scenarios for social distancing- "strengthening community and seeking similarity strategies". - Individuals choose their contact partners based on similarity of a predetermined individual characteristic. This facilitates forming small groups e.g. neighbourhood/ small organization. - Individuals consider who their contact partners interact and do not see people outside of a defined contact network. Build bubbles through repeat contacts. Individuals decide who they want to interact with. This can be used with work units as well. It is difficult for the virus to penetrate these micro-communities.
(St-Onge et al., 2020) *Preprint*	Canadian authors (Laval University) SIS/SIR models using a network science framework to look at the impact of having structures aka gatherings (groups/ classrooms/ sports teams etc.).	- They demonstrate that localized epidemics can collapse if the group or gathering size remains below a threshold. - The threshold for the mesoscopic localization regime, with a transmission rate $\beta = 0.07$ was 23 people and below.
(Sneppen & Simonsen, 2020) *Preprint*	This agent-based model explored the impact of super-spreading events. In the base model super-spreading events had little effect on the epidemic, however under various intervention strategies, limiting diffuse social contacts – random gathering events - in settings such as bars, transportation, restaurants, parties, concerts and lecture halls is far more effective than limiting the same amount of contact events in the home and work setting.	- Limiting random gathering events had a large impact on the risk of super spreading events in this model under scenarios where various intervention strategies are implemented.

ON-GOING RESEARCH PROTOCOL

One systematic review protocol was identified that will summarize the evidence on isolation, quarantine, and social distancing strategies.

Table 2: Research protocols

Reference	Study Description	
(Regmi & Lwin, 2020)	What has been the impact of social distancing measures for preventing coronavirus disease 2019 [COVID-19]?	Studies will be targeted from July to October 2020 and will be restricted to peer-reviewed articles in English.

Methods:

A daily scan of the literature (published and pre-published) is conducted by the Emerging Sciences Group, PHAC. The scan has compiled COVID-19 literature since the beginning of the outbreak and is updated daily. Searches to retrieve relevant COVID-19 literature are conducted in Pubmed, Scopus, BioRxiv, MedRxiv, ArXiv, SSRN, Research Square and cross-referenced with the literature on the WHO COVID literature list, and COVID-19 information centers run by Lancet, BMJ, Elsevier and Wiley. The daily summary and full scan results are maintained in a Refworks database and an excel list that can be searched. Targeted keyword searching is conducted within these databases to identify relevant citations on COVID-19 and SARS-CoV-2. Search terms used included: social AND (bubble or bubbles or network). Results were crosschecked with the evergreen review on Public Health Interventions. This review contains research published up to June 15, 2020
Each potentially relevant reference was examined to confirm it had relevant data and relevant data is extracted into the review.

Emerging Evidence on COVID-19

Evidence Brief on Infectiousness and Symptom Onset

Introduction

Case studies, case series, contact and cluster investigations, and large population studies have demonstrated that transmission from pre- and asymptomatic cases frequently occur. This review aimed to summarize the literature on whether there is a difference in risk of transmission from persons who are pre- and asymptomatic infected cases compared to symptomatic cases.

Key Points

- Literature from healthcare settings highlight that transmission of COVID-19 is complex and related to the situation, duration of exposure, and individual factors.
    - Potential asymptomatic transmission has been documented in healthcare settings among facility residents, healthcare workers, and visitors [9, 10]. One outbreak in a skilled nursing facility in Washington State found that over half of residents who had positive results were asymptomatic at time of testing and that viable virus was cultured from pre-symptomatic cases up to 6 days prior to symptom development [9].
    - Another study was unable to demonstrate that asymptomatic transmission occurred among close contacts and in healthcare settings [8]. This study had low power, which may not have been sufficient to estimate a risk of transmission.
- Asymptomatic transmission has been shown to occur and may be linked to time spent in close contact with an infected person and other attributes of the scenario under which transmission occurred.
    - In a meta-analysis of mild (n=8) and asymptomatic cases (n=36), high rates of transmission were observed in situations of close quarters such as meals/family events, talking while travelling in car, private meetings, and prayer service [1]. It is likely that in such situations, asymptomatic spread is facilitated via contact (contamination of hands and fomites) as well as droplet generation via talking and singing.
- The estimated viral load in aerosols emitted by patients while breathing normally was on average 0.34-11.5 copies/cm^3 while the corresponding numbers for patients exhibiting respiratory symptoms were much higher at 10,900-366,00 copies/cm^3 per cough [2]. An individual spending time in a room with a person breathing normally (i.e. not exhibiting respiratory symptoms) was still likely to inhale tens to hundreds of copies of the virus.

- The proportion of transmission events from pre- and asymptomatic individuals in epidemiological investigations are highly variable (range <10-73%) (Table 1). Predictive models estimate 40-80% of transmission events occur from pre- and asymptomatic individuals [3-5].

- Transmission probabilities for symptomatic and asymptomatic cases may be very similar:

    - An analysis reported no significant difference in transmission rates between symptomatic and asymptomatic patients (6.3/100 and 4.1/100, respectively) [6].

    - Similar SARS-CoV-2 upper respiratory viral loads have been reported among asymptomatic and symptomatic patients [7].

Overview of the Evidence

There are few studies that directly compare transmission potential and infectivity between cases exhibiting respiratory symptoms and cases not exhibiting respiratory symptoms. For the purposes of this review the majority of evidence on this topic has been extrapolated from studies comparing symptomatic and pre-symptomatic/asymptomatic cases in general as well as in the healthcare setting.

Evidence on this subject is mainly described via case reports and contact tracing studies, which are at high risk of bias and thus are considered of low quality. Many studies are pre-prints and have not undergone a peer-review process. Overall, the outcomes should be interpreted with caution.

There were no risk assessments or studies that estimated the risk of infection for healthcare workers from caring for pre- or asymptomatic patients compared to symptomatic patients.

Estimates are changing as new research becomes available and there are many knowledge gaps. New research addressing these gaps could significantly change our understanding of SARS-CoV-2 infectivity among symptomatic and asymptomatic cases. More evidence demonstrating cultivatable virus from asymptomatic, pre-symptomatic, and symptomatic infections is required to determine infectiousness at different stages with greater certainty.

CONTENTS

EVIDENCE OF PRE- AND ASYMPTOMATIC TRANSMISSION POTENTIAL

It is important to keep in mind that transmission between cases depends on context and multiple factors. Individuals exhibiting respiratory symptoms are much more likely to isolate than asymptomatic individuals, explaining the high rates of pre- and asymptomatic transmission reported in this literature. Transmission studies of pre- and asymptomatic cases have shown that pre- and asymptomatic transmission does occur at high proportions in this pandemic, both in the general population and within healthcare settings. Thus, cases not exhibiting obvious signs of infection, including droplet generating events such as coughing and sneezing, can still be highly infectious.

Table 1: Studies providing evidence related to infectivity and transmission potential of pre- and asymptomatic infections. An indicator of the quality of evidence is provided (low, moderate, high) based on the risk of bias in the study design and reporting.

Reference	Description	Quality
Pre-symptomatic transmission estimations		
Arons, MM et al [9]	Outbreak investigation of residents of a skilled nursing facility in Washington, US Apr 3, 2020 end date -48 (63%) of residents that participated in point-prevalence surveys tested positive. -24 were pre-syptomatic and 2 were asymptomatic. - Viable virus was isolated from specimens collected 6 days before to 9 days after onset of symptoms. -This indicates that pre- and asymptomatic infection was a major factor in the transmission of SARS-CoV-2 within the facility.	low
Du, Z et al [12]	Case review of publically available data in China 468 infector–infectee pairs identified via contact tracing Jan 21-Feb 8, 2020 -Fifty-nine of 468 infector-infectee pairs (12.6%) indicated that the infectee had symptoms earlier than the infector. -These negative serial intervals suggest that pre-symptomatic transmission likely occurred.	low
Chun, JY et al [13]	Case review of publically available data in South Korea 72 infector-infectee transmission pairs Jan 23-Mar 31, 2020 -The pre-symptomatic transmission proportion was 37% (16–52% 95%CI).	low
He, X et al [14]	Contact tracing study in Vietnam, Malaysia, Japan, China, Taiwan, USA, Singapore 77 infector–infectee transmission pairs Dec 18-Mar 5, 2020 -Estimated that 44% (25-69% 95%CI) of secondary cases were infected during the index cases' pre-symptomatic stage.	low
Pham, TQ et al [15]	Case review of publically available data in Vietnam 33 infector-infectee transmission pairs	low

	Apr 15 – May 1, 2020 - Serial intervals were calculated from infector-infectee pairs and used to estimate the proportion of pre-symptomatic transmission events -27.5% (15.7%-40.0% 95%CI) of transmissions occurred pre-symptomatically	
Wei, WE et al [16]	Contact tracing study of 243 cases and 7 clusters in Singapore Jan 23-March 16, 2020 - seven clusters of cases with probable pre-symptomatic transmission were identified. -The overall proportion of transmission from pre-symptomatic cases comprised 6.3% of overall transmission.	low
Xia, W et al [17]	Investigation of 50 clusters in China Symptom onset prior to Jan 25, 2020 -124 cases where the secondary case contact with the first generation case occurred before symptom onset. The infectious curve showed that in 73.0% of the infectees, their date of being infected was before symptom onset of their infectors, particularly in the last three days of the incubation period.	Moderate
Casey, M et al [18]	Secondary analysis of published data reporting serial interval or generation time originating from Hong Kong, Tianjin, Singapore, Mainland China excluding Hubei, mixed sources, Shenzhen, northern Italy and Wuhan Dec 1 – Apr 15, 2020 -Subtracted incubation period from serial interval or generation time to infer pre-symptomatic infectious period and to estimate the proportion of pre-symptomatic transmission -Pre-symptomatic transmission was estimated to be 56.1% based on serial interval estimates and 65.5% based on generation time estimates.	low
Prakash, MK et al [19]	Secondary analysis of published data 1251 individuals reported in the literature -Estimated that 68.4% (67.0-69.7% 95%CI) of infections are caused by pre-symptomatic infectors.	low
Nishiura, H et al [20]	Log-normal distributed Bayesian model built from case review of published research and investigation reports 28 infector-infectee pairs Feb 12, 2020 end date -Accounting for right truncation and analyzing all pairs, authors estimated a serial interval of 4.0 days (3.1-4.9 95%CI). -This interval is shorter than preliminary estimates of the incubation period of approximately 5 days. - This suggests that pre-symptomatic transmission may make up a substantial proportion of secondary transmission.	low
Asymptomatic transmission estimates		
McMichael, TM et al [10]	Outbreak investigation of residents, healthcare workers, and visitors of a long-term care facility in Washington, US Mar 18, 2020 end date -167 confirmed cases of Covid-19, including 101 residents, 50 health care personnel, and 16 visitors were found to be epidemiologically linked to the facility. -No symptoms were documented in 7 (6.9%) of residents.	low
Yin, G et al [6]	Re-analysis of case and contact data in Ningbo, China 157 symptomatic cases and 30 asymptomatic cases	low

	January 21st to March 6th 2020 -Transmission rates for the symptomatic and asymptomatic patients were 0.063 and 0.041 respectively (no significant difference). -Odds of transmitting to a healthy individual by a symptomatic patient is 1.2 times of that by an asymptomatic patient (not statistically significant)	
Danis, K et al [21]	Cluster investigation in the French Alps with exportation and spread to several countries in Europe. Pre-symptomatic index case and 15 contacts in chalet; 172 contacts identified overall of cases. January 25, 2020 onward -Attack rate from asymptomatic index case 12/15 (75%) over 4 days contact; 1/15 asymptomatic. Only one of the 172 subsequent contacts was positive. -Viral load in one symptomatic case similar to asymptomatic case.	low
Wang, R et al [22]	Retrospective study in China 125 patients confirmed by real-time RT-PCR. Jan 20 to Feb 18, 2020. -22.4% of cases reported no known exposure to ill individuals.	low
Wong, J et al [23]	Case review in travelers and returning residents to Brunei 53 symptomatic infector-infectee pairs. Mar 5 – Apr 24, 2020 -21 (39.6%) had a SI of ≤3 days and 6 (11.3%) had zero or negative SI values, suggesting potential infectivity when asymptomatic.	low
Zou, L et al [7]	Viral load study of 17 symptomatic patients and 1 asymptomatic patient in China Jan 7 –26, 2020 - Analyzed the viral load in nasal and throat swabs - The viral load detected in the asymptomatic patient was similar to that in the symptomatic patients. This suggests the transmission potential of asymptomatic or pauci- symptomatic patients.	low
Li, R et al [5]	Mathematical model that simulates the spatiotemporal dynamics of infections in China Jan 10 – Feb 8, 2020 -estimated 86% of all infections were undocumented prior to the Wuhan travel shutdown, and that per person, these undocumented infections (many of whom were likely not severely symptomatic) were 55% as contagious as documented infections and the source of infection for 79% of documented cases	low
Riediker, M et al [2]	A one-compartment model was used to estimate the virus load concentration for a perfectly mixed room of volume 50 m^3 with one patient as source - The cumulative total emission per breath from normal breathing patients was 0.34 copies/cm^3 (air) for an average patient, and 11.5 copies/cm^3 for high emitters. -Virus emissions from coughing patients were much higher with a cumulative total emission per cough of 19,400 copies/cm^3 for an average patient and 651,315 copies/cm^3 for high emitters. - A person spending time in a room with an average emitting patient breathing normally has a high probability of inhaling tens to hundreds of	low

	copies of the virus even when practicing distancing. The probability is higher in the presence of a high emitter or if the patient is a coughing high emitter. -Conclude that the high predicted virus concentrations may be why frequent community transmission from asymptomatic cases and high rates of infection in medical staff have been reported. -Authors recommend strict respiratory protection when being in a room with a patient, whether the patient is symptomatic or not.	
Aguirre-Duarte, N [24]	Systematic Review and narrative report of Cluster/contact investigations. Primary studies of the ability of asymptomatic carriers to infect others. 9 articles reported on 83 asymptomatic or pre-symptomatic persons. Published in indexed journals January 1 to March 31, 2020. -While no specific estimates reported, there is evidence that Asymptomatic and pre-symptomatic people can infect others with COVID-19.	Moderate
Prakash, MK [1]	This synthesis is not conducted using standard systematic review methodology although a through search was conducted. 20 situations that resulted in 418 infections across 32 instances from 44 individuals (8 had mild symptoms, 36 were asymptomatic). Situation (transmission rate): • Meals/ family events (15.7% to 66.7%) • Meetings (1 hour private meeting, 72.7% (43.6-98.0) • Open work space with people movement (78.7% (CI. 70.3-85.3%)) • Singing (e.g. 2 hour practice 86.7% (CI.76.2- 93.2%), (25)) • Prayer service (resulted in 1-7 secondary infections per infected individual) • Travelling in a car (closed environment) and talking had a high risk (100% (CI.20-100%)) • Public transportation, wearing a mask with no talking (~0%) • Hotels 53.3% (30.1-75.2%)/cruise ships 28.1% (27.3-29.0%) where space is shared for days • Direct interaction with an infected sales agent 25.0% (10.2-49.5%) • Nightclub, attack rate among direct contacts >50%, among patrons of the nightclub 6.27% (5.15-7.61%) (26) • Restaurant overall attack rate (9.9% (CI: 5.3-17.7%) vs. those in the flow of the air conditioner 45.0% (25.8- 65.8%)	Moderate

Methods:

A daily scan of the literature (published and pre-published) is conducted by the emerging sciences group, PHAC. The scan has compiled COVID-19 literature since the beginning of the outbreak and is updated daily. Searches to retrieve relevant COVID-19 literature are conducted in Pubmed, Scopus, BioRxiv, MedRxiv, ArXiv, SSRN, Research Square and cross-referenced with the literature on the WHO COVID literature list, and COVID-19 information centers run by Lancet, BMJ, Elsevier and Wiley. The daily summary and full scan results are maintained in a refworks database and an excel list that can be searched. Targeted keyword searches were done using a combination of the terms "outbreak", "hospital", "long-term care" and "nursing". Previous evidence summaries and briefs on asymptomatic infection, super-spreading events, and infectious period, were used to gather evidence related to respiratory symptoms and infectivity. This review contains research published up to May 29, 2020. Each potentially relevant reference was examined to confirm it had relevant data and relevant data is extracted into the review.

Emerging Evidence on COVID-19

Evidence Brief on SARS-CoV-2 Virus Dispersion Distance

Introduction

What is the impact of physical distancing of 1 meter, 1.5 meters and 2 meters on SARS-CoV-2 virus transmission risk?

The complex physics and particle dynamics surrounding droplet and aerosol dispersion, as well as the limited evidence on infectious dose and virus viability within expelled particles, make it difficult to confidently quantify SARS-CoV-2 exposure risk based on distance. This evidence brief highlights specific literature on expelled droplet and aerosol particle dispersion distance published up to June 22, 2020.

Key Points

- The body of evidence suggest particle speed, evaporation, air flow, humidity, temperature, all play a role in the distances virus laden respiratory particles can travel after being released by an infectious individual. As such, the protective effects of physical distancing at different distances also depend on the conditions in which they are practiced.
- The available empirical and modeled evidence suggests in some circumstances respiratory droplets and aerosols expelled from infectious individuals may travel distances greater than 2 meters (Table 1), but face coverings are effective at limiting dispersion distances to less than 0.5 meters (Table 2).
- According to mathematical models and fluid dynamic analysis, droplet size, humidity, temperature, air flow, and air turbulence all impact the movement and decay of virus containing airborne particles (Table1).
    - Some models predict small droplets and aerosols can travel distances as far as ten meters when generated by coughs or sneezes, and frequently conclude social distance of two meters is not always sufficient to negate airborne SARS-CoV-2 transmission (Feng, Marchal, Sperry, & Yi, 2020; Guerrero, Brito, & Cornejo, 2020; Zhao, Qi, Luzzatto-Fegiz, Cui, & Zhu, 2020).
    - Low temperature and high humidity are found to facilitate respiratory droplet transmission and dispersion. High temperature and low humidity are found to promote the rapid loss of respiratory droplet mass (from evaporation) thereby reducing droplet travel distance (Feng et al., 2020; Zhao et al., 2020).

- A multidisciplinary research consortium applied evidence based Monte-Carlo models and 3D simulations to investigate the physics of SARS-CoV-2 aerosol dispersion (Vuorinen et al., 2020). The investigators use computer simulations to demonstrate SARS-CoV-2 aerosols can travel distances up to ten meters, and the inhalation of sufficient concentrations of aerosols (100 virus laden particles was assumed to be infectious) is possible within one second to one hour depending on the surrounding conditions.
- Results from an agent based model reported a decreasing risk of a transmission event within indoor settings (e.g. supermarket) when the distance between individuals are increase from 30 cm to 2 meters (Hernandez Mejia & Hernandez-Vargas, 2020).
- Speed of movement also impacts droplet travel distance. Computer fluid dynamic simulations find, although a distance of 1.5 meters may be sufficient when standing still, distances greater than 1.5 meters are necessary when two individuals are running or moving fast as inertia of expelled droplets also impacts droplet spread (Blocken, Malizia, van Druenen, & Marchal, 2020).

- Laboratory simulation studies report human and manikin generated cough droplets can travel distances between one to two meters, and a maximum of four meters in some simulations (Loh et al., 2020; Rodriguez-Palacios, Cominelli, Basson, Pizarro, & Ilic, 2020; Viola et al., 2020).
- Two simulation studies investigated the effects of face covers on expelled particle dispersion distance. Both studies find the inclusion of face covers, such as face shields, filtering face piece respirators, surgical face masks, and homemade masks, reduced the dispersion of expelled droplets to less than 0.5 meter, even when coughing.
- A recent systematic review by Chu et al., quantifies the relative risk of beta-corona virus infection based on distance (Chu et al., 2020). The authors report transmission of viruses to be lower with physical distancing of 1 m or more, compared with a distance of less than 1 m (n=10 736, pooled adjusted odds ratio [aOR] 0·18, 95% CI 0·09 to 0·38; risk difference [RD] −10·2%, 95% CI −11·5 to −7·5; moderate certainty); protection was increased as distance was lengthened (change in relative risk [RR] 2·02 per m; p interaction=0·041; moderate certainty). There appears to be some ambiguity in the measurement of physical distance for some of the evidence included in this review and as such is of low quality. Therefore, it may be premature to quantify the relative risk of SARS-CoV-2 infection based on incremental differences in physical distance, due to the lack of sufficient evidence.
- Presently there are no observational studies that estimate SARS-CoV-2 infection transmission risk based on varied distance from an infectious source.

Overview of the Evidence

Publications appearing in the emerging literature up to June 22, 2020 have informed this evidence brief. The available body of evidence is limited and largely based on simulations under controlled conditions. These studies are of good quality but the generalizability of these results to real world situations is unknown. For this reason additional research on transmission of SARS-CoV-2 under varying situations and distances may change the conclusions of this review.

CONTENTS

SARS-COV-2 DISPERSION DISTANCE

Table 1: Primary literature on droplet aerosol dispersion distance

Publication Title	Key Outcomes	Reference
Experimental Simulation Studies		
The impact of high-flow nasal cannula (HFNC) on coughing distance: implications on its use during the novel coronavirus disease outbreak	A simulation study using healthy volunteers (n=5) found cough-generated droplets spread a mean distance of 2.48 meters (1.03 standard deviation) at baseline, maximum of 3.90 meters. When wearing well-fitting High Flow Nasal Cannula, mean cough generated droplet spread was 2.91 meters (1.09) with a maximum distance of 4.50 meters.	(Loh et al., 2020)
Face Coverings, Aerosol Dispersion and Mitigation of Virus Transmission Risk	Researchers use a background oriented Schlieren technique to visualize airflow and investigate the effectiveness of different face covers in mitigating aerosol dispersion during breathing and coughing. The study reports a thermal plume containing respiratory particles were visible at distances less than 0.5 meters during normal breathing simulated by human subjects and manikins. Thermal plume were visible approximately 1.1 meter away from the source mouth during manikin generated coughing.	(Viola et al., 2020)
Textile Masks and Surface Covers- A Spray Simulation Method and a "Universal Droplet Reduction Model" Against Respiratory Pandemics	Dispersion distances of respiratory droplets when wearing face coverings made of common household materials was measured using a bacterial-suspension spray simulation (mimicking a sneeze). Most bacteria-carrying droplets landed within 1.2 meters of the source with a textile mask compared to droplet travel distances of greater than 1.8 meters when no barriers (meant to mimic no face covering) were in place.	(Rodriguez-Palacios et al., 2020)
Mathematical Models and Simulations		
Publication Title	**Key Outcomes**	**Reference**
Towards aerodynamically equivalent COVID19 1.5 m social distancing for walking and running	Computer Fluid Dynamics study informed by previous data on droplet dispersion around a runner takes into account the potential aerodynamic effects introduced by a person movements (e.g. walking fast, running and cycling) on droplet travel distance. The study investigates whether a leading infectious person standing still and moving nearby a second susceptible person at a distances of 1.5 meters or more can pose any infection transmission risk. Although particle exposure is negligible when two people are standing 1.5 meter apart, if	(Blocken et al., 2020)

	the individuals are running or walking fast even at 1.5 meters apart there is some risk of infectious particle exposure. The study results suggest the greatest exposure to the trailing person occurs if they are directly behind the leading person (positioned in the slipstream). Substantial droplet exposure risk reduction can be achieved by 1) avoiding to walk or run in the slipstream of the leading person, 2) keeping the 1.5 m distance in staggered or side by side arrangement, or 3) by keeping social distances greater than 1.5 meters when moving fast or running.	
When is SARS-CoV-2 in your shopping list?	The spread of COVID-19 in a commercial supermarket and the potential for contagions are estimated using agent based modeling. This method maps all desired characteristics of customers and staff (e.g. number infected vs. susceptible, simultaneous users) and the infectious agent, as well as possible interactions/trajectories in a hypothetical layout. The model analysis finds increasing the distance between individuals in a supermarket setting (tested distances were 30cm, 50cm, 1 meter, 1.5 meters, and 2 meters), as well as limiting the number of individuals within the supermarket improved the percentage of potential transmission events avoided in the simulations.	(Hernandez Mejia & Hernandez-Vargas, 2020)
COVID-19: Effects of weather conditions on the propagation of respiratory droplets	A comprehensive mathematical model is established to explore speech generated droplet evaporation, heat transfer and kinematics under different conditions (e.g. temperature, humidity and ventilation). Low temperature and high humidity facilitate droplet transmission and dispersion, but supresses the formation of aerosols. On the other hand, high temperature and low humidity promotes rapid loss of respiratory droplet mass (from evaporation) and reduce droplet travel distance but these conditions increases transmission risk from aerosol particles. The study concludes current social distancing recommendations may not be sufficient to diminish airborne transmission risks as droplets can travel distances up to 6 meters.	(Zhao et al., 2020)
COVID-19. Transport of respiratory droplets in a microclimatologic urban scenario	Examined the spread of respiratory droplets in outdoor environments by applying a computational model of a sneezing person in an urban scenario under a medium intensity climatological wind. The spread of respiratory droplets is characterized by the dynamics of droplet size: larger droplets (400 – 900µm) are spread between two to five meters during 2.3 seconds while smaller droplets (100 – 200µm) are transported between eight and eleven meters in 14.1 seconds when influenced by turbulent wind.	(Guerrero et al., 2020)
Influence of wind and relative	Air transmission of cough droplets with condensation and evaporation effects are modeled between two virtual humans under different	(Feng et al., 2020)

humidity on the social distancing effectiveness to prevent COVID-19 airborne transmission: A numerical study	environments and wind velocities. Micro-droplets follow airflow streamlines and can be deposited on virtual human bodies (including head regions) at greater than 3.05 meter (10 feet) distances. High relative humidity (99.5%) also leads to larger droplet sizes and greater deposition of cough droplets on surfaces (due to hygroscopic growth effects). Suspended microdroplets could be transmitted between the two virtual humans in less than 5 seconds. The study concludes due to environmental wind, convection effects, and relative humidity on respiratory particles emitted by humans, the frequently recommended 1.83 meters (six feet) of social distancing may not be sufficient to prevent inter-person aerosol transmission.	
Modelling aerosol transport and virus exposure with numerical simulations in relation to SARS-CoV-2 transmission by inhalation indoors	Available evidence on aerosol transport in air is combined with 0D-3D simulations in physics-based models and theoretical calculations. Monte Carlo simulations indicate droplets produced by speech and cough (diameter < 20 µm) can become airborne and linger in air from 20 minutes up to one hr, and be inhaled by others. The exposure time to inhale 100 aerosols (assumed to be an adequate infectious dose) is variable based on the situation and can range from one second, to one minute, to one hour. 3D computational fluid dynamic (CFD) simulations suggest aerosols (dp <20 µm) can be transported over 10 meter distances in generic environments, dependent on relative humidity and airflow. Finally the rapid drying of expelled mucus droplets would yield droplet nuclei and aerosols which could potentially carry airborne virus particles. Such droplets (initial particle diameter of 50µm to 100µm) could remain airborne for approximately 20 seconds to three minutes.	(Vuorinen et al., 2020)
Field Studies		
Publication Title	**Key Outcomes**	**Reference**
Aerosol and Surface Transmission Potential of SARS-CoV-2	Air and surface samples from isolation spaces housing individuals with COVID-19, in the United States, were collected and tested for SARS-CoV-2 viral RNA. High volume air samples, and low volume personal air samples were tested for SARS-CoV-2 presence by RT-PCR. 63.2% of air samples from patient isolation areas were positive for viral RNA, and 58.3% of air samples from hallways outside of patient isolation areas were also positive for the virus. The findings suggest viral aerosol particles can be produced by infected individuals even during the absence of cough, and travel distances greater than 6 feet (1.8 meters).	(Santarpia et al., 2020)

SARS-COV-2 DISPERSION DISTANCE AND FACE COVERING

Table 2: Primary literature on effectiveness of face covering and distance

Publication Title	Key Outcomes	Reference
Textile Masks and Surface Covers—A Spray Simulation Method and a "Universal Droplet Reduction Model" Against Respiratory Pandemics	Dispersion distances of respiratory droplets when wearing face coverings made of common household materials was measured using a bacterial-suspension spray simulation (mimicking a sneeze). Most bacteria-carrying droplets landed within 1.2 meters of the source, but some droplets did travel distances greater than 1.8 meters when no barriers (meant to mimic no face covering) were in place. All tested textiles reduced the number of droplets reaching surfaces, restricting their dispersion to <30 cm, when used as single layers. When used as double-layers, textiles were as effective as medical mask/surgical-cloth materials, reducing droplet dispersion to <10 cm, and the area of circumferential contamination to ~0.3%.	(Rodriguez-Palacios et al., 2020)
Face Coverings, Aerosol Dispersion and Mitigation of Virus Transmission Risk	Researchers use a background oriented Schlieren technique to visualize airflow and investigate the effectiveness of different face covers in mitigating aerosol dispersion during breathing and coughing. The study reports a thermal plume containing respiratory particles were visible at distances less than 0.5 meters during normal breathing generated by human subjects and manikins. Thermal plume were visible approximately 1.1 meter away from the source mouth during manikin generated coughing. All tested face covers (including surgical mask, homemade mask, filtering face piece respirators, and face shields) were found to reduce front flow of respiratory jets by more than 90%, and thermal plumes were visible at less than 0.5 meters for coughing. Several backward and downward leakage jets were also detected at distances less than 0.2 from the source for coughing.	(Viola et al., 2020)

Methods:

A daily scan of the literature (published and pre-published) is conducted by the Emerging Sciences Group, PHAC. The scan has compiled COVID-19 literature since the beginning of the outbreak and is updated daily. Searches to retrieve relevant COVID-19 literature are conducted in Pubmed, Scopus, BioRxiv, MedRxiv, ArXiv, SSRN, Research Square and cross-referenced with the literature on the WHO COVID literature list, and COVID-19 information centers run by Lancet, BMJ, Elsevier and Wiley. The daily summary and full scan results are maintained in a RefWorks database and an Excel list that can be searched. Targeted keyword searching is conducted within these databases to identify relevant citations on COVID-19 and SARS-CoV-2. Search terms used included: distance.

Each potentially relevant reference was examined to confirm it had relevant data and relevant data is extracted into the review. This review contains research published up to June 22, 2020.

Emerging Evidence on COVID-19

Evidence Brief on Adherence to Isolation and Quarantine Recommendations During COVID-19

Introduction

What is the evidence on the proportion of people that adhere to isolation and quarantine for COVID-19 and what drivers and barriers determine adherence?

Public health measures to control the spread of COVID-19 infections have included both isolation of people diagnosed with COVID-19 and quarantine of close contacts of cases and incoming travellers. Current Public Health Agency of Canada guidance recommends a mandatory 14 day quarantine for travellers entering Canada, suspect cases and/or known contact(s) of a confirmed COVID-19 case (1).

In a related evidence brief on quarantine strategies, December 2020 (available upon request), modeling studies show the benefits of quarantine in reducing transmission relies heavily on high adherence (2-4). This evidence review identifies and summarizes published and pre-published evidence on drivers and barriers, such as sociodemographic characteristics, knowledge and attitudes associated with adherence to COVID-19 isolation and quarantine recommendations. Studies up to January 15, 2021 were included.

Key Points

- A total of nine studies were identified, including seven observational studies reporting on COVID-19 infection isolation and/or quarantine adherence (Table 1), one study on intent to adhere to the recommendations (Table 2) and one rapid review summarising literature on factors associated with adherence to quarantine pre-COVID-19 (Table 3).
- Studies were from Europe (n=4), Asia (n=3) and the Middle East (n=1). The rapid review included three studies from Canada conducted during SARS.
- Adherence to COVID-19 isolation and quarantine were reported in four studies and ranged from 75% in a study from South Korea to 25% in a study from the UK (5, 6, 8, 10).
- Drivers of adherence to isolation and quarantine recommendations included increased quarantine and self-isolation adherence among adults of female gender, higher levels of education, being married or co-inhabiting with others and employment as a healthcare worker. Adherence by age group was variable from study to study.
- Individuals self-reporting symptoms, those with a confirmed COVID-19 test and those who received a COVID-19 diagnosis (suspect or confirmed) from a healthcare provider were more likely to comply

with isolation instructions compared with people told to quarantine due to their contacts with other COVID-19 cases and those who were not feeling ill themselves.

- Barriers to adherence were: lack of support from someone outside of the household, which is consistent with reported reasons for violation such as shopping for essential items and medication, and work demands. Support outside of the home was a driver of adherence during the SARS outbreak summarized in the rapid review (9).

- Higher perceptions of COVID-19 infection risk, infection transmission and confidence in effectiveness of isolation and quarantine were linked to improved adherence. These findings are consistent with the rapid review on adherence to quarantine due to other infections (9).

- Monetary compensation for lost wages, trust in public health regulations and worry about infection was linked to increased intent to adhere to quarantine. However, stricter sanctions, higher fines and penalties for violators of quarantine did not impact the degree of adherence with COVID-19 quarantine in a South Korean cohort.

- A study of quarantined children reported that increased adherence was attributed to female gender, older age of child, fewer children within the household, primary caregivers that were female and younger, as well as clear communications of quarantine instructions.

Overview of the Evidence

Nine articles were included in this review. There were seven published studies and one pre-print on adherence to isolation and quarantine during COVID-19, and one rapid review on adherence to quarantine for non-COVID-19 infections.

There were a number of limitations to the evidence. Most studies were conducted in Europe or Asia, therefore, the findings may not be reflective of the Canadian situation. Adherence is difficult to objectively measure and in most studies it was based on self-reports. This can lead to selection and social desirability biases. Some studies included efforts to adjust for selection bias and ensure representativeness of the study findings through random sampling, weighting of data to match the national populations and reporting adjusted effect estimates. However, not all of the studies reported efforts to adjust for selection biases.

The definitions of isolation and quarantine were not consistent across studies; the majority of studies did not distinguish between isolation and quarantine. This meant the identified barriers and drivers influencing isolation and quarantine adherence were often combined. Most studies examined a long list of potential risk factors that they may not have had appropriate power to include in an analysis without overfitting the regression model or they performed multiple comparisons where statistical adjustments such as a Bonferroni correction were needed. Such adjustments were not adopted by all included studies and may have led to spurious results. Carefully planned and executed analyses are needed to avoid this bias.

Important knowledge gaps within the available literature include the lack of Canadian data that consider local public health and infection transmission contexts. Data on the impact of multiple lockdowns and local infection prevalence are also lacking. Research in Canada, objective measures of adherence (over self-report) and measures of adherence over time would improve this body of research.

CONTENTS

COVID-19 ISOLATION AND QUARANTINE ADHERENCE

Seven studies that consider factors linked to quarantine and isolation adherence, are summarized in Table 1.

- Four cross-sectional surveys evaluated sociodemographics, knowledge and attitudes as drivers or barriers to adherence to isolation and quarantine of adults (n=3) and children (n=1) (7, 10-12).
- Adherence drivers included female gender, higher levels of education, being married or co-inhabiting with others, fewer children within a household and employment as a healthcare worker.
- Two longitudinal trend analysis studies with multiple survey cycles in Norway examined self-reported adherence to isolation and quarantine recommendations. One study found age to have an impact on quarantine adherence, while the other found gender, age and level of education to have a small impact on adherence (5, 6).
- Across studies individuals who had a positive test result or were diagnosed by a health care provider, those who perceived the infection to be more serious, or had received healthcare guidance on isolation were more likely to adhere to isolation and quarantine (5-7, 11, 12)
- The analysis of a South Korean cohort finds increased penalties for individuals who violated quarantine did not lead to better adherence (8).

Table 1: Studies Reporting on COVID-19 Isolation and Quarantine Adherence (n=7)

STUDY	METHOD	KEY OUTCOMES
Adults		
Ryu 2020 (8) Population-based Cohort South Korea Mar-Jun 2020	Public health data on the quarantined population (14 day quarantine) and quarantine violations was analysed via Poisson regression to measure the impact 1-strike out sanctions implemented April 5, 2020 with increased penalties (e.g. imprisonment, fines, deportation or electronic bracelets) for violators. Korean public health was "monitoring" quarantined individuals, but details are not provided.	High stake penalties, the "1-strike out" sanction, was not a driver of adherence as it did not have a significant effect (p=0.99) on the daily violation rate, among Koreans or foreigners. A median 36,561 (range, 8335-59,918) individuals were quarantined per day during the study period. Overall, adherence levels were high. The median number of daily violations was 6 (0-13), and the median rate of violation was 1.6/10,000 (0.0-8.0) quarantined individuals.
Carlsen (2020) (5) *Preprint* Longitudinal trend Study Norway Aug-Oct 2020	Participants from two prospective cohorts participated in a sub-study and submitted data every 14 days ~85000 responses per survey cycle) on illness, COVID-19 testing and quarantine. In the summer, testing became more accessible and the public health recommendation was to get tested if symptoms occurred and that confirmed or suspected cases should quarantine. This study analyzes self-reported adherence to isolation and quarantine from survey responders between Aug - Oct 2020. Response rates ranged from 55%-83%, across cohorts and survey cycles.	Illness was reported by 8.6-13% of people surveyed, 12%, 13% and 10% over the 4 survey cycles, 35-45% of men and 40% -45% women of respondents reported being tested in the past 14 days due to illness; and 4-5% of respondents reported being quarantined or isolated. Adherence to quarantine was higher in women. Among those that received a positive test result 79% were men and 91% women; suspect or confirmed diagnosis from a physician 65% men and 72% women; tested for SARS-CoV-2 53% of men and 59% of women; or reported illness in the last 14 days 26% men and 33% women. Norwegian county of residence, gender, older age and higher level of education were reported to have a small effect on increased odds of quarantine and self-isolation adherence.

		Adherence to recommendations for testing and quarantine was lower than expected in Norway despite high trust in government.
Steens (2020) (6) Longitudinal trend study Norway Apr – Jun 2020 (Multiple survey cycles)	An online survey was conducted among a representative sample (n=1400, 7% response rate) of adults to measure self-reported adherence to isolation and quarantine repeated every 3-6 weeks for 4 cycles. Response rates for cycle 2-4 ranged from 74% to 86%. The analysis was weighted by age and sex for representativeness. Isolation is required in Norway only for those with confirmed or probable COVID-19. Note: Participants were considered to have adhered to isolation/quarantine if they reported doing so for at least one day. This study also recruited additional people in each wave from their balanced internet population sample to try to balance dropouts which may bias the results.	1704 participants provided 4525 responses over the 4-cycle survey and the analysis was weighted to the national population. Participants reported 25% (95% CI 23-27) had received a quarantine request within 7 days of the survey and of these people 42% (37-48) adhered to quarantine. Adherence was higher for people with symptoms (75%, 95% CI 63-79) compared to those without (28%, 95% CI 23-34). 65% (60-70) of participants reported to have not adhered to a quarantine request. Adherence was highest among the 18-29 age group (72%; 95% CI 58-83), compared to those aged 30 or older. Reported adherence to quarantine/isolation declined over time, from 66% in April to 33% - 38% in May and June samples. Waning of adherence was particularly high in older age groups. In Norway, fines can be issued for violation of quarantine, but there is no active follow-up of cases. The authors suggest drivers were risk perception, knowledge, social norms and having symptoms; barriers were adverse financial consequences from adherence.
Carlucci (2020) (11) Cross-sectional Study Italy Mar 2020	Online survey of 3964 quarantined Italian adults, sampled at week 3 of national lockdown, on adherence to quarantine due to a COVID-19 infection. Sociodemographic, preventative behaviours including adherence to quarantine and risk perception factors were evaluated	Sociodemographic variables associated with higher adherence to quarantine: women ($p<0.001$), higher education (0.007), married/cohabitating ($p<0.001$), healthcare workers ($p<0.001$). Age: 50-59 ($p<0.001$) had higher adherence than 30-39, which was higher than 18-29

	in the survey and analyzed by analysis of variance.	($p<0.01$). Notably those over 60 were less likely to adhere to quarantine. Regional variation, higher adherence in southern Italy ($p<0.01$). Lower adherence was noted for single people, students. Higher risk perception and anxiety levels were associated with higher adherence to quarantine. Reasons for compliance included reducing spread (79.8%), transmission (75.7%), trust in government (40.2%). Reasons for going out during quarantine were: 23.9% receiving medical treatments or going to the pharmacy, 9.7% for essential necessities (e.g. groceries), 8.5% work demands, 5% to walk domestic animals and 1% assisting families.
Smith (2020) (7) Cross-sectional study UK May 2020	An online survey included 2240 adults from an established representative population sample. Quota sampling was used to ensure representativeness. The survey investigated factors associated with adherence to self-isolation and lockdown measures. Logistic regression was conducted with a Bonferroni correction to the results with $p<0.001$. Adjusted for gender, age, having a child in the household, being extremely clinically vulnerable, employment status, education, deprivation, social grade, rural or urban, living alone, marital status and region.	75.1% of the 217 individuals reporting symptoms in self or household reported having left their home at least once (i.e. not complying with self-isolation or quarantine) in the previous 24 hours. Adjusted analysis for not having left self-isolation or quarantine in the previous 24 hours included: - Females (OR_{adj} 0.32 (95% CI 0.14-0.76) - Report of symptoms in self OR_{adj} 0.23 (95% CI 0.09–0.61) - Increased worry of COVID OR_{adj} 0.61 (95% CI 0.37–0.98) - Received help from someone outside the household OR_{adj} 0.30 (95% CI 0.09-0.96) - Perception of high infection contraction risk OR_{adj} 0.40 (95% CI 0.16-0.99) - A sense of community with neighbours OR_{adj} 1.52 (95% CI 1.03-2.24)

		Perceptions of COVID-19 influenced higher adherence if responders thought they had COVID-19, were self isolating, possessed good knowledge of prevention, were worried about COVID-19 and had intentions to follow government advice.
Xu (2020) (10) Cross-sectional survey China Feb 2020	2956 community dwellers in China (≥16 years of age) completed a voluntary survey on compliance with mitigation measures which included home quarantine defined as leaving home <1 time over 3 days. The data was analysed via chi-square and logistic regression employing Bonferroni correction.	75.6% of respondents reported being compliant to home quarantine. Compliance with home quarantine was lower in men (OR =0.61 (0.51–0.73)). The age 31-40 group (OR=0.71 (0.54–0.93)) and 41–50 age group (OR=0.67 (0.46–0.97)) was found to be less compliant with home quarantine when compare to individuals less than or 20 years of age. No other indicators for compliance were identified within the study data.
Children and Adolescents		
Lou (2020) (12) Cross-sectional Study China Feb 2020	This study followed up on quarantine adherence 8 days after the children presented to a fever clinic (n=495). Data was collected by phone interviews. Multivariate logistic regression including gender and age of patients, gender and age of caregivers, education level of caregivers, place of residence, number of children in the family and whether a nurse explained the quarantine measures were taken as the independent variables.	Odds of quarantine compliance increased with female gender of the child and caregiver, higher age of children OR 0.25 (95% CI 0.19-0.32) and the explanation of quarantine measures by nurses OR 2.13 (95% CI 1.33-3.41). Children with elderly caregivers were OR 2.46 (95% CI 1.37-4.42) times more likely to report poor compliance, when compared to children with young adult caregivers.

COVID-19 ISOLATION AND QUARANTINE ADHERENCE INTENTION

- One survey conducted in Israel assessed the intention to adhere to COVID-19 quarantine in relation to the presence and absence of compensation for lost wages. Intention to comply with quarantine varied from 57% to 71% between February and March 2020 when wage compensation was not assumed. When monetary compensation was offered, intention increased to over 95% suggesting a lack of wages was a significant barrier to adherence to quarantine recommendations.

Table 2: Studies Reporting on COVID-19 Isolation and Quarantine Adherence Intention (n=1)

STUDY	METHOD	KEY OUTCOMES
Bodas 2020 (13) Cross-sectional Study Israel Feb-Mar 2020	Surveyed the intent to comply with medical official requested two-week self-quarantine. One question assumed compensation for lost wages by the state, and another question assumed no such compensation. The survey was administered in February (563 responders) and in March (511 responders). After pooling the two study samples, univariate and multivariate regression analyses identified factors associated with intention to comply with quarantine. Response rate of 25% for both time points.	When monetary compensation was assumed, 94% of respondents (in February) and 95.5% of responders (in March) reported they would comply with self-quarantine. When monetary compensation was NOT assumed, quarantine adherence was 57%, (in February) and 71.4% (in March). Assuming no monetary compensation, significant associations with the intent to adhere to quarantine in the multivariate analysis were: age OR_{adj} 1.01 (95% CI 1.01-1.03), religion OR_{adj} 0.48 (95% CI 0.33-0.70), worry over COVID-19 OR_{adj} 1.26 (95% CI 1.10-1.47) and trust in health regulations OR_{adj} 1.26 (95% CI 1.10-1.44).

PRE-COVID-19 RAPID REVIEW OF ISOLATION AND QUARANTINE ADHERENCE

- The review summarizes evidence from 14 studies that consider quarantine adherence following SARS, H1N1, Ebola and Mumps outbreaks, including three Canadian studies on quarantine adherence conducted during the SARS outbreak.

- The review highlights that perceived risk of disease and benefit of quarantine, but not knowledge of the disease were important drivers of adherence.
- Similarly cultural norm and societal acceptance of quarantine were important, this includes trust in government.
- Mainly Canadian research from SARS highlights that reasons for breaking quarantine include fear of lost wages and work, and the need to seek supplies or medical attention. These findings are consistent with other studies included in this evidence brief.

Table 3: Rapid Review of Factors Impacting Isolation and Quarantine Adherence during pre-COVID-19 Outbreaks (n=1)

STUDY	METHOD	KEY OUTCOMES
Webster 2020 (9) Rapid review Jan 2020	A rapid review of factors associated with adherence to quarantine during infectious disease outbreaks described in 14 studies. The infections were H1N1 (swine flu), Ebola, SARS and Mumps.	Adherence rates ranged from 0-92.8% and were conducted in healthcare workers, school staff, residents of cities, parents and individuals testing positive for infection. The quarantine periods were variable. Making quarantine mandatory or enforced by law increased adherence. Culture and societal norms are important, examples from the Ebola outbreaks show improved adherence when the head of a household favoured quarantine. In contrast, adherence was reduced when caretaking of the sick was of high cultural priority. Whereas studies from SARS show high adherence to quarantine when there was societal pressure or laws to do so. Drivers of adherence were: perceived high risk of disease, quarantine or isolation protocol and benefit of quarantine; however perceived knowledge of the disease was not. The studies in Canada during SARS highlight work and fear of lost wages as major drivers of non-adherence as well as the need to get supplies or seek medical attention. There was mixed evidence on length of quarantine and adherence.

		Trust in government was associated with adherence to quarantine.

Methods:

A daily scan of the literature (published and pre-published) related to COVID-19 is conducted by the Emerging Science Group, PHAC; and has been ongoing since the beginning of the outbreak. The literature is retrieved from Pubmed, Scopus, BioRxiv, MedRxiv, ArXiv, SSRN, Research Square and cross-referenced with the WHO COVID-19 literature list, and COVID-19 information centers run by Lancet, BMJ, Elsevier and Wiley. A search to retrieve relevant literature for this evidence summary was conducted in the Refworks database. Targeted keyword searching is conducted within these databases to identify relevant citations on COVID-19 and SARS-CoV-2. The search algorithms used (isolation OR quarantine) AND (compliance OR adherence). 53 citations were screened for relevance and data was extracted from relevant articles into the review. This review contains research related to isolation and quarantine adherence published up to January 15, 2021.

Preuve émergente sur la COVID-19

Synthèse en bref sur le respect des recommandations d'isolement et de quarantaine pendant la COVID-19

Introduction

Quelles sont les données probantes sur la proportion de personnes qui respectent l'isolement et la quarantaine en raison de la COVID-19 et quels facteurs et obstacles déterminent l'adhésion à ces mesures obligatoires?

Les mesures de santé publique visant à contrôler la propagation de l'infection par la COVID-19 incluent tant l'isolement des personnes ayant reçu un diagnostic de COVID-19 que la mise en quarantaine de celles qui ont eu des contacts étroits avec des cas et des voyageurs qui arrivent au pays. Les lignes directrices actuelles de l'Agence de la santé publique du Canada recommandent une quarantaine obligatoire de 14 jours pour les voyageurs qui entrent au Canada, les cas suspects ou tout contact connu d'un cas confirmé de COVID-19 (1).

Dans une synthèse en bref portant sur les stratégies de mise en quarantaine datant de décembre 2020 (disponible sur demande), les études de modélisation montrent que les avantages de la mise en quarantaine pour réduire la transmission dépendent fortement d'un niveau élevé de respect des mesures (2 à 4). Cette synthèse en bref vise donc à cerner et à résumer les données publiées et prépubliées sur les facteurs et les obstacles, comme les caractéristiques sociodémographiques, les connaissances et les attitudes associées au respect des recommandations sur l'isolement et la mise en quarantaine en raison de la COVID-19. Les études publiées et prépubliées jusqu'au 15 janvier 2021 ont été incluses dans la présente synthèse.

Points clés

- Au total, neuf études ont été recensées, dont sept études d'observation sur le respect de l'isolement de la quarantaine en raison d'une infection à la COVID-19 (tableau 1), une étude sur l'intention de respecter les recommandations (tableau 2) et une revue rapide résumant la documentation sur les facteurs associés au respect de la quarantaine avant la pandémie de COVID-19 (tableau 3).

- Les études ont été réalisées en Europe (n = 4), en Asie (n = 3) et au Moyen-Orient (n = 1). La revue rapide comprenait trois études canadiennes effectuées pendant la crise du SRAS.

- Le respect de l'isolement et de la quarantaine de la COVID-19 a été signalé dans quatre études et variait de 75 % dans une étude effectuée en Corée du Sud à 25 % dans une étude menée au Royaume-Uni (5, 6, 8, 10).

- Les facteurs de respect des recommandations en matière d'isolement et de quarantaine comprenaient une quarantaine prolongée et le respect de l'isolement chez des adultes de sexe féminin, ayant des

niveaux de scolarité plus élevés, être marié ou cohabitant avec d'autres personnes, et l'emploi dans le milieu de la santé. L'observance selon le groupe d'âge variait d'une étude à l'autre.

- Les personnes ayant déclaré elles-mêmes leurs symptômes, celles dont le test de dépistage de la COVID-19 a été confirmé et celles qui ont reçu un diagnostic de COVID-19 (soupçonné ou confirmé) d'un fournisseur de soins de santé, étaient plus susceptibles de se conformer aux instructions d'isolement que les personnes à qui on avait simplement dit de mettre en quarantaine en raison de leurs contacts avec d'autres cas de COVID-19 et celles qui ne se sentaient pas malades.

- Les exigences associées au travail ainsi que le manque de soutien d'une personne à l'extérieur du foyer, ce qui inclut le fait de devoir sortir pour aller acheter des fournitures essentielles et des médicaments, constituent les principaux obstacles au respect des mesures sanitaires et ont été mentionnés comme motifs de non-respect des mesures imposées. Le fait d'avoir du soutien à l'extérieur du foyer a été l'un des facteurs qui ont fait augmenter l'adhésion pendant l'éclosion du SRAS, comme cela est indiqué dans la revue rapide (9).

- Une plus grande perception du risque d'être infecté par la COVID-19, le niveau de transmission de l'infection et la confiance dans l'efficacité de l'isolement et de la mise en quarantaine ont tous été associés à une meilleure adhésion aux mesures. Ces différentes constatations concordent avec la revue rapide sur le respect de la quarantaine mise en œuvre pour faire face à d'autres infections (9).

- Le fait de recevoir un certain montant en compensation pour le salaire perdu, le fait d'avoir confiance en la réglementation sur la santé publique et le niveau d'inquiétude en raison de l'infection ont tous été associés à une plus grande intention de respecter la quarantaine. Une étude effectuée auprès d'une cohorte en Corée du Sud a révélé que des sanctions plus sévères, ainsi que des amendes et des pénalités plus élevées pour les contrevenants, n'avaient aucune incidence sur le degré de respect de la quarantaine en raison de la COVID-19.

- Une étude sur les enfants en quarantaine a révélé que l'augmentation du taux d'adhésion était attribuable au sexe (féminin), à l'âge de l'enfant (plus âgé), au fait qu'il y avait moins d'enfants dans un ménage, aux principaux fournisseurs de soins (plus jeunes et de sexe féminin), ainsi qu'à la communication claire des directives à propos de la quarantaine.

Vue d'ensemble des éléments de preuve

Cette revue comportait neuf articles, soit sept études publiées, une étude en préimpression sur le respect de l'isolement et de la quarantaine pendant la COVID-19, et une revue rapide sur le respect de la quarantaine pour les infections autres qu'associées à la COVID-19.

Les preuves obtenues comportaient cependant un certain nombre de limites. Par exemple, puisque la plupart des études ont été effectuées en Europe ou en Asie, les résultats ne reflètent peut-être pas la situation au

Canada. En outre, il est difficile de mesurer l'adhésion de façon objective et comme elle était autodéclarée dans bon nombre des études, cela peut créer des biais en raison de la sélection et de la désirabilité sociale. Certaines études ont également tenté de corriger ces biais de sélection afin de garantir la représentativité des résultats de l'étude en effectuant un échantillonnage aléatoire, en pondérant les données afin qu'elles correspondent aux populations nationales et en diffusant des estimations fondées sur des effets ajustés. Les études n'ont cependant pas toutes indiqué les efforts utilisés pour corriger ces biais.

Par exemple, les définitions de l'isolement et de la quarantaine n'étaient pas uniformes entre les études et la majorité d'entre elles ne faisaient aucune distinction entre l'isolement et la quarantaine. En un mot, les obstacles et les facteurs qui influencent l'isolement et le respect de la quarantaine ont souvent été combinés. La plupart des études ont cependant évalué une longue liste de facteurs de risque potentiels qu'elles n'avaient peut-être pas le pouvoir approprié d'inclure dans une analyse sans que cela ne dépasse le modèle de régression ou ont effectué de multiples comparaisons pour lesquelles des ajustements statistiques comme une correction de Bonferroni auraient été requis. De tels ajustements n'ont pas été utilisés dans toutes les études incluses et peuvent avoir entraîné de faux résultats. Des analyses soigneusement planifiées et exécutées sont donc nécessaires pour éviter un tel biais.

Parmi les lacunes importantes dans la documentation disponible, mentionnons le manque de données canadiennes qui tiennent compte des contextes locaux de la santé publique et de la transmission des infections. Il manque également des données sur l'incidence des confinements multiples et de la prévalence des infections à l'échelle locale. La recherche au Canada, les mesures objectives de l'adhésion (par l'entremise de l'auto-déclaration) et les mesures d'adhésion au fil du temps sont des éléments qui permettraient d'améliorer le corpus de recherche.

TABLE DES MATIÈRES

ISOLEMENT EN RAISON DE LA COVID-19 ET RESPECT DE LA QUARANTAINE

Le tableau 1 résume sept études qui tiennent compte des facteurs liés à la quarantaine et à l'isolement.

- Quatre enquêtes transversales ont évalué les caractéristiques sociodémographiques, les connaissances et les attitudes comme facteurs ou obstacles à l'isolement et à la mise en quarantaine des adultes (n = 3) et des enfants (n = 1) (7, 10 à 12).

- Les facteurs d'adhésion comprenaient le sexe féminin, des niveaux de scolarité plus élevés, le fait d'être marié ou de cohabiter avec d'autres personnes, le fait qu'il y ait moins d'enfants dans un ménage et le fait d'occuper un emploi dans le milieu de la santé.
- Deux études d'analyse des tendances longitudinales comportant de multiples cycles d'enquête en Norvège ont examiné l'adhésion autodéclarée aux recommandations en matière d'isolement et de quarantaine. Une étude a révélé que l'âge a un effet sur le respect de la quarantaine, alors que l'autre a constaté que le sexe, l'âge et le niveau de scolarité n'avaient que peu d'incidence sur l'adhésion (5, 6).
- Dans toutes les études, les personnes qui ont obtenu un résultat positif au test de dépistage ou celles qui ont été diagnostiquées par un fournisseur de soins de santé, celles qui ont perçu l'infection comme étant plus grave ou celles qui ont reçu des conseils de santé sur l'isolement étaient plus susceptibles de respecter les mesures sur l'isolement et la quarantaine (5 à 7, 11, 12)
- L'analyse d'une cohorte de la Corée du Sud révèle que l'imposition de peines plus sévères aux personnes qui ont contrevenu à la quarantaine n'a pas eu pour effet d'entraîner une meilleure adhésion (8).

Tableau 1 : Études portant sur l'isolement en raison de la COVID-19 et le respect de la quarantaine (n = 7)

ANNÉE	MÉTHODE	PRINCIPAUX RÉSULTATS
Adultes		
Ryu 2020 (8) Cohorte basée sur la population Corée du Sud Mars à juin 2020	Les données de santé publique sur la population en quarantaine (quarantaine de 14 jours) et les infractions à la quarantaine ont été analysées avec la régression de Poisson pour mesurer l'incidence des sanctions accrues imposées à compter du 5 avril 2020 aux contrevenants dès la première infraction (p. ex., emprisonnement, amendes, expulsion ou bracelets électroniques). La santé publique coréenne a indiqué que les personnes en quarantaine étaient « surveillées », mais aucun autre détail n'a été fourni.	Le fait d'imposer des sanctions ayant d'importants enjeux, comme lors de la première infraction, n'a pas été un facteur d'adhésion, puisque ces sanctions n'ont pas eu d'effet significatif (p = 0,99) sur le taux quotidien d'infraction, tant pour les Coréens que pour les étrangers. La médiane comportait 36 561 personnes (fourchette variant entre 8 335 et 59 918) mises en quarantaine chaque jour pendant la période de l'étude et dans l'ensemble, les niveaux d'adhésion étaient élevés. Le nombre médian d'infractions quotidiennes était de 6 (0 à 13) alors que le taux médian d'infractions était de 1,6/10 000 (0,0 à 8,0) pour les personnes en quarantaine.

Carlsen (2020) (5) *Prépublication* Étude de tendance longitudinale Norvège Août à octobre 2020	Les participants provenant de deux cohortes prospectives ont pris part à une sous-étude à laquelle ils ont soumis des données tous les 14 jours (environ 85 000 réponses par cycle d'enquête) sur la maladie, les tests de dépistage de COVID-19 et la quarantaine. Pendant l'été, les tests sont devenus plus accessibles, et la santé publique a recommandé aux gens de se soumettre à des tests s'ils avaient des symptômes, en plus de préciser que les cas confirmés ou soupçonnés devaient se mettre en quarantaine. Cette étude analyse donc le respect autodéclaré de l'isolement et de la quarantaine par les personnes qui ont répondu au sondage entre août et octobre 2020. Les taux de réponse ont varié de 55 % à 83 %, entre les cohortes et les cycles d'enquête.	Parmi les personnes interrogées, de 8,6 à 13 % ont dit avoir été malades, soit des taux de 12 %, de 13 % et de 10 % pendant les quatre cycles de l'enquête. De 35 à 45 % des hommes et de 40 à 45 % des femmes ont dit avoir subi un test de dépistage au cours des 14 derniers jours pour cause de maladie alors que 4 à 5 % des répondants ont dit s'être mis en quarantaine ou s'être isolés. Le respect de la quarantaine était plus élevé chez les femmes. Parmi les répondants qui ont reçu un résultat positif, 79 % étaient des hommes et 91 % des femmes. De ce nombre, 65 % des hommes et 72 % des femmes ont reçu un diagnostic de COVID-19 soupçonnée ou confirmée par un médecin, 53 % des hommes et 59 % des femmes ont subi un test de dépistage du SRAS-CoV-2 et 26 % des hommes et 33 % des femmes ont dit avoir été malade au cours des 14 derniers jours. Le comté de résidence, le sexe, être plus âgé et avoir un niveau de scolarité élevé n'ont eu que peu d'effet sur la probabilité accrue de respecter tant la mise en quarantaine que l'isolement. En fait, le respect des recommandations en ce qui concerne les tests et la quarantaine a été plus faible que prévu en Norvège, malgré la grande confiance que les Norvégiens accordent à leur gouvernement.
Steens (2020) (6) Étude de tendance longitudinale Norvège	Un sondage en ligne a été mené auprès d'un échantillon représentatif (n = 1 400, taux de réponse de 7 %) d'adultes afin de mesurer l'adhésion autodéclarée à l'isolement et à la quarantaine. Ce sondage a ensuite été répété toutes les 3 à 6 semaines pendant	1 704 participants ont ainsi fourni 4 525 réponses pendant les quatre cycles du sondage et l'analyse a été pondérée en fonction de la population nationale. Ainsi, 25 % (IC à 95 % : 23 à 27) des participants ont dit avoir reçu une demande de mise en quarantaine dans les 7 jours suivant le sondage et de ce nombre, 42 % (37 à 48) ont dit avoir

Avril et juin 2020 (de multiples cycles d'enquête)	4 cycles. Les taux de réponse pour les cycles 2 à 4 se situaient entre 74 % et 86 %. Pour des raisons de représentativité, l'analyse a ensuite été pondérée par âge et par sexe. En Norvège, l'isolement n'était requis que pour les personnes dont le diagnostic de COVID-19 est confirmé ou probable. Remarque : On considérait que les participants avaient respecté l'isolement ou la quarantaine s'ils avaient déclaré l'avoir fait pendant au moins une journée. Cette étude a également recruté des participants supplémentaires dans chacune des vagues de l'épidémie, des participants provenant d'un échantillon équilibré de population sur Internet, pour contrebalancer les participants qui ont abandonné en cours de route, une mesure qui peut cependant avoir faussé les résultats.	respecté la quarantaine. L'adhésion était plus élevée chez les personnes symptomatiques (75 %, IC à 95 % : 63 à 79) que chez celles qui n'en présentaient pas (28 %, IC à 95 % : 23 à 34). 65 % (60 à 70) des participants ont dit ne pas avoir respecté la demande de mise en quarantaine. L'adhésion était la plus élevée dans le groupe des 18 à 29 ans (72 %; IC à 95 % : 58 à 83) que chez les 30 ans et plus. Le respect de la quarantaine et de l'isolement a cependant diminué avec le temps, passant de 66 % en avril à un taux variant entre 33 % et 38 % en mai et en juin. Cette diminution de l'observance était particulièrement élevée chez les groupes plus âgés. En Norvège, des amendes pouvaient être imposées pour violation de la quarantaine, mais il n'y a eu aucun suivi actif des cas. Les auteurs ont notamment indiqué que la perception du risque, les connaissances, les normes sociales et les symptômes étaient des facteurs favorisant le respect alors que les conséquences financières négatives découlant de l'adhésion à la quarantaine et à l'isolement constituaient plutôt un obstacle.
Carlucci (2020) (11) Étude transversale Italie Mars 2020	Sondage en ligne effectué auprès de 3 964 adultes italiens en quarantaine. L'échantillonnage a été effectué pendant la troisième semaine du confinement national et portait sur le respect de la quarantaine en raison d'une infection à la COVID-19. Les comportements sociodémographiques et	Variables sociodémographiques associées à une plus grande adhésion à la quarantaine : femmes ($p < 0,001$), études supérieures (0,007), personnes mariées ou vivant en cohabitation ($p < 0,001$), travailleurs de la santé ($p < 0,001$). Age : les personnes âgées de 50 à 59 ans ($p < 0,001$) sont celles qui ont indiqué le plus haut taux de respect de la quarantaine ou de l'isolement, suivi des personnes de 30 à 39 ans et finalement des 18 à 29 ans ($p < 0,01$). Fait à

	préventifs, y compris le respect de la quarantaine et les facteurs de perception du risque, ont été évalués dans le sondage et analysés à l'aide d'une analyse de la variance.	noter, les personnes de plus de 60 ans sont celles qui étaient les moins susceptibles de respecter la quarantaine. Variation régionale : la plus forte adhésion au respect des mesures a eu lieu dans le sud de l'Italie ($p < 0,01$). On a cependant noté un niveau d'adhésion plus faible chez les personnes seules et les étudiants. Les niveaux plus élevés de perception du risque et d'anxiété étaient associés à une plus grande observance de la quarantaine. Les motifs ayant entraîné le respect des mesures incluaient la réduction de la propagation (79,8 %), la transmission (75,7 %) et la confiance dans le gouvernement (40,2 %). Quant aux raisons qui ont poussé les gens à sortir de la quarantaine, 23,9 % ont indiqué qu'ils l'ont fait parce qu'ils devaient recevoir des traitements médicaux ou se rendre à la pharmacie, 9,7 % ont dit être sortis pour acheter des biens essentiels (p. ex., épicerie), 8,5 % ont dû sortir en raison de leur travail, 5 % devaient aller promener leurs animaux domestiques alors que 1 % des participants ont dit être sortis de la quarantaine pour aller aider d'autres personnes.
Smith (2020) (7) Étude transversale Royaume-Uni Mai 2020	Un sondage en ligne a été mené auprès de 2 240 adultes provenant d'un échantillon représentatif établi de la population. L'échantillonnage par quota a été utilisé pour assurer la représentativité.	Parmi les 217 personnes ayant déclaré qu'elle-même ou un membre de leur famille avait eu des symptômes, 75,1 % ont dit être sorties de chez elles au moins une fois (c.-à-d. qu'elles n'ont pas respecté l'auto-isolement ou la quarantaine) au cours des 24 heures précédentes. L'analyse ajustée pour ne pas avoir quitté l'isolement volontaire ou la quarantaine au

	Le sondage a porté sur les facteurs associés au respect des mesures d'isolement et de confinement. La régression logistique a été effectuée en utilisant la correction de Bonferroni pour les résultats avec $p < 0,001$. Les données ont ainsi été ajustées en fonction du sexe, de l'âge, du fait d'avoir un enfant à la maison, du fait d'être extrêmement vulnérable sur le plan clinique, de la situation d'emploi, de l'éducation, de la privation, de la classe sociale, du fait de vivre dans un milieu rural ou urbain, du fait de vivre seul, de l'état matrimonial et de la région habitée.	cours des 24 heures précédentes incluait les éléments suivants : - Femmes : $RC_{ajusté}$ 0,32 (IC à 95 % : 0,14 à 0,76) - Personne ayant déclaré avoir des symptômes : $RC_{ajusté}$ 0,23 (IC à 95 % : 0,09 à 0,61) - Plus grande inquiétude par rapport à la COVID-19 : $RC_{ajusté}$ 0,61 (IC à 95 % : 0,37 à 0,98) - A reçu de l'aide d'une personne extérieure au ménage : $RC_{ajusté}$ 0,30 (IC à 95 % : 0,09 à 0,96) - Perception d'un risque élevé de contracter l'infection : $RC_{ajusté}$ 0,40 (IC à 95 % : 0,16 à 0,99) - Sentiment de communauté avec les voisins : $RC_{ajusté}$ 1,52 (IC à 95 % : 1,03 à 2,24) Les perceptions à l'égard de la COVID-19 favorisaient le respect des mesures lorsque les répondants croyaient avoir la COVID-19, s'étaient isolés, avaient une bonne connaissance des mesures de prévention, avaient des inquiétudes par rapport à la COVID-19 et avaient l'intention de suivre les conseils du gouvernement.
Xu (2020) (10) Enquête transversale Chine Février 2020	En Chine, 2 956 habitants d'une même communauté (âgés de 16 ans et plus) ont répondu à un sondage volontaire sur la conformité aux mesures d'atténuation, ce qui incluait la quarantaine à domicile (définie comme le fait de sortir une fois ou moins pendant une période de trois jours). Les données ont été analysées au moyen de la régression du chi carré et de la régression logistique utilisant la correction de Bonferroni.	75,6 % des répondants ont dit s'être conformés à la quarantaine à domicile. Le respect de la quarantaine à domicile était plus faible chez les hommes (RC = 0,61 (0,51 à 0,73)). Lorsqu'on les compare aux personnes de 20 ans et moins, le groupe des 31 à 40 ans (RC = 0,71 (0,54 à 0,93)) et celui des 41 à 50 ans (RC = 0,67 (0,46 à 0,97)) sont ceux qui ont le moins respecté la quarantaine à domicile.

		Aucun autre indicateur de conformité n'a été identifié dans les données de l'étude.
Enfants et adolescents		
Lou (2020) (12) Étude transversale Chine Février 2020	Cette étude a suivi l'adhésion à la quarantaine huit jours après que les enfants se soient présentés dans une clinique pour contagieux (n = 495). Lesdonnées ont été recueillies par des entrevues téléphoniques. La régression logistique multivariée a utilisé différentes variables indépendantes, soit le sexe et l'âge des patients, le sexe et l'âge des soignants, le niveau de scolarité des soignants, le lieu de résidence, le nombre d'enfants dans la famille et le fait qu'une infirmière ait ou non expliqué les mesures de quarantaine.	Les probabilités de conformité à la quarantaine ont augmenté lorsque tant l'enfant que le soignant étaient de sexe féminin, lorsque les enfants étaient plus âgés RC 0,25 (IC à 95 % : 0,19 à 0,32) et lorsque les mesures de quarantaine avaient été expliquées par les infirmières RC 2,13 (IC à 95 % : 1,33 à 3,41). Comparativement aux enfants dont les soignants étaient de jeunes adultes, les enfants dont les soignants étaient âgés étaient plus susceptibles de ne pas se conformer à la quarantaine (RC 2,46 (IC à 95 % : 1,37 à 4,42)).

INTENTION DE S'ISOLER EN RAISON DE LA COVID-19 ET DE RESPECTER LA QUARANTAINE

- Un sondage effectué en Israël a évalué l'intention de respecter la quarantaine en raison de la COVID-19 selon que les personnes recevaient ou non une compensation pour le salaire perdu. L'intention de respecter la quarantaine a varié entre 57 % et 71 % entre février et mars 2020 lorsqu'aucune compensation n'était présumée. Lorsqu'une compensation financière a été offerte, l'intention a augmenté à plus de 95 %, ce qui laisse sous-entendre que le fait de ne pas recevoir de salaire constituait un obstacle important au respect des recommandations en matière de quarantaine.

Tableau 2 : Études portant sur l'intention de s'isoler en raison de la COVID-19 et de respecter la quarantaine (n = 1)

ANNÉE	MÉTHODE	PRINCIPAUX RÉSULTATS
Bodas 2020 (13) Étude transversale Israël Février et mars 2020	Enquête qui a porté sur l'intention de se conformer à la demande officielle, émise par un médecin, de mise en quarantaine volontaire pendant deux semaines. Une des questions laissait entendre que l'État offrirait une compensation financière aux personnes alors que l'autre laissait présumer qu'elles ne recevraient rien. Le sondage a été réalisé en février (563 répondants) et en mars (511 répondants). Après avoir regroupé les deux échantillons de l'étude, les analyses de régression univariée et multivariée ont permis de déterminer les facteurs associés à l'intention de respecter la mise en quarantaine. Taux de réponse de 25 % pour les sondages.	Lorsque la question laissait entendre qu'une compensation financière serait versée, 94 % des répondants (en février) et 95,5 % des répondants (en mars) ont déclaré qu'ils se conformeraient aux mesures de quarantaine volontaire. À l'inverse, lorsque la question présumait qu'AUCUNE compensation ne serait versée, le taux d'adhésion à la quarantaine a atteint 57 % (en février) et 71,4 % (en mars). Si l'on présume qu'aucune compensation financière ne sera versée, on peut voir que les éléments suivants ont un lien important avec l'intention ou non de respecter la quarantaine dans l'analyse multivariée : âge $RC_{ajusté}$ 1,01 (IC à 95 % : 1,01 à 1,03), religion $RC_{ajusté}$ 0,48 (IC à 95 % : 0,33 à 0,70), inquiétude au sujet de la COVID-19 $RC_{ajusté}$ 1,26 (IC à 95 % : 1,10 à 1,47) et confiance dans les règlements sanitaires $RC_{ajusté}$ 1,26 (IC à 95 % : 1,10 à 1,44).

REVUE RAPIDE SUR LE RESPECT DE L'ISOLEMENT ET DE LA QUARANTAINE AVANT LA COVID-19

- La revue résume les données probantes tirées de 14 études qui ont tenu compte du respect de la quarantaine après les éclosions de SRAS, de grippe H1N1, d'Ebola et d'oreillons, ce qui inclut trois études canadiennes sur le respect de la quarantaine effectuées pendant l'éclosion de SRAS.
- La revue montre l'effet positif du risque perçu de maladie et des avantages de la quarantaine, mais démontre également que la connaissance de la maladie n'a qu'un petit rôle dans le taux d'adhésion.
- La norme culturelle et l'acceptation sociale de la quarantaine étaient également importantes, tout comme la confiance dans le gouvernement.
- La recherche principalement canadienne sur le SRAS démontre, quant à elle, que les motifs pour mettre fin à la quarantaine incluaient la crainte de perdre son salaire et son emploi, ainsi que la

nécessité de se procurer des fournitures ou d'obtenir des soins médicaux. Ces conclusions sont conformes à d'autres études incluses dans la présente synthèse en bref.

Tableau 3 : Revue rapide des facteurs qui ont eu une incidence sur le respect de l'isolement et de la quarantaine lors des éclosions antérieures à la COVID-19 (n = 1)

ANNÉE	MÉTHODE	PRINCIPAUX RÉSULTATS
Webster 2020 (9) Revue rapide Janvier 2020	Revue rapide portant sur 14 études sur les facteurs associés au respect de la quarantaine lors des éclosions de maladies infectieuses. Ces études portaient sur la grippe H1N1 (grippe porcine), Ebola, le SRAS et les oreillons.	Les taux d'adhésion variaient de 0 à 92,8 % et ont été observés chez les travailleurs de la santé, le personnel des écoles, les résidents des villes, les parents et les personnes ayant reçu un résultat positif au test de dépistage de l'infection. Les périodes de quarantaine étaient variables. Le fait de rendre la quarantaine obligatoire ou de s'assurer qu'elle tombe sous le coup de la loi a permis d'augmenter l'adhésion. La culture et les normes sociétales sont importantes et les différents exemples tirés des épidémies d'Ebola montrent une meilleure adhésion lorsque le chef de famille a dit qu'il favorisait la quarantaine. En revanche, l'adhésion était plus basse lorsque la prise en charge des malades était vue comme une priorité culturelle importante. Les études sur le SRAS montrent, quant à elles, une forte adhésion à la quarantaine en raison des pressions sociétales ou des lois à cet effet. Les facteurs d'adhésion incluaient la perception d'un risque élevé d'être malade, le protocole de mise en quarantaine ou d'isolement et les avantages de la quarantaine, mais la perception associée à la connaissance de la maladie ne faisait pas partie des facteurs ayant eu un effet positif. Les études effectuées au Canada pendant la crise du SRAS mettent en lumière la perte du salaire et de l'emploi comme facteurs principaux pour le non-respect, tout comme la nécessité d'obtenir des fournitures ou des soins médicaux.

		Les preuves en ce qui concerne la durée de la quarantaine et le respect des règles sont donc mitigées. La confiance dans le gouvernement a, quant à elle, été associée au respect de la quarantaine.

Méthodologie :

Une analyse quotidienne de la littérature (publiée et prépubliée) liée à la COVID-19 est effectuée par le Groupe des sciences émergentes de l'ASPC et se continue depuis le début de l'éclosion. Les recherches visant à extraire les ouvrages pertinents sur la COVID-19 sont menées dans Pubmed, Scopus, BioRxiv, MedRxiv, ArXiv, SSRN et Research Square, et les résultats sont recoupés avec les ouvrages figurant sur la liste de la documentation sur la COVID de l'Organisation mondiale de la Santé et des centres d'information sur la COVID-19 gérés par Lancet, BMJ, Elsevier et Wiley. Une recherche visant à extraire la documentation pertinente pour inclusion dans cette synthèse a été effectuée dans la base de données Refworks. Une recherche ciblée par mot-clé est effectuée dans ces bases de données pour identifier les citations pertinentes sur la COVID-19 et le SRAS-CoV-2. Algorithmes de recherche utilisés : (isolation OU quarantine) ET (compliance OU adherence). 53 références potentiellement pertinentes ont été examinées pour confirmer qu'elles comportaient des données pertinentes, qui ont été extraites dans la revue. La présente revue contient des recherches relatives à l'isolement et au respect de la quarantaine publiées jusqu'au 15 janvier 2021.

Emerging Evidence on COVID-19

Evidence Brief of Maximum Incubation Period

Introduction

What evidence exists that the incubation period of SARS-CoV-2 is greater than two weeks?

What policies are currently used for quarantine durations to account for longer incubation periods?

The incubation period determined by the World Health Organization (WHO), the European Centers for Disease Control (ECDC), US Centers for Disease Control and Prevention (CDC) and Public Health Agency of Canada ranges from 0-14.0 days, 0-14.0 days, 2.0-14.0 days, and 1.0-14.0 days, respectively. A comparison across coronaviruses in one review reported average incubation periods of SARS 4.6 days (95% CI: 3.8-5.8 d) and MERS 5.2 days (95% CI: 1.9-14.7 d) (1). This evidence brief focuses on the evidence up to January 25, 2020, on prolonged incubation periods beyond a 14-day quarantine period, and regions that have recently extended the quarantine period for some or all travellers.

Key Points

- The incubation period across all meta-analyses was an average or median of 5-7 days with the longest incubation period reported to be 32 days. There was some evidence the average incubation period may be longer for children and older adults compared to adults (Table 1). Over dispersion in the tail of incubation periods was noted, which may result in the mean and confidence intervals being skewed towards higher values due to a few very long incubation periods in the dataset. The reported range in upper percentiles across meta-analyses were:
    - 90th percentile: 9.7 days (95% CI: 8.1–11.6)
    - 95th percentile: 11.2 days (95% CI: 10.7–11.8) to 11.7 days (95% CI: 9.7–14.2)
    - 97.5th percentile: 11.5 days (95% CI: 8.2–15.6) to 19.2 days (95% CI: 17.4-21.4)
- Study point estimates ranged from 1%-6.7% and 0-1.4% of infected individuals would still be in their incubation periods at 14 days and 21 days, respectively.
- The Canadian model estimating incubation period over the pandemic up to November 2020 reported a mean of 6.89 days, a median of 6 days and 90th, 95th, 99th percentiles of 11, 12, 13.5 days. They also indicated results suggested a slight increase in the incubation period over time.
- As of January 25, 2021, four regions have increased the quarantine duration for travellers entering their borders (Table 2). No evidence was found for longer incubation periods of COVID-19 or a larger proportion of cases falling beyond the commonly accepted 14-day threshold (including the variants of concern) within the literature.

Overview of the Evidence

Eleven reviews were included, mainly systematic reviews and meta-analysis, which summarized studies that measured incubation periods. In addition, eleven primary research studies presented evidence of incubation periods beyond 14 days. The final paper is a quantitative model on incubation period developed using Canadian data (Table 1).

Most incubation period data comes from public health contact tracing investigations mainly from studies done in Asia. Contact tracing investigations were at high risk of bias due to their retrospective nature. The data may also be affected by the fact that people do not know with certainty that they were exposed at a certain time or place. The systematic reviews were not evaluated by AMSTAR-2 due to the speed that this brief was developed, however the quality of individual reviews is highly variable ranging from few systematic review attributes to well conducted systematic reviews. The systematic reviews and meta-analyses overlap in the studies included. The quantitative model uses Canadian data to estimate the incubation period in the Canadian context. This model would be sensitive to the quality of the data used to develop the model.

As noted above, most of the data used to estimate incubation period were from studies conducted in Asia and are largely from early in the pandemic. Knowledge gaps include few recent studies and limited global representation of data on incubation period.

Other related evidence reviews are available on SARS-CoV-2 infectious period (2) and the efficacy of various quarantine strategies (3) by request.

CONTENTS

INCUBATION PERIODS

Table 1: Evidence of Incubation Period Beyond 14 Days (n=23)

STUDY	METHODS	KEY OUTCOMES
Reviews (n=11)		
Public Health Ontario (2020) (4) Rapid review NA	Search included references found in Nov 2020; and 16 meta-analyses were included. PHO compiled 4 systematic reviews and meta-analysis studies	Range of median incubation periods (tail-end analysis) reported across included meta-analyses: • 50th percentile: 5.1 days (95% CI: 4.5–5.8) to 5.4 days (95% CI: 5.0–5.7)

Nov 2020	(Quesada, 2020; McAloon, 2020; Li, 2020; Lauer, 2020) for tail-end analysis of the pooled estimates of the median incubation period.	• 75th percentile: 6.7 days (95% CI: 5.7–7.9) to 8.5 days (95% CI: 7.9–9.1) • 90th percentile: 9.7 days (95% CI: 8.1–11.6) • 95th percentile: 11.2 days (95% CI: 10.7–11.8) to 11.7 days (95% CI: 9.7–14.2) • 97.5th percentile: 11.5 days (95% CI: 8.2–15.6) to 16.5 days (95% CI: 14.8–18.3) Mean incubation period ranged from 4.2 to 6.7 days across all studies.
Quesada (2021) (5) Systematic review and meta-analysis NA Mar 2020	Systematic review was conducted with a search up to March 21, 2020. The meta-analysis included 7 studies.	The mean incubation period ranged from 5.6 (95% CI: 5.2 to 6.0) to 6.7 days (95% CI: 6.0 to 7.4), high heterogeneity (I^2 83.0%, p <0.001), depending on the statistical model used. A meta-regression of the 95th percentile data including mean age explained observed heterogeneity. Where for each 10 year increase in age, there was a 1 day increase in incubation period. Where the 95th percentile by mean age was 10.5, 11.5 and 12,5 days for 40, 50 and 60 year old, respectively.
McAloon (2020) (6) Rapid review and meta-analysis NA Apr 2020	Rapid review and meta-analysis with search conducted April 8, 2020. 24 studies were included for review, 9 of them were analysed.	Mean incubation period was 5.8 days (95% CI: 5.0 to 6.7) days with uncertainty in tail of the distribution. Median incubation period of 5.1 (95% CI: 4.5 to 5.8) days. The 95th percentile was 11.7 (95% CI: 9.7 to 14.2) days.
Li (2020) (7) Preprint Systematic review NA May 2020	Systematic review search conducted May 30, 2020, 64 studies were included, 30 studies were analysed, 12 of which included incubations greater than 14 days.	Incubation period 4.9 days (95% CI: 4.6-5.2) and a 97.5th percentile of 19.2 days (95% CI: 17.4-21.4).
Lauer (2020) (8) Meta-analysis	Pooled analysis of 181 cases reported Jan 4 – Feb 24, 2020 outside of Hubei province.	Median incubation period 5.1 days (95% CI: 4.5 to 5.8 days).

NA Jan – Feb 2020		97.5% of symptomatic cases developed symptoms within 11.5 days (CI: 8.2 to 15.6 days). Authors report that these estimates indicate that from 10,000 cases, 101 would develop symptoms after 14 days.
Daley (2020) (9) Preprint Systematic Review NA Jul 2020	Systematic review, search conducted July 18, 2020 and included 21 studies reporting incubation period.	Across studies the mean 5.9 days and median 5.6 days were in agreement.
Khalili (2020) (10) Systematic review and meta-analysis NA Mar 2020	A systematic review was conducted up to March 11, 2020, 18 studies were included in the meta-analysis of incubation period, only 2 were from outside China.	The pooled mean incubation period was 5.68 (99% CI: 4.78- 6.59) days, I^2= 98.4%.
Wang (2020) (1) Review NA Mar 2020	Narrative review of SARS, MERS, and SARS-CoV-2.	Average incubation period: • SARS : 4.6 d (95% CI: 3.8-5.8 d), • MERS : 5.2 d (95% CI: 1.9-14.7 d), • SARS-CoV-2: 6.4 d (range, 0-24.0 d)/ median 4 days (IQR 2-7) (Guan 2020)
Lin (2020) (11) Systematic Review NA Jun 2020	Search date was Feb 21, 2020. 8 studies were included in the meta-analysis of incubation period.	The median incubation 5.90 days (IQR 4.78–6.25) across 9 studies.
Wei (2020) (12) Preprint Systematic review NA Apr 2020	56 studies in the meta-analysis (4095 observations).	Median incubation period of 5.8 days (95% CI: 5.3 - 6.2, I^2 = 96.1%, P < 0.0001) and mean 6.9 days. Incubation period was longer for asymptomatic cases (median, 7.7; 95% CI: 6.3–9.4, P = 0.0408) and children (median, 7.3 d; 95% CI: 6.2–8.6, P = 0.0219). An estimated 6.7% (95% CI: 2.4–11.2%) and 1.4% (95% CI: 0.1–3.6%) of infected

		people had incubation periods over 14 d and 21 d respectively. The 97.5th percentile was 18 days incubation period for symptomatic cases, 14 days for asymptomatic and 25 days for children.
Bikbov (2021) (13) Letter to the Editor NA Jul 2020	Letter to the Editor, the authors summarize as a narrative synthesis the evidence of COVID-19 incubation period beyond 14-days (Koff, 2020; Guan, 2020; Tan, 2020; Jiang, 2020; Bai, 2020; Qiu, 2020; Bi, 2020).	The author's strongly advocate the need for open access data, specifically concerning incubation period of COVID-19 infection.
Primary Literature (n=11)		
Koff (2020) (14) Case Report USA Oct 2020	A case report of a patient who developed COVID-19 in California.	Patient with a confirmed incubation period of at least 21 days.
Guan (2020) (15) Case Series China Feb 2020	The study reported clinical data for 1099 patients.	The preprint mentioned 1 individual with an incubation period of 24 days, but this was labelled as a double exposure when WHO objected the data. The accepted article does not use this 24 day length in quantifying the incubation period and does not provide an upper limit.
Tan (2020) (16) Preprint Case Series China Jan-Feb 2020	A cohort of 67 patients admitted to hospital in China from Jan 26 – Feb 5, 2020. Cases confirmed by observation of corona viral particles by transmission electron microscopy.	Median incubation period of 6.0 days (range 1-15 days). The study notes a longer incubation period is observed in children. 1/67 (1.5%) were observed to have an incubation period greater than 14 days (15 days reported).
Jiang (2020) (17) Preprint Case Series China Jan 2020	Data from 136 patients who travelled to Hubei from Jan 5 - 31, 2020 and returned to their respective 21 cities after 48 hours or less in Hubei.	Cases 15-64 years old had a median incubation period of 7.0 days (95% CI, 6.1-8.1 days). Cases in the 65-86 year old range had a median incubation period of 10.9 days (95% CI, 8.9-13.6 days). A maximum of 17 days was observed (within the 65-86 year cohort).

Bai (2020) (18) Case Series China Jan-Feb 2020	This case series follows a familial cluster of 5 symptomatic patients and 1 asymptomatic family member.	The asymptomatic case had a reported incubation period of 19 days from initial contact with family members on January 10, 2020 to a positive RT-PCR test on Jan 28 (negative tests reported Jan 26, Feb 5, and Feb 8). It should be noted that this period is from first potential exposure, and may reflect a longer period than clinically experienced.
Qiu (2020) (19) Contact tracing investigations China Jan-Feb 2020	Results of contact investigations of 104 cases of COVID-19 in Hunan province, all were confirmed by RT-PCR.	The median incubation period was 6 (range, 1-32) days, which of 8/104 patients had incubation periods longer than 14 days: 18-32 days.
Bi (2020) (20) Contact tracing investigations China Jan-Feb 2020	Results of contact investigations of 391 cases of COVID-19 in Shenzhen province, all were confirmed by RT-PCR. 183 cases were considered to have well defined timelines for exposure and symptom onset.	Median incubation period reported as 4.8 days (95% CI: 4.2-5.4 days). 95% of symptomatic cases developed symptoms within 14 days (95% CI: 12.2-15.9 days)
Li (2021) (21) Preprint Case series China NR	787 cases from outside Wuhan were identified from a database in China. Gamma distribution best fit the data, thus a long tail.	The mean incubation period is 7.8 (7.4-8.5) days. Percentiles: 50th, 7.0 (6.7~7.3) days 75th 10.0 (9.7~10.4) days 97.5th 17.9 (17.1~18.7) days
Liu (2020) (22) Retrospective Cohort China Jan-Mar 2020	Until the end of March 2020, 93 patients were identified in Jilin province China. This study details the epidemiology and clinical results of the 93 RT-PCR confirmed COVID-19 cases.	The mean period of incubation for 87 patients was 10.4 days (range 2-25 days). The authors acknowledge this is longer than many other reports.
Leung (2020) (23) Case series China	A Google search for cases in China was conducted up to Feb 12, 2020. 175 cases with exposure data that included travel to Wuhan or known contact with	The Weibull distribution provided the best fit of the incubation period data and there was a dichotomy by whether the person had travelled to Hubei (mean 1.8 days, variance 0.7) or was not a traveller,

Jan-Feb 2020	infected person/place were included.	meaning local exposure, (mean 7.2 days, variance 16.2). This study found incubation period length at the 95% confidence interval was between 14.6-17.1 days, which is longer than current quarantine interventions.
Zhu (2020) (24) Preprint Contact tracing investigations China Feb-Apr 2020	Analysis of 670 COVID-19 cases imported into China that underwent quarantine and RT-PCR testing.	Median incubation period was 3 days (IQR 1-6 days.) The 95th percentile 11.6 days. (Table 3 lists incubation periods of 19 studies and the 95th percentile crosses 14 days in most estimates).
Model (n=1)		
Paul (2020) (25) Preprint Model Canada Nov 2020	SEIR model of the Canadian epidemic was developed to estimate the incubation period up to Nov 2020.	Estimates include a mean incubation period of 6.89 days, a median of 6 days and 90th percentile of 11 days, 95th percentile of 12 days and 99th percentile of 13.5 days. The model predicts a peak incubation period at 6 days with a second smaller peak at 10 days. This model also detected a slight increase over time in incubation period.

NR = not reported, NA = Not applicable

QUARANTINE POLICIES BEYOND 14 DAYS

Early in the COVID-19 pandemic, a maximum incubation period of 14 days was established by WHO and accepted as a standard quarantine or isolation period for travelers, cases and contacts by many countries and regions. At this point in the pandemic a few countries have eliminated or have very little local transmission of SARS-CoV-2, while other countries are reporting their highest case counts. There are also new variants of concern that have been identified and may be more transmissible than the original SARS-CoV-2. As such, countries with well controlled SARS-CoV-2 situations have amended their policies on quarantine duration as a precaution (Table 2). The table below describes the current quarantine requirements from countries with extended quarantine as of January 25, 2021.

Table 2: Government Quarantine Policies (n=4)

POLICY	KEY OUTCOMES
Australia	Hotel quarantine is required for those entering Australia, minimum 14 days, to a maximum of 24 days.

National Policy, Hotel Quarantine FAQ Posted Jan 22, 2021 (Accessed Jan 25, 2021)	Testing is conducted on days 2 and 12. Quarantine ends after 14 days for those with negative test results and no symptoms. A positive test, symptoms or close contact with a case restarts the 14 day count. Those refusing testing are quarantined the full 24 days.
Beijing, China Entry/exit requirements, listed by Government of Canada Posted Jan 21, 2021 (Accessed Jan 25, 2021)	Nationally, China requires a 14 day quarantine in a government designated facility. This procedure may vary by port of entry or final destination. International travellers entering Beijing will be subject to: • 21 days of quarantine in a local government designated facility; you may be allowed to self-isolate at home for the last 7 days. • An additional 7 days of health monitoring. International travellers entering Beijing via any other Chinese city will be subject to: • 21 days of self-isolation at the international point-of-entry, before they can continue to Beijing. • An additional 7 days of health monitoring upon arrival to Beijing.
Hong Kong Quarantine Extension, Press Release Posted Dec 25, 2020 (Accessed Jan 25, 2021)	Those arriving in Hong Kong who have been anywhere other than China in the past 21 days are subject to a 21 day quarantine in a designated hotel. Further, anyone who has spent more than 2 hours in the United Kingdom or South Africa in the past 21 days are not allowed entry to Hong Kong.
Singapore Quarantine Requirements Posted Jan 25, 2021 (Accessed Jan 26, 2021)	Singapore requires a 14 days quarantine for all travelers entering the country. Quarantine is spent at a designated facility. Recently, the quarantine for travellers from the United Kingdom and South Africa has been increased to a mandatory 21 days. The first 14 days are spent at a designated facility, with an addition 7 days at their place of residence.

Methods:

A daily scan of the literature (published and pre-published) is conducted by the Emerging Science Group, PHAC. The scan has compiled COVID-19 literature since the beginning of the outbreak and is updated daily. Searches to retrieve relevant COVID-19 literature are conducted in Pubmed, Scopus, BioRxiv, MedRxiv, ArXiv, SSRN, Research Square and cross-referenced with the COVID-19 information centers run by Lancet, BMJ,

Elsevier, Nature and Wiley. The daily summary and full scan results are maintained in a refworks database and an excel list that can be searched. Targeted keyword searching was conducted within these repositories to identify relevant citations on COVID-19 and SARS-CoV-2. Search terms used included: (incubation period AND (prolonged OR review). This review contains research published up to January 25, 2021.

A Google search and search of targeted government websites was conducted to find publicly available reports, protocols and clinical data pertinent to the evidence questions. Search terms used included: COVID-19 AND incubation period; quarantine AND increase; quarantine AND length; variant AND quarantine. Searches were conducted and websites accessed on January 25, 2021.

Each potentially relevant reference was examined to confirm it had relevant data, and relevant citations were explored for further detail; relevant data was extracted into the review.

Emerging Evidence on COVID-19

Evidence Brief of SARS-CoV-2 Incubation Periods

Introduction

What is the incubation period for SARS-CoV-2 and has it changed with variants of concern (VOC)?

The incubation period is defined as the time between exposure to an infectious pathogen and symptom onset. The incubation period of SARS-CoV-2 determined by the World Health Organization (WHO) and the European Centers for Disease Control (ECDC) is 0-14.0 days, the US Centers for Disease Control and Prevention (CDC) is 2.0-14.0 days and the Public Health Agency of Canada is 1.0-14.0 days. A comparison across what was known on incubation periods for other coronaviruses reported the average incubation periods of SARS was 4.6 days (95% CI: 3.8-5.8 d) and MERS was 5.2 days (95% CI: 1.9-14.7 d) (1). This review summarizes the incubation period of the original SARS-CoV-2 variants prior to the emergence of variants of concern (VOC) from several systematic reviews that included studies from the first 12 months of the pandemic (Table 2) and more recent research that has focused on establishing the incubation period of the VOCs (Table 1).

SARS-CoV-2 VOCs are circulating variants that have been flagged by national or global public health organizations. There are currently four VOCs: B.1.1.7 (Alpha), B.1.351 (Beta), P.1 (Gamma) and B.1.617.2 (Delta). VOCs are of concern when compared to the original SARS-CoV-2 variants, as their complement of mutations lead to increased transmissibility, increased virulence (morbidity or mortality), changes in clinical disease presentation, immune evasion, reduced effectiveness of treatments, vaccines and/or public health measures and/or are associated with diagnostic detection failures (2-4). Canada has established a national definition for VOCs (3). In May 2021, the WHO released a naming system for VOCs and variants of interest (VOIs) using Greek letters to improve the ease of communication on variants and potential stigma related to places where variants were first identified. This naming system has been adopted in this report (2).

This evidence brief focuses on the evidence up to August 17th, 2021 on incubation periods for SARS-CoV-2 and whether there is evidence that the incubation period for any VOC is different than previously circulating variants. In this summary, "original variant" refers to any variant that was not designated as a VOC or VOI.

Key Points

Incubation period for the original SARS-CoV-2 variants (prior to VOCs):

- The incubation period of SARS-CoV-2 based on a range of estimates from meta-analyses of studies conducted in 2020 prior to the emergence of VOCs estimated pooled mean incubation periods of 4.9-6.9 days (9 meta-analyses) and pooled median incubation periods of 4.8-5.9 days (8 meta-analyses) (Table 2).

- The largest meta-analysis included 99 studies with a range of 2.33-17.60 days incubation period reported across studies and the pooled mean incubation period 6.38 days (95%CI 5.79-6.97) and median 5.41 days (95%CI 4.74- 6.07) had high between study heterogeneity (5).
- In most meta-analyses the incubation period mean estimate is longer than the median estimate because there appears to be a few cases in each dataset with very long incubation periods, which causes a right skew in the data, also known as over dispersion in the tail of incubation periods. Long incubation periods are well documented particularly for immunocompromised populations, which have been covered in previous reviews and can be requested here.
- Two reviews reported evidence of a longer incubation period in children compared to adults: median, 7.3 days in children vs. 5.8 days in adults (6), median 10 days vs. 7 days, respectively (7).
- The majority (up to 90%) of the studies included in the meta-analyses were from China and represented data collected in the first half of 2020 (8, 9). The incubation period estimated prior to the end of January 2020 was shorter than after January 2020 in these studies, which is hypothesized to represent a bias in the data as cases were increasing exponentially (9).
- The Canadian model estimating incubation period over the pandemic up to November 2020 reported a mean of 6.89 days, a median of 6 days and 90th, 95th, 99th percentiles of 11, 12, 13.5 days. The results suggested a slight increase in the incubation period over time (10).

Incubation period for VOCs:

- Four studies were found on the incubation period for VOCs; one that looked at Alpha, two that looked at Delta, and one that looked at both Alpha and Delta (Table 1). No studies reporting on the incubation period for Beta or Gamma were found.
- The two studies included in this summary on Alpha incubation period found it could be shorter than original strains by 2 days. The first study is a small retrospective cohort study in Japan that reported incubation period of Alpha was shorter compared to other strains (mean: 3.53 days vs. 5.71 days / median 3.0 days vs. 5.0 days) (11). The other was a surveillance report from England that reported the median incubation period for Alpha was 4 days and no mean incubation period was provided (12). Both results indicate that Alpha incubation period may be shorter, however there is low confidence in these estimates, which are likely to change as additional research is published.
- The three studies on Delta incubation period included two contact tracing investigations from Guangdong, China. All results indicated that Delta incubation period may be shorter, however the difference may not be significant and there is low confidence in these estimates, which are likely to change as additional research is published. The first study reported the mean incubation period was 5.8 days (95%CI 5.2-6.4) and the latent period was 4.0 days (95%CI 3.5-4.4) (13). The latent period is defined as the time from acquiring infection to infectiousness onset. The other study estimated time to first positive PCR test, latent period rather than incubation period, in quarantined cases with Delta compared to a sample of cases from the initial epidemic wave in 2020: median 4 days (IQR 3-5) vs. 6

days (IQR 5-8), respectively (11). The third estimate was a surveillance report from England that reported the median incubation period for Delta was 4 days (12).

Overview of the Evidence

Thirteen reviews on incubation periods prior to the emergence of VOCs were included in this review including systematic reviews and meta-analysis (n=9), meta-analyses (n=2), a rapid review (n=1), and a scoping review (n=1). In addition, one recently published primary research study and one quantitative model using Canadian data were included for information on pre-VOC incubation period estimates as they were not included in the 13 reviews (Table 2). Studies reporting on incubation period for any VOC were reported in four studies or reports (Table 1).

Most incubation period data comes from public health contact tracing investigations mainly from studies done in Asia. One study reported contact tracing surveillance data for VOCs in the UK. Contact tracing investigations are at high risk of bias due to their retrospective nature. The data may also be affected by the fact that people do not know with certainty when or where they were exposed. The systematic reviews were not evaluated by the AMSTAR-2, a tool for evaluating systematic reviews, however the methods synopsis indicates the missing steps of each systematic review. The quality of the reviews was highly variable in both conduct and reporting across reviews. The systematic reviews and meta-analyses that are included in this brief overlap with the studies that were included. The quantitative model uses Canadian data to estimate the incubation period in the Canadian context. This model would be sensitive to the quality of the data used to develop the model.

The evidence for the non-VOC incubation period is abundant but not conclusive and the evidence for the VOC incubation period is sparce. This has resulted in large knowledge gaps on all SARS-CoV-2 viruses. Additional cohort studies are needed to assess early signals that the incubation period for original variants have evolved over time and to establish incubation periods for all the VOCs including pediatric studies to assess the early signal that children exposed to VOCs have a longer incubation period than adults.

CONTENTS

VOC INCUBATION PERIODS

Table 1: Evidence of Incubation Period for VOCs (n=4): Alpha (n=2), Delta (n=3)

STUDY	METHODS	KEY OUTCOMES
Primary Literature on Alpha and Delta		
Homma (2021) (11) Retrospective cohort study Japan Mar 2020-2021	A small retrospective cohort that included 30 Alpha cases from March 2021 and compared them to other SARS-CoV-2 strains from Mar 2020-Jan 2021.	• The reported incubation period of Alpha was shorter compared to other strains: mean 3.53 vs 5.71 days/ median 3.0 vs 5.0 days, respectively. • The incubation period for Alpha in close-contact environments was 0.62 times shorter than other strains (95% CI: 0.47, 0.82) after adjusting for age and sex.
Li (2021) (14) Preprint Outbreak investigation China June 2021	A study from China reported a shorter time interval between exposure and first PCR positive test in quarantined cases involved in an outbreak of Delta across the province of Guangdong (n=34) compared to cases caused by 19A/19B genetic strains during the early 2020 epidemic (n=29).	• Shorter time interval between exposure and first PCR positive test (latent period) in quarantined cases infected with Delta was a median 4 days (IQR 3-5) compared to a sample of traced cases from the initial epidemic wave in 2020, 6 days (IQR 5-8).
Kang (2021) (13) Preprint Outbreak investigation China May - June 2021	The transmission and epidemiological characteristics of the outbreak in Southern China is described. Analysis includes 167 cases of Delta in Guangdong.	• Mean estimate of the incubation period from 95 symptomatic cases was 5.8 days (95%CI 5.2-6.4) • The 95th percentile for Delta incubation cases was 11.5 days (95%CI 10.1-13.0) • Latent period was mean 4.0 days, (95%CI 3.5-4.4) • In this study, 73.9% of transmission occurred before symptom onset with peak infectiousness estimated at 2.1 days (95%CI 1.5-2.7) before symptom onset.
Public Health England (2021) (12) Report Surveillance data analysis UK	Contact tracing surveillance data from the UK between March 29 and June 9, 2021.	• For both household and non-household contacts the median incubation period was 4 days (estimated IQR from graph 2–7 days) for Delta and Alpha.

CI = Confidence interval, IQR= Interquartile range, PCR= Polymerase Chain Reaction

ORIGINAL VARIANTS (NON-VOC) INCUBATION PERIODS

Table 2: Estimates of Incubation Period for the original variants prior to the emergence of VOCs from Systematic Reviews (n=9), Meta-analyses (n=2), Rapid Reviews (n=1) and Scoping Reviews (n=1) and select primary research not included in the syntheses (n=2)

STUDY	METHODS	KEY OUTCOMES
Reviews (n=13)		
Song (2021) (7) Systematic review NA Jun 2021	This systematic review conducted a search up to 10 March 2021 on COVID-19 family clusters. Eighteen studies (published Jan-May 2020) involving 34 children and 98 adults from 28 families were included. Incubation period was reported in 31 children and 72 adults. No risk of bias assessment conducted.	• The median (IQR) incubation period was longer in children 10 days (1–30) compared to adults 7 days (1–29) (p=0.045).
Elias (2021) (5) Short communication Meta-analysis Jan 2021	A systematic search was carried out on studies published from 1 January 2020 to 10 January 2021 reporting the SARS-CoV-2 incubation period. No studies on VOCs were identified. There is no systematic review protocol or risk of bias assessment reported. The meta-analysis included 99 studies, of which 23 (23.2%) were cohort studies, 61 (61.6%) were case series, and 15 (15.2%) were modeling studies. Results of meta-analysis available here.	• The mean incubation period was 6.38 days (95%CI 5.79-6.97, I^2=100%, 99 studies), range 2.33-17.60 days. • The median incubation period was estimated at 5.41 days (95%CI 4.74-6.07, I^2=95%, 99 studies). • In the meta-regression, study design only explained 10% of the between study heterogeneity, the finding was the incubation period for cohort studies and predictive models was shorter than case series (p<0.01).
Li (2021) (15) Scoping review NA Apr 2021	This scoping review conducted a search up to 10 December 2020. There were 1920 confirmed cases included. Individual patient analysis was conducted by transforming case data to be double interval-censored, which was considered	• The median incubation period was 4.8 days (4.6–5.0), with the 95th and 99th percentile of the distribution being 15.1 days (95%CI 14.4–15.7) and 22.9 days (95%CI 21.7–24.3).

	to be best for obtaining a precise estimate. An accelerated failure time model was used to estimate the time to event distribution. This scoping review included a search, inclusion/exclusion criteria and data extraction and analysis. Thus, other than the omission of a risk of bias assessment resembles a systematic review more than a scoping review.	
Dhouib (2021) (8) Systematic review and meta-analysis NA Apr 2021	This systematic review was conducted with a search from December 2019 to December 1, 2020. Forty-two studies were included and consisted of 9 strong, 19 moderate, and 14 weak quality studies. The meta-analysis included 10 studies on mean incubation period. This systematic review has a registered protocol CRD42020196347, included a risk of bias and SIGN assessment of the certainty of the evidence. Random effects meta-analysis was conducted.	• The median incubation period ranged from 2-12 days with an IQR lower bound of 2 days and higher bound of 14 days (n=17 studies). The 95th percentile range was 10.3-16 days and the 99th percentile was up to 24 days. • The mean incubation period ranged between 3.9-9.0 days (n=9 studies). The total incubation period ranged from 0-26 days. • The pooled mean incubation period was 6.2 days (95% CI 5.4-7.0, I^2=77.1%, p < 0.001, 10 studies). Note included studies were from China (8), Singapore (1) and Argentina (1). Subgroup analysis revealed that heterogeneity was explained by study quality and method of calculation. • One study reported the mean incubation period for children was 8 days (range 1-13).
Xin (2021) (9) Systematic review and meta-analysis NA Apr 2021	This systematic review included a search conducted from 1 February 2020 and 25 September 2020. The meta-analysis included 31 studies that reported mean incubation period and 41 studies that reported median incubation period. The search strategy is presented, articles were evaluated with the	• 62/72 studies were using data from China. The pooled median of the point estimates of the mean incubation period was 6.3 days (range: 1.8–9.1 days). • The pooled estimate of mean incubation periods before the epidemic peak in China (January 2020) was 5.2 days (9 studies; 95%CI 4.8–5.7; I^2 = 56.5%), significantly lower than the

	STROBE checklist for quality and a random effects meta-analyses and meta-regression were conducted.	pooled estimate for studies conducted after the peak (March 2020) (18 studies; 7.2 days, 95%CI, 6.6–7.8; I^2 = 89.5%). • The pooled median of the point estimates of the median incubation period were 5.4 days (range, 2.0–17.6 days). The median value is lower than the mean due to the right skew in the data. • The 95th percentile of the incubation period was 11.0 days (5 studies; 95%CI 9.9–12.0; I^2=0.0%) before peak and 14.6 days (7 studies; 95%CI 13.7–15.5; I^2=66.9%) after peak of the outbreak in China. • Analysis of incubation period data from China in Jan-May 2020 suggests that when cases were rising exponentially there was a bias towards shorter estimates.
Daley (2020) (16) Preprint Systematic Review NA Jul 2020	The systematic review search was conducted 18 July 2020 and included 21 studies reporting incubation period. There is no protocol, a brief search description, no risk of bias assessment and the statistical analysis was averaging.	• Across studies the mean 5.9 days and median 5.6 days were in agreement.
Alene (2021) (17) Systematic review and meta-analysis NA Mar 2021	This systematic review was conducted on studies published up to 30 June 2020. Search, screening and data extractions details provided. Risk of bias was assessed using the Ottawa-Newcastle Scale. Random effects meta-analysis included 14 studies on mean incubation period.	• The mean incubation period of COVID-19 ranged from 4.8-9 days. • The weighted pooled mean incubation period of COVID-19 was 6.5 days (95%CI 5.9–7.1, I^2=97%, 14 studies, 1453 observations). • 71.4% of the studies were assessed to be of good quality.
Wei (2020) (6) Preprint	The systematic review search was conducted up to 26 April 2020.	• Median incubation period of 5.8 days (95%CI 5.3-6.2, I^2=96.1%, p<0.0001) and mean 6.9 days.

Systematic review and meta-analysis NA Apr 2020	56 studies were included in the meta-analysis (4095 observations). Methods for the search, selection, data extraction and quality assessment (AHRQ) of studies are described. Random effects meta-analysis was conducted. Bayesian meta-analysis was also employed to better simulate the distribution of the incubation period. Meta-regression was used to explore heterogeneity.	• Incubation period was longer for asymptomatic cases (median, 7.7 days; 95%CI 6.3–9.4, p=0.0408) and children (median, 7.3 days; 95%CI 6.2–8.6, p =0.0219). • A linear relationship between age and median incubation period was detected with a 16% increase for every 10 years age. • An estimated 6.7% (95%CI 2.4–11.2%) and 1.4% (95%CI 0.1–3.6%) of infected people had incubation periods over 14 days and 21 days, respectively. • The 97.5th percentile was 18 days incubation period for symptomatic cases, 14 days for asymptomatic and 25 days for children.
McAloon (2020) (18) Rapid review and meta-analysis NA Apr 2020	Rapid review and meta-analysis included a search conducted 8 April 2020. 24 studies were included for review, 9 of them were analyzed. The search, selection criteria, data extraction details and quality assessment using the Ottawa-Newcastle scale was described. Random effects meta-analysis was conducted.	• Mean incubation period was 5.8 days (95%CI 5.0-6.7) with uncertainty in the tail of the distribution. • Median incubation period of 5.1 days (95%CI 4.5-5.8). • The 95th percentile was 11.7 days (95%CI 9.7-14.2).
Quesada (2021) (19) Systematic review and meta-analysis NA Mar 2020	This systematic review was conducted with a search up to 21 March 2020. The meta-analysis included 7 studies. Search, selection strategies and meta-analysis methods are reported. Quality assessment was not done.	• The mean incubation period ranged from 5.6 (95%CI 5.2-6.0) to 6.7 days (95%CI 6.0-7.4), high heterogeneity (I^2 83.0%, p<0.001), depending on the statistical model used. • A meta-regression of the 95th percentile data including mean age explained observed heterogeneity. For each 10 year increase in age, there was a 1 day increase in incubation period. Where the 95th percentile by mean age was 10.5, 11.5 and 12.5 days for 40, 50 and 60 year old, respectively.

Khalili (2020) (20) Systematic review and meta-analysis NA Mar 2020	A systematic review was conducted up to 11 March 2020. 18 studies were included in the meta-analysis of incubation period, only 2 were from outside China. Search, selection strategies and meta-analysis methods are reported. Quality assessment was not done.	• The pooled mean incubation period was 5.68 (99% CI: 4.78-6.59) days, I^2= 98.4%.
Lauer (2020) (21) Meta-analysis NA Jan – Feb 2020	Pooled analysis of 181 cases reported Jan 4 – Feb 24, 2020 outside of Hubei province. The analysis in this paper is individual patient data meta-analysis. However the data was scraped from many different sources.	• Median incubation period was 5.1 days (95%CI 4.5-5.8 days). • 97.5% of symptomatic cases developed symptoms within 11.5 days (95%CI 8.2-15.6 days). • Authors reported that these estimates indicate that from 10,000 cases, 101 would develop symptoms after 14 days.
Lin (2020) (22) Systematic Review NA Jun 2020	Search date was Feb 21, 2020. 8 mathematical or statistical models that estimated incubation period were included. The search strategy, selection criteria and data extraction are described. The ISPOR-SMDM Modelling Good Research Practices Task Force tool was used to evaluate the models. Estimates are descriptively summarized.	• The median incubation was 5.90 days (IQR 4.78–6.25) across 9 studies.
Primary Literature (n=1)		
Huang (2021) (23) Preprint Retrospective cohort China NR	787 cases from outside Wuhan with sufficient information about exposure and symptom onset were identified from a national database of cases during 2020 in China. An interval-censored data estimation methods was used to study the data and factors that may explain the variability in incubation period. A gamma	The mean incubation period was 7.8 (7.4-8.5) days. Percentiles: 50th (median), 7.0 (6.7~7.3) days 75th 10.0 (9.7~10.4) days 97.5th 17.9 (17.1~18.7) days Factors that may explain heterogeneity in incubation period estimates were analysed and the findings indicate longer incubation periods were associated with

	distribution best fit the data which was right skewed.	females, older people and those with mild disease.
Model (n=1)		
Paul (2021) (10) Model Canada Nov 2020	SEIR model of the Canadian epidemic was developed to estimate the incubation period up to Nov 2020.	Estimates include a mean incubation period of 6.74 days (95%CI 6.35-7.13), a median of 6 days and 90th percentile of 11.64 days (95%CI 11.22-12.17), 95th percentile of 12 days and 99th percentile of 13.5 days. The model predicts a peak incubation period at 6 days with a second smaller peak at 10 days. This model also detected a slight increase over time in incubation period.

CI = Confidence interval NR = Not reported, NA = country not applicable, IQR = Interquartile range,

Methods:

A daily scan of the literature (published and pre-published) is conducted by the Emerging Science Group, PHAC. The scan has compiled COVID-19 literature since the beginning of the outbreak and is updated daily. Searches to retrieve relevant COVID-19 literature are conducted in Pubmed, Scopus, BioRxiv, MedRxiv, ArXiv, SSRN, Research Square and cross-referenced with the COVID-19 information centers run by Lancet, BMJ, Elsevier, Nature and Wiley. The daily summary and full scan results are maintained in a Refworks database and an excel list that can be searched. Targeted keyword searching was conducted within these repositories to identify relevant citations on COVID-19 and SARS-CoV-2. Search terms used included: (incubation period AND (review OR "variant of concern terms")). This review contains research published up to August 17, 2021.

A Google search and search of targeted government websites was conducted to find publicly available reports, protocols and clinical data pertinent to the evidence questions. Search terms used included: COVID-19 AND incubation period. Searches were conducted and websites accessed on August 17, 2021.

Each potentially relevant reference was examined to confirm it had relevant data, and relevant citations were explored for further detail; relevant data was extracted into the review.

Peer-review

This document underwent peer-review by a subject matter expert, and editorial and science to policy review by the Office of the Chief Science Officer.

Nouveaux éléments de preuve sur la COVID-19

Synthèse en bref sur la période d'incubation maximale

Introduction

Existe-t-il des preuves qui montrent que la période d'incubation du SRAS-CoV-2 peut durer plus de deux semaines?

Les politiques actuelles qui portent sur les périodes de quarantaine ont-elles prévu des périodes d'incubation plus longues?

L'Organisation mondiale de la santé (OMS), les European Centers for Disease Control (ECDC), les Centers for Disease Control and Prevention (CDC) des États-Unis et l'Agence de la santé publique du Canada ont déterminé que la période d'incubation du SRAS-CoV-2 variait de 0 à 14,0 jours, de 0 à 14,0 jours, de 2,0 à 14,0 jours et de 1,0 à 14,0 jours, respectivement. Une étude comprenant une comparaison entre différents coronavirus a, quant à elle, révélé des périodes d'incubation moyennes de 4,6 jours pour le SRAS (IC à 95 % : 3,8 à 5,8 jours) et de 5,2 jours pour le SRMO (IC à 95 % : 1,9 à 14,714,7 jours) (1). La présente synthèse en bref se fonde donc sur les données probantes recueillies jusqu'au 25 janvier 2020 à propos des périodes d'incubation qui se sont prolongées au-delà de la quarantaine de 14 jours et des régions qui ont récemment décidé d'allonger cette période de quarantaine pour certains voyageurs ou pour tous les voyageurs.

Points clés

- Toutes les méta-analyses examinées ont mentionné une période d'incubation moyenne ou médiane de 5 à 7 jours, à l'exception d'une méta-analyse qui a mentionné une période beaucoup plus longue (32 jours). Certains éléments de preuve indiquent que la période d'incubation moyenne peut cependant être plus longue chez les enfants et les adultes plus âgés que chez les adultes (tableau 1). Certaines études ont également mentionné qu'une surdispersion s'était produite pendant l'extrémité supérieure de la fourchette de la période d'incubation, ce qui peut faire augmenter la moyenne et les intervalles de confiance en raison de quelques très longues périodes d'incubation indiquées dans l'ensemble de données. Les méta-analyses ont indiqué les tranches de centiles supérieurs suivantes :
    - 90^{e} centile : 9,7 jours (IC de 95 % : 8,1 à 11,6)
    - 95^{e} centile : 11,2 jours (IC de 95 % : 10,7 à 11,8) à 11,7 jours (IC à 95 % : 9,7 à 14,2)
    - 97,5^{e} centile : 11,5 jours (IC de 95 % : 8,2 à 15,6) à 19,2 jours (IC à 95 % : 17,4 à 21,4)
- Les estimations ponctuelles présentées dans l'étude indiquaient qu'entre 1 et 6,7 % des personnes infectées seraient encore en période d'incubation au 14^{e} et qu'entre 0 et 1,4 % le seraient encore au 21^{e} jour.

- Le modèle canadien utilisé pour estimer la période d'incubation créé pendant la pandémie en fonction des données disponibles jusqu'en novembre 2020 a cependant donné une moyenne de 6,89 jours, une médiane de 6 jours et des 90^{e}, 95^{e} et 99^{e} centiles de 11, de 12 et de 13,5 jours pour la période d'incubation. Les résultats obtenus suggéraient également une période d'incubation qui s'allongeait légèrement avec le temps.
- Quatre régions ont décidé de prolonger, à compter du 25 janvier 2021, la durée de la quarantaine pour les voyageurs qui traversent leurs frontières (tableau 2). Aucun des documents consultés n'incluait de preuve sur des périodes d'incubation plus longues pour la COVID-19 ou sur un plus grand nombre de cas ayant dépassé le seuil communément accepté de 14 jours (ce qui inclut les différentes variantes préoccupantes).

Vue d'ensemble des éléments de preuve

Onze études ont été incluses dans cette synthèse, principalement des revues systématiques et des méta-analyses qui résumaient différentes études ayant mesuré les périodes d'incubation. Onze autres études de recherche originale comprenant des preuves sur les périodes d'incubation de plus de 14 jours ont également été incluses dans la synthèse. Le document final est donc un modèle quantitatif sur la période d'incubation élaboré à partir de données canadiennes (tableau 1).

La plupart des données sur la période d'incubation proviennent d'enquêtes de santé publique axées sur la recherche des contacts effectuées principalement en Asie. Les enquêtes avec recherche des contacts présentent un risque élevé de biais en raison de leur nature rétrospective. Les données peuvent aussi être biaisées du fait que les gens ne savent pas avec certitude à quel endroit et à quel moment ils ont été exposés. Les revues systématiques n'ont pas été évaluées avec AMSTAR-2 en raison de la rapidité avec laquelle ce dossier a été élaboré, mais la qualité des différentes études est très variable, allant de quelques attributs d'examen systématique à des revues systématiques bien effectuées. Les revues systématiques et les méta-analyses se chevauchent dans les études incluses dans la présente synthèse. Quant au modèle quantitatif, il utilise des données canadiennes pour estimer la période d'incubation dans le contexte canadien. Ce modèle serait sensible à la qualité des données utilisées pour le développer.

Comme il a été mentionné précédemment, la plupart des données utilisées pour estimer la période d'incubation provenaient d'études effectuées en Asie, en grande partie au début de la pandémie. Il y a donc des lacunes en matière de connaissances du fait qu'il n'y a que peu d'études récentes et une représentation mondiale limitée des données sur la période d'incubation.

D'autres revues connexes sur les données probantes sont disponibles à la demande. Elles portent notamment sur la période infectieuse du SRAS-CoV-2 (2) et sur l'efficacité de diverses stratégies de quarantaine (3).

TABLE DES MATIÈRES

PÉRIODES D'INCUBATION

Tableau 1 : Preuve d'une période d'incubation supérieure à 14 jours (n = 23)

ANNÉE	MÉTHODES	PRINCIPAUX RÉSULTATS
Revues (n = 11)		
Santé publique Ontario (2020) (4) Revue rapide Sans objet Novembre 2020	La recherche comprenait des références trouvées en novembre 2020, ainsi que 16 méta-analyses. Santé publique Ontario a compilé quatre examens et méta-analyses (Quesada, 2020; McAloon, 2020; Li, 2020; Lauer, 2020) pour l'extrémité supérieure de la distribution des estimations regroupées de la période médiane d'incubation.	Fourchette de la période d'incubation médiane (analyse de l'extrémité de la période) déclarée dans les méta-analyses examinées : • 50e centile : de 5,1 jours (IC de 95 % : 4,5 à 5,8) à 5,4 jours (IC de 95 % : 5,0 à 5,7) • 75e centile : de 6,7 jours (IC de 95 % : 5,7 à 7,9) à 8,5 jours (IC de 95 % : 7,9 à 9,1) • 90e centile : 9,7 jours (IC de 95 % : 8,1 à 11,6) • 95e centile : de 11,2 jours (IC de 95 % : 10,7 à 11,8) à 11,7 jours (IC de 95 % : 9,7 à 14,2) • 97,5e centile : de 11,5 jours (IC de 95 % : 8,2 à 15,6) à 16,5 jours (IC de 95 % : 14,8 à 18,3) La période moyenne d'incubation varie de 4,2 à 6,7 jours pour l'ensemble des études.
Quesada (2021) (5) Revue systématique et méta-analyse Sans objet Mars 2020	Revue systématique avec recherche jusqu'au 21 mars 2020. La méta-analyse comprenait 7 études.	La période moyenne d'incubation variait de de 5,6 (IC à 95 %) : 5,2 à 6,0) à 6,7 jours (IC à 95 % : 6,0 à 7,4), une hétérogénéité élevée (I^2 83,0%, p < 0,001) selon le modèle statistique utilisé. Une métarégression des données du 95e centile, y compris l'âge moyen, explique l'hétérogénéité observée. Pour chaque augmentation de 10 ans dans l'âge, la période d'incubation a augmenté d'une journée. Le 95e centile selon l'âge moyen était de 10,5, de 11,5 et de 12,5

		jours pour les gens de 40, de 50 et de 60 ans, respectivement.
McAloon (2020) (6) Examen rapide et méta-analyse Sans objet Avril 2020	Revue rapide et méta-analyse avec recherches effectuées le 8 avril 2020. 24 études ont été incluses dans la revue, dont 9 ont été analysées.	La période moyenne d'incubation était de 5,8 jours (IC à 95 % : 5,0 à 6,7) jours avec une incertitude dans l'extrémité de la distribution. La période d'incubation médiane est de 5,1 (IC à 95 % : 4,5 à 5,8) jours. Le 95^{e} centile était de 11,7 (IC à 95 % : 9,7 à 14,2) jours.
Li (2020) (7) Prépublication Revue systématique Sans objet Mai 2020	Recherche des revues systématiques effectuée le 30 mai 2020 ayant permis d'inclure 64 études. 30 de ces études ont été analysées, dont 12 comportaient une incubation ayant duré plus de 14 jours.	La période d'incubation est de 4,9 jours (IC à 95 % : 4,6 à 5,2) et un 97,5^{e} centile de 19,2 jours (IC à 95 % : 17,4 à 21,4).
Lauer (2020) (8) Méta-analyse Sans objet Janvier et février 2020	Analyse combinée comprenant 181 cas signalés entre le 4 janvier et le 24 février 2020 à l'extérieur de la province du Hubei.	La période médiane d'incubation est de 5,1 jours (IC à 95 % : 4,5 à 5,8 jours). 97,5 % des cas symptomatiques ont présenté des symptômes dans les 11,5 jours (IC : 8,2 à 15,6 jours). Les auteurs signalent que ces estimations présument que, sur 10 000 cas, 101 développeraient des symptômes après 14 jours.
Daley (2020) (9) Prépublication Revue systématique Sans objet Juillet 2020	Revue systématique avec recherche effectuée le 18 juillet 2020 comprenant 21 études mentionnant la période d'incubation.	Dans l'ensemble des études, la moyenne de 5,9 jours et la médiane de 5,6 jours correspondaient.
Khalili (2020) (10) Revue systématique et méta-analyse Sans objet Mars 2020	Revue systématique effectuée jusqu'au 11 mars 2020 comprenant 18 études qui ont été incluses dans la méta-analyse de la période d'incubation, seules 2 études provenaient de l'extérieur de la Chine.	La période moyenne d'incubation combinée était de 5,68 (IC de 99 % : 4,78 à 6,59) jours, I^2= 98,4 %.

Wang (2020) (1) Revue Sans objet Mars 2020	Revue narrative portant sur le SRAS, le SRMO et le SARS-CoV-2.	Période moyenne d'incubation : • SRAS : 4,6 jours (IC à 95 % : 3,8 à 5,8 jours), • SRMO : 5,2 jours (IC à 95 % : 1,9 à 14,7 jours), • SARS-CoV-2 : 6,4 jours (fourchette, 0 à 24,0 jours)/médiane de 4 jours (EI 2 à 7) (Guan 2020)
Lin (2020) (11) Revue systématique Sans objet Juin 2020	Recherche effectuée le 21 février 2020. La méta-analyse de la période d'incubation comprenait 8 études.	L'incubation médiane est de 5,90 jours (EI 4,78 à 6,25) dans 9 études.
Wei (2020) (12) Prépublication Revue systématique Sans objet Avril 2020	Méta-analyse ayant porté sur 56 études (4 095 observations).	La période médiane d'incubation est de 5,8 jours (IC à 95 % : 5,3 à 6,2, I^2 = 96,1%, P < 0,0001) alors que la moyenne est de 6,9 jours. La période d'incubation était plus longue chez les cas asymptomatiques (médiane de 7,7 jours; IC à 95 % : 6,3 à 9,4, P = 0,0408) et les enfants (médiane de 7,3 jours; IC à 95 % : 6,2 à 8,6, P = 0,0219). On estime que 6,7 % (IC à 95 % : 2,4 à 11,2 %) et 1,4 % (IC à 95 % : 0,1 à 3,6 %) des personnes infectées ont eu des périodes d'incubation de 14 et de 21 jours respectivement. Le 97,5^{e} centile était de 18 jours d'incubation pour les cas symptomatiques, de 14 jours pour les cas asymptomatiques et de 25 jours pour les enfants.
Bikbov (2021) (13) Lettre à l'éditeur Sans objet Juillet 2020	Dans leur lettre à l'éditeur, les auteurs résument, sous forme de synthèse narrative, les preuves associées à une période d'incubation qui dépasse 14 jours pour la COVID-19 (Koff, 2020; Guan, 2020; Tan, 2020; Jiang, 2020; Bai, 2020; Qiu, 2020; Bi, 2020).	L'auteur défend fermement le besoin d'avoir des données en libre accès, particulièrement en ce qui concerne la période d'incubation de l'infection à COVID-19.
Littérature primaire (n = 11)		

Koff (2020) (14) Exposé de cas É.-U. Octobre 2020	Exposé de cas sur un patient de Californie qui a eu la COVID-19.	Patient ayant eu une période d'incubation confirmée d'au moins 21 jours.
Guan (2020) (15) Série de cas Chine Février 2020	Étude qui présente des données cliniques sur 1 099 patients.	La page préenregistrée mentionnait une période d'incubation de 24 jours pour une personne, mais cette mention a plutôt été indiquée comme une double exposition lorsque l'OMS s'est opposée aux données présentées. L'article accepté n'utilise donc pas cette durée de 24 jours pour quantifier la période d'incubation et ne fournit aucune limite supérieure.
Tan (2020) (16) Prépublication Série de cas Chine Entre janvier et février 2020	Cohorte de 67 patients admis dans un hôpital en Chine, entre le 26 janvier et le 5 février 2020. Les cas ont été confirmés par l'observation des particules virales du coronavirus par microscope électronique à transmission.	La période d'incubation médiane est de 6,0 jours (fourchette de 1 à 15 jours). L'étude mentionne qu'une période d'incubation plus longue a été observée chez les enfants. Un seul patient sur les 67 (1,5 %) a été indiqué comme ayant eu une période d'incubation de plus de 14 jours (durée indiquée de 15 jours).
Jiang (2020) (17) Prépublication Série de cas Chine Janvier 2020	Données sur 136 patients qui se sont rendus à Hubei entre le 5 et le 31 janvier 2020, avant de retourner dans leurs 21 villes respectives après un séjour de 48 heures ou moins à Hubei.	Les patients âgés de 15 à 64 ans ont eu une période médiane d'incubation de 7,0 jours (IC à 95 %, 6,1 à 8,1 jours). Les patients âgés de 65 à 86 ans ont eu une période médiane d'incubation de 10,9 jours (IC à 95 %, 8,9 à 13,6 jours). Un maximum de 17 jours a cependant été observé (dans la cohorte des 65 à 86 ans).
Bai (2020) (18) Série de cas Chine Entre janvier et février 2020	Cette série de cas suit un groupe familial de cinq patients symptomatiques et d'une personne asymptomatique.	Le cas asymptomatique a eu une période d'incubation indiquée de 19 jours entre le premier contact avec les membres de la famille le 10 janvier 2020 et un test RT-PCR positif le 28 janvier (tests négatifs déclarés les 26 janvier, 5 février et 8 février). Il faut savoir que cette période a été calculée à partir de la première exposition potentielle et peut donc refléter une période plus longue que celle qui a été indiquée en clinique.

Qiu (2020) (19) Enquête sur la recherche des contacts Chine Entre janvier et février 2020	Les résultats des recherches de contacts effectuées sur 104 personnes atteintes de la COVID-19 dans la province du Hunan ont tous été confirmés par RT-PCR.	La période d'incubation médiane était de 6 (fourchette de 1 à 32) jours. Des 104 patients, 8 ont eu des périodes d'incubation de plus de 14 jours, soit entre 18 à 32 jours.
Bi (2020) (20) Enquête sur la recherche des contacts Chine Entre janvier et février 2020	Les résultats des recherches de contacts effectuées sur 391 personnes atteintes de la COVID-19 dans la province de Shenzhen ont tous été confirmés par RT-PCR. 183 cas ont été jugés avoir des cadres bien définis pour l'exposition et l'apparition des symptômes.	La période médiane d'incubation indiquée était de 4,8 jours (IC à 95 %) : 4,2 à 5,4 jours). 95 % des cas symptomatiques ont développé des symptômes dans les 14 jours (IC à 95 % : 12,2 à 15,9 jours)
Li (2021) (21) Prépublication Série de cas Chine Non déclaré	787 cas à l'extérieur de Wuhan ont été identifiés à l'aide d'une base de données de Chine. La distribution gamma correspond le mieux aux données, ce qui veut dire une longue extrémité.	La période moyenne d'incubation est de 7,8 (7,4 à 8,5) jours. Percentiles : 50^{e}, 7,0 (6,7 à 7,3) jours 75^{e}, 10,0 (9,7 à 10,4) jours 97,5^{e}, 17,9 (17,1 à 18,7) jours
Liu (2020) (22) Cohorte rétrospective Chine Janvier à mars 2020	Jusqu'à la fin du mois de mars 2020, 93 patients ont été identifiés dans la province du Jilin, en Chine. Cette étude décrit en détail l'épidémiologie et les résultats cliniques des 93 cas de COVID-19 confirmés par RT-PCR.	La période moyenne d'incubation pour 87 patients était de 10,4 jours (entre 2 et 25 jours). Les auteurs reconnaissent que cette période d'incubation est plus longue que ce qui est indiqué dans de nombreux autres rapports.
Leung (2020) (23) Série de cas Chine Entre janvier et février 2020	Recherche effectuée sur Google jusqu'au 12 février 2020 pour des cas en Chine. 175 cas dont les données d'exposition comprennent des déplacements à Wuhan ou des contacts connus avec une personne ou dans un endroit infectés ont été inclus.	La distribution de Weibull a la meilleure correspondance avec les données sur la période d'incubation. On a cependant vu une dichotomie selon que la personne s'était rendue à Hubei (moyenne de 1,8 jour, variance de 0,7) ou n'avait pas voyagé, ce qui signifie qu'elle avait subi une exposition locale (moyenne de 7,2 jours, variance de 16,2). Cette étude a révélé que la durée de la période d'incubation avec l'intervalle de confiance de 95 % se situait entre 14,6 et

		17,1 jours, ce qui est plus long que les quarantaines actuelles.
Zhu (2020) (24) Prépublication Enquête sur la recherche des contacts Chine Février à avril 2020	Analyse de 670 cas de COVID-19 importés en Chine qui ont été en quarantaine et ont passé des tests RT-PCR.	La période médiane d'incubation était de 3 jours (EI 1 à 6 jours). Le 95e centile était de 11,6 jours. (Le tableau 3 dresse la liste des périodes d'incubation présentées dans 19 études et le 95e centile passe à 14 jours dans la plupart des estimations).
Modèle (n = 1)		
Paul (2020) (25) Prépublication Modèle Canada Novembre 2020	Le modèle susceptible-exposé-infectieux-retiré (modèle SEIR) de l'épidémie canadienne a été développé afin d'estimer la période d'incubation jusqu'en novembre 2020.	Les estimations comprennent une période d'incubation moyenne de 6,89 jours, une médiane de 6 jours et un 90e centile de 11 jours, un 95e centile de 12 jours et un 99e centile de 13,5 jours. Le modèle prédit une pointe dans la période d'incubation à 6 jours et une deuxième plus petite à 10 jours. Il a également détecté une légère augmentation au fil du temps pendant la période d'incubation.

NR = non déclaré, NA = sans objet

POLITIQUES DE QUARANTAINE DE PLUS DE 14 JOURS

Au début de la pandémie de COVID-19, une période d'incubation maximale de 14 jours a été établie par l'OMS et acceptée comme période standard de quarantaine ou d'isolement pour les voyageurs, les cas et les contacts par de nombreux pays et régions. À ce stade-ci de la pandémie, alors quelques pays ont réussi à éliminer la transmission locale du SRAS-CoV-2 ou n'en ont eu que très peu, d'autres continuent de déclarer les nombres de cas les plus élevés à ce jour. De nouvelles variantes préoccupantes ont également été identifiées et pourraient se révéler encore plus transmissibles que le SRAS-CoV-2 original. Par conséquent, les pays dans lesquels la situation associée au SRAS-CoV-2 est bien contrôlée ont décidé de modifier leurs politiques sur la durée de la quarantaine à titre préventif (tableau 2). Le tableau ci-dessous décrit les exigences actuelles en matière de quarantaine des pays dans lesquels la quarantaine a été prolongée en date du 25 janvier 2021.

Tableau 2 : Politiques gouvernementales de quarantaine (n = 4)

POLITIQUE	PRINCIPAUX RÉSULTATS
Australie Politique nationale, FAQ sur la quarantaine dans les hôtels Publiée le 22 janvier 2021 (document consulté le 25 janvier 2021)	La quarantaine à l'hôtel est obligatoire pour toute personne qui entre en Australie. Durée : minimum de 14 jours et maximum de 24 jours. Les tests sont effectués les jours 2 et 12. La quarantaine prend fin au bout de 14 jours pour les personnes dont les résultats des tests de dépistage sont négatifs et qui ne présentent aucun symptôme. Un test positif, des symptômes ou un contact étroit avec un cas sont tous des éléments qui redémarrent le décompte des 14 jours. Ceux qui refusent les tests sont mis en quarantaine pendant 24 jours.
Beijing, Chine Exigences d'entrée et de sortie, indiquées par le gouvernement du Canada Publié le 21 janvier 2021 (document consulté le 25 janvier 2021)	À l'échelle nationale, la Chine exige une quarantaine de 14 jours dans un établissement désigné par le gouvernement. Cette procédure peut varier selon le point d'entrée ou la destination finale. Les voyageurs internationaux qui entrent à Beijing sont assujettis à ce qui suit : • 21 jours de quarantaine dans un établissement désigné par l'administration locale; ils peuvent être autorisés à s'isoler à la maison pendant les 7 derniers jours. • Sept jours supplémentaires pendant lesquels l'état de santé est surveillé. Les voyageurs internationaux qui arrivent à Beijing en provenance de n'importe quelle autre ville chinoise sont assujettis à ce qui suit : • 21 jours d'auto-isolement au point d'entrée international, avant qu'ils puissent se rendre à Beijing. • Lors de leur arrivée à Beijing, sept jours supplémentaires pendant lesquels leur état de santé sera surveillé.
Hong Kong Prolongation de la quarantaine, Communiqué de presse Publié le 25 décembre 2020 (document consulté le 25 janvier 2021)	Les personnes qui arrivent à Hong Kong en provenance d'un pays autre que la Chine pendant les 21 derniers jours sont soumises à une quarantaine de 21 jours dans un hôtel désigné. De plus, quiconque a passé plus de deux heures au Royaume-Uni ou en Afrique du Sud au cours des 21 derniers jours n'est pas autorisé à entrer à Hong Kong.
Singapour	Singapour exige une quarantaine de 14 jours pour tous les voyageurs qui arrivent au pays. La quarantaine doit être effectuée dans un établissement désigné.

Exigences en matière de quarantaine Publiées le 22 janvier 2021 (document consulté le 26 janvier 2021)	La durée de la quarantaine pour les voyageurs en provenance du Royaume-Uni et de l'Afrique du Sud a récemment été augmentée, ce qui fait qu'ils doivent désormais effectuer une quarantaine obligatoire de 21 jours. Les 14 premiers jours doivent être passés dans un établissement désigné, avec 7 jours supplémentaires au lieu de résidence des voyageurs.

Méthodologie :

Une analyse documentaire quotidienne (ouvrages publiés et en prépublication) est effectuée par le Groupe des sciences émergentes de l'ASPC. L'analyse a compilé les ouvrages sur la COVID-19 depuis le début de l'éclosion et est mise à jour quotidiennement. Les recherches visant à extraire les ouvrages pertinents sur la COVID-19 sont menées dans Pubmed, Scopus, BioRxiv, MedRxiv, ArXiv, SSRN et Research Square, et les résultats sont recoupés avec les ouvrages figurant sur la liste de la documentation sur la COVID de l'Organisation mondiale de la Santé et des centres d'information sur la COVID-19 gérés par Lancet, BMJ, Elsevier, Nature et Wiley. Le résumé quotidien et les résultats complets de l'analyse sont conservés dans une base de données RefWorks et dans une liste Excel consultable. Une recherche ciblée par mot-clé a été effectuée dans ces systèmes d'archivage pour recenser les citations pertinentes sur la COVID-19 et le SRAS-CoV-2. Les termes de recherche utilisés comprenaient : (incubation period ET (prolonged OU review). Cette synthèse contient des recherches publiées jusqu'au 25 janvier 2021.

Une recherche sur Google et sur des sites web gouvernementaux ciblés a été effectuée pour trouver des rapports, des protocoles et des données cliniques accessibles au public et pertinents pour les questions de preuve. Les termes de recherche utilisés comprenaient : COVID-19 ET incubation period; quarantine ET increase; quarantine ET length; variant ET quarantine. Les recherches ont été effectuées et les sites web consultés le 25 janvier 2021.

Chaque référence potentiellement pertinente a été examinée pour confirmer qu'elle comportait des données pertinentes et les citations pertinentes ont été explorées plus en détail, alors que les données pertinentes ont été extraites dans la revue.

Emerging Evidence on COVID-19

COVID-19 Summary of Heating, Ventilation, Air Conditioning (HVAC) Systems and Transmission of SARS-CoV-2

Introduction

What is the impact of Heating, Ventilation, Air Conditioning (HVAC) systems on SARS-CoV-2 virus transmission?

This evidence brief summarizes relevant literature up to August 13, 2020 on the potential role of HVAC systems in the transmission of SARS-CoV-2. Evidence from other related respiratory infections (i.e. SARS, MERS-CoV) was also identified to improve our understanding of the possible role of HVAC systems in transmission of similar viruses.

Key Points

- SARS-CoV-2 RNA contamination in air samples and HVAC system surfaces (e.g. air grates and filters) from healthcare settings indicate it may be possible for SARS-CoV-2 to spread through the HVAC system (Table 1). The viability of isolated viral RNA has not been confirmed by cell culture in the majority of studies, with the exception of two studies that collected viable virus from air samples in COVID-19 patients' rooms.
    - Lednicky and colleagues demonstrate viable SARS-CoV-2 can be found in air 2 to 4.8 meters away from patients in hospital care settings, using virus culture (RT-qPCR) (Lednicky et al., 2020). Moreover, the authors suggest virus particles becoming inactivated during sample collection to be the reason for studies failing to culture viable SARS-CoV-2 in air samples.
    - Air samples from a hospital setting treating SARS-CoV-2 patients were contaminated with viral RNA. Minor indications of cytopathic effects and viral replication were observed in an air and surface sample (Santarpia et al., 2020).
- A single study reports on the presence of SARS-CoV-2 RNA downstream of air filters in a hospital ventilation system, however the viability of the isolated virus was not evaluated (Table 1). As such, the potential for SARS-CoV-2 infection from air circulated through a ventilation system remains unestablished.
- A small number of SARS-CoV-2 clusters has been attributed to air conditioning units and air recirculation (Table 2) at a dine-in restaurant (Lu et al., 2020), bus ride to a worship event, and a professional workshop (Shen et al., 2020). Strong air jets created by air conditioning units and the recirculation of indoor air are considered likely modes transmitting infectious respiratory particles

from the index case to other susceptible individuals nearby (Yuguo Li et al., 2020). Other investigations into SARS-CoV-2 outbreak in a cruise ship have failed to implicate the HVAC system in infection transmission (Almilaji & Thomas, 2020; Xu et al., 2020).

- Transmission of other coronavirus infections (i.e. MERS and SARS) predating SARS-CoV-2 point to an association between poor ventilation (i.e. insufficient movement and clearance of contaminated indoor air) and infection transmission, this association likely extends to SARS-CoV-2 (Table 4).
- Expert statements and guidance documents advocate for HVAC testing and certification to ensure properly functioning systems to minimize air contaminants in indoor settings based on local standards.
- Commentaries and reviews that consider the body of evidence on the topic, and mathematical models, consistently report that increasing the flow of outside fresh air into built environments (e.g. open windows) and reducing occupancy within enclosed indoor settings, where feasible and appropriate, to be simple strategies that can mitigate SARS-CoV-2 transmission in indoor settings (Dai & Zhao, 2020; Dietz et al., 2020; Morawska & Cao, 2020).

Overview of the Evidence

Various investigations have aimed to evaluate the evidence connecting HVAC systems and indoor air to infection transmission, both before and following the emergence of COVID-19. The variability of studies in their design, experimental settings (healthcare vs. non healthcare), examined viral pathogens, and HVAC systems do not allow direct comparison of the literature.

Nine surveys of environmental contamination in hospitals with COVID-19 patients provide a snapshot of virus laden surfaces (Table 1). These studies are of moderate risk of bias as they are point in time observational surveys that confirm the presence of viral RNA, but many do not confirm the infectiousness of identified viral particles. Four outbreaks where HVAC systems were investigated as a source of infection transmission have been described in various retrospective epidemiological investigations (Table 2). These epidemiological investigations are at high risk of bias, as demonstrated by the conflicting reports about the Diamond Princess cruise ship where different analytical approaches and assumptions led to different conclusions. Mathematical models and computer simulations were parameterized using observational data from a small number of outbreaks to explore scenarios of how HVAC systems can impact SARS-CoV-2, MERS, and SARS transmission (Table 2 and Table 4). Caution should be exercised when interpreting these findings, as the extent to which the results can be generalized is variable.

There are several knowledge gaps in the current COVID-19 literature. The available evidence has not directly established infectious SARS-CoV-2 particles can travel through an HVAC system or system generated air flow to cause infection when reintroduced to a susceptible population of individuals. Evidence on the optimal number of air changes per hour required in non-healthcare settings, ideal ventilation system configurations, and the role of HEPA filters in mitigating SARS-CoV-2 transmission is limited.

CONTENTS

LITERATURE ON INFECTION TRANSMISSION AND HVAC SYSTEMS

There are no studies that specifically quantify SARS-CoV-2 transmission risk due to HVAC systems or indoor ventilation. Nine studies conducting environmental sampling identified SARS-CoV-2 viral RNA in air samples and on surfaces of HVAC system components (e.g. pre and post air re-circulation filters, air dampers, air grates) in healthcare settings treating COVID-19 cases; virus viability and infectiousness was not established in the majority of studies (Table 1). Thus, dispersion of viable SARS-CoV-2 by a HVAC system has not been demonstrated.

A single cluster of COVID-19 cases from three unrelated families are reported to be associated with air circulation and uni-directional air streams generated by a ductless air conditioning unit in a Chinese restaurant (Lu et al., 2020). In this cluster, the index case from Family A dined upwind of Families B and C, who did not have any other connections or exposures to Family A. Staff and other patrons were not affected. Air re-circulation in enclosed environments linked to air conditioning units, indoor ventilation and fans are reported to have played a role in two unrelated SARS-CoV-2 outbreaks, from a religious worship event and a professional workshop(Shen et al., 2020). Moreover, the HVAC system on-board the Diamond Princess cruise ship that had a large COVID-19 outbreak was also investigated for evidence of its contribution to SARS-CoV-2 spread. One study took into account the lock-down, quarantine period, and incubation period and provides evidence that the quarantine of passengers in cabins stopped transmission on board the ship and no transmission could be attributed to ventilation (Xu et al., 2020). A second study that analysed the same data suggests transmission via circulating air may have occurred, but failed to account for the incubation period (Almilaji & Thomas, 2020).

Investigations of clusters of coronaviruses that predate the emergence of COVID-19 have been linked to poor indoor ventilation and HVAC systems being non-functional (Haselbach et al., 2009; Y Li, Huang, Yu, Wong, & Qian, 2005; Satheesan, Mui, & Wong, 2020; Wong et al., 2004). Multiple investigations into a MERS-CoV cluster within a patient isolation unit attribute high air flow near an infected patient, imbalanced supply and exhaust airflow rates, and a malfunctioning exhaust and air supply to infection spread to healthcare workers (Y Li et al., 2005; Wong et al., 2004). A US study of acute respiratory infections occurring in several army barracks of different designs attributed the HVAC configurations (i.e. the number of individuals that come in contact with and share recirculated air in an HVAC system) to increased infection rates, however they failed to rule out direct transmission (Haselbach et al., 2009). Although this literature is not specific to SARS-CoV-2, it does provide evidence that poor ventilation and non-functional HVAC systems are associated with respiratory infection transmission in indoor settings.

The American Society of Heating, Refrigerating, and Air-Conditioning Engineers (ASHRAE), a leading US authority on HVAC system design, operation and maintenance, published a position statement on COVID-19,

in April 2020. The position statement advocates for properly functioning HVAC systems as these systems are designed to reduce contaminants in indoor air and as a result minimize airborne transmission of pathogens such as SARS-CoV-2. This statement has been adopted by other organizations, including the Center for Disease Control and Prevention, in back to work and business re-opening guidance.

Table 1: Literature on SARS-CoV-2 contamination of air and air vents in healthcare settings

Reference	Publication Title	Key Outcomes
Environmental Surveys		
(Lednicky et al., 2020) *preprint*	Viable SARS-CoV-2 in the Air of a Hospital Room with COVID-19 Patients.	Air samples were collected from a designated SARS-CoV-2 hospital ward housing infected patients, in Florida, USA. VIV AS and BioSpot air samplers that preserved virus viability were used for sample collection. Viable virus was isolated from air samples collected 2-4.8 meters away from infected patients, thus supporting viable SARS-CoV-2 virus dispersion within airborne aerosols in healthcare settings. Genomic sequencing establishes a relationship between viral RNA isolated from air samples and an infected patient occupying the ward. Finally, viable virus was only isolated from air samples collected without a HEPA filter cover on inlet tubes, based on cytopathic effects on Vero E6 cells. Isolated virus concentrations in air samples ranged from 2-74 $TCID_{50}$ units/L of air.
(Horve et al., 2020) *preprint*	Identification of SARS-CoV-2 RNA in Healthcare Heating, Ventilation, and Air Conditioning Units.	Surfaces of air handling units in a healthcare facility treating COVID-19 patients in Oregon, USA were tested for the presence of viral RNA within HVAC systems. The presence of viral RNA was confirmed by RT-PCR. 25% of sampled surfaces from multiple air handlers were contaminated with SARS-CoV-2 RNA; positive samples were identified on pre-filters (35%), supply air dampers (20.8%), and final filters (16.67%). Recovered viral gene copies decreased from the pre-filter to final filter surfaces.

		The supply air dampers and air sampled in this study represent re-circulated air that is mixed with outside air pre and post HVAC filtration. Samples were found to be contaminated with viral RNA, which is concerning. Since no attempt was made to culture the virus, further research is needed to further investigate the implications of this study; typical filtration systems in healthcare settings may not completely eliminate the passage of viral particles.
(Cheng et al., 2020)	Air and Environmental Sampling for SARS-CoV-2 Around Hospitalized Patients with Coronavirus Disease 2019 (COVID-19).	Air samples near asymptomatic and symptomatic COVID-19 patients (n=6) with and without surgical masks in an airborne infection isolation room (AIIR), in Hong Kong and China, were tested for SARS-CoV-2 contamination. All collected air samples were negative for SARS-CoV-2 RNA.
(Chia et al., 2020)	Detection of Air and Surface Contamination by SARS-CoV-2 in Hospital Rooms of Infected Patients.	Environmental surface and air samples from airborne infection isolation rooms (AIIR) housing COVID-19 patients in Singapore were tested for SARS-CoV-2 RNA. Among the contaminated surface samples, the floors followed by air exhaust vents were the most contaminated. 66% (n=2/3) of the air samples collected from AIIR environments were SARS-CoV-2 RNA positive. The authors suggest the presence of SARS-CoV-2 in the air is likely highest during the first week of illness when respiratory viral load is high. The infectiousness of the recovered viral particles were not assessed.
(Liu et al., 2020)	Aerodynamic Analysis of SARS-CoV-2 in Two Wuhan Hospitals.	SARS-CoV-2 RNA concentrations in aerosol samples, the size and deposition of airborne SARS-CoV-2 aerosols from Wuhan, China hospital settings was quantified. Sampled environments included patient care, public and staff areas within or near a hospital, and field hospital settings. In patient care areas SARS-CoV-2 concentrations from air samples were very low to undetectable, suggesting the negative pressure isolation room and high rate of air exchange was effective.

		In the field hospital setting, the greatest SARS-CoV-2 suspended aerosols were identified in a temporary patient toilet room (1 m^2 area) with low ventilation. In public areas low to undetectable SARS-CoV-2 suspended aerosol concentrations were identified for the majority of sampled public areas. However, virus concentrations were detected in two public sites, a department store entrance and an outdoor site near the hospital. Results suggest high traffic flow and crowding may play a role in the presence of SARS-CoV-2 detection in air samples. Healthcare worker staff areas had the highest SARS-CoV-2 concentrations and aerosol size distributions. Samples from the field hospital staff personal protective equipment removal and changing rooms demonstrated the greatest virus concentrations and aerosol size distribution. The authors hypothesize the observed high concentrations are due to resuspension of virus containing aerosols from healthcare worker PPE surfaces and apparel. The infectiousness of recovered viral particles was not established.
(Guo et al., 2020)	Aerosol and Surface Distribution of Severe Acute Respiratory Syndrome Coronavirus 2 in Hospital Wards, Wuhan, China, 2020.	35% of air samples collected from hospital ICU and general wards in Wuhan, China tested positive for SARS-CoV2 virus particles. Positive samples were identified near air outlets (35.7%), patient rooms (44.4%) and physician offices (12.5%). Virus-laden samples were most often identified downstream from COVID-19 patients. In the ICU ward space, patient care and treatment areas were positive for SARS-CoV-2 virus aerosols, and positive samples were identified up to 4 meters from a COVID-19 patient. In the general ward's space, areas positive for SARS-CoV-2 were within 2.5 meters upstream of the patient. No SARS-CoV-2 virus aerosols were identified in patient corridor areas.

		The infectiousness of recovered viral particles was not established.
(Ong et al., 2020)	Air, Surface Environmental, and Personal Protective Equipment Contamination by Severe Acute Respiratory Syndrome Coronavirus 2 (SARS-CoV-2) From a Symptomatic Patient.	Survey of air samples collected from negative pressure airborne infection isolation rooms (AIIR), containing anterooms and bathrooms, in the dedicated SARS-CoV-2 outbreak center in Singapore, housing three symptomatic confirmed cases of COVID-19. Although some environmental samples were found to be SARS-CoV-2 contaminated, no air samples were positive for SARS-CoV-2 virus. The infectiousness of recovered viral particles was not established.
(Santarpia et al., 2020) *preprint*	Aerosol and Surface Transmission Potential of SARS-CoV-2.	Air and surface samples from isolation spaces housing COVID-19 cases at the University of Nebraska, United States were collected and tested for SARS-CoV-2 viral RNA by RT-PCR. 63.2% of air samples from patient isolation areas were positive for viral RNA, particularly under the patient's bed and window ledges at the edge of the room. Based on airflow modelling, the authors suggest turbulent eddies (i.e. swirling of a fluid and the reverse current created when the fluid is in a turbulent flow) that form under the patient's bed, and dominate airflow carrying respiratory/viral particles away from the patient toward the edges of the rooms led to the observed contamination. 58.3% of air samples collected in hallways outside of patient isolation areas also contained the virus. The surface of an air grate was found to be contaminated with SARS-CoV-2; the highest viral load observed was recovered from this study surface (1.75 copies/µL). The study findings suggest viral aerosol particles can be produced by infected individuals even during the absence of

		cough, with the virus travelling distances greater than 6 feet (1.8 meters). Cultivation of the isolated viral RNA could not be confirmed via Vero E6 cell assay due to low concentrations of recovered virus. However, minor indications of cytopathic effects and viral replication were observed in an air and surface sample.
(Zhou et al., 2020)	Investigating SARS-CoV-2 Surface and Air Contamination in an Acute Healthcare Setting During the Peak of the COVID-19 Pandemic in London.	Levels of SARS-CoV-2 surface and air contamination in a London, UK hospital at the peak of the COVID-19 pandemic was investigated. Environmental surface swabs from clinical and public areas of the hospital were collected. Viral RNA was detected by RT-PCR in 52.3% of the collected surface samples (most often in COVID-19 patient care areas), and 38.7% of the air samples collected. Contaminated samples were more frequent in areas occupied by a COVID-19 patient. The reclaimed virus could not be cultured in Vero E6 cell lines, as the recovered viral load was less than 30 Ct.
Mathematical Models		
(Dai & Zhao, 2020) *preprint*	Association of Infected Probability of COVID-19 with Ventilation Rates in Confined Spaces: a Wells-Riley Equation Based Investigation.	The Wells-Riley mathematical equation is applied to determine associations between infection probability and indoor ventilation rates. The authors report that less than 1% of the susceptible unmasked population would be infected in confined indoor spaces if the following ventilation rates and exposure periods are applied (100-350 m^3/h and 1200-4000 m^3/h for 15 minutes and 3 hours). If both the infected and susceptible individuals wear masks, the ventilation rate can be reduced to 50-180 m^3/h and 600-2000 m^3/h correspondingly. The authors state former rates would be easier to be achieved by normal ventilation models in typical office, classrooms, buses and aircraft cabin settings.
Commentaries		
(Melikov, Ai, & Markov, 2020)	Intermittent Occupancy Combined with Ventilation: An Efficient Strategy for the	Due to inherent limitations of most mechanical ventilation systems the fresh air flow supply cannot be increased to eliminate infection risk from expiratory airborne aerosols in indoor settings. As such, authors propose a source control

	Reduction of Airborne Transmission Indoors.	strategy based on intermittent breaks for room occupants (i.e. all occupants leaving the room periodically) and minimized room occupancy rates to maximize the effectiveness of indoor ventilation systems reducing airborne infectious pathogens.
(Morawska & Cao, 2020)	Airborne Transmission of SARS-CoV-2: The World Should Face the Reality.	Based on the available evidence, the authors conclude SARS-CoV-2 can likely be transmitted via airborne route. Therefore, all possible precautions against airborne transmission in indoor scenarios should be taken. Precautions include increased ventilation rate, using natural ventilation, avoiding air recirculation, avoiding staying in another person's direct air flow, and minimizing the number of people sharing the same environment. Of significance is maximizing natural ventilation in buildings that are or can be naturally ventilated ensuring that the ventilation rate is sufficiently high.
(Dietz et al., 2020)	2019 Novel Coronavirus (COVID-19) Pandemic: Built Environment Considerations To Reduce Transmission.	A review of the available evidence on the build environment that can be applied to the current COVID-19 pandemic. SARS-CoV-2 has been observed in aerosolized particles and droplets in a range of sizes, including 0.25 to 0.5 µm, which require high efficacy filtration for removal from shared indoor air. Residential and commercial ventilation systems with minimum efficiency reporting values (MERV) of 8 can only capture 70 to 85% of particles ranging from 3.0 to 10.0 µm (not sufficient for SARS-CoV-2 aerosols). Ventilation systems of MERV 13 or higher and HEPA filters commonly used in healthcare settings would effectively remove particle matter in the 0.25 to 0.5 µm size range. However, authors point to limitations within healthcare HVAC systems and filters arising from gaps at the edges of filters. Overall, the authors note that although higher ventilation rates, outdoor air fractions and higher grade filters can reduce and dilute air contaminants (i.e. infectious particles) within indoor air, the risk of airborne infection transmission is never fully eliminated.

Table 2: COVID-19 clusters primarily attributed to indoor ventilation

Reference	Publication Title	Key Outcomes
(Lu et al., 2020)	COVID-19 Outbreak Associated with Air Conditioning in Restaurant, Guangzhou, China.	Indoor ventilation air flow and droplet transmission at distances less than one meter are considered to be the primary modes of transmission for a cluster (n=10) attributed to an air conditioning unit at a dine-in restaurant. The only interaction for multiple cases in the cluster (Family B and Family C) with the index case (Family A) was sitting at neighbouring tables. In the table arrangement, the air outlet and the return air inlet for the central air conditioner were located above table of Family C, and all three tables were in line with the airflow for the same air conditioning unit. Droplet and aerosol infection transmission linked to air conditioning air flow is considered the mode of transmission between the three families.
(Yuguo Li et al., 2020) *preprint*	Evidence for Probable Aerosol Transmission of SARS-CoV-2 in a Poorly Ventilated Restaurant.	A thorough follow-up analysis of the restaurant outbreak by computer simulations and aerodynamic analysis concludes transmission to be consistent with a viral spread from poor ventilation, air flow zones created by the air condition unit, and index case exhaled virus-laden respiratory particles.
(Almilaji & Thomas, 2020) *preprint*	Air Recirculation Role in the Infection with COVID-19, Lessons Learned from Diamond Princess Cruise Ship.	Based on the analysis of clinical data from cruise ship passengers, symptomatic infections diagnosed after the initiation of quarantine was the same in cabins with and without an infected person. The authors' conclude airborne transmission of SARS-CoV-2 through the ventilation system of the cruise ship could explain infection rates observed during the quarantine period.
(Xu et al., 2020) *preprint*	Transmission Routes of COVID-19 Virus in the Diamond Princess Cruise Ship.	Analysis of passenger and COVID-19 case data (n=343) from the Diamond Princess cruise ship cluster, considered the HVAC and sewage systems of the ship and the epidemiological risk factors of each case and close contact to explore the most plausible modes of transmission. Based on the analyses the authors conclude the cruise ship's air condition (HVAC) system did not play a role in long-range airborne transmission of COVID-19 on the ship and that most passenger cases were likely exposed prior to the ship being quarantined.

(Shen et al., 2020) *preprint*	Airborne Transmission of COVID-19: Epidemiologic Evidence from Two Outbreak Investigation.	Airborne transmission by aerosols is assumed to be enhanced by fans and air conditioning units (re-circulating air) in shared transportation and indoor spaces and to have contributed to two independent COVID-19 outbreaks. One involving bus riders to and from a worship event (n=172), and another involving a three day conference workshop (n=30) where attendees shared indoor meeting space. In the worship, event outbreak COVID-19 infection risk among Bus #2 passengers was 41.5 (95% CI: 2.6–669.5) times higher compared to Bus #1 passengers and 11.4 (95% CI: 5.1–25.4) times higher compared to all other individuals attending the worship event. The overall attack rate from the conference outbreak was 48.3%.

Table 3: Grey literature on COVID-19 transmission and HVAC systems

Reference	Organization	Key statements
(ASHRAE, 2020) Accessed here	American Society of Heating, Refrigerating, and Air-Conditioning Engineers	ASHRAE Position Document on Infectious Aerosols released in April 2020. Transmission of SARS-CoV-2 through the air is sufficiently likely and airborne exposure to the virus should be controlled. Changes to building operations, including the operation of heating, ventilating and air conditioning systems can reduce airborne exposures. Ventilation and filtration provided by HVAC systems can reduce airborne concentration of SARS-CoV-2 and thus the risk of transmission through the air.
(CSA Group, 2020) Accessed here	CSA Group	HVAC equipment (intended for healthcare settings) testing and certification standards for manufacturers. Standard CSA Z317.2:19: Special requirements for HVAC systems in health care facilities Standard CAN/CSA-Z317.13-17: Infection control during construction, renovation, and maintenance of health care facilities, among others.

(CDC, 2020) Accessed here	Center for Disease Control and Prevention	Expert guidance on preparations and reopening businesses reference ASHRAE statement on HVAC systems, and HVAC start up guide. The guidance alludes to ensuring HVAC systems are operating properly. Increasing circulation of outdoor air by opening windows and doors after assessing the risks of outdoor air to occupants. Additional recommendations outlined in the documents include: increasing airflow supply to occupied spaces, disabling demand-control ventilation controls that reduce air supply based on temperature or occupancy, using natural ventilation, improving central air filtration, running the ventilation system during unoccupied times, generating clean-to-less-clean air movement, considering using portable high-efficiency particulate air (HEPA) fan/filtration systems, ensuring exhaust fans in restroom facilities are functional and operating, and considering using ultraviolet germicidal irradiation as a supplement.
(ECDC, 2020) Accessed here	European Center for Disease Prevention and Control	Guidance on heating, ventilation and air-conditioning systems in the context of COVID-19. The document covers maintenance, avoidance of recirculation, fan direction, and air exchange rate.
(AHS, 2020) Accessed here	Alberta Health Services	Rapid Evidence Report Outlines the available evidence and grey literature on COVID-19 transmission and HVAC systems in healthcare and non-healthcare settings, up to May 11, 2020. The key findings from the evidence review state HVAC system factors may contribute to pathogen transmission, especially when HVAC systems are not operating properly. The exact potential of HVAC systems to contribute to SARS-CoV-2 infection transmission could not be assessed due to limited evidence on viable virus in air samples, variability in HVAC systems, and complexities in transmission modalities. The Reviewer Committee recommend a committee with the necessary expertise be established to explore the role of

		HVAC systems in the transmission of viral pathogens including SARS CoV-2.

Table 4: Other Infection transmission (not SARS-CoV-2) and HVAC systems

Reference	Publication Title	Key Outcomes
(Wong et al., 2004)	Cluster of SARS Among Medical Students Exposed to Single Patient, Hong Kong.	SARS outbreak at a Hong Kong hospital isolation ward, among healthcare workers is described. Epidemiological data of exposed healthcare workers, an inspection of the ventilation system, and computational fluid dynamic analysis find index patient's cubicle had the highest supply flow rate, while the adjacent exhaust grille had the lowest flow rate among all four functional exhaust grilles in the ward. The authors discuss the possibility of aerosol transmission from the index patient via the ventilation system.
(Y Li et al., 2005)	Role of Air Distribution in SARS Transmission During the Largest Nosocomial Outbreak in Hong Kong.	A second retrospective analysis of in-patient cases and healthcare worker cases from the above SARS hospital outbreak is detailed. On-site inspections, measurements of the ventilation design and air distribution, and computational fluid dynamics simulations conclude airflow rate imbalances and non-functional HVAC system components (e.g. supply diffusers and exhaust grilles) to have contributed to infection transmission. The analysis revealed the need for improved ventilation and air-conditioning systems in the isolation ward to effectively reduce the risk of infection spread between patients and health care workers.
(Satheesan et al., 2020)	A Numerical Study of Ventilation Strategies for Infection Risk Mitigation in General Inpatient Wards.	Simulations are applied to examine the transport mechanisms and deposition patterns of MERS-CoV within a general ward. The authors concluded that air change and exhaust airflow rates had significant impacts on airflow and particle distribution.

		Within the mechanically vented space, exhaust grilles near a patient (ideally above each patient's bed), and high exhaust airflow rates are recommended to reduce transmission.
(Haselbach et al., 2009)	Airborne Transmission via HVAC of Acute Respiratory Infections in Military Facilities? Review of a Basic Training Cohort Study.	Examination of acute respiratory infections among military recruits living in military barracks, while considering HVAC system configurations and the sum of occupants from multiple zones that share return air mixed within the same HVAC system and redistributed as supply (termed contact population). The study found significant risk of airborne ARI transmission through HVAC systems. Higher rates of infection were found in the systems with both higher HVAC contact populations and less access to windows allowing for outside ventilation and air supply.
(Sundell et al., 2011)	Ventilation Rates and Health: Multidisciplinary Review of the Scientific Literature.	A multidisciplinary review team explore the evidence (published up to 2005) linking ventilation rate to multiple health endpoints. The evidence show biological plausibility for an association of health outcomes with ventilation rates, but does not provide clear evidence on particular agent(s) or infectious loads.
(Y. Li et al., 2007)	Role of Ventilation in Airborne Transmission of Infectious Agents in the Built Environment - a Multidisciplinary Systematic Review.	Review of literature published between 1960 and 2005 identified ten articles linking infection transmission to HVAC systems. The reviewers conclude there is strong and sufficient evidence to demonstrate an association between ventilation, air movements in buildings and the transmission/spread of infectious diseases such as measles, tuberculosis, chickenpox, influenza, smallpox and SARS. However, there was insufficient data to specify and quantify the minimum ventilation requirements in hospitals, schools, offices, homes and isolation rooms in relation to spread of infectious diseases via the airborne route.

Methods:

A daily scan of the literature (published and pre-published) is conducted by the Emerging Science Group, PHAC. The scan has compiled COVID-19 literature since the beginning of the outbreak and is updated daily. Searches to retrieve relevant COVID-19 literature are conducted in Pubmed, Scopus, BioRxiv, MedRxiv, ArXiv, SSRN, Research Square and cross-referenced with the literature on the WHO COVID literature list, and COVID-19 information centers run by Lancet, BMJ, Elsevier and Wiley. The daily summary and full scan results are maintained in a Refworks database and an Excel list that can be searched. Targeted keyword searching is conducted within these databases to identify relevant citations on COVID-19 and SARS-CoV-2. Search terms included in this review were (indoor and air), ventilation, HVAC, air conditioning. Each potentially relevant reference was examined to confirm it relevance data and relevant data was extracted. This review contains COVID-19 research published up to August 13, 2020. Relevant literature predating COVID-19 was identified by examining the reference lists of the relevant reviews and papers included in this summary.

Preuve émergente sur la COVID-19

COVID-19 – Résumé en ce qui concerne les systèmes de chauffage, de ventilation, de climatisation (CVCA) et la transmission du virus SRAS-CoV-2

Introduction

Quelles répercussions les systèmes de chauffage, de ventilation et de climatisation (CVCA) ont-ils sur la transmission du virus SRAS-CoV-2?

Cette synthèse en bref résume la documentation pertinente disponible jusqu'au 13 août 2020 à propos du rôle que peuvent jouer les systèmes de CVCA dans la transmission du SRAS-CoV-2. Des données probantes associées à d'autres infections respiratoires connexes (c.-à-d. SRAS, MERS-CoV) ont également été incluses afin d'obtenir une meilleure compréhension du rôle que les systèmes de CVCA peuvent possiblement jouer dans la transmission de virus semblables.

Points clés

- La contamination des échantillons d'air et de surface du système de CVCA (p. ex., grilles d'air et filtres) par l'ARN du SRAS-CoV-2 dans les établissements de soins de santé indique qu'il est possible que ce système puisse permettre au virus de se propager (Tableau 1). La viabilité de l'ARN viral isolé n'a cependant pu être confirmée par la culture cellulaire dans la majorité des études, sauf dans deux études dans lesquelles des virus viables présents dans les échantillons d'air provenant des chambres de patients atteints de la COVID-19 ont pu être recueillis.
    - À l'aide d'une culture de virus (RT-qPCR), Lednicky et ses collaborateurs ont pu démontrer la présence dans l'air, d'un virus SRAS-CoV-2 viable, à une distance de 2 à 4,8 mètres des patients dans un milieu hospitalier (Lednicky et al., 2020). Les auteurs ont également suggéré que le fait que les particules de virus s'inactivent pendant le prélèvement d'échantillons explique pour quelle raison les études n'ont pas réussi à cultiver de virus SRAS-CoV-2 viable dans les échantillons d'air.
    - Des échantillons d'air prélevés dans un contexte hospitalier où étaient traités des patients atteints du SRAS-CoV-2 ont été contaminés par de l'ARN viral. Des indications mineures d'effet cytopathologiques et de réplication virale ont également pu être observées dans un échantillon d'air et de surface (Santarpia et al., 2020).
- Une seule étude a cependant fait état de la présence d'ARN du SRAS-CoV-2 en aval des filtres à air dans le système de ventilation d'un hôpital, mais la viabilité du virus isolé n'a pu être évaluée

(Tableau 1). Le risque d'infection au SRAS-CoV-2 en raison de l'air qui circule dans un système de ventilation n'a donc pas encore été établi.

- Un petit nombre de grappes de SRAS-CoV-2 ont cependant été attribuées à des unités de climatisation et de recirculation d'air (Tableau 2) dans un restaurant (Lu et al., 2020), dans un trajet d'autobus à destination d'un événement religieux et dans un atelier professionnel (Shen et al., 2020). Les puissants jets d'air créés par les climatiseurs et la recirculation de l'air intérieur sont jugés être des modes probables de transmission de particules respiratoires infectieuses d'un cas index vers d'autres personnes vulnérables se trouvant à proximité (Yuguo Li et al., 2020). D'autres enquêtes sur la flambée de SRAS-CoV-2 à bord d'un navire de croisière n'ont cependant pas permis de mettre en cause le système de CVCA dans la transmission de l'infection (Almilaji & Thomas, 2020; Xu et al., 2020).
- Puisqu'un lien entre une mauvaise ventilation (c.-à-d. niveau insuffisant de déplacement d'air et d'élimination de l'air intérieur contaminé) et la transmission de l'infection a été établi pour la transmission d'autres infections par coronavirus (c.-à-d. MERS et SRAS) antérieures au SRAS-CoV-2, il devrait en être de même pour le SRAS-CoV-2 (Tableau 4).
- Les déclarations d'experts et les documents d'orientation préconisent la mise à l'essai et la certification du système de CVCA afin d'en assurer le bon fonctionnement et de réduire au minimum, conformément aux normes locales, la présence de contaminants atmosphériques dans les environnements intérieurs.
- Les commentaires et revues qui tiennent compte de l'ensemble des données probantes sur le sujet ainsi que les modèles mathématiques indiquent constamment que l'apport d'air frais en provenance de l'extérieur dans les environnements bâtis (p. ex., par des fenêtres ouvertes) et la réduction de l'occupation dans les environnements intérieurs fermés, lorsque cela est possible et approprié, sont deux stratégies simples qui peuvent permettre d'atténuer la transmission du SRAS-CoV-2 à l'intérieur (Dai & Zhao, 2020; Dietz et al., 2020; Morawska & Cao, 2020).

Vue d'ensemble des éléments de preuve

Diverses enquêtes visaient à évaluer les données probantes qui établissent un lien entre les systèmes de CVCA/l'air intérieur et la transmission des infections, tant avant qu'après l'émergence de la COVID-19. La variabilité dans la conception des études, dans les milieux expérimentaux (établissements de soins de santé c. environnements non médicaux), dans les pathogènes viraux examinés et dans les systèmes de CVCA ne permet cependant pas d'effectuer de comparaison directe de la documentation disponible.

Neuf enquêtes sur la contamination de l'environnement dans les hôpitaux où se trouvaient des patients atteints de la COVID-19 ont permis de déceler des surfaces contaminées de virus (Tableau 1). Ces études présentent cependant un risque modéré de biais, puisqu'il s'agit d'observations ponctuelles qui, même si elles confirment la présence d'ARN viral, n'ont pu confirmer l'infectiosité de ces particules virales. Quatre éclosions dans lesquelles les systèmes de CVC ont été étudiés comme source de transmission d'infection ont

été décrites dans différentes études épidémiologiques rétrospectives (Tableau 2). Ces études épidémiologiques présentent un risque élevé de biais, comme le démontrent les rapports contradictoires à propos du navire de croisière Diamond Princess dans lesquels différentes approches et hypothèses analytiques ont mené à des conclusions différentes. Des modèles mathématiques et des simulations informatiques ont été paramétrés avec des données d'observation provenant d'un petit nombre d'éclosions pour explorer différents scénarios sur la façon dont les systèmes de CVC peuvent avoir une incidence sur le SRAS-CoV-2, le MERS et la transmission du SRAS (Tableaux 2 et 4). Il faut cependant faire preuve de prudence dans l'interprétation de ces constatations puisque la mesure dans laquelle les résultats peuvent être généralisés est variable.

Plusieurs lacunes ont également été notées dans la documentation actuelle sur la COVID-19. Les données probantes disponibles n'ont pas permis d'établir directement que les particules infectieuses du SRAS-CoV-2 aient pu se déplacer dans un système de CVCA ou dans le débit d'air généré par le système et entraîner une infection lorsqu'elles sont réintroduites dans une population de personnes vulnérables. Les données probantes sur le nombre optimal de changements d'air par heure requis dans des environnements non médicaux, sur les configurations idéales du système de ventilation et sur le rôle des filtres HEPA dans l'atténuation de la transmission du SRAS-CoV-2 sont cependant limitées.

CONTENU

DOCUMENTATION SUR LA TRANSMISSION DES INFECTIONS ET LES SYSTÈMES DE CVCA

Aucune étude ne quantifie spécifiquement le risque de transmission du SRAS-CoV-2 lié aux systèmes de CVCA ou à la ventilation intérieure. Neuf études ayant effectué un échantillonnage environnemental ont identifié l'ARN viral du SRAS-CoV-2 dans des échantillons d'air et sur les surfaces des composants du système de CVCA (p. ex., filtres de recirculation d'air avant et après, registres d'air, grilles d'air) dans des établissements de soins de santé où des patients atteints de COVID-19 étaient traités, mais la viabilité du virus et l'infectiosité n'ont pu être établies dans la majorité des études (Tableau 1). Par conséquent, la dispersion par un système de CVCA du virus viable du SRAS-CoV-2 viable n'a pas été démontrée.

Une seule grappe de cas de COVID-19 ayant touché les membres de trois familles non apparentées a été associée à la circulation d'air et aux courants d'air unidirectionnels générés par une unité de climatisation sans conduit dans un restaurant chinois (Lu et al., 2020). Dans cette grappe, le cas index de la famille A a mangé en amont des membres des familles B et C. Aucun autre lien ni exposition n'a pu être établi entre ces familles et la famille A et aucun autre membre du personnel ni aucun autre client du restaurant n'a été infecté

par le virus. La recirculation de l'air dans les environnements clos associée aux climatiseurs, à la ventilation intérieure et aux ventilateurs a joué un rôle dans deux éclosions non liées de SRAS-CoV-2 à la suite d'un événement à caractère religieux et d'un atelier professionnel (Shen et al., 2020). De plus, le système de CVCA à bord du navire de croisière Diamond Princess où l'on a dénombré une importante éclosion de COVID-19 a également fait l'objet d'une enquête afin d'avoir des preuves en ce qui concerne sa contribution à la propagation du SRAS-CoV-2. Une étude ayant cependant tenu compte du confinement, de la période de quarantaine et de la période d'incubation a fourni la preuve que la mise en quarantaine des passagers dans les cabines avait arrêté la transmission à bord du navire et qu'aucune transmission ne pouvait donc être attribuée à la ventilation (Xu et al., 2020). Une seconde étude qui a analysé les mêmes données a, quant à elle, suggéré que la transmission par l'air circulant aurait pu se produire, mais n'a pas tenu compte de la période d'incubation (Almilaji & Thomas, 2020).

Les enquêtes sur les grappes de coronavirus qui existaient avant l'apparition de la COVID-19 ont été associées à une mauvaise ventilation à l'intérieur et à des systèmes de CVC non fonctionnels (Haselbach et al., 2009; Y Li, Huang, Yu, Wong, & Qian, 2005; Satheesan, Mui, & Wong, 2020; Wong et al., 2004). De multiples enquêtes sur une grappe de cas de MERS-CoV dans une unité d'isolement ont attribué le fait que l'infection se soit propagée aux travailleurs de la santé à un débit d'air élevé près d'un patient infecté, à des débits d'air déséquilibrés en ce qui concerne l'alimentation en air et l'élimination de l'air vicié, ainsi qu'au mauvais fonctionnement du système d'échappement et de l'alimentation en air (Y Li et al., 2005; Wong et al., 2004). Une étude américaine sur les infections respiratoires aiguës qui se sont déclarées dans plusieurs casernes de l'armée de terre a cependant attribué l'augmentation des taux d'infection aux différentes configurations du système de CVCA (c.-à-d. le nombre de personnes qui entrent en contact avec l'air recirculé et respirent le même air provenant d'un système de CVCA). Elle n'a cependant pas pu exclure la transmission directe (Haselbach et al., 2009). Bien que cette documentation ne porte pas spécifiquement sur le SRAS-CoV-2, elle fournit des preuves indiquant qu'une mauvaise ventilation et des systèmes de CVCA non fonctionnels sont associés à la transmission des infections respiratoires dans les environnements intérieurs.

L'American Society of Heating, Refrigerating, and Air-Conditioning Engineers (ASHRAE), une autorité américaine de premier plan en matière de conception, d'exploitation et d'entretien des systèmes de CVCA, a publié un énoncé de position en avril 2020 sur la COVID-19. Elle y préconise notamment le bon fonctionnement des systèmes de CVCA, puisque ces systèmes sont conçus pour réduire les contaminants dans l'air intérieur et, par conséquent, minimiser la transmission aérienne de pathogènes comme le SRAS-CoV-2. Cet énoncé de déclaration a été adopté par d'autres organisations, y compris le Center for Disease Control and Prevention, dans le cadre des directives en ce qui concerne le retour au travail et la réouverture des entreprises.

Tableau 1 : Documentation sur la contamination de l'air par le SRAS-CoV-2 et les éventsdans les établissements de soins de santé

Référence	Titre de la publication	Principaux résultats
Études de l'environnement		
(Lednicky et al., 2020) *prépublication*	Un cas de SRAS-CoV-2 viable dans l'air d'une chambre d'hôpital où se trouvaient des patients atteints de COVID-19.	Des échantillons d'air ont été prélevés dans un hôpital désigné où étaient traités des patients infectés au SRAS-CoV-2 en Floride, aux États-Unis. Des échantillonneurs d'air VIV AS et BioSpot qui ont pu préserver la viabilité du virus ont été utilisés pour le prélèvement de ces échantillons. Un virus viable a ainsi pu être isolé dans des échantillons d'air prélevés à des distances variant entre 2 et 4,8 mètres des patients infectés, ce qui indique la dispersion d'un virus SRAS-CoV-2 viable dans les aérosols en suspension dans l'air dans les établissements de soins de santé. Le séquençage génomique a établi une relation entre l'ARN viral isolé des échantillons d'air et un patient infecté qui se trouvait dans le service. Ce virus viable n'a cependant pu être isolé qu'à partir d'échantillons d'air prélevés dans des tubes d'admission sans couvercle de filtre HEPA en fonction des effets cytopathiques sur les cellules Vero E6. Les concentrations de virus isolés dans les échantillons d'air variaient de 2 à 74 unités $TCID_{50}$/L d'air.
(Horve et al., 2020) *prépublication*	Identification de l'ARN du SRAS-CoV-2 dans les unités de chauffage, de ventilation et de conditionnement d'air des établissements de soins de santé.	Les surfaces des unités de traitement de l'air d'un établissement de soins de santé où étaient traités des patients atteints de la COVID-19 en Oregon, aux États-Unis, ont été testées pour y déceler la présence d'ARN viral dans les systèmes de CVCA. Le RT-PCR a confirmé la présence d'ARN viral. Ainsi, 25 % des surfaces échantillonnées provenant de plusieurs unités de traitement de l'air étaient contaminées par l'ARN du SRAS-CoV-2. Des échantillons positifs ont ainsi pu être obtenus sur des préfiltres (35 %), des registres d'air d'alimentation (20,8 %) et des filtres finaux (16,67 %). Le

		nombre de copies de gènes viraux récupérés a cependant diminué entre la surface du préfiltre et celle du filtre final. Les registres d'air d'alimentation et l'air échantillonné dans le cadre de cette étude comprenaient de l'air recirculé mélangé à de l'air provenant de l'extérieur avant et après le filtrage par le système CVCA. Les échantillons étaient cependant contaminés par de l'ARN viral, ce qui est préoccupant. Comme aucune tentative de culture du virus n'a été faite, d'autres recherches seront nécessaires pour étudier plus à fond les répercussions de cette étude puisque les systèmes de filtration typiques dans les établissements de soins de santé pourraient ne pas pouvoir éliminer complètement le passage des particules virales.
(Cheng et al., 2020)	Prélèvement d'échantillons d'air et d'échantillon sur le terrain pour déceler la présence du SRAS-CoV-2 près de patients hospitalisés et atteints de la maladie au coronavirus 2019 (COVID-19).	Des échantillons d'air prélevés près de patients asymptomatiques et symptomatiques atteints de COVID-19 (n=6) portant ou non un masque chirurgical dans une chambre d'isolement des infections aéroportées à Hong Kong et en Chine ont été analysés pour déterminer s'ils étaient contaminés par le SRAS-CoV-2. Tous les échantillons d'air prélevés étaient négatifs pour l'ARN du SRAS-CoV-2.
(Chia et al., 2020)	Détection de la contamination de l'air et des surfaces par le SRAS-CoV-2 dans les chambres d'hôpital des patients infectés.	Des échantillons de surface et d'air prélevés dans des chambres d'isolement des infections aéroportées où se trouvaient des patients atteints de la COVID-19 à Singapour ont été analysés afin de détecter la présence de l'ARN du SRAS-CoV-2. Parmi les échantillons de surface contaminés, les planchers étaient les plus contaminés, suivis des évents d'évacuation. 66 % (n=2/3) des échantillons d'air prélevés dans des chambres d'isolement des infections aéroportées étaient positifs pour l'ARN du SRAS-CoV-2. Les auteurs suggèrent que la présence du SRAS-CoV-2 dans l'air est plus importante pendant la première semaine de maladie, alors que la charge virale respiratoire est élevée.

		L'infection des particules virales récupérées n'a cependant pas été évaluée.
(Liu et al., 2020)	Analyse aérodynamique du SRAS-CoV-2 dans deux hôpitaux de Wuhan	Les concentrations d'ARN du SRAS-CoV-2 dans les échantillons d'aérosols, ainsi que la taille et le dépôt des aérosols du SRAS-CoV-2 en suspension dans l'air provenant d'hôpitaux de Wuhan, en Chine, ont été quantifiés. Les environnements échantillonnés comprennent les services de soins aux patients, les espaces publics et les espaces réservés au personnel au sein ou à proximité d'un hôpital, et les environnements des hôpitaux de campagne. Dans les espaces de soins aux patients, les concentrations de SRAS-CoV-2 provenant d'échantillons d'air étaient très faibles à indétectables, ce qui indique que la chambre d'isolement à pression négative et le taux élevé d'échange d'air étaient efficaces. Dans le cadre de l'hôpital de campagne, les plus fortes concentrations de SRAS-CoV-2 dans les aérosols en suspension ont été identifiées dans la salle de toilette temporairement mal ventilée d'un patient (1 m^2). Dans les zones publiques, des concentrations faibles à indétectables de SRAS-CoV-2 dans les aérosols en suspension ont été identifiées dans la majorité des espaces publics échantillonnés. Cependant, les concentrations de virus ont été détectées dans deux sites publics, à l'entrée d'un grand magasin et sur un site extérieur près d'un hôpital. Les résultats indiquent qu'une circulation élevé et un grand nombre de personnes peuvent tous deux jouer un rôle dans la détection du SRAS-CoV-2 dans les échantillons d'air. Les secteurs où se trouvaient des travailleurs de la santé affichaient les concentrations les plus élevées de SRAS-CoV-2 et les plus grandes distributions de la taille des aérosols. Les échantillons prélevés sur l'équipement de protection individuelle que portait les membres du personnel des

		hôpitaux de campagne et dans les vestiaires de ces hôpitaux ont montré les plus fortes concentrations de virus et la plus grande distribution de la taille des aérosols. Les auteurs ont émis l'hypothèse que ces concentrations élevées observées étaient attribuables à la remise en suspension du virus contenant des aérosols provenant des surfaces de l'EPI et des vêtements que portaient les travailleurs de la santé. L'infection des particules virales récupérées n'a cependant pas été établie.
(Guo et al., 2020)	Distribution en aérosol et en surface du coronavirus 2 du syndrome respiratoire aigu sévère dans les services hospitaliers, Wuhan, Chine, 2020	35 % des échantillons d'air prélevés dans les services de soins intensifs des hôpitaux et les services généraux de Wuhan, en Chine, et testés pour détecter des particules du virus SRAS-CoV-2 se sont révélés positifs. Des échantillons positifs ont été identifiés près des sorties d'air (35,7 %), des chambres des patients (44,4 %) et des bureaux des médecins (12,5 %). Les échantillons chargés de virus ont été le plus souvent identifiés en aval des patients souffrant de la COVID-19. Dans l'espace des unités de soins intensifs, les zones de soins et de traitement des patients, des aérosols du virus SRAS-CoV-2 ont été trouvés et des échantillons positifs ont également été identifiés jusqu'à 4 mètres des patients atteints de COVID-19. Dans les espaces de soins généraux, les zones testées positives au SRAS-CoV-2 se trouvaient à moins de 2,5 mètres en amont d'un patient. Aucun aérosol du virus SRAS-CoV-2 n'a été identifié dans les couloirs fréquentés par les patients. L'infection des particules virales récupérées n'a cependant pas été établie.
(Ong et al., 2020)	Contamination de l'air, des surfaces environnementales et des équipements de	Enquête sur des échantillons d'air prélevés dans des chambres d'isolement des infections aéroportées à pression négative qui comprennent des antichambres et des salles de bain, dans le centre spécialisé d'éclosion du SRAS-CoV-2 à

	protection individuelle par le coronavirus 2 du syndrome respiratoire aigu sévère (SRAS-CoV-2) chez un patient symptomatique	Singapour, où se trouvent trois cas symptomatiques confirmés de COVID-19. Bien que certains échantillons environnementaux aient été contaminés par le SRAS-CoV-2, aucun échantillon d'air n'a révélé la présence du virus du SRAS-CoV-2. L'infection des particules virales récupérées n'a cependant pas été établie.
(Santarpia et al., 2020) *prépublication*	Potentiel de transmission du SRAS-CoV-2 par les aérosols et les surfaces	Des échantillons d'air et de surface provenant d'espaces isolés abritant des cas de COVID-19 à l'Université du Nebraska aux États-Unis ont été recueillis et testés par RT-PCR pour détecter la présence de l'ARN viral du SRAS-CoV-2. 63,2 % des échantillons d'air prélevés dans les espaces isolés pour les patients étaient positifs pour l'ARN viral, en particulier sous le lit du patient et sur les rebords des fenêtres à l'extrémité de la pièce. Selon la modélisation du débit d'air, les auteurs suggèrent que des tourbillons turbulents (c.-à-d. des tourbillons d'un fluide et le courant inverse qui est créé lorsque le fluide se trouve dans un flux turbulent) qui se forment sous le lit du patient et le flux d'air dominant transportent les particules respiratoires/virales loin du patient, vers les extrémités de la pièce. Ce serait donc ce qui a permis d'obtenir la contamination observée. Le virus se trouvait également dans 58,3 % des échantillons d'air prélevés dans les couloirs à l'extérieur des espaces isolés pour les patients. L'étude a également permis de récupérer la charge virale la plus élevée (1,75 copie/µL) observée de la surface contaminée d'une grille d'aération. Les conclusions de l'étude suggèrent que les particules d'aérosol viral peuvent être produites par les personnes infectées même en l'absence de toux, puisque le virus peut parcourir des distances supérieures à 1,8 mètre.

		La culture de l'ARN viral isolé n'a pu être confirmée par un essai sur les cellules Vero E6 en raison des faibles concentrations du virus récupéré. Toutefois, des indications mineures d'effet cytopathologiques et de réplication virale ont pu être observées dans un échantillon d'air et de surface.
(Zhou et al., 2020)	Enquête sur la contamination de la surface et de l'air par le SRAS-CoV-2 dans un service de soins actifs au plus fort de la pandémie de COVID-19 à Londres	Les niveaux de contamination de surface et d'air du SRAS-CoV-2 dans un hôpital de Londres, au Royaume-Uni, au plus fort de la pandémie de COVID-19 ont été évalués. Des écouvillons de surface ont été utilisés pour effectuer des prélèvements dans les zones cliniques et publiques de l'hôpital. L'ARN viral a été détecté par RT-PCR dans 52,3 % des échantillons de surface prélevés (le plus souvent dans les espaces de soins aux patients atteints de la COVID-19) et dans 38,7 % des échantillons d'air prélevés. Les échantillons contaminés étaient plus nombreux dans les espaces occupés par des patients atteints de la COVID-19. Le virus récupéré n'a pas pu être cultivé dans les lignées cellulaires Vero E6, puisque la charge virale récupérée était inférieure à 30 Ct.
Modèles mathématiques		
(Dai & Zhao, 2020) *prépublication*	Lien entre la probabilité d'infection à la COVID-19 et les taux de ventilation dans les espaces confinés : une enquête fondée sur l'équation de Wells-Riley	L'équation mathématique de Wells-Riley a été utilisée pour déterminer le lien entre la probabilité d'infection et les taux de ventilation intérieure. Les auteurs indiquent que si les taux de ventilation et les périodes d'exposition suivants étaient appliqués (valeur variant entre 100 et 350 m^3/h et 1 200 et 4 000 m^3/h pendant 15 minutes et 3 heures), moins de 1 % de la population vulnérable ne portant pas de masque serait infectée dans des espaces intérieurs confinés. Par contre, si les personnes infectées et les personnes vulnérables portent un masque, le débit de ventilation pourra alors être réduit à une valeur variant entre 50 et 180 m^3/h et entre 600 et 2 000 m3/h. Les auteurs affirment que les anciens taux seraient plus faciles à atteindre grâce aux modèles de ventilation normalement utilisés dans les

		bureaux, les salles de classe, les autobus et les cabines d'aéronefs.
Commentaires		
(Melikov, Ai, & Markov, 2020)	Occupation intermittente combinée à la ventilation : une stratégie efficace pour réduire la transmission aéroportée à l'intérieur	En raison des limites inhérentes à la plupart des systèmes de ventilation mécanique, il n'est pas possible d'augmenter l'alimentation en air frais pour éliminer le risque d'infection par les aérosols en suspension dans l'air expiatoire en milieu intérieur. Par conséquent, les auteurs proposent une stratégie de contrôle à la source fondée sur des pauses intermittentes pour les occupants (c.-à-d. que tous les occupants quittent périodiquement la pièce) et sur des taux d'occupation de la pièce réduits afin de maximiser l'efficacité des systèmes de ventilation intérieure qui réduisent les pathogènes infectieux en suspension dans l'air.
(Morawska & Cao, 2020)	Transmission aérienne du SRAS-CoV-2 : le monde devrait faire face à la réalité.	Selon les preuves disponibles, les auteurs concluent que le virus SRAS-CoV-2 peut probablement être transmis par voie aérienne. Par conséquent, il faut donc prendre toutes les précautions possibles contre la transmission par voie aérienne dans les scénarios intérieurs. Les précautions comprennent augmenter le débit de ventilation, utiliser une ventilation naturelle, éviter la recirculation de l'air, éviter de rester dans le flux d'air direct d'une autre personne et réduire le nombre de personnes qui se trouvent dans le même environnement. Il est important de maximiser la ventilation naturelle dans les bâtiments qui sont ou peuvent être ventilés naturellement en s'assurant d'obtenir un débit de ventilation suffisamment élevé.
(Dietz et al., 2020)	Pandémie du nouveau coronavirus de 2019 : considérations en ce qui concerne l'environnement bâti pour réduire la transmission	Un examen des données probantes disponibles sur l'environnement bâti qui peuvent être appliquées à la pandémie actuelle de COVID-19. Le SRAS-CoV-2 a été observé dans des particules et des gouttelettes aérosolisées d'une gamme de tailles, y compris de 0,25 à 0,5 µm, qui nécessitent une filtration haute efficacité pour les éliminer de l'air intérieur partagé. Les systèmes de ventilation résidentiels et commerciaux ayant des valeurs minimales d'efficacité (VEEM) de 8 peuvent seulement capter de 70 à 85 % des particules de 3,0 à

		10,0 µm (ce qui n'est pas suffisant pour les aérosols du virus SRAS-CoV-2). Les systèmes de ventilation des filtres VEEM 13 ou supérieurs et HEPA couramment utilisés dans les établissements de soins de santé élimineraient efficacement les particules de 0,25 à 0,5 µm. Toutefois, les auteurs indiquent des limites dans les systèmes et filtres de CVCA dans les établissements de soins de santé en raison des espaces dans les bordures des filtres. Dans l'ensemble, les auteurs font remarquer que, bien que des taux de ventilation plus élevés, de l'air extérieur et des filtres de qualité supérieure puissent réduire et diluer les contaminants atmosphériques (c.-à-d. les particules infectieuses) dans l'air intérieur, ces éléments ne permettent toutefois jamais d'éliminer complètement le risque de transmission des infections par voie aérienne.

Tableau 2 Les grappes d'infection à la COVID-19 sont principalement attribuées à la ventilation intérieure

Référence	Titre de la publication	Principaux résultats
(Lu et al., 2020)	Foyer de COVID-19 liée à la climatisation d'un restaurant, Guangzhou, Chine	Le débit d'air de la ventilation intérieure et la transmission de gouttelettes à des distances inférieures à 1 mètre sont vus comme les principaux modes de transmission pour une grappe (n=10) attribuée à un système de climatisation utilisé dans un restaurant lors d'un repas. La seule interaction entre les cas multiples de cette grappe (famille B et famille C) et le cas index (famille A) était le fait d'avoir été assis à des tables voisines. En raison de la façon dont les tables étaient disposées, la sortie d'air et l'entrée d'air de retour du climatiseur central étaient situées au-dessus de la table de la famille C, et les trois tables étaient alignées avec le flux d'air diffusé par le même appareil de climatisation. La transmission de l'infection par les gouttelettes et les aérosols en raison de la circulation de l'air conditionné est

		donc vue comme le mode de transmission qui a infecté les membres de ces trois familles.
(Yuguo Li et al., 2020) *prépublication*	Preuve de la transmission probable du SRAS-CoV-2 par aérosol dans un restaurant mal ventilé	Une analyse de suivi approfondie de l'éclosion dans le restaurant par des simulations informatiques et une analyse aérodynamique a permis de conclure que la transmission était conforme à une propagation virale associée à une mauvaise ventilation, aux zones de débit d'air créées par l'unité de traitement de l'air et aux particules respiratoires chargées de virus qu'expirait le cas index.
(Almilaji & Thomas, 2020) *prépublication*	Rôle de la recirculation de l'air dans l'infection à la COVID-19, leçons tirées du bateau de croisière Diamond Princess.	D'après l'analyse des données cliniques des passagers de ce navire de croisière, les infections symptomatiques diagnostiquées après le début de la quarantaine étaient les mêmes dans les cabines, qu'elles aient ou non inclus une personne infectée. Les auteurs concluent que la transmission aéroportée du SRAS-CoV-2 par le système de ventilation du navire de croisière pourrait expliquer les taux d'infection observés pendant la période de quarantaine.
(Xu et al., 2020) *prépublication*	Itinéraires de transmission du virus de la COVID-19 à bord du navire de croisière Diamond Princess	L'analyse des données sur les passagers et les cas de COVID-19 (n=343) du groupe de navires de croisière Diamond Princess a tenu compte des systèmes de CVCA et d'égouts du navire et des facteurs de risque épidémiologiques de chaque cas et d'un contact étroit pour explorer les modes de transmission les plus plausibles. D'après les analyses, les auteurs ont conclu que le système de CVCA du navire de croisière n'a pas joué un rôle dans la transmission aéroportée sur longue distance du virus de la COVID-19 à bord du navire et que la plupart des passagers ont probablement été exposés avant que le navire ne soit mis en quarantaine.
(Shen et al., 2020) *prépublication*	Transmission aérienne de COVID-19 : preuves épidémiologiques issues de l'enquête sur deux foyers	On suppose que la transmission aéroportée par aérosols a été favorisée par les ventilateurs et les unités de climatisation (recirculation d'air) dans les espaces de transport et dans les espaces intérieurs communs et qu'elle a contribué à deux éclosions indépendantes de COVID-19. La première a touché les passagers d'un autobus qui se rendaient dans un lieu de culte et en revenaient (n=172) et la deuxième visait plutôt un

		atelier-conférence de trois jours (n=30) dans lequel les participants ont partagé un espace de réunion intérieur. En ce qui concerne la première éclosion, le risque d'infection par la COVID-19 chez les passagers de l'autobus nº 2 était 41,5 fois plus élevé (IC à 95 %, de 2,6 à 669,5) que pour les passagers de l'autobus nº 1 et de 11,4 fois plus élevé (IC à 95 %, de 5,1 à 25,4) que pour toutes les autres personnes ayant pris part à cet événement. Le taux d'attaque global à la suite de l'éclosion dans le cadre de la conférence était de 48,3 %.

Tableau 3 Littérature grise sur la transmission de la COVID-19 et les systèmes de CVCA

Référence	Organisation	Déclarations clés
(ASHRAE, 2020) Accéder ici	American Society of Heating, Refrigerating, and Air-Conditioning Engineers	Document de position de l'ASHRAE sur les aérosols infectieux publié en avril 2020. La transmission du SRAS-CoV-2 par l'air est assez probable et l'exposition au virus par voie aéroportée devrait être contrôlée. Les changements apportés au fonctionnement de l'immeuble, y compris le fonctionnement des systèmes de chauffage, de ventilation et de climatisation, peuvent réduire l'exposition par voie aéroportée. La ventilation et la filtration fournies par les systèmes de CVCA peuvent réduire la concentration atmosphérique de SRAS-CoV-2 et donc le risque de transmission dans l'air.
(CSA Group, 2020) Accéder ici	Groupe CSA	Normes d'essai et de certification de l'équipement de CVCA (destiné aux établissements de soins de santé) pour les fabricants. Norme CSA Z317.2:19 : Systèmes de chauffage, de ventilation et de conditionnement d'air (CVCA) dans les établissements de soins de santé : exigences particulières

		Norme CAN/CSA-Z317.13-17 : Lutte contre l'infection pendant les travaux de construction, de rénovation et d'entretien dans les établissements de santé
(CDC, 2020) Accéder ici	Center for Disease Control and Prevention	Les conseils d'experts en ce qui concerne les préparatifs des entreprises et la réouverture de ces dernières font référence à l'énoncé de déclaration de l'ASHRAE sur les systèmes de CVC et au guide de démarrage du système de CVC. Les lignes directrices font allusion au fait de s'assurer que les systèmes de CVCA fonctionnent correctement. Accroître la circulation de l'air provenant de l'extérieur en ouvrant les fenêtres et les portes après avoir évalué les risques de l'air extérieur pour les occupants. Parmi les autres recommandations énoncées dans les documents, mentionnons augmenter l'approvisionnement en air dans les espaces occupés, désactiver les contrôles de la ventilation de contrôle de la demande qui réduisent l'approvisionnement en air selon la température ou l'occupation, utiliser une ventilation naturelle, améliorer la filtration centrale de l'air, faire fonctionner le système de ventilation pendant les périodes inoccupées, générer des mouvements d'air propre à moins propre, penser à utiliser des systèmes portatifs de ventilation et de filtration à haute efficacité des particules d'air (HEPA), s'assurer que les ventilateurs d'évacuation des toilettes sont fonctionnels et en état de fonctionner; et envisager d'utiliser l'irradiation germicide aux ultraviolets comme supplément.
(ECDC, 2020) Accéder ici	Centre européen de prévention et de contrôle des maladies	Conseils sur les systèmes de chauffage, de ventilation et de climatisation dans le contexte de la COVID-19. Le document traite de l'entretien, de l'évitement de la recirculation, de la direction du ventilateur et du taux d'échange d'air.
(AHS, 2020) Accéder ici	Services de santé de l'Alberta	Rapid Evidence Report Décrit les données probantes et la littérature grise sur la transmission de la COVID-19 et les systèmes de CVCA dans les milieux de soins de santé et les milieux non médicaux disponibles jusqu'au 11 mai 2020. Les principales

		constatations découlant de l'examen des données probantes indiquent que les facteurs associés au système de CVCA peuvent contribuer à la transmission d'agents pathogènes, surtout lorsque ces deniers ne fonctionnent pas correctement. Le potentiel exact dans lequel les systèmes de CVCA peuvent contribuer à la transmission de l'infection par le SRAS-CoV-2 n'a pas pu être évalué en raison du peu de données probantes sur les virus viables dans les échantillons d'air, de la variabilité des systèmes de CVCA et de la complexité des modalités de transmission. Le Comité d'examen recommande la création d'un comité possédant l'expertise nécessaire pour explorer le rôle des systèmes de CVCA dans la transmission des pathogènes viraux, y compris le CoV-2 du SRAS.

Tableau 4 Transmission d'autres infections (excluant le SRAS-CoV-2) et systèmes de CVCA

Référence	Titre de la publication	Principaux résultats
(Wong et al., 2004)	Grappe de cas du SRAS chez des étudiants en médecine ayant été exposés à un seul patient, Hong Kong.	Description de l'éclosion de SRAS dans une unité d'isolement d'un hôpital de Hong Kong, chez les travailleurs de la santé. Des données épidémiologiques sur les travailleurs de la santé exposés, une inspection du système de ventilation et une analyse dynamique des fluides de calcul ont révélé que la chambre du patient avait le débit d'approvisionnement le plus élevé alors que la grille d'échappement adjacente présentait le débit le plus faible parmi les quatre grilles d'échappement fonctionnelles de l'unité. Les auteurs discutent de la possibilité de transmission d'aérosols du patient index par l'entremise du système de ventilation.
(Y Li et al., 2005)	Rôle de la distribution de l'air dans la transmission du SRAS lors de la plus grande épidémie nosocomiale à Hong Kong	Une deuxième analyse rétrospective des cas de patients hospitalisés et des cas de travailleurs de la santé associés à l'éclosion de SRAS mentionnée ci-dessus est présentée plus en détail.

		Les inspections sur place, les mesures de la conception de la ventilation et de la distribution de l'air, ainsi que les simulations de la dynamique des fluides par calcul concluent que les déséquilibres dans le débit d'air et les composants non fonctionnels du système de CVCA (p. ex., diffuseurs d'alimentation et grilles d'échappement) ont contribué à la transmission de l'infection. L'analyse a révélé la nécessité d'améliorer les systèmes de ventilation et de climatisation dans l'unité d'isolement afin de réduire efficacement le risque de propagation de l'infection entre les patients et les travailleurs de la santé.
(Satheesan et al., 2020)	Une étude numérique des stratégies de ventilation visant à atténuer les risques d'infection dans les services d'hospitalisation générale	Des simulations ont été appliquées pour examiner les mécanismes de transport et les modèles de dépôt du MERS-CoV dans une unité générale. Les auteurs ont conclu que les taux de changement d'air et de débit d'air d'extraction avaient des répercussions importantes sur le débit d'air et la distribution des particules. Dans l'espace ventilé mécaniquement, des grilles d'échappement près d'un patient (idéalement au-dessus du lit de chaque patient) et des débits d'air d'extraction élevés sont recommandés pour réduire la transmission.
(Haselbach et al., 2009)	Transmission aéroportée des infections respiratoires aiguës dans les installations militaires en raison du système de CVCA? Examen d'une étude de cohorte sur la formation de base.	Examen des infections aiguës des voies respiratoires chez les nouveaux militaires qui vivaient dans les casernes militaires qui tient compte de la configuration des systèmes de CVCA et du nombre d'occupants de plusieurs zones qui se partagent l'air de retour mélangé dans le même système de CVCA et redistribué comme air d'approvisionnement (population de contact). L'étude a révélé un risque important de transmission aérienne des particules aéroportées par les systèmes de CVCA. Des taux d'infection plus élevés ont été observés dans les systèmes où les populations avaient un plus grand contact avec le système de CVCA et où l'accès aux fenêtres était

		réduit, empêchant la ventilation extérieure et l'alimentation en air.
(Sundell et al., 2011)	Taux de ventilation et santé : revue pluridisciplinaire de la documentation scientifique.	Une équipe d'examen multidisciplinaire a exploré les données probantes (publiées jusqu'en 2005) établissant un lien entre le taux de ventilation et de multiples effets sur la santé. Les données probantes démontrent la plausibilité biologique d'un lien entre les résultats pour la santé et les taux de ventilation, mais ne fournissent pas de preuves claires sur aucun agent ou aucune charge infectieuse particuliers.
(Y. Li et al., 2007)	Rôle de la ventilation dans la transmission aéroportée d'agents infectieux dans l'environnement bâti - étude systématique multidisciplinaire.	L'examen de la documentation publiée entre 1960 et 2005 a permis de trouver dix articles établissant un lien entre la transmission des infections et les systèmes de CVCA. Les examinateurs ont conclu qu'il existe des preuves solides et suffisantes démontrant un lien entre la ventilation, les mouvements de l'air dans les bâtiments et la transmission ou la propagation de maladies infectieuses comme la rougeole, la tuberculose, la varicelle, la grippe, la variole et le SRAS. Il n'y avait toutefois pas suffisamment de données pour préciser et quantifier les exigences minimales en matière de ventilation dans les hôpitaux, les écoles, les bureaux, les maisons et les salles d'isolement en ce qui a trait à la propagation des maladies infectieuses par voie aérienne.

Méthodes :

Une analyse quotidienne de la littérature (publiée et prépubliée) est effectuée par le groupe des sciences émergentes de l'ASPC. L'analyse a permis de compiler la littérature sur la COVID-19 depuis le début de l'épidémie et est mise à jour quotidiennement. Les recherches pour trouver la littérature pertinente sur la COVID-19 sont menées par Pubmed, Scopus, BioRxiv, MedRxiv, ArXiv, SSRN, Research Square et sont recoupées avec la littérature de la liste de littérature COVID de l'OMS, et les centres d'information de la COVID-19 gérés par Lancet, BMJ, Elsevier et Wiley. Le résumé quotidien et les résultats complets de l'analyse sont conservés dans une base de données Refworks et une liste Excel consultable. Une recherche ciblée par mot-clé est effectuée dans ces bases de données pour identifier les citations pertinentes sur la COVID-19 et le SRAS-CoV-2. Les termes de recherche inclus dans cette revue étaient (indoor et air), ventilation, HVAC, air conditioning. Chaque référence potentiellement pertinente a été examinée pour confirmer qu'elle comportait des données pertinentes et les données pertinentes ont été extraites. Cette revue contient des recherches

publiées sur la COVID-19 jusqu'au 13 août 2020. La documentation pertinente antérieure à la COVID-19 a été établie en examinant les listes de référence des revues et des documents pertinents inclus dans la présente synthèse.

Nouveaux éléments de preuve sur la COVID-19

COVID-19 – Résumé des études sur l'utilisation d'écrans faciaux pour prévenir la transmission du SRAS-CoV-2

Introduction

Quelle est l'efficacité des écrans faciaux pour prévenir la transmission du virus SRAS-CoV-2, en combinaison avec le masque et sans masque?

Cette note d'information résume les recherches pertinentes sur les écrans faciaux utilisés dans la prévention de la transmission par gouttelettes et par aérosols de personnes infectées aux personnes vulnérables, publiées avant le 7 juillet 2020. La protection des yeux et l'utilisation de lunettes de protection ne sont pas prises en compte dans cette revue.

Points clés

- Les écrans faciaux sont une forme d'équipement de protection individuelle utilisée dans les établissements de santé (p. ex. soins chirurgicaux/médicaux, dentaires, vétérinaires) pour couvrir le visage et les muqueuses (yeux, nez, bouche) et prévenir l'exposition aux particules infectieuses provenant d'aérosols et de projections de liquides organiques. Un écran facial est souvent utilisé lors de procédures médicales au cours desquelles le risque d'aérosols ou de projections de liquides organiques provenant du patient est accru. Il est porté avec d'autres équipements de protection individuelle (p. ex. masques médicaux, respirateurs, blouses médicales) (Roberge, 2016).
- Toutes les études incluses dans cette revue sont des expériences menées dans des conditions contrôlées. À l'exception d'une étude qui a utilisé des liquides contaminés par la grippe (Lindsley et al., 2014), les études de cette revue n'ont pas utilisé de liquides contaminés par des virus.
- Les études sur l'utilisation des écrans faciaux par les travailleurs de la santé font état d'un effet protecteur, notamment contre les projections de liquides organiques produites par les patients lors de procédures médicales particulières, lorsqu'ils sont utilisés en combinaison avec d'autres équipements de protection tels qu'un masque chirurgical (tableau 1 et tableau 2) (Mansour et al., 2009; Mostaghimi et al., 2020; Shoham et al., 2016). Des écrans faciaux ont également été conçus pour que le patient puisse les porter lorsqu'il subit une procédure générant des aérosols afin de contenir ces derniers et de protéger les travailleurs de la santé qui effectuent la procédure contre l'exposition (Anon, Denne et Rees, 2020).
- Deux études de simulation recensées portent sur l'inhalation de gouttelettes et l'exposition dans des situations où l'écran facial est le seul équipement de protection porté (tableau 1). Les deux études indiquent que 90 % des grosses gouttelettes générées par une toux dirigée vers le milieu de l'écran facial ont été bloquées (Lindsley et al., 2014; Ronen et al., 2020). Cependant, les effets protecteurs

diminuent lorsque la direction de la toux varie (plus haut/plus bas/côté). Au fil du temps (30 minutes), l'inhalation de petites gouttelettes n'a été réduite que de 23 % par l'écran facial (Lindsley et al., 2014).

- Trois études ont simulé la toux chez une personne portant l'écran facial et ont rapporté le niveau de contamination résultant des particules respiratoires projetées (tableau 1 et tableau 2). Deux études font état de la libération de gouttelettes et d'aérosols par les ouvertures de l'écran facial (Anon et al., 2020; Viola et al., 2020), tandis qu'une troisième indique que le masque facial constituait une bonne barrière vers l'avant, car aucune gouttelette n'a atteint un simulateur situé à 60 cm (Ronen et al., 2020).
- La conception du masque facial serait importante. Les écrans faciaux qui s'enroulent davantage autour du visage, protégeant entièrement la zone des joues, et qui s'enroulent sous le menton, ainsi que toute amélioration qui réduit au minimum les fuites/entrées de bioaérosols autour des bords du masque, offraient une meilleure protection (Viola et al., 2020; Anon et al., 2020; Mostaghimi et al., 2020).

Vue d'ensemble des éléments de preuve

Peu d'études examinent et rapportent les effets protecteurs des écrans faciaux portés en combinaison avec un masque ou sans masque. Toutes les études recensées font état de résultats d'études de simulation menées dans des laboratoires contrôlés et ne tiennent pas nécessairement compte des paramètres du monde réel (par exemple, les différences de taille entre les personnes, les températures, l'humidité, la vitesse du vent, etc.) ni de la dose infectieuse. Aucune des études n'a utilisé le SARS-CoV-2 dans la simulation. Les différences entre les études en ce qui concerne leur conception, la manière dont les résultats ont été mesurés et les écrans utilisés font en sorte que les résultats ne sont pas directement comparables. Bien que l'ensemble des preuves disponibles soutiennent l'utilisation d'écrans faciaux parallèlement aux masques médicaux dans les établissements de soins de santé, les résultats des études sur le port d'écrans faciaux seuls ont révélé de manière moins systématique un effet protecteur.

CONTENU

EFFICACITÉ DES ÉCRANS FACIAUX

Parmi les études recensées, aucune n'a évalué l'efficacité de l'utilisation d'un écran facial sur le terrain pour prévenir la transmission d'infections respiratoires.

Dans les établissements de soins de santé, deux études de simulation évaluant diverses procédures médicales ont montré que les écrans faciaux, généralement portés avec un masque médical, protègent le visage des

travailleurs de la santé contre les projections de liquides en fournissant une barrière physique, ainsi qu'une certaine protection contre l'inhalation de petits aérosols et de noyaux de gouttelettes (tableau 1) (Mansour et al., 2009; Shoham et al., 2016). Une étude a montré que la combinaison d'un couvre-visage et d'un écran facial est plus efficace que l'un ou l'autre utilisé seul (Mansour et al., 2009), tandis que dans une autre étude, on a constaté qu'un écran facial complet offrait une meilleure protection que la combinaison d'un écran oculaire et d'un masque chirurgical (Shoham et al., 2016).

Deux études portant sur l'efficacité des écrans faciaux utilisés comme seul équipement de protection, dans le cadre desquelles on a comparé les écrans faciaux et les autres couvre-visage, ont révélé que les écrans faciaux sont des barrières efficaces pour le blocage à court terme des gouttelettes (Lindsley et al., 2014; Ronen et al., 2020). L'étude de Ronan et coll. décrit les effets protecteurs à court terme d'un écran facial bloquant 90 % des projections générées par une toux à 60 cm de distance, dirigées vers le centre de l'écran facial. Dans la même simulation, un masque facial a bloqué la moitié des gouttelettes. L'effet protecteur de l'écran facial diminue de manière significative lorsque la direction de la toux (plus haut/plus bas/côté) est modifiée (Ronen et al., 2020). De même, Lindsley et coll. ont rapporté que les écrans faciaux réduisent de 90 % l'inhalation de grosses gouttelettes et de plus de 60 % l'inhalation de petites gouttelettes immédiatement après une toux. Cependant, l'inhalation de gouttelettes plus petites n'a été réduite que de 23 %, car le temps écoulé depuis la toux (c'est-à-dire l'événement de génération d'aérosols) a été augmenté à 30 minutes. Cette augmentation du risque d'inhalation d'aérosols et de petites gouttelettes est attribuée à la formation, au fil du temps, de noyaux de gouttelettes plus petites qui peuvent s'infiltrer par les bords de l'écran facial (Lindsley et al., 2014).

Les trois études de simulation évaluant le niveau de contamination par les particules respiratoires d'une personne portant un écran facial ont fait état d'une bonne barrière vers l'avant pour la projection de gouttelettes respiratoires (Ronen et al., 2020). Cependant, de puissantes projections de bioaérosols fuyant vers l'arrière et vers le bas ont été mesurées (Viola et al., 2020; Anon et al., 2020). La projection de grosses gouttelettes et la contamination sous le cou et au niveau de la poitrine ont eu lieu lorsqu'un patient portant un écran facial standard a subi une procédure simulant la production d'aérosols, comme l'endoscopie souple (Anon et al., 2020). L'observation du flux d'air et de l'éjection de bioaérosols lorsque l'on porte différents types d'écrans faciaux montre que le flux d'air frontal généré par la respiration, la parole forte et la toux est largement réduit, mais qu'il y a toujours des fuites importantes d'aérosols. De puissantes projections de bioaérosols fuyant de l'écran facial ont été observées près de la région du front du porteur et vers le bas.(Viola et al., 2020). Cependant, malgré les fuites mesurées dans deux études, la troisième étude a fait état d'une bonne barrière vers l'avant. Cette constatation est fondée sur les résultats expérimentaux obtenus au moyen d'un simulateur de respiration placé à 60 cm d'un simulateur de toux avec écran facial, sur lequel on n'a observé aucune inhalation ni présence de projections de gouttelettes(Ronen et al., 2020). Par conséquent, les bioaérosols s'échappent dans l'environnement lorsqu'un individu porte un écran facial.

Tableau 1 : Littérature sur l'efficacité des écrans faciaux

Titre de la publication	Principaux résultats	Référence

Études expérimentales et de simulation		
Efficacy of Face Shields Against Cough Aerosol Droplets from a Cough Simulator	Expérience de simulation (écrans faciaux uniquement) : L'efficacité des écrans faciaux pour bloquer la transmission des aérosols est mesurée à l'aide d'un simulateur de respiration destiné à imiter un travailleur de la santé, et d'un simulateur d'aérosols projetés lors d'une toux qui contiennent le virus de la grippe. L'étude révèle une réduction de plus de 90 % du risque d'inhalation des grands aérosols (diamètre moyen de 8,5 µm) avec utilisation d'un écran facial, et une réduction de plus de 60 % du risque d'inhalation des petits aérosols (taille de 3,4 µm) immédiatement après la toux. Les écrans faciaux n'ont entraîné qu'une réduction de 23 % du risque d'inhalation des petits aérosols lorsque la toux générant les aérosols s'est produite dans les 30 minutes précédentes. L'augmentation du risque est due au fait que les petites particules restent en suspension plus longtemps, flottent autour de l'écran facial et peuvent ensuite être inhalées.	(Lindsley et al., 2014)
Face Coverings, Aerosol Dispersion and Mitigation of Virus Transmission Risk	Expérience de simulation et étude menée sur des humains (comparaison entre l'écran facial et le masque chirurgical, le masque fait maison et le respirateur) Les chercheurs utilisent la technique schlieren pour étudier l'éjection de flux d'air par des volontaires individuels et des mannequins utilisant différents couvre-visage pendant la respiration, la toux et les procédures générant des aérosols. Les fuites de bioaérosols observées avec différents masques faciaux (c.-à-d. masques faits maison et masques chirurgicaux, respirateurs filtrants [FFP1, FFP2], respirateurs N95 et écrans faciaux légers et robustes) ont été visualisées. Dans l'ensemble, l'étude révèle que tous les dispositifs de protection du visage ont réduit considérablement le flux frontal des bioaérosols. Seul le FFP testé a permis de diminuer les projections fuyant vers l'arrière et vers le bas, alors que les masques chirurgicaux testés, les masques faits maison, les respirateurs N95 et les écrans faciaux ont montré des projections fuyant vers l'arrière et vers le bas à des degrés divers. En ce qui concerne les écrans faciaux précisément, on a constaté que les bioaérosols contenant un flux d'air fuyaient par les coutures et les joints des écrans faciaux testés et qu'ils se déplaçaient horizontalement de façon minimale (sur une distance	(Viola et al., 2020)

	de quelques centimètres). Les écrans faciaux ont également généré des projections fuyant vers le haut (région des sourcils), vers le bas, sur les côtés et vers l'arrière. Les projections vers l'arrière se produisent lorsque l'air s'échappe par les côtés des couvre-visage et sont projetées vers l'arrière à grande vitesse, ce qui peut entraîner un déplacement important. De puissantes projections fuyant vers le bas ont été observées pour les écrans faciaux qui ne se courbent pas sous le menton, ce qui permet une circulation d'air sans entrave à l'entrée et à la sortie.	
Examining the Protection Efficacy of Face Shields Against Cough Aerosol Droplets Using Water Sensitive Papers	Expérience de simulation (comparaison entre le port d'un écran facial uniquement et le port du masque, du respirateur ou d'aucun équipement) Cette expérience de simulation a fait état de l'efficacité des écrans faciaux utilisés comme seul équipement de protection. L'objectif de cette étude est d'informer sur l'utilisation des écrans faciaux par la population générale en dehors d'un établissement de soins de santé. Pour mener cette étude, on a utilisé un simulateur de toux qui a été soigneusement réglé pour reproduire la toux humaine en termes de répartition de la taille des gouttelettes et de vitesse de sortie. Les équipements de protection individuelle testés ont été placés sur une tête de mannequin simulant la respiration humaine. Un granulomètre aérodynamique et du papier hydrosensible ont été utilisés pour analyser la concentration et la répartition de la taille des particules qui atteignent la tête du mannequin. L'étude indique que les écrans faciaux sont aussi efficaces que les masques faciaux pour bloquer les gouttelettes respiratoires (3 µm de diamètre) générées par une toux, et qu'ils sont plus efficaces pour bloquer les particules fines (0,3µm) que les masques médicaux, à court terme. En d'autres termes, alors que le masque médical réduisait le nombre de particules inhalées selon un facteur d'environ deux, l'écran facial offrait une protection supérieure en bloquant plus de 90 % des particules autrement inhalées lorsqu'une toux simulée était dirigée directement sur l'écran facial. Ces effets de blocage ont été réduits lorsque la contamination des zones situées au-delà du milieu du visage (c.-à-d. les joues et le cou) a été prise en compte. De plus, dans les expériences où la distance verticale entre les simulateurs de toux et de respiration était variable, les	(Ronen et al., 2020)

	dépôts de gouttelettes sur le visage n'étaient pas différents de ceux qui se déposaient sur l'écran, et l'efficacité de blocage n'était que de 45 % dans certains cas. Aucune contamination respiratoire des environs n'a été constatée lorsque le simulateur de toux était recouvert d'un écran facial (simulant une personne infectée portant l'écran facial).	
Eye Protection in Orthopaedic Surgery	Expérience de simulation (écran facial avec un masque) : Des têtes de mannequins portant de différents équipements de protection individuelle et vaporisées avec des jets de colorants fluorescents ont révélé que les écrans faciaux qui couvrent les yeux et qui sont portés en combinaison avec un masque facial sont des barrières efficaces. Cette combinaison d'équipements de protection individuelle a permis de réduire de 64 % la contamination par gouttelettes et/ou débris macroscopiques lors d'ostéotomies fémorales simulées.	(Mansour et al., 2009)
Comparison of Protection Against Ocular Contamination with Disposable Eyewear Products	Présentation sur affiche – 2016 (comparaison entre l'écran facial et la protection des yeux avec un masque) Une étude de simulation menée sur des têtes de mannequins portant un écran oculaire ou facial, avec ou sans masque facial et respirateur N95. Au moyen d'un système de colorant fluorescent Glo Germ, on a observé que la contamination des yeux par des micro-gouttelettes s'est produite lorsque le masque chirurgical était porté en combinaison avec un écran oculaire, mais qu'aucune contamination du visage (c.-à-d. des yeux, du nez ou de la bouche) n'a eu lieu lorsqu'un écran facial complet a été utilisé.	(Shoham et al., 2016)
Revue de la littérature		
Face Shields for Infection Control: A Review	Une revue de la littérature sur les écrans faciaux comme forme d'équipement de protection individuelle pour les travailleurs de la santé; on y aborde les différents modèles d'écrans faciaux. Toutes les preuves décrites sont antérieures à l'émergence de la COVID-19.	(Roberge, 2016)
Facial Protection for Healthcare Workers During Pandemics: A Scoping Review	Un examen de la portée de la protection faciale chez les travailleurs de la santé. L'examen a permis d'isoler une étude sur l'efficacité des écrans faciaux (Lindsley et al., 2014) et a conclu que les écrans faciaux ne devraient pas être utilisés par les travailleurs de la santé comme principale protection pour prévenir la transmission des maladies respiratoires, mais qu'ils	(Godoy et coll., 2020)

	peuvent être utilisés en combinaison avec d'autres types de protection faciale.	

NOUVEAUX SYSTÈMES D'ÉCRAN FACIAL

D'autres options de systèmes de protection faciale sont présentées comme des barrières physiques qui offrent une meilleure protection contre les projections de liquides organiques générées par le patient.

Tableau 2 : Nouveaux systèmes d'écran facial

Titre de la publication	Principaux résultats	Référence
Patient-Worn Enhanced Protection Face Shield for Flexible Endoscopy	Expérience de simulation (comparaison entre l'écran facial et l'écran facial amélioré) Une étude de validation de principe par simulation compare l'exposition à des colorants en aérosol et la contamination lorsqu'un patient porte un écran facial standard par rapport à un écran facial de conception améliorée avec un système de fermeture à languette (couvrant l'espace sous le menton) pendant les procédures d'endoscopie. La conception améliorée aurait permis de contenir les projections respiratoires simulées dans les limites de l'espace clos autour du visage des patients et d'empêcher que des bioaérosols s'échappent sous la zone du cou/menton.	(Anon et al., 2020)
Rapid Prototyping and Clinical Testing of a Reusable Face Shield for Health Care Workers Responding to the COVID-19 Pandemic	Création/évaluation d'écrans faciaux améliorés L'utilité clinique et le confort d'utilisation de 3 prototypes d'écran faciaux chez les travailleurs de la santé sont étudiés. L'efficacité de chaque concept pour prévenir les projections de gouttelettes n'a pas été étudiée.	(Mostaghimi et al., 2020)

Méthodologies

Une recension quotidienne de la littérature (publiée et prépubliée) est effectuée par le Groupe des sciences émergentes de l'ASPC. Cette recension a permis de compiler la littérature sur la COVID-19 depuis le début de l'épidémie et est mise à jour quotidiennement. Les recherches pour trouver de la littérature pertinente sur la COVID-19 sont menées dans Pubmed, Scopus, BioRxiv, MedRxiv, ArXiv, SSRN, Research Square et sont mises en correspondance avec les publications figurant sur la liste de littérature de l'OMS au sujet de la COVID, et

les centres d'information sur la COVID-19 gérés par Lancet, BMJ, Elsevier et Wiley. Le résumé quotidien et les résultats complets de la recension sont conservés dans une base de données Refworks et une liste Excel qui peut être consultée. Une recherche ciblée par mot-clé est effectuée dans ces bases de données pour y relever des citations pertinentes sur la COVID-19 et le SARS-CoV-2. Les termes de recherche utilisés comprennent : (visage et écran). Une recherche supplémentaire a été menée dans PubMed pour obtenir les recherches plus anciennes, non liées à la COVID-19, sur l'utilisation des écrans faciaux : (visage et écran et [virus ou respiratoire]).

Chaque référence potentiellement pertinente a été examinée pour confirmer qu'elle comportait des données pertinentes, lesquelles ont été extraites et incluses dans la recension de la littérature. Cette revue contient des recherches publiées avant le 7 juillet 2020.

Nouveaux éléments de preuve sur la COVID-19

Résumé des connaissances relatives à la transmission du SRAS-CoV-2 par les instruments à vent et le chant

Introduction

Quel est le risque de transmission du virus du SRAS-CoV-2 par le chant ou l'utilisation d'un instrument à vent dans une chorale, un orchestre ou lors de répétitions avec d'autres personnes?

Cette note de synthèse résume les connaissances relatives à la transmission aérodynamique des gouttelettes et aérosols respiratoires provenant d'activités impliquant de respirer profondément et de chanter, les données probantes épidémiologiques se rapportant aux activités liées à la musique qui ont entraîné la transmission du SRAS-CoV-2 et les évaluations des risques, les stratégies d'atténuation ou autres analyses décisionnelles qui peuvent être pertinentes concernant la création de musique en groupe. Cette synthèse met en évidence la littérature spécifique portant sur la possibilité de transmission d'infections par le chant, publiée au 26 juin 2020.

Points clés

- Les données probantes disponibles suggèrent que le chant, pratiqué dans un espace intérieur, peut contribuer à amplifier la transmission de l'infection par le SRAS-CoV-2, si une personne infectée y participe. Les rapports épidémiologiques portant sur des grappes de cas de COVID-19 présentant des taux d'atteinte élevés et associées à la pratique de la chorale aux États-Unis, à Singapour et aux Pays-Bas, ainsi que du karaoké dans un bar en Corée du Sud, fournissent des données probantes selon lesquelles la transmission s'est produite au cours d'activités impliquant le chant (tableaux 2 et 3).
- Il n'a pas été possible d'identifier des données probantes primaires relatives à l'utilisation d'instruments à vent et de cuivres ni son incidence sur la transmission du SRAS-CoV-2. Toutefois, une évaluation descriptive des risques et une étude de la littérature grise portant sur les instruments à vent indiquent qu'il faudrait faire davantage de recherches sur le risque de transmission du SRAS-CoV-2 par les aérosols produits par les instruments à vent (Tableau 3). Un protocole d'étude des instruments à vent et de la sécurité liée à leur utilisation a été identifié (Miller, Vance, Hertzberg, & Toohey, 2020).
- Aucune donnée probante relative à des stratégies d'atténuation s'appliquant aux musiciens n'a été identifiée.
- Données probantes expérimentales et scénarios modélisés relatifs à la dispersion des gouttelettes et à l'aérosolisation du SRAS-CoV-2:

- Les particules infectieuses sont généralement expulsées dans l'air ambiant par une personne infectée (par exemple, en respirant, en parlant, en éternuant, en chantant et en toussant) et ces particules peuvent transmettre le SRAS-CoV-2 à une autre personne lorsqu'elles sont inhalées (Tableau 1).
- Les particules de SRAS-CoV-2 en suspension dans l'air peuvent exister sous forme d'aérosols, de gouttelettes, de noyaux de gouttelettes ou d'autres petites particules contenant de l'ARN viral. Selon une étude, le virus du SRAS-CoV-2 peut rester viable dans des aérosols pendant plus de trois heures (van Doremalen et al., 2020).
- Aucune étude de simulation n'a examiné la production de particules pendant le chant ou l'utilisation d'instruments à vent, mais des études font état de la parole et de la toux. Par exemple, on estime que des milliers de particules contenant des virus sont produites pendant une minute de conversation à haute voix et restent en suspension dans l'air pendant plus de huit minutes (Tableau 1) (Stadnytskyi, Bax, Bax, & Anfinrud, 2020).
- Les modèles mathématiques fondés sur la physique des particules et l'aérodynamique prédisent que les particules respiratoires et salivaires peuvent rester en suspension dans l'air suffisamment longtemps pour être inhalées par un autre individu, et qu'elles peuvent être dispersées à une certaine distance de la source infectieuse (Vuorinen et al., 2020) (Guerrero, Brito, & Cornejo, 2020; Zhao, Qi, Luzzatto-Fegiz, Cui, & Zhu, 2020) (Feng, Marchal, Sperry, & Yi, 2020). Selon les modèles mathématiques, la taille des gouttelettes, l'humidité, la température, le flux d'air et les turbulences de l'air ont tous un impact sur le mouvement et la décomposition des virus contenant des particules en suspension dans l'air (Tableau 1).

Vue d'ensemble des éléments de preuve

L'ensemble des données probantes empiriques disponibles sur la transmission du SRAS-CoV-2 pendant le chant provient de quelques grappes de cas apparues dans des chorales dès le début de l'épidémie de SRAS-CoV-2. Ces études constituent des enquêtes réalisées rétrospectivement sur les éclosions et il convient de considérer qu'elles présentent un risque de biais élevé et offrent des données probantes de mauvaise qualité.

Les simulations en laboratoire et les scénarios modélisés fournissent également des données probantes théoriques à l'appui de l'hypothèse de transmission accrue du SRAS-CoV-2 par des activités telles que le fait de parler fort. Ces études semblent avoir été menées sans lacune manifeste dans la méthodologie utilisée et sont considérées comme des données probantes de qualité moyenne à élevée.

Des lacunes majeures dans les connaissances ont été identifiées lors de l'analyse des données probantes qui sous-tendent l'examen; des recherches supplémentaires sont nécessaires afin d'évaluer le risque de

transmission associé au fait de chanter ou de jouer d'un instrument dans un contexte de groupe. Le manque de données probantes expérimentales caractérise de manière complète le risque et les circonstances qui conduisent à la transmission. Le risque de transmission lié au fait de chanter et de jouer des instruments à vent dans une chorale, un orchestre et/ou dans le cadre d'une pratique avec d'autres personnes est inconnu, mais des données probantes théoriques et des grappes attestées, attribuées à cette activité, indiquent qu'il existe un risque.

TABLE DES MATIÈRES

GOUTTELETTES ET AÉROSOLS CONTENANT DU SRAS-COV-2

Six expériences et cinq modèles étudient l'aérosolisation du SRAS-CoV-2 et définissent certaines des circonstances dans lesquelles se produisent l'aérosolisation ou la dispersion des gouttelettes. Les particules infectieuses sont généralement expulsées dans l'air ambiant par une personne infectée (par exemple, en respirant, en parlant, en éternuant, en chantant ou en toussant) et ces particules peuvent transmettre le SRAS-CoV-2 à une autre personne, lorsqu'elles sont inhalées (Tableau 1). Le risque de transmission dépend vraisemblablement des caractéristiques de l'environnement, de l'activité, de la distance et du temps passé avec une personne infectée. Les particules de SRAS-CoV-2 en suspension dans l'air peuvent exister sous forme d'aérosols, de gouttelettes, de noyaux de gouttelettes ou d'autres petites particules contenant de l'ARN viral. L'étude de van Doremalen fournit les données probantes primaires relatives à la viabilité des particules du virus SRAS-CoV-2 sous forme d'aérosols. L'étude indique que le virus du SRAS-CoV-2 peut rester viable dans les aérosols pendant plus de trois heures (van Doremalen et al., 2020).

Aucune étude de simulation n'a examiné la production de particules pendant le chant ou l'utilisation d'instruments à vent, mais des études ont fait état de la parole et de la toux. Les simulations ont permis de visualiser avec succès des milliers de gouttelettes et aérosols respiratoires minuscules qui sont émis lorsque l'on parle normalement et restent en suspension dans l'air pendant plus de huit minutes (Anfinrud, Bax, Stadnytskyi, & Bax, 2020; Chanpong, Tang, Rosenczweig, Lok, & Tang, 2020; Stadnytskyi et al., 2020). En outre, on estime que des milliers de particules contenant des virus sont produites pendant une minute de conversation à haute voix et restent en suspension dans l'air pendant plus de huit minutes (Stadnytskyi et al., 2020). La toux génère également des gouttelettes respiratoires et des aérosols qui parcourent des distances moyennes comprises entre deux mètres et demi et quatre mètres maximum, ainsi que des projections importantes de gouttelettes sur les travailleurs de la santé se trouvant à proximité (Chanpong et al., 2020; Loh et al., 2020). En tant que tel, il est probable que le chant entraîne également la dispersion de particules infectieuses.

Les modèles mathématiques fondés sur la physique des particules et l'aérodynamique prédisent que les particules respiratoires et salivaires peuvent rester en suspension dans l'air suffisamment longtemps pour être inhalées par un autre individu et peuvent potentiellement être dispersées à une certaine distance de la source infectieuse (Vuorinen et al., 2020) (Guerrero et al., 2020; Zhao et al., 2020) (Feng et al., 2020). Selon les modèles mathématiques, la taille des gouttelettes, l'humidité, la température, le flux d'air et les turbulences de l'air ont tous un impact sur le mouvement et la décomposition des virus contenant des particules en suspension dans l'air (Tableau 1).

Tableau 1 : Littérature primaire relative aux aérosols et gouttelettes contenant du SRAS-CoV-2

Titre de la publication	Principaux résultats	Référence
Études expérimentales et de simulation		
Aerosol and surface stability of SARS-CoV-2 as compared with SARS-CoV-1	La stabilité et la décomposition du SRAS-CoV-2 et du SRAS-CoV-1 contenus dans les aérosols ont été estimées à l'aide d'un modèle de régression bayésien Le virus du SRAS-CoV-2 est resté viable en aérosols jusqu'à trois heures (durée de l'expérience), avec une réduction du titre infectieux de $10^{3.5}$ à $10^{2.7}$ $TCID_{50}$ par litre d'air.	(van Doremalen et al., 2020)
The impact of high-flow nasal cannula (HFNC) on coughing distance: implications on its use during the novel coronavirus disease outbreak	Une étude de simulation impliquant des volontaires sains (n=5) a révélé que les gouttelettes produites par la toux se répandaient sur une distance moyenne de 2,48 mètres (1,03 écart-type) au départ, et sur une distance maximale de 3,90 mètres. Lorsque l'on porte une canule nasale à haut débit bien ajustée, la dispersion moyenne des gouttelettes générées par la toux est de 2,91 mètres (1,09) avec une distance maximale de 4,50 mètres.	(Loh et al., 2020)
Aerosol-generating procedures and simulated cough in dental anesthesia	La projection d'aérosols et de gouttelettes a été visualisée à l'aide d'un système Glo Germ. On a constaté que la simulation de la toux produisait des projections plus importantes que les procédures dentaires d'essai générant des aérosols.	(Chanpong et al., 2020)
Could SARS-CoV-2 be transmitted via speech droplets?	Un faisceau plan de lumière laser traversant une enceinte sans poussière est utilisé pour détecter les gouttelettes de salive émises en parlant. L'étude apporte la preuve visuelle que la transmission de l'infection par les gouttelettes et les aérosols est possible. Les observations préliminaires démontrent que les milliers de gouttelettes respiratoires et de salive émises en parlant sont beaucoup plus petites que celles émises en toussant, et des phrases simples comme « Bonne santé! » peuvent générer des milliers de petites gouttelettes susceptibles de transmettre une infection. Les chercheurs affirment que des études supplémentaires sont nécessaires afin d'évaluer le titrage viral présent dans les gouttelettes induites par la parole en fonction de la gravité de la COVID-19.	(Anfinrud et al., 2020)

The airborne lifetime of small speech droplets and their potential importance in SARS-CoV-2 transmission	Les observations par diffusion d'un faisceau laser planaire sensible et les mesures d'un spectromètre aérodynamique (APS) sont utilisées afin de visualiser la dispersion et la désintégration des gouttelettes. Les expériences ont révélé que les gouttelettes émises en parlant normalement se désintègrent en 8 à 14 minutes dans des milieux clos où l'air est stagnant (tels que les espaces fermés, en particulier mal ventilés) et les durées de désintégration les plus longues observées concernaient les gouttelettes ayant un diamètre de 12 µm ou plus au moment de leur émission. Les chercheurs estiment qu'une minute de parole à voix haute peut générer un minimum de 1 000 virions contenant des noyaux de gouttelettes qui restent en suspension dans l'air pendant plus de 8 minutes. Les résultats suggèrent que les particules en suspension dans l'air chargées de virus pourraient être inhalées par d'autres personnes.	(Stadnytskyi et al., 2020)
Modèles mathématiques		
Titre de la publication	**Principaux résultats**	**Référence**
COVID-19 : Effects of weather conditions on the propagation of respiratory droplets	Un modèle mathématique complet a été établi afin d'explorer l'évaporation des gouttelettes générées par la parole, le transfert de chaleur et la cinématique dans différentes conditions (par exemple, la température, l'humidité et la ventilation). Une température basse et une humidité élevée favorisent la transmission et la dispersion des gouttelettes, mais suppriment la formation d'aérosols. D'autre part, une température élevée et une faible humidité favorisent la perte rapide de la masse des gouttelettes respiratoires (par évaporation) et réduisent la distance de parcours des gouttelettes, mais ces conditions augmentent le risque de transmission des particules d'aérosol. L'étude conclut que les recommandations actuelles en matière de distanciation sociale pourraient ne pas suffire à diminuer les risques de transmission par voie aérienne, car les gouttelettes peuvent parcourir des distances allant jusqu'à 6 mètres.	(Zhao et al., 2020)
COVID-19. Transport of respiratory droplets	Examen de la propagation des gouttelettes respiratoires dans les environnements extérieurs en appliquant le modèle de calcul d'une personne qui éternue en milieu urbain sous un vent	(Guerrero et al., 2020)

in a microclimatologic urban scenario	climatologique d'intensité moyenne. La propagation des gouttelettes respiratoires est caractérisée par la dynamique de la taille des gouttelettes : les gouttelettes les plus grosses (400 - 900 µm) se propagent entre deux et cinq mètres en 2,3 secondes, tandis que des gouttelettes plus petites (100 - 200 µm) sont transportées entre huit et onze mètres en 14,1 secondes sous l'action d'un vent turbulent.	
Influence of wind and relative humidity on the social distancing effectiveness to prevent COVID-19 airborne transmission: A numerical study	La transmission aérienne des gouttelettes de toux avec des effets de condensation et d'évaporation est modélisée à partir de l'observation de 2 personnes virtuelles soumises à différents environnements et vitesses de vent. Les microgouttelettes suivent les courants d'air et peuvent être déposées sur des corps humains virtuels (y compris la région de la tête) à des distances supérieures à 3,05 mètres. Une humidité relative élevée (99,5 %) entraîne également des gouttelettes plus grosses et un dépôt plus important de gouttelettes de toux sur les surfaces (en raison des effets de croissance hygroscopique). Des microgouttelettes en suspension peuvent se transmettre d'une personne virtuelle à l'autre en moins de 5 secondes. L'étude conclut que compte tenu des effets du vent ambiant, de la convection et de l'humidité relative sur les particules respiratoires émises par l'homme, la distance sociale fréquemment recommandée de 1,83 mètre pourrait ne pas être suffisante pour prévenir la transmission d'aérosols entre les personnes.	(Feng et al., 2020)
Modelling aerosol transport and virus exposure with numerical simulations in relation to SARS-CoV-2 transmission by inhalation indoors	Les données probantes disponibles sur le transport des aérosols dans l'air sont combinées à des simulations 0D-3D dans des modèles basés sur la physique et des calculs théoriques. Les simulations de Monte Carlo indiquent que les gouttelettes produites par la parole et la toux (diamètre inférieur à 20 µm) peuvent rester en suspension dans l'air, y rester de 20 minutes à 1 heure et être inhalées par d'autres personnes. La durée d'exposition conduisant à inhaler 100 aérosols (dose infectieuse présumée suffisante) est variable en fonction de la situation et peut varier d'une seconde, à une minute, voire à une heure. Les simulations 3D de la dynamique des fluides numériques (CFD) suggèrent que les aérosols (dp < 20 µm) peuvent être transportés sur des distances pouvant atteindre 10 mètres dans	(Vuorinen et al., 2020)

	des environnements génériques, en fonction de l'humidité relative et du débit d'air. Enfin, le séchage rapide des gouttelettes de mucus expulsées produirait des noyaux de gouttelettes et des aérosols qui susceptibles de transporter des particules de virus en suspension dans l'air. Ces gouttelettes (diamètre initial des particules de 50 µm à 100 µm) pourraient rester en suspension dans l'air pendant environ 20 secondes à 3 minutes.	

LES GRAPPES DE CAS DE COVID-19 ATTRIBUÉES AU CHANT

Cinq articles publiés décrivant les éclosions de cas de COVID-19 liées au chant et/ou à l'utilisation d'instruments ont été identifiés. Une éclosion de cas de COVID-19 apparue dans la chorale de Skagit Valley, WA, avec un taux d'atteinte secondaire de 53 à 87 % (Hamner et al., 2020), et une estimation des émissions générées dans ce scénario basée sur un modèle mathématique (Miller et al., 2020) suggèrent que la transmission des infections dans cette grappe est principalement due au partage d'un espace fermé dans lequel un seul individu infectieux chantait. Plusieurs résumés relatifs à l'apparition de grappes de cas mettent en exergue les pratiques liées aux cours de chant, au karaoké, aux concerts de musique et aux chorales au Japon et à Singapour (Furuse et al., 2020 ; Dalton, Katelaris, & Wilson, 2020, Wei et al., 2020). Le risque de transmission dépend des caractéristiques propres à l'environnement, l'activité, la distance et le temps passé avec une personne infectée (Waddell., 2020).

Tableau 2 : Littérature relative aux enquêtes épidémiologiques qui attribuent (partiellement) la transmission au chant

Titre de la publication	Principaux résultats	Référence
High SARS-CoV-2 attack rate following exposure at a choir practice — Skagit County, Washington, March 2020	Un groupe de chorale à Washington, aux États-Unis, impliquant 61 chanteurs, y compris le cas de référence symptomatique, a donné lieu à 32 cas confirmés et 20 cas secondaires probables de COVID-19 (taux d'atteinte de 53,3 % à 86,7 %); 3 patients ont été hospitalisés et 2 sont décédés. Les auteurs concluent que la transmission a vraisemblablement été facilitée par la proximité physique (moins de 1,80 m) pendant la pratique du chant et augmentée par l'activité de chant.	(Hamner et al., 2020)
Transmission of SARS-CoV-2 by inhalation of respiratory aerosol in the Skagit Valley	Étude de cas de l'éclosion associée à la chorale du comté de Skagit qui explore la variabilité du risque d'infection en fonction des taux d'élimination des aérosols respiratoires grâce à la	(Shelly L. Miller et al., 2020)

Chorale superspreading event	ventilation, au dépôt sur les surfaces et à la décomposition virale. En raison du taux élevé d'atteintes secondaires, on suppose que l'hypothèse d'un vecteur passif commun ou d'une transmission de personne à personne est peu probable. On estime que l'exposition commune à l'air intérieur sur le lieu des répétitions et les fortes émissions d'aérosols respiratoires pendant le chant sont les principaux facteurs liés à la transmission de l'infection. L'évaluation modélisée du risque d'infection par particules en suspension infère, dans le scénario présent, un taux d'émission de E = 970 (± 390) quanta par heure, à partir du cas de référence infectieux unique.	
Presymptomatic Transmission of SARS-CoV-2 — Singapore, January 23–March 16, 2020	L'étude portant sur 7 grappes de cas COVID-19 identifiées à Singapour a révélé qu'une transmission asymptomatique s'était produite. Dans deux grappes indépendantes, la transmission de l'infection est attribuée à plusieurs femmes ayant assisté à un cours de musique (grappe B, grappe F) dont les cas ont été confirmés.	(Wei et al., 2020)
Clusters of coronavirus disease in communities, Japan, January-April 2020	Étude sur 61 grappes de plus de 5 cas au Japon, du 15 janvier au 4 avril. 18 établissements de soins de santé (30 %); 10 établissements de soins d'autres types, tels que des maisons de soins infirmiers et des centres de jour (16 %); 10 restaurants ou bars (16 %); 8 lieux de travail (13 %); 7 événements liés à la musique, tels que des concerts de musique en direct, des répétitions de chorales et des soirées karaoké (11 %); 5 gymnases (8 %); 2 cérémonies (3 %); et 1 incident lié au transport en avion (2 %). La plus grande grappe de cas non liée aux soins de santé était composée de plus de 30 personnes ayant participé à un concert de musique en direct, y compris les artistes, les membres du public et le personnel de l'événement. De nombreuses grappes de cas de COVID-19 ont été liées à l'exposition à des situations impliquant une forte respiration associée à une proximité physique, comme le chant lors de soirées karaoké, les acclamations des clubs, les conversations dans les bars et l'exercice physique dans des gymnases.	(Furuse et al., 2020)
Open with care: minimising COVID-	Évaluation des risques et des avantages	(Dalton, Katelaris, & Wilson, 2020)

19 superspreading settings in Australia	Les salles de karaoké et les groupes de chorale, impliquant le chant, sont considérés comme des sources vraisemblables d'amplification du risque de transmission en raison du rapprochement physique des personnes rassemblées et de l'action même de chanter. Des éclosions associées à des églises et à des rassemblements religieux ont été enregistrées aux États-Unis, en Corée du Sud et à Singapour. Les caractéristiques propres aux rassemblements religieux peuvent augmenter le risque de transmission en raison d'activités telles que le chant, les accolades et les poignées de main à l'occasion des salutations et des offices religieux, la transmission d'objets sacramentels, la disposition des sièges à proximité les uns des autres et le partage de nourriture et de rafraîchissements. L'article avertit que, dans le contexte australien, la levée des restrictions doit être faite avec précaution. Dans des conditions de très faible propagation communautaire et de fortes proportions de populations sensibles, ces événements de super propagation peuvent constituer des sources très importantes de cas.	

LITTÉRATURE GRISE SUR LE RISQUE DE COVID-19 ASSOCIÉ AUX INSTRUMENTS À VENT ET AU CHANT

Le tableau suivant résume la littérature grise pertinente. Deux éclosions, l'une aux Pays-Bas impliquant une grande chorale et un orchestre et l'autre associée à une éclosion apparue dans un karaoké en Corée du Sud. Une évaluation des risques, une expérience et un protocole à l'appui des futures recherches sur le risque de transmission lié à l'utilisation des instruments à vent. Ainsi que deux notes de synthèse précédemment réalisées par l'Alberta (22 mai) et Terre-Neuve (1er juin), qui reprennent elles-mêmes plusieurs documents d'orientation et déclarations de position.

Tableau 3 : Littérature grise sur la transmission de l'infection attribuée au chant et aux instruments à vent

Titre de la publication	Principaux résultats	Référence
Wind instrument aerosol in COVID	Évaluation des risques	(Schwalje & Hoffman, 2020)

Era - COVID-19 and horns, trumpets, trombones, euphoniums, tubas, recorders, flutes, oboes, clarinets, saxophones and bassoons	Cette évaluation des risques donne un aperçu des différentes activités liées à la pratique des instruments à vent pouvant entraîner la formation d'aérosols ou une transmission directe. • Il n'existe aucune donnée probante directe, mais les données probantes indirectes suggèrent qu'il peut y avoir un risque de transmission supérieur au risque de fond normal. • Les auteurs décrivent des pratiques courantes, parmi les musiciens, qui ont le potentiel de propager le virus. La pratique consistant à partager ou à toucher les anches d'autres musiciens a été décrite comme étant à haut risque et il n'y avait pas de recommandations relatives à la désinfection des anches. • Les auteurs concluent qu'il n'y a pas suffisamment de données probantes permettant d'évaluer correctement le risque de transmission du SRAS-CoV-2 lié au fait de jouer d'un instrument avec d'autres personnes.	
Aerosol generation from playing band instruments and risk of infectious disease transmission	Il s'agit d'un protocole pour une étude menée à l'université du Colorado. L'objectif de ce projet est de fournir des mesures et des estimations de modélisation des risques en temps utile afin de mieux comprendre les émissions de particules provenant des instruments de musique. Quatre actions sont proposées : 1. Études d'imagerie des flux afin de documenter qualitativement l'émission et le panache de particules par la photographie et les lasers 2. Études en laboratoire d'essai afin de mesurer les taux de génération de particules provenant des activités suivantes : a. 5 bois : flûte, clarinette, hautbois, saxophone, basson b. 4 cuivres : cor, trompette, trombone, tuba c. 4 gammes vocales : soprano, alto, ténor, basse d. Comédie musicale : paroles, monologue, chant, danse (acteurs et actrices) e. Élémentaire - garçons et filles de la troisième à la cinquième année f. Simulation aérobie (fanfare, spectacle de chorale, danse, etc.)	(Shelly L. Miller et al., 2020)

	3. Études sur le terrain relatives aux répétitions mesurant les concentrations dans une salle de répétition comptant plusieurs musiciens et située à l'Université du Colorado à Boulder (sous réserve de l'approbation de l'IRB et du campus) 4. Modélisation du risque de transmission à l'aide du modèle Wells-Riley	
Bamberg Symphony Orchestra: Scientists measure aerosol emissions	Publication en ligne (en allemand) Les scientifiques présents auprès de l'Orchestre symphonique de Bamberg utilisent les flux d'air pour mesurer le nombre d'aérosols émis par un trombone, une clarinette ou un cor. On considère que les matières en suspension émises représentent l'air potentiellement contaminé par le SRAS-CoV-2 qui serait expulsé par l'instrument si le musicien était infecté.	("Bamberg Symphony Orchestra: Scientists measure aerosol emissions," 2020)
(LEAD) Itaewon-tied cases rise to 153, karaoke facilities emerge as infection routes	Article de journal en ligne Infections à Séoul, en Corée du Sud, liées à des boîtes de nuit dans le quartier d'Itaewon : les installations de karaoké sont des sites de transmission d'infections présumés.	("(LEAD) Itaewon-tied cases rise to 153, karaoke facilities emerge as infection routes," 2020)
That one passion that did go on, with disastrous consequences.	Article de journal en ligne L'éclosion dont il est question ici a impliqué 102 cas de COVID-19 parmi 130 membres d'une chorale et d'un orchestre à Amsterdam, aux Pays-Bas. Au début de l'éclosion, le groupe a continué à pratiquer bien que des membres de la chorale commençaient à tomber malades. D'après la séquence des événements et des maladies, plusieurs événements de transmission se sont potentiellement croisés.	(van der Lint, P., 2020)
COVID-19 quick response report: choirs and COVID-19	Rapport de réponse rapide sur les données probantes concernant les chorales et la COVID-19 disponibles au 3 juin2020. Les auteurs résument un grand nombre de documents d'orientation, d'avis d'experts et de données probantes portant sur les chorales et la transmission du SRAS-CoV-2.	(Williams, S et Navarro, P., 2020)
Singing as a risk for transmission of SARS-CoV-2 virus	Examen rapide des données et des orientations concernant le chant comme risque de transmission. La dernière évaluation date du 22 mai 2020.	(Kania-Richmond, A et Sharpe H., 2020)

	L'examen comprend des documents qui ne sont pas liés au SRAS-CoV-2 mais relatifs au chant et au potentiel de propagation des agents pathogènes. Rapport sur les événements de transmission de la grippe A et de la tuberculose liés aux chorales.	

Méthodologies

Une analyse quotidienne de la littérature (publiée et pré-publiée) est effectuée par le groupe des sciences émergentes de l'ASPC. L'analyse compile la littérature disponible sur le COVID-19 depuis le début de l'épidémie et est mise à jour quotidiennement. Les recherches pour trouver la littérature COVID-19 pertinente sont menées dans Pubmed, Scopus, BioRxiv, MedRxiv, ArXiv, SSRN, Research Square et sont croisées avec la littérature de la liste de l'OMS relative à la littérature COVID, et les centres d'information COVID-19 gérés par Lancet, BMJ, Elsevier et Wiley. Le résumé quotidien et les résultats complets de l'analyse sont conservés dans une base de données Refworks et une liste Excel qui peut être consultée. Une recherche ciblée par mot-clé est effectuée dans ces bases de données pour identifier les citations pertinentes se rapportant à la COVID-19 et au SRAS-CoV-2. Les termes de recherche utilisés sont les suivants : chanter, karaoké, chorale, vent et instrument, musique, chant, vocaliser, religieux, église. Une recherche supplémentaire de littérature grise a été effectuée à l'aide de chaînes de recherche (COVID-19 ou SRAS-CoV-2) ET (chorale ou musique ou (vent et instrument)) dans Google. Les examens effectués précédemment sont issus des Référentiels du CCNMO, ACMTSet SPOR evidence alliance.

Chaque référence potentiellement pertinente a été examinée afin de confirmer qu'elle comportait des données pertinentes, puis ces données ont été extraites aux fins de l'élaboration de l'examen. Le présent examen contient les recherches publiées au 26 juin 2020.

Emerging Evidence on COVID-19

Evidence Brief of Potential Health Risks of Hard-Surface Disinfectants in Environments Shared by School-aged Children

Introduction

What evidence exists to inform the potential health risks (contact exposure, inhalation toxicity, poisoning) of increased use of hard-surface disinfectants in environments (e.g. school/ home/ recreation) shared by school-aged children during the COVID-19 pandemic?

Schools are re-opening with more frequent sanitation and hygiene requirements in an effort to mitigate the spread of SARS-CoV-2, the virus that causes the COVID-19 disease, between students and staff. In addition, many public facilities, businesses and homes have adopted enhanced sanitation procedures, which includes increased use of hard-surface disinfectants to reduce the risk of spread of the virus. Hard-surface disinfectants are known to have some associated health risks and their increased use may pose additional health risks to school-aged children.

Hard-surface disinfectants are intended for use as disinfectants on hard, non-porous surfaces and contain active ingredients permitted by Health Canada. Enveloped viruses such as coronaviruses are readily inactivated by many disinfectants (Rai, 2020). A list of approved products (n=526) effective against SARS-CoV-2 is available on Health Canada's website (Health Canada, 2020). Common categories of active ingredients for hard-surface disinfectants include quaternary ammonium compounds, phenolic, idophor, chlorine releasing compounds, and peroxygen (Health Canada, 2015). A general overview of each category is provided in the appendix table. Each of these classes of active ingredients have warnings about the proper use of each chemical.

Disinfectants are regulated as drugs in Canada and although the *Food and Drugs Act* and the Food and Drug Regulations do not specify acute toxicity hazard classification criteria for disinfectant drugs, manufacturers are recommended to consider referencing the Consumer Chemicals and Containers Regulations, 2001 for products intended for non-commercial uses (domestic) by consumers (Canada, 2020a); or Hazardous Products Regulations, 2015 for products intended for use in workplaces or commercial use (Canada, 2020b). When Health Canada approves a disinfectant, precautionary statements to ensure their appropriate use are included on the product labels. These statements describe recommended actions that can be taken to minimize, mitigate and/or prevent adverse reactions from occurring. They are displayed prominently on the labelling of disinfectants to ensure the safe use and handling of the product by the end users in accordance with the label directions. The precautionary statements are relevant to the potential acute toxicity exposure

hazards of the product. In determining the appropriate precautionary statements, Health Canada takes into consideration all the ingredients in the formulation including inert or non-medicinal ingredients. Health Canada ensures that the overall risk benefit of using a product is positive and that potential risks can be mitigated by appropriate labelling.

Contact, inhalation or ingestion of disinfectants can lead to immediate irritation or poisoning. These compounds could cause contact burns or sensitivities to skin and eyes, are harmful if ingested and have inhalation risks during handling and application (CDC, 2020 and Health Canada, 2020). Some disinfectants may leave chemical residues which can become airborne and inhaled; to use safely, these products need to be rinsed off after use. Of particular interest are disinfectant by-products, such as those from chlorine containing compounds like household bleach that may form volatile organic compounds (VOCs) if accidentally mixed with other cleaning products or when it comes into contact with organic matter on a dirty surface (Odabasi, 2014). Some categories of disinfectants have been associated with respiratory issues including asthma due to long term occupational exposure (Appendix table). Measures to address these risks include: using soap and water to clean all visibly dirty surfaces before disinfecting, not mixing disinfectants with other products, opening windows to increase ventilation, wearing gloves when disinfecting, and allowing surfaces to air dry completely before using and staying out of a freshly disinfected area for 20-30 minutes after cleaning (Bello, 2010). Long-term exposure toxicology data is incomplete for many disinfectants, and is generally supported by animal studies. While some have limited adult human data, few have data on children, see the appendix table for a summary for each category of disinfectant.

This review focuses on health risks associated with hard-surface disinfectant use around school-age children both before and during the COVID-19 pandemic. It includes literature published up to October 5, 2020 (Methods are at the end of the document).

Key Points

There is limited evidence on the health risks of hard surface disinfectant use in school-aged children, this review demonstrates that

- Compared with previous years, reports on calls to poison control centres in both the United States (USA) and Canada have documented an increase in calls during the COVID-19 pandemic related to disinfectants and cleaners, with exposures frequently involving children (Table 1).
- People using disinfectants may lack knowledge of their safe use and potential harms based on a consumer survey in the USA (Table 1).
- Studies of children that reside in homes with high disinfectant use have a higher frequency of skin and respiratory effects as well as sensitization to disinfectants (Table 2).

- Some cross-sectional studies have shown an association between the frequency of disinfectant use around children and health effects such as asthma and wheezing in young children (Table 2).
- Chloroform (one of the VOCs that can form when bleach comes into contact with other products or organic matter) has been found at unacceptable concentrations in several early childhood education centres; most of these centres reported using bleach regularly (Table 2).
- Overall, there remains considerable knowledge gaps in the literature on both the short and long term effects that may be experienced by children as a result of the increased use of hard-surface disinfectants.

Overview of the Evidence

Publications that directly report on the potential health risks of increased use of hard-surface disinfectants in environments shared by school-aged children are scarce. We examined not only literature reviews and information about calls to poison control centres during the pandemic (Table 1), but also included available evidence on the health impacts on children from the use of hard-surface disinfectants prior to the COVID-19 pandemic (Table 2). Sixteen relevant publications on exposure to hard-surface disinfectants informed this review. These included epidemiological studies (cohort and cross sectional), reports from poison control, a consumer knowledge survey, risk assessments, literature reviews and commentaries. The overall body of research is very small, of low quality and is insufficient to provide conclusive evidence on the health risks of disinfectant use is school-age children. Additional research in this area is needed.

Excluded from this review were studies that focused on adult or occupational exposure, as well as animal studies, as their exposure levels may differ from school-aged children. General features of disinfectant categories and links to additional information on each category is provided in the appendix table.

CONTENTS

HARD-SURFACE DISINFECTANTS EXPOSURE DURING THE COVID-19 PANDEMIC

Seven studies on the effect of exposure to hard-surface disinfectants in children during the COVID-19 pandemic are summarized in Table 1. This includes two reports from poison control centres, one consumer knowledge survey, one risk assessment, one literature review and two relevant commentaries.

Poison control centres in both the USA and Canada have reported a rise in calls related to disinfectants and general household cleaning products in 2020 compared to previous years (Chang, 2020; Yasseen, 2020). In the Canadian study that tracked calls on cleaners and disinfectants, 42% of calls were related to bleaches and 21% to disinfectants (Yasseen, 2020). The increase was seen in all age groups, but the majority were for adults, not children. In the USA study, bleaches accounted for the largest percentage increase in calls followed by non-alcohol disinfectants. Calls due to exposures among children aged ≤5 years consistently represented a large percentage of total calls from 2018 to 2020 (range = 39.9–47.3%) (Chang, 2020).

A survey conducted in May 2020 found sixty percent of respondents reported cleaning or disinfecting their home more frequently since the pandemic started compared to the preceding months (Gharpure, 2020). It also reported that respondents had limited knowledge of how to safely prepare their cleaning products and disinfectant solutions and 25% of respondents reported experiencing at least one adverse health effect that they believed had resulted from using these products (Gharpure, 2020).

A risk assessment found three-year-old children had the highest potential exposure to disinfected surfaces compared to any other age group due to the higher likelihood of hand contact and mouthing activities (Li, 2020). This risk assessment looked at several chemicals, but not all were hard-surface disinfectants. They also assumed that disinfectants were used at full strength without dilution, the individual was exposed via direct hand contact, and that disinfectants were not wiped off after surface application, which may not be representative of how such disinfectants were actually used by consumers.

Reviews of approved disinfectants which contain quaternary ammonium, sodium hypochlorite or hydrogen peroxide and their use during the COVID-19 pandemic highlight the majority of hard-surface disinfectants used against SARS-CoV-2 (Samara, 2020, Rai, 2020). The literature review identified that residues from some hard-surface disinfectants can contribute to poor air quality, and there is evidence of higher cancer rates attributed to regular use of some of these disinfectants in adults from occupational exposure (Rai, 2020). In some high exposure occupations, studies have shown an association with increased risk of chronic obstructive pulmonary disease, asthma and eye irritation (Rai, 2020; Samara, 2020). Similar data was not identified for children and although 5% percent of childhood cancer and 30% of childhood asthma are related to chemical exposures, the proportion that may be attributed to hard-surface disinfectant use is unknown (Rai, 2020).

Table 1: Studies and reviews on the health risks of hard-surface disinfectants use for school-aged children (n=7)

Study	Method	Key Outcomes
Poison Control Calls		
Chang, 2020 Before/after study USA Jan– Mar 2018, 2019 and 2020	The National Poison Data System calls were analysed for the number of exposures reported for January–March 2020 compared with the same 3-month period in 2018 and 2019.	During January–March 2020, poison centres received 45,550 exposure calls related to cleaners (28,158) and disinfectants (17,392), representing overall increases of 20.4% and 16.4% from 2019 and 2018, respectively. The increase in calls was seen across all age groups but exposures among children aged ≤5 years represented 39.9%–47.3% of calls in the three time periods. Inhalation accounted for the largest percentage increase in calls from 2019 to 2020. The largest increase in calls possibly related to hard-surface disinfectants (2019 vs 2020) were for bleach (62.1%) and non-alcohol disinfectants (36.7%).
Yasseen, 2020 Before/after study Canada Jan – Jun 2019 and 2020	Five Canadian Poison Control Center exposure reports for Jan – June 2020 were compared with the same 6-month period in 2019.	There was a 35% rise in total number of exposures to cleaning products/ disinfectants/ hand sanitizers in 2020 compared to 2019. Of 8187 calls reporting exposures between January and June in 2019 and 2020, those possibly related to hard-surface disinfectants were: 42% for bleach, 21% disinfectants, 12% chlorine gas, and 2% chloramine gas (the latter are bi-products of mixing bleach with other disinfectants or cleaners, see appendix). In the 2020 period, the number of calls peaked in March and generally decreased after April 2020. Exposure calls were predominately among those aged 19+ for both years. The results do not suggest that there was a large increase among those aged <19 years between 2019 and 2020.
Knowledge Survey		
Gharpure, 2020 Opt-in adult internet survey on household cleaning USA May, 2020	The survey included questions to assess knowledge and practices regarding household cleaning and disinfection during the COVID-19 pandemic.	Included 502 adults (18+) 60% reported more frequent home cleaning/ disinfection use compared with preceding months. Limited knowledge of safe preparation of cleaning and disinfectant solutions was reported across several questions. 39% of respondents reported high-risk practices not recommended by CDC including: 1) Applying bleach to food (19%)

		2) Use of household cleaners and disinfectants on hands (18%) 3) Misting the body with cleaners and disinfectants (10%) 4) Inhaling vapors (6%) 5) Drinking or gargling diluted bleach solutions (4%), soapy water (4%), or other cleaner/ disinfectant solutions (4%). 25% reported at least one adverse health effect that they believed resulted from using cleaners or disinfectants. These were more common (33% vs. 25%) in respondents who reported a high risk practice.
Risk Assessment		
Li, 2020 Risk assessment and quantitative exposure model of 22 disinfecting chemicals which have been highlighted to kill SARS-CoV-2 USA and Canada[1] September, 2020[1]	Risk assessment use PROTEX an indoor fate and chemical exposure model. Three exposure routes (mouthing-mediated oral ingestion, inhalation, and dermal absorption) were investigated. The application scenario relevant to this review was disinfection of indoor surfaces and objects (surface application). Three age groups were modelled: 3, 14, and 24 year olds.	<u>Exposure risk assessment</u> Three-year-old children had highest overall exposure, especially to disinfected surfaces, due to higher frequency of hand contact and mouthing activity. Surface disinfectant exposure risk, especially for young children were noted. Mouthing-mediated ingestion dominates the exposure to non-volatile disinfectants whose residues can stay on surfaces until removed by normal cleaning (e.g. quaternary ammonium compounds). For older age groups this exposure was through dermal absorption and was also noted for phenolic chemicals. For disinfectants like triethylene glycol (low toxicity) that are aerosolized to disinfect and clean the air, exposure was mainly due to inhalation. Although this risk assessment looked at 22 chemicals, many were not hard-surface disinfectants.
literature reviews		
Rai, 2020 Literature review Jun 2020	Studies on the potential harmful effect of disinfectants and safe alternatives were summarized in the context of COVID-19.	5% of childhood cancer and 30% of childhood asthma are related to chemical exposures, it is unknown if any of these are attributed to hard-surface disinfectants. The majority of products recommended by the EPA for use against COVID-19 contain the active ingredients from quaternary ammonium compounds (Quats).

		Many of these are linked with an increased risk of chronic obstructive pulmonary disease (COPD), asthma, and eye irritation when used regularly (occupational exposure). Quats have been shown to possibly cause fertility issues in animal studies. When not rinsed properly after use, biodegradable disinfectants will leave an active chemical residue on the surface applied. Disturbance of the residue can cause it to be airborne, which may cause irritation for some people. Thorough rinsing and general cleaning removes the residue.
Commentaries		
Rivera, 2020 Commentary USA[1] Jan – May 2020	Using Google Trends, evaluated search interests for the purchase and consumption of disinfectants and for poison control centres after the USA president implied injecting disinfectants may be a potential treatment for COVID-19. Confidence intervals for each trend were calculated by averaging multiple samples collected daily over a 3-week period.	The relative search fraction (RSF) values from January-February, 2020 for purchasing, drinking, or injecting disinfectants were minimal (<1). A day after Trump's comment, RSF for drinking disinfectants was 32.3 and injecting disinfectants was 100. RSF for poison control centres peaked a day later (RSF=11·05), indicating an increase in interest or possibly for information or assistance following off-label use of disinfectants.
Samara, 2020 Commentary United Arab Emirates[1] 2020[1]	Safety of disinfectants is presented for some of the most widely used natural and synthetic surface disinfectants approved by the Environmental Protection Agency for the prevention of SARS-CoV-2 and reviews associated health effects.	Hard-surface disinfectants can cause irritation of the skin and eyes, irritation to the respiratory tract, and asthma in some individuals. The use of bleach can result in the formation of VOCs in the indoor air, and high concentrations of VOCs are reported 30 minutes after application. This indicates that the use of bleach may be an important source of VOC inhalation exposure. An ideal disinfectant should have a low toxicity profile with short and long term exposure e.g. Quaternary ammonium compounds and peracetic acid: (see appendix table).

[1] The country was based on author location or the date was based on date of publication.

GENERAL EXPOSURE TO HARD-SURFACE DISINFECTANTS

While there are no recent studies on how the increased exposure to hard-surface disinfectants during the pandemic will affect the health and safety of school-aged children, studies conducted prior to the COVID-19 pandemic can provide additional information on the effects of exposure to hard-surface disinfectants among children.

The biologic monitoring study of 34 early childhood education centres in California reported that chloroform, a VOC related to chlorine bleach use, exceeded the acceptable cancer risk levels in 38% of facilities (Hoang, 2016).

Two exposure assessment studies found that bleach is commonly used in daycare centers in the USA. A survey in fourteen childcare facilities in Washington, DC reported on the use of chlorine bleach (92.8%) in their facilities for sanitation purposes and chloroform was detected in all facilities (Quirós-Alcalá, 2016). The most common sanitized surfaces were tables, bathrooms, chairs along with beds, changing tables and children's toys. Bleach has been reported to be an airway irritant if inhaled and can release VOCs (e.g. chloroform) when it reacts with organic material, which is a known carcinogen. The third risk assessment measured and modelled the quantity of VOCs produced during normal indoor cleaning tasks. The results suggest that there is potential for exposure to above-average levels of VOCs to anyone who enters the room up to 20 minutes after cleaning sinks, mirrors, or toilets with disinfectants containing quaternary ammonium compounds or sodium hydroxide (Bello, 2010). Increasing ventilation and decreasing time in a newly cleaned room would reduce exposure to VOCs. Three epidemiologic studies have been published. A prospective cohort study from Germany of youth ages 19-24 showed the use of disinfection products was associated with an increase in asthma and atopic dermatitis. Self-reported exposure to household disinfectants and high use of disinfectants was associated with a two-fold increased odds of asthma incidence compared to those who reported no use (Weinmann, 2017). Youth who reported low or medium use of disinfectants were also more likely to report remittent asthma (Weinmann, 2017). In a cross-sectional study of 4-year olds in several European countries, households with high use of disinfectant room sprays were associated with increased atopic dermatitis and itchy rashes, but not asthma (Krauss-Etschmann, 2009). A weakness of this study was general disinfectant use was not recorded (Krauss-Etschmann, 2009). A cross-sectional study from Sweden found that use of chlorine bleach in the home had a protective association with developing asthma and sensitization to indoor allergens, but did not specify whether children were present during cleaning (Nickmilder, 2007).

Three literature reviews summarized the evidence on the potential risk to children which is mostly cross-sectional studies of cleaning/disinfection products and the VOCs associated with those products (Holm, 2019; Mendell, 2007; Slaughter, 2019). The most common categories of disinfectants reported across studies included bleach, quaternary ammonium compounds and peroxides, chosen for their broader range of disinfection across pathogens (Holme 2019). Indoor cleaning activities were associated with allergies, asthma and other respiratory issues in infants and young children (Mendell, 2017). Most of these studies did not

specify the products being used, and often multiple types of products were used, so separating out the impact of one product over another was not possible.

Table 2: Reports on health risks of hard-surface disinfectants from pre-pandemic literature (n=9)

Study	Method	Key Outcomes
Exposure / Risk Assessments		
Hoang, 2017 Biological monitoring study USA May 2010 - May 2011	38 VOCs were measured in single-day air samples collected in 2010-2011 from 34 ECE facilities serving California children and evaluated "No Significant Risk Levels" (NSRLs) defined as the daily dose posing a one in 100 000 excess risk of cancer over a lifetime.	Chloroform - a VOC associated with the use of chlorine bleach - was identified in some samples. Other VOCs were not associated with hard-surface disinfectants, however they maybe VOCs produced by fragrances that are added to a cleaning or disinfection product. The 95th percentile dose estimates for chloroform exceeded the age-specific NSRL in all four age groups assessed. Findings: VOC levels in ECE facilities resemble those in school and home environments and, if reflective of long-term averages, child dose estimates exceeded age-adjusted NSRL benchmarks for benzene, chloroform, ethylbenzene, and naphthalene in 71%, 38%, 56%, and 97% of facilities, respectively. In bivariate analysis: Levels of VOCs were similar in facilities that reported use/purchase of low-toxicity cleaners compared with those using traditional cleaners. However, some VOCs were significantly higher in facilities with higher mopping frequency, suggesting VOC emissions from floor cleaners.
Bello, 2010 Exposure assessment study USA[1] 2010[1]	Sink, mirror, and toilet bowl cleaning tasks were simulated for 20 minutes in a large ventilated bathroom and a small unventilated bathroom using a general purpose, a glass, and a bathroom cleaner. Airborne total volatile organic compounds generated during the tasks were measured.	The household cleaners used contained Quaternary Ammonium Compound or sodium hydroxide. Exposures above the background level were present for approximately 20 minutes after the tasks ended. The highest concentration of ammonia occurred while mirrors were being cleaned. Results suggest that there is potential exposure to anyone who is cleaning the room or who enters the room shortly after cleaning.
Quirós-Alcalá, 2016	Childcare center directors were initially contacted via email and letters. A	Chloroform (a VOC that may originate from products containing chlorine bleach) was detected in every

Exposure assessment study Washington, DC. Fall of 2012 and 2013	questionnaire was administered to childcare center directors. They also collected information on the number of children with asthma at each facility and whether any children experienced asthma attacks or wheezing episodes in the three months prior. To characterize VOCs within the facilities, they collected between two and five 10-h air samples and real-time particulate matter instrument samples at 1 min intervals.	facility. It is important to note that there may be other sources of chloroform. 92.9% of center respondents stated that chlorine bleach was used for sanitizing in the facility. The most commonly reported surfaces sanitized were tables, bathrooms, and chairs, however, respondents also reported the use of chlorine bleach to sanitize beds, changing tables, and children's toys. The indoor pollutants from using chlorine bleach are known respiratory irritants. The authors recommend looking at bleach-free alternatives for disinfection to avoid introducing other hazards into the childcare setting.
Epidemiological Studies		
Weinmann, 2017 Prospective cohort study Germany 2007-2009	2051 young adults between the ages of 19-24 years living in two major German cities took part in a study to self report their exposure to household sprays and disinfectants. Associations with clean product exposure and asthma or wheezing were investigated.	In this sample 83.8% of respondents did not report using disinfectants. No information on what disinfectants were used were collected. Asthma was reported in 5.4% of the sample: - High use of disinfectants was seen to be associated with two-fold increase odds of asthma compared to those with no use (OR 2.79, 95% CI 1.14 to 6.83). - Low and medium disinfectant use was associated with remittent asthma (OR 2.39, 95% CI 1.29 to 4.47). Wheezing in the last 12 months (not related to cold) 17.1%. There was no clear association between exposures and wheezing identified. No causal inferences can be drawn from this data, additional exposure assessments are warranted.
Krauss-Etschmann, 2009 Cross sectional study of 4 year olds (106 Spanish, 45 German, and 25 Hungarian infants).	Children at the age of 4 years underwent a medical and neurophysiologic examination. During this visit, parents completed a standardized questionnaire, which included questions about allergies and asthma in childhood and lifestyle	No information on room disinfectant used was provided. Use was categorized as daily, weekly, occasional or never. Application of room disinfectants was not associated with higher effect estimates for asthma but significantly increased effect estimates for atopic dermatitis and itchy rash. No data on the type of disinfectant was reported.

Spain, Germany and Hungary 2009[1]	related factors. Descriptive categorical data were analyzed with χ^2 analysis. The likelihood of allergic symptoms in relation to household room spray application was assessed in bivariate analyses.	
Nickmilder, 2007 Cross sectional study Sweden Mar-May 2002	The study evaluated the extent that regular house cleaning products with bleach influence the risk of allergies and respiratory diseases. A group of 234 schoolchildren aged 10–13 years old among whom 78 children were living in a house cleaned with bleach at least once per week. Parents of children were asked to complete a questionnaire that included a total of 38 questions.	Children living in houses regularly cleaned with chlorine bleach: - Lower risk of developing asthma, which was significant if both physician diagnosed and screening test positive children were included in the analysis. - They were less likely to be sensitized to indoor allergens including house dust mites (significant). - They were less likely to report wheezing (not significant).
Literature reviews		
Mendell, 2007 Literature review of epidemiologic studies USA[1] Up to mid 2004	Assessed the association between indoor residential chemical emissions, materials or emission-related activities and respiratory or allergic effects in children and infants.	Types of indoor residential materials and coatings, as well as renovation or cleaning activities, were associated with health effects related to asthma or allergy in infants or children. Use of many chemical-based cleaning products (women used more than one, however 87.4% were disinfectants, 84.8% were bleach) by mothers was measured by questionnaire and total chemical burden (TCB) in one study (Sherrif 2005). High TCB was associated with a significant dose–response increase in persistent wheeze in young children (adjusted OR 2.3 (95% CI 1.2 to 4.4) and late-onset wheeze in young children (adjusted OR 2.0 (95% CI 0.8 to 5.2)). No single product was implicated in children wheezing. These findings could be impacted by numerous confounders and conclusions about a causal relationship cannot be inferred from the studies presented.

Slaughter, 2019 Literature review New Zealand[1] Jan 1950 to Jun 2018	Review of hypochlorite poisoning.	Sodium hypochlorite is used as a bleaching and disinfecting agent and is commonly found in household bleach. 110 citations were deemed relevant. Estimates of greater than 40 mL or 5 mL/kg in children of dilute solutions have been suggested as amounts likely to cause corrosive or systemic poisoning. This review describes multiple case reports/series of children ingesting bleach. Common effects included minor gastrointestinal features, such as nausea, vomiting, and superficial burns in the mouth/esophagus. Brief skin exposure to household bleach normally causes minimal effects. Prolonged or extensive exposure may cause skin irritation or hypersensitivity.
Holm, 2019 Literature review USA[1] 2018[1]	Summarized findings from: (1) Environmental Protection Agency registration data on the efficacy of hospital-grade disinfectants (n= 1907 products, 529 of which were included). (2) A review of the research on the toxicities/health risks of common disinfectants in childcare settings.	Bleach is the most common disinfectant used in childcare settings. A bi-product of bleach is the VOC chloroform. Without optimal ventilation rates, some studies have reported chloroform levels above those considered safe for managing cancer risk. Similar findings were reported for formaldehyde which can be a bi-product of improper mixing of cleaning and disinfectant chemicals. Data on the effects of cleaning products on children are limited. Cross-sectional studies have indicated that homes cleaned with bleach were not more likely to have asthma whereas others have found an increased risk with use of sprays and disinfectants in the home. A relationship between use of cleaning sprays and wheezing has been reported across a couple studies in infants and young children. Classes of disinfectants with at least one product that had wide pathogen coverage included bleach, peroxides, quaternary ammonia compounds, and combination products that included quaternary ammonia compounds. Health Risks: Bleach: airway irritant if inhaled and can release VOCs e.g. chloroform when it reacts with organic material, which is a known carcinogen. Skin and eye irritation is common, poisonings have been reported and long-

		term exposure in adults has resulted in respiratory effects, asthma. Quaternary ammonium compounds: Increased risk of asthma and allergic sensitization has been reported. Some have been shown to be mutagenic and reduce fertility rates in animal models. Carcinogenicity has not been shown. Peroxides: Acute toxicity includes poisoning and eye irritation. No other toxicity data have been published. All disinfectants are less effective in the presence of organic material.

Abbreviations: ECE: Early Childhood Education, VOC: Volatile Organic Compounds

Methods:

A daily scan of the literature (published and pre-published) is conducted by the Emerging Sciences Group, PHAC. The scan has compiled COVID-19 literature since the beginning of the outbreak and is updated daily. Searches to retrieve relevant COVID-19 literature are conducted in Pubmed, Scopus, BioRxiv, MedRxiv, ArXiv, SSRN, Research Square and cross-referenced with the literature on the WHO COVID literature list, and COVID-19 information centers run by Lancet, BMJ, Elsevier and Wiley. The daily summary and full scan results are maintained in a refworks database and an excel list that can be searched. Targeted keyword searching is conducted within these databases to identify relevant citations on COVID-19 and SARS-CoV-2. Additional searches for supporting evidence published prior to the COVID-19 pandemic was conducted by keyword searches of PubMed, using a snowball technique and reviewing reference lists. Search terms used included: Disinfect*, Chemical, Safety, Risk, Child*. This review contains research published up to October 5, 2020. Each potentially relevant reference was examined to confirm it had relevant data and relevant data is extracted into the review.

APPENDIX

Appendix table of common categories of hard-surface disinfectants that comprise the active ingredients in disinfectants used in a range of settings: home, public, hospital [1]

Category (Examples)	Properties and Uses	Potential health impacts: longer term[2]	Safety measures[3]
Chlorine and Chlorine compounds Includes "household bleach" (sodium hypochlorite)- aqueous solution of 5.25%-6.25%, solid calcium hypochlorite. Other compounds designed to hold chlorine longer: demand-release chlorine dioxide, sodium dichloroisocyanurate, and chloramine-T.	Does not leave a residue, inexpensive, fast acting. Rapidly inactivated by organic material. Diluted and applied to surface. Do not mix with: - Ammonia or household cleaning agents as it produces toxic chlorine gas - Formaldehyde and hypochlorite solutions as it produces a carcinogen bis(chloromethyl) ether	Low incidence of serious toxicity. Household bleach (5.25-6.15%) can produce ocular irritation or oropharyngeal, esophageal, and gastric burns. Associated with asthma and other respiratory issues. Chloramines create "organic chloramines" as they attach to organic materials are known as VOCs, studies have shown they increase during household cleaning and some are known carcinogens (Odabasi, 2014). However no adverse effects are expected from normal exposure and proper use.	Diluted household bleach solutions: Use bleach containing 5.25%–8.25% sodium hypochlorite. Do not use a bleach product if the percentage is not in this range or is not specified. Ensure proper ventilation during and after application. Check to ensure the product is not past its expiration date. Never mix household bleach with ammonia or any other cleanser. This can cause fumes that may be very dangerous to breathe in. Prepare a bleach solution by mixing: 5 tablespoons (1/3rd cup) of 5.25–8.25% bleach per gallon of room temperature water or 4 teaspoons of 5.25–8.25% bleach per quart of room temperature water. Bleach solutions will be effective for disinfection up to 24 hours.

Quaternary Ammonium Compound Includes approximately 300 product registrations. Group 1 is hydroxyalkyl substituted quats, Group II non-halogenatred benzyl substituted. Group III is the di and tri-chlorobenzyl substituted quats Group IV are quats with unusual substitutions. (e.g. alkyl dimethyl benzyl ammonium chloride, alkyl didecyl dimethyl ammonium chloride, and dialkyl dimethyl ammonium chloride; twin-chain or dialkyl quaternaries e.g. didecyl dimethyl ammonium bromide and dioctyl dimethyl ammonium bromide).	Non-volatile, leaves residue. Generally approved for disinfection of surfaces and are okay on use of equipment that touches skin. They can be applied as a liquid spray or in a wipe.	No long term health impacts reported: Not dermal sensitizers, not developmental or reproductive toxicants and not carcinogenic or genotoxic (Luz, 2020). Some cases of occupational asthma (e.g. among cleaners) has been reported with exposure to benzalkonium chloride.	Follow the label instructions for use of any disinfectant. Health Canada considers the overall risk benefit prior to approval, ensuring that potential risks can be mitigated by appropriate labelling.
Hydrogen peroxide: Peroxygen, several liquid disinfectants contain hydrogen peroxide. Concentrations range from 6-25% in a premixed -ready to use- chemical. Common combination: 7.5% hydrogen peroxide and 0.85% phosphoric acid.	Leaves residue. Generally approved for disinfection of surfaces. Found in disinfectants at 3-9%. They can be applied as a liquid spray or in a wipe. Is unstable and readily decomposes.	The data on carcinogenicity is inconclusive. Can cause respiratory effects.	Follow the label instructions for use of any disinfectant. Health Canada considers the overall risk benefit prior to approval, ensuring that potential risks can be mitigated by appropriate labelling.
Phenol and phenol derivatives The newer versions-phonolic (chloroxylenol, thymol, O-phenylphenol, triclosan, ortho-phenylphenol ortho-benzyl-para-chlorophenol	Leaves a residue. Generally approved for dis-infection of surfaces. They can be applied as a liquid spray or in a wipe.	Residues can be irritating to skin and dermal absorption is the main route of exposure. Has been linked to hyperbilirubinemia in infants in nurseries using this on bassinettes.	Follow the label instructions for use of any disinfectant. Health Canada considers the overall risk benefit prior to approval, ensuring that potential risks can be mitigated by appropriate labelling.

Peracetic Acid: Peracetic or peroxyacetic	No harmful decomposition products, enhances removal of organic material, leaves no residue, strong pungent odor. They can be applied as a liquid spray. Remains active at low temperatures and in the presence of organic matter. It is unstable when diluted, so should be mixed just prior to use. Can be used in "non-rinse" applications.	Considered a chemical of low concern, low dermal adsorption and no long term health concerns are listed.	Follow the label instructions for use of any disinfectant. Health Canada considers the overall risk benefit prior to approval, ensuring that potential risks can be mitigated by appropriate labelling.
Ortho-phthalaldehyde (OPA or 1,2-benzenedicarboxaldehyde)	Is not a known irritant, no odor, does not require exposure monitoring. Stable at a range of pH from 3-9.	Causes skin staining as it turns proteins gray. Has also been associated with anaphylaxis. Long term exposure is associated with asthma.	Follow the label instructions for use of any disinfectant. Health Canada considers the overall risk benefit prior to approval, ensuring that potential risks can be mitigated by appropriate labelling.
Idophors povidone-iodine aka polybinylpyrrolidone with iodine is most common	Can be used as a surface disinfectant (but better known as an antiseptic). Explodes if mixed with hydrogen peroxide.	Can cause hypothyroidism if ingested in large quantities. Fetus and neonates are particularly sensitive.	Follow the label instructions for use of any disinfectant. Health Canada considers the overall risk benefit prior to approval, ensuring that potential risks can be mitigated by appropriate labelling.

VOC=Volatile organic compounds (VOCs) are compounds that have a high vapor pressure and low water solubility and are emitted as gases from certain solids or liquids. VOCs are released by a wide array of products including paints, cleaning supplies, pesticides, new materials, printers, markers etc. VOCs are higher indoors than outdoors.

[1] Sources: https://www.cdc.gov/infectioncontrol/guidelines/disinfection/index.html, https://pubchem.ncbi.nlm.nih.gov/ and https://www.cdc.gov/coronavirus/2019-ncov/prevent-getting-sick/cleaning-disinfection.html

[2]Health impacts related to improper use are not listed: e.g. none of these are safe to ingest, most cause skin irritation and damage to the eye if the product comes in contact with these surfaces. Many of the spray products and bleach also have inhalation warnings during their use.

[3] General safety precautions when using disinfectants: wear skin protection and consider eye protection for potential splash hazards, ensure adequate ventilation, use no more than the amount recommended on the label, use water at room temperature for dilution (unless stated otherwise on the label), avoid mixing chemical products.

Preuve émergente sur la COVID-19

Synthèse en bref sur les risques potentiels pour la santé de l'utilisation des désinfectants pour surfaces dures dans les environnements où se trouvent des enfants d'âge scolaire

Introduction

Quelles preuves existe-t-il en ce qui concerne les risques potentiels pour la santé (exposition par contact, toxicité par inhalation, empoisonnement) découlant de l'utilisation accrue des désinfectants pour surfaces dures dans les environnements (p. ex., école, maison, loisirs) où se trouvent des enfants d'âge scolaire pendant la pandémie de COVID-19?

Les écoles rouvrent et doivent se conformer à des exigences plus strictes en ce qui concerne l'hygiène et la fréquence d'assainissement pour atténuer la propagation du SRAS-CoV-2, le virus qui cause la COVID-19, parmi les élèves et les membres du personnel. De plus, de nombreux établissements publics, entreprises et résidences ont également adopté des procédures d'assainissement plus strictes, qui incluent l'utilisation accrue de désinfectants pour surfaces dures afin de réduire le risque de propagation du virus. On sait que les désinfectants pour surfaces dures présentent certains risques pour la santé, et leur utilisation accrue pourrait entraîner des risques supplémentaires pour la santé des enfants d'âge scolaire.

Les désinfectants pour surfaces dures qui sont conçus pour être utilisés comme désinfectants pour surfaces dures non poreuses contiennent des ingrédients actifs autorisés par Santé Canada. Les virus enveloppés comme les coronavirus sont facilement inactivés par de nombreux désinfectants (Rai, 2020). Une liste de produits approuvés (n = 526), efficaces contre le SRAS-CoV-2, figure sur le site web de Santé Canada (Santé Canada, 2020). Les composés d'ammonium quaternaire, les phénoliques, les idophores, les composés dégageant du chlore et le peroxygène font partie de certaines catégories courantes d'ingrédients actifs que l'on retrouve dans les désinfectants pour surfaces dures (Santé Canada, 2015). Le tableau en annexe donne un aperçu général de chacune des catégories. Chacune de ces catégories d'ingrédients actifs comporte des mises en garde quant à l'utilisation appropriée de chacun des produits chimiques.

Les désinfectants sont réglementés comme des médicaments au Canada et, bien que la *Loi sur les aliments et drogues* et le Règlement sur les aliments et drogues ne précisent pas les critères de classification pour les dangers de toxicité aiguë pour les désinfectants assimilés aux drogues, l'on recommande aux fabricants de penser à faire référence au Règlement sur les produits chimiques et contenants destinés aux consommateurs

de 2001 lorsque ces produits sont conçus pour des utilisations non commerciales (domestiques) par des consommateurs (Canada, 2020a) ou au Règlement sur les produits dangereux de 2015 lorsque ces produits seront utilisés dans les lieux de travail ou à des fins commerciales (Canada, 2020b). Lorsque Santé Canada approuve un désinfectant, des mises en garde visant à garantir son utilisation appropriée sont incluses sur les étiquettes des produits. Ces mises en garde décrivent les mesures recommandées qui peuvent être prises pour minimiser, atténuer et/ou prévenir les effets indésirables. Elles sont indiquées et mises en évidence sur les étiquettes afin de garantir une utilisation et une manipulation sécuritaires du produit par les utilisateurs finaux lorsque ces derniers les utilisent de la façon indiquée sur l'étiquette. Ces mises en garde sont également pertinentes en ce qui concerne les dangers potentiels d'exposition à la toxicité aiguë du produit. Pour déterminer les mises en garde appropriées, Santé Canada tient compte de tous les ingrédients présents dans la préparation, y compris les ingrédients inertes ou non médicinaux. Santé Canada s'assure également que les risques-avantages globaux associés à l'utilisation d'un produit sont positifs et que les risques potentiels peuvent être atténués par un étiquetage approprié.

Tout contact avec les désinfectants, ou toute inhalation ou ingestion de ces derniers, peut entraîner une irritation ou un empoisonnement immédiat. Les composés que l'on retrouve dans ces produits peuvent également causer des brûlures par contact, augmenter la sensibilité au niveau de la peau et des yeux, être nocifs s'ils sont ingérés et présenter des risques en cas d'inhalation tant pendant la manipulation qu'au moment de l'utilisation (CDC, 2020 et Santé Canada, 2020). Certains désinfectants peuvent aussi laisser des résidus chimiques qui pourront ensuite se retrouver dans l'air et être inhalés. Pour assurer une utilisation sûre, il faudrait donc rincer les surfaces après avoir utilisé des désinfectants. Les sous-produits des désinfectants, comme ceux qui proviennent de composés contenant du chlore, comme l'eau de Javel d'usage courant, présentent un intérêt particulier, car ils peuvent former des composés organiques volatils (COV) s'ils sont accidentellement mélangés à d'autres produits de nettoyage ou s'ils entrent en contact avec des matières organiques sur une surface sale (Odabasi, 2014). Certaines catégories de désinfectants également ont été associées à des problèmes respiratoires, y compris à l'asthme, en raison d'une exposition professionnelle prolongée (voir le tableau en annexe). Les mesures qui visent à contrer ces risques incluent notamment l'utilisation du savon et de l'eau, avant le désinfectant, pour retirer la saleté visible des surfaces, éviter de mélanger les désinfectants à d'autres produits, ouvrir les fenêtres pour augmenter la ventilation, porter des gants pendant la désinfection, laisser les surfaces sécher complètement à l'air avant de les utiliser et éviter de s'approcher d'une zone qui vient d'être désinfectée pendant 20 à 30 minutes (Bello, 2010). Les données toxicologiques sur l'exposition à long terme sont incomplètes pour bon nombre de désinfectants et sont généralement appuyées par des études sur les animaux. Bien que certaines études comprennent des données limitées sur les adultes, peu d'entre elles comportent des données sur les enfants (voir le tableau en annexe pour un résumé de chacune des catégories de désinfectants).

Cette synthèse porte donc sur les risques pour la santé associés à l'utilisation de désinfectants pour surfaces dures près des enfants d'âge scolaire, tant avant la pandémie de COVID-19 que pendant celle-ci. Elle

comprend la documentation publiée jusqu'au 5 octobre 2020 (la méthodologie utilisée est présentée à la fin du document).

Principaux points

Bien qu'il n'existe que peu de données probantes sur les risques pour la santé associés à l'utilisation de désinfectants pour surfaces dures auprès des enfants d'âge scolaire, la présente synthèse démontre ce qui suit :

- Comparativement aux années précédentes, les rapports sur les appels qu'ont reçus les centres antipoison aux États-Unis (É.-U.) et au Canada ont fait état d'une augmentation du nombre d'appels pendant la pandémie de COVID-19, en lien avec les désinfectants et les nettoyants, en raison d'expositions souvent liées aux enfants (tableau 1).
- Selon une enquête effectuée auprès des consommateurs aux États-Unis, les personnes qui utilisent des désinfectants manqueraient peut-être de connaissances sur l'utilisation sécuritaire et les risques potentiels qui y sont associés (tableau 1).
- Les études effectuées sur les enfants qui vivent dans des foyers qui utilisent un grand nombre de produits désinfectants montrent qu'ils présentent une fréquence beaucoup plus élevée d'effets cutanés et d'effets respiratoires, en plus d'une plus grande sensibilisation aux désinfectants (tableau 2).
- Certaines études transversales ont montré un lien entre la fréquence d'utilisation des désinfectants près des enfants et les effets sur la santé comme l'asthme et la respiration sifflante chez les jeunes enfants (tableau 2).
- Le chloroforme (un des COV qui peut se former lorsqu'un agent de blanchiment entre en contact avec d'autres produits ou matières organiques) a été trouvé dans des concentrations inacceptables dans plusieurs centres de la petite enfance et la plupart de ces centres ont indiqué utiliser régulièrement de tels agents de blanchiment (tableau 2).
- Dans l'ensemble, il subsiste cependant de grandes lacunes dans la documentation en ce qui concerne les effets à court et à long terme que l'utilisation accrue de désinfectants pour surfaces dures peut avoir sur les enfants.

Vue d'ensemble des éléments de preuve

Les publications qui font directement état des risques potentiels pour la santé découlant de l'utilisation accrue des désinfectants pour surfaces dures dans des environnements où se trouvent des enfants d'âge scolaire sont rares. Nous avons examiné non seulement la revue de la littérature et l'information sur les appels

reçus par les centres antipoison pendant la pandémie (tableau 1), mais avons également inclus les données disponibles sur les effets sur la santé des enfants en raison de l'utilisation de désinfectants pour surfaces dures avant la pandémie de COVID-19 (tableau 2). Seize publications pertinentes sur l'exposition aux désinfectants pour surfaces dures ont orienté cette synthèse. Elles comprenaient notamment des études épidémiologiques (cohortes et études transversales), des rapports publiés par les centres antipoison, un sondage sur les connaissances des consommateurs, des évaluations des risques, des revues de la littérature et des commentaires. Le corpus de recherche global est cependant très petit, de piètre qualité et est insuffisant pour fournir des preuves concluantes sur les risques pour la santé découlant de l'utilisation de désinfectants autour des enfants d'âge scolaire. Des recherches supplémentaires seront donc nécessaires à ce sujet.

Différentes études ont cependant été exclues de cet examen, soit celles qui portaient sur l'exposition des adultes ou sur l'exposition professionnelle aux désinfectants, ainsi que les études sur les animaux, puisque leurs niveaux d'exposition peuvent différer de ceux des enfants d'âge scolaire. Les caractéristiques générales des catégories de désinfectants et les liens vers des renseignements supplémentaires sur chacune des catégories sont présentés dans le tableau en annexe.

TABLE DES MATIÈRES

EXPOSITION À DES DÉSINFECTANTS POUR SURFACES DURES PENDANT LA PANDÉMIE DE COVID-19

Sept études sur l'effet de l'exposition aux désinfectants pour surfaces dures chez les enfants pendant la pandémie de COVID-19 sont résumées dans le tableau 1. Cela inclut notamment deux rapports publiés par des centres antipoison, un sondage sur les connaissances des consommateurs, une évaluation des risques, une revue de la littérature et deux commentaires pertinents.

Les centres antipoison des États-Unis et du Canada ont signalé une augmentation du nombre d'appels relatifs aux désinfectants et aux produits d'entretien ménager généraux en 2020 comparativement aux années précédentes (Chang, 2020; Yasseen, 2020). Dans l'étude canadienne qui a fait le suivi des appels portant sur les produits de nettoyage et les désinfectants, 42 % des appels étaient liés à des agents de blanchiment et 21 % à des désinfectants (Yasseen, 2020). L'augmentation a été observée dans tous les groupes d'âge, mais la majorité des appels portaient sur des adultes plutôt que sur des enfants. Dans l'étude menée aux États-Unis, les agents de blanchiment, suivis des désinfectants sans alcool, ont été à l'origine de la plus forte

augmentation en pourcentage du nombre d'appels. Entre 2018 et 2020, les appels attribuables à l'exposition des enfants de ≤ 5 ans à ces produits ont représenté de façon consistante un pourcentage élevé du nombre total d'appels (intervalle = de 39,9 à 47,3 %) (Chang, 2020).

Un sondage réalisé en mai 2020 a révélé que 60 % des répondants ont déclaré nettoyer ou désinfecter leur maison plus fréquemment depuis le début de la pandémie comparativement aux mois précédents (Gharpure, 2020). Il a également indiqué que les répondants avaient une connaissance limitée sur la façon de préparer leurs produits de nettoyage et solutions désinfectantes de façon sécuritaire. En outre, 25 % d'entre eux ont ajouté que selon eux, l'utilisation de ces produits aurait contribué à au moins un effet néfaste sur leur santé (Gharpure, 2020).

Une évaluation des risques a révélé que les enfants de trois ans étaient ceux qui présentaient la plus grande possibilité d'exposition potentielle à des surfaces désinfectées comparativement à tout autre groupe d'âge puisqu'ils sont plus susceptibles de toucher ces surfaces et qu'ils se mettent souvent les doigts dans la bouche (Li, 2020). Bien que cette évaluation des risques ait porté sur plusieurs produits chimiques, elle ne comportait pas uniquement des désinfectants pour surfaces dures. L'évaluation des risques a également présumé que les désinfectants étaient utilisés à concentration intégrale sans dilution, que la personne y était exposée par contact direct avec la main et que les désinfectants n'avaient pas été essuyés après l'application sur la surface, ce qui peut ne pas être représentatif de la façon dont ces désinfectants étaient véritablement utilisés par les consommateurs.

Les examens des désinfectants approuvés qui contenaient de l'ammonium quaternaire, de l'hypochlorite de sodium ou du peroxyde d'hydrogène et leur utilisation pendant la pandémie de COVID-19 incluent la majorité des désinfectants pour surfaces dures qui ont été utilisées contre le SRAS-CoV-2 (Samara, 2020, Rai, 2020). La revue de la littérature a révélé que les résidus de certains désinfectants pour surfaces dures peuvent contribuer à la mauvaise qualité de l'air. Elle présente également des éléments de preuve qui montrent des taux de cancer plus élevés attribuables à l'utilisation régulière de certains de ces désinfectants chez les adultes qui y ont été exposés en milieu de travail (Rai, 2020). Dans certaines professions dans lesquelles les travailleurs étaient fortement exposés à ces produits, des études ont montré un lien entre ces produits et un risque accru de maladie pulmonaire obstructive chronique, d'asthme et d'irritation oculaire (Rai, 2020; Samara, 2020). Bien qu'aucune donnée semblable n'a pu être obtenue pour les enfants et que 5 % des cancers chez les enfants et 30 % de l'asthme chez les enfants soient liés à une exposition à des produits chimiques, la proportion pouvant être attribuée à l'utilisation des désinfectants pour surfaces dures est cependant inconnue (Rai, 2020).

Tableau 1 : Études et analyses des risques pour la santé découlant de l'utilisation de désinfectants pour surfaces dures chez les enfants d'âge scolaire (n = 7)

Année	Méthode	Principaux résultats
Appels aux centres antipoison		
Chang, 2020 Avant/après l'étude États-Unis De janvier à mars 2018, 2019 et 2020	Les appels au Système national de données sur les poisons (National Poison Data System) ont été analysés afin de déterminer le nombre d'expositions signalées pour la période de janvier à mars 2020 comparativement à la même période de trois mois en 2018 et en 2019.	Ainsi, de janvier à mars 2020, les centres antipoison ont reçu 45 550 appels pour une exposition liée à des produits nettoyants (28 158) et à des désinfectants (17 392), ce qui représente des augmentations globales de 20,4 % et de 16,4 % par rapport à 2019 et 2018, respectivement. L'augmentation des appels a été observée dans tous les groupes d'âge, mais l'exposition chez les enfants de ≤5 ans a représenté entre 39,9 % et 47,3 % des appels durant les trois périodes mentionnées L'inhalation est l'élément qui a vu la plus forte augmentation en pourcentage dans le nombre des appels entre 2019 et 2020. La plus forte augmentation du nombre d'appels possiblement liée aux désinfectants pour surfaces dures (2019 comparativement à 2020) portait sur des agents de blanchiment (62,1 %) et les désinfectants sans alcool (36,7 %).
Yasseen, 2020 Avant/après l'étude Canada De janvier à juin 2019 et 2020	Cinq rapports d'exposition provenant des centres antipoison canadiens entre janvier et juin 2020 ont été comparés à la même période de six mois en 2019.	Le nombre total d'expositions aux produits de nettoyage/désinfectants/désinfectants pour les mains a augmenté de 35 % en 2020 par rapport à 2019. Parmi les 8 187 appels signalant des expositions reçus entre janvier et juin 2019 et janvier et juin 2020, ceux qui pourraient être liés aux désinfectants pour surfaces dures étaient les suivants : 42 % concernaient des agents de blanchiment, 21 % des désinfectants, 12 % du chlore gazeux et 2 % de la chloramine gazeuse (ces derniers sont des sous-produits provenant du mélange d'un agent de blanchiment avec d'autres désinfectants ou nettoyants, voir l'annexe). Pendant la période examinée en 2020, le nombre d'appels a atteint un pic en mars pour ensuite diminuer de manière générale après avril 2020. Le plus grand nombre d'appels signalant une exposition portait principalement sur des personnes âgées de plus de 19 ans et plus pour les deux années. Les résultats ne donnent pas à penser qu'il y ait eu une forte augmentation chez les personnes âgées de moins de 19 ans entre 2019 et 2020.
Sondage sur les connaissances		

Gharpure, 2020 Sondage volontaire sur Internet destinée aux adultes et portant sur l'entretien ménager États-Unis Mai 2020	L'étude comprenait des questions visant à évaluer les connaissances et les pratiques relatives à l'entretien ménager et à la désinfection utilisées par les ménages pendant la pandémie de COVID-19.	Cette étude comprenait 502 adultes (âgés de 18 ans et plus). 60 % ont déclaré avoir utilisé plus souvent des produits de nettoyage et de désinfection à la maison comparativement aux mois précédents. Plusieurs questions ont cependant révélé une connaissance limitée sur la façon sécuritaire de préparer les solutions de nettoyage et de désinfection. 39 % des répondants ont déclaré avoir eu recours à des pratiques à risque élevé non recommandées par le CDC, y compris : 1) Mettre de l'eau de Javel sur les aliments (19 %); 2) Appliquer des nettoyants et des désinfectants ménagers sur leurs mains (18 %); 3) Vaporiser des produits nettoyants et désinfectants sur leur corps (10 %); 4) Inhaler des vapeurs (6 %); 5) Avoir bu des solutions d'eau de Javel diluée (4 %), de l'eau savonneuse (4 %) ou d'autres solutions nettoyantes ou désinfectantes (4 %) ou s'être gargarisé avec de telles solutions. En outre, 25 % des répondants ont dit avoir ressenti au moins un effet indésirable sur la santé découlant, à leur avis, de l'utilisation de nettoyants ou de désinfectants. Ces cas étaient plus fréquents (33 % comparativement à 25 %) chez les répondants qui ont dit avoir eu recours à une pratique à risque élevé.
Évaluation du risque		
Li, 2020 Évaluation des risques et modèle d'exposition quantitative relatifs à 22 produits chimiques désinfectants qui ont été indiqués comme étant capables de tuer le SRAS-CoV-2	L'évaluation des risques utilise le modèle PROTEX qui évalue le devenir et l'exposition chimique à l'intérieur. Trois voies d'exposition ont été étudiées dans cette évaluation, soit ingestion orale par la bouche, inhalation et absorption cutanée. Le scénario d'application utilisé	<u>Évaluation du risque d'exposition</u> Les enfants de trois ans présentaient la plus forte exposition globale, tout particulièrement aux surfaces désinfectées, en raison du plus grand nombre de contacts entre leurs mains et la surface, puisqu'ils mettent souvent leurs doigts dans leur bouche. Le risque d'exposition aux désinfectants de surface, en particulier chez les jeunes enfants, a été mentionné. L'ingestion par la bouche est le principal mode d'exposition aux désinfectants non volatils dont les résidus peuvent rester sur les surfaces jusqu'à ce qu'ils aient été éliminés par un nettoyage normal (p. ex., les composés d'ammonium quaternaire). Pour les groupes d'âge plus âgés, cette

États-Unis et Canada[1] Septembre 2020[1]	dans cette évaluation portait sur la désinfection des surfaces intérieures et des objets (application de surface). Trois groupes d'âge ont été modélisés : 3, 14 et 24 ans.	exposition s'est plutôt produite par l'absorption cutanée et a également été mentionnée à propos des produits chimiques phénoliques. En ce qui concerne les désinfectants comme le triéthylèneglycol (faible toxicité) qui sont aérosolisés pour désinfecter et nettoyer l'air, l'exposition s'était principalement produite par l'inhalation. Bien que cette évaluation des risques ait porté sur 22 produits chimiques, bon nombre d'entre eux n'étaient pas des désinfectants pour surfaces dures.
Revues de la littérature		
Rai, 2020 Revue de la littérature Juin 2020	Les études sur les effets potentiellement nocifs des désinfectants et des solutions alternatives sécuritaires ont été résumées dans le contexte de la COVID-19.	On sait que 5 % des cas de cancer chez les enfants et 30 % des cas d'asthme chez les enfants sont liés à des expositions à des produits chimiques. On ne sait cependant pas si l'une de ces maladies est attribuée à des désinfectants pour surfaces dures. La majorité des produits que recommande l'EPA contre la COVID-19 contiennent des ingrédients actifs tirés des composés d'ammonium quaternaire (Quats). Bon nombre de ces composés sont associés à un risque accru de maladie pulmonaire obstructive chronique (MPOC), d'asthme et d'irritation oculaire lorsqu'ils sont utilisés de façon régulière (exposition professionnelle). Il a été démontré que les quats pouvaient également entraîner des problèmes de fertilité dans les études sur les animaux. Lorsque les surfaces ne sont pas rincées correctement après l'utilisation, les désinfectants biodégradables vont laisser un résidu chimique actif sur la surface. Toute perturbation du résidu peut ensuite en entraîner la propagation dans l'air, ce qui peut alors causer une irritation chez certaines personnes. Un rinçage complet et un nettoyage général permettent cependant d'éliminer les résidus.
Commentaires		
Rivera, 2020 Commentaires É.-U.[1] Janvier à mai 2020	L'étude a évalué, avec Google Trends, l'intérêt d'effectuer une recherche sur les achats et la consommation de désinfectants, et sur les appels aux centres antipoison, après que le	Les valeurs des fractions de recherche relatives obtenues entre janvier et février 2020 en ce qui concerne l'achat, la consommation ou l'injection de désinfectants étaient minimes (< 1). La journée qui a suivi le commentaire de Donald Trump sur l'injection de désinfectants, la fraction de recherche relative pour la consommation de désinfectants a atteint 32,3 alors qu'elle était de 100 pour l'injection de désinfectants.

	président des États-Unis ait laissé entendre que de s'injecter des désinfectants pourrait être un traitement possible pour la COVID-19. Les intervalles de confiance pour chacune des tendances ont été calculés en faisant la moyenne de plusieurs échantillons recueillis quotidiennement pendant une période de trois semaines.	La fraction de recherche relative pour les centres antipoison a atteint un sommet une journée plus tard (fraction de recherche relative = 11,05), ce qui indique une augmentation de l'intérêt ou peut-être des demandes d'information ou d'aide après un usage hors indication des désinfectants.
Samara, 2020 Commentaires Émirats arabes unis[1] 2020[1]	L'étude indique la sécurité d'emploi de certains des désinfectants pour surfaces naturels et synthétiques les plus utilisés et approuvés par l'Environmental Protection Agency pour la prévention du SRAS-CoV-2 et examine les effets connexes de ces produits sur la santé.	Les désinfectants pour surfaces dures peuvent causer une irritation de la peau et des yeux, une irritation des voies respiratoires et de l'asthme chez certaines personnes. L'utilisation d'un agent de blanchiment peut entraîner la formation de COV dans l'air intérieur, et des concentrations élevées de COV ont été signalées 30 minutes après l'application de ce produit, ce qui démontre que l'utilisation de l'eau de Javel peut être une source importante d'exposition aux COV par inhalation. Le désinfectant idéal devrait avoir un profil de toxicité faible lié à une exposition à court et à long terme, p. ex., composés d'ammonium quaternaire et acide peracétique : (voir le tableau en annexe).

[1] Le pays indiqué est lié à l'endroit où se trouvait l'auteur ou la date est fondée sur la date de publication.

EXPOSITION GÉNÉRALE AUX DÉSINFECTANTS POUR SURFACES DURES

Bien qu'il n'y ait aucune étude récente sur l'effet que l'exposition accrue aux désinfectants pour surfaces dures pendant la pandémie aura sur la santé et la sécurité des enfants d'âge scolaire, les études menées avant la pandémie de COVID-19 peuvent fournir des renseignements supplémentaires sur les effets de l'exposition aux désinfectants pour surfaces dures chez les enfants.

L'étude de surveillance biologique réalisée dans 34 centres de la petite enfance en Californie a révélé que dans 38 % des établissements, le chloroforme, un COV découlant de l'utilisation d'un agent de blanchiment avec chlore, dépassait les niveaux acceptables en ce qui concerne les risques de cancer. (Hoang, 2016).

Deux études d'évaluation de l'exposition ont révélé que l'eau de Javel est couramment utilisée dans les garderies aux États-Unis. Une enquête menée dans quatorze garderies de Washington (D.C.) a fait état de l'utilisation d'eau de Javel avec chlore (92,8 %) dans les établissements à des fins d'assainissement et de la présence de chloroforme dans tous les établissements (Quirós-Alcalá, 2016). Les surfaces les plus couramment désinfectées étaient les tables, salles de bain, chaises, lits, tables à langer et jouets des enfants. L'eau de Javel a été signalée comme étant un irritant des voies respiratoires si elle est inhalée, sans oublier qu'elle peut libérer des COV (p. ex., du chloroforme), qui sont des cancérogènes connus, lorsqu'elle réagit avec des matières organiques. La troisième évaluation des risques a permis de mesurer et de modéliser la quantité de COV produits pendant un nettoyage normal à l'intérieur. Les résultats laissent entendre qu'il existe un risque d'exposition à des niveaux de COV supérieurs à la moyenne pour toute personne qui entre dans la pièce jusqu'à 20 minutes après le nettoyage des éviers, des miroirs ou des toilettes avec des désinfectants contenant des composés d'ammonium quaternaire ou de l'hydroxyde de sodium (Bello, 2010). Augmenter la ventilation et réduire le temps passé dans une pièce qui vient d'être nettoyée réduiraient cependant l'exposition aux COV. Trois études épidémiologiques ont été publiées. Une étude de cohorte prospective effectuée en Allemagne chez des jeunes âgés de 19 à 24 ans a montré que l'utilisation de produits de désinfection était associée à une augmentation de l'asthme et de la dermatite atopique. L'exposition autodéclarée à des désinfectants ménagers et la forte utilisation de désinfectants ont été associées à une probabilité deux fois plus élevée d'incidence d'asthme que chez les personnes qui ont déclaré ne pas en avoir utilisé (Weinmann, 2017). Les jeunes qui ont déclaré une utilisation faible ou moyenne des désinfectants étaient également plus susceptibles d'indiquer qu'ils souffraient d'une forme récurrente d'asthme (Weinmann, 2017). Dans une étude transversale portant sur des enfants de quatre ans provenant de plusieurs pays d'Europe, un lien a été établi entre la forte utilisation de désinfectants en spray dans les pièces et une augmentation de la dermatite atopique et des éruptions cutanées avec démangeaisons, mais pas avec l'asthme (Krauss-Etschmann, 2009). Cette étude comportait cependant une faiblesse, puisque l'utilisation générale des désinfectants n'a pas été consignée (Krauss-Etschmann, 2009). Une étude transversale menée en Suède a révélé que l'utilisation d'eau de Javel chlorée à la maison avait une association protectrice avec le développement de l'asthme et la sensibilisation aux allergènes intérieurs, mais ne précisait cependant pas si les enfants étaient présents pendant le nettoyage (Nickmilder, 2007).

Trois revues de la littérature ont résumé les données probantes sur le risque potentiel pour les enfants. Elles comprennent principalement des études transversales des produits de nettoyage et de désinfection et des COV associés à ces produits (Holm, 2019; Mendell, 2007; Slaughter, 2019). Les catégories les plus courantes de désinfectants mentionnées dans les études comprenaient l'agent de blanchiment (eau de Javel), les composés d'ammonium quaternaire et les peroxydes, choisis en fonction de leur gamme élargie de désinfection pour différents pathogènes (Holme, 2019). Les activités de nettoyage à l'intérieur étaient

associées à des allergies, à de l'asthme et à d'autres problèmes respiratoires chez les nourrissons et les jeunes enfants (Mendell, 2017). La plupart de ces études ne précisaient cependant pas les produits utilisés, et souvent, plusieurs types de produits étaient utilisés, de sorte qu'il n'était pas possible de séparer les effets des différents produits.

Tableau 2 : Rapports sur les risques pour la santé associés à l'utilisation des désinfectants pour surfaces dures tirés de la littérature publiée avant la pandémie (n = 9)

Année	Méthode	Principaux résultats
Évaluations de l'exposition / des risques		
Hoang, 2017 Surveillance biologique États-Unis Mai 2010 à mai 2011	L'étude a permis de mesurer 38 COV dans des échantillons d'air prélevés en une seule journée en 2010 et 2011 dans 34 CPE où se trouvaient des enfants californiens. Elle a également établi la « concentration sans risque » comme la dose quotidienne qui représente un risque supplémentaire de cancer au cours d'une vie de un sur 100 000.	Le chloroforme, un COV associé à l'utilisation de l'eau de javel, a été identifié dans certains échantillons. Même si d'autres COV n'étaient pas associés à des désinfectants pour surfaces dures, ils peuvent cependant être produits par des parfums ajoutés à un produit de nettoyage ou de désinfection. Les estimations du 95^{e} percentile de la dose de chloroforme dépassaient la concentration sans risque spécifique à l'âge pour les quatre groupes d'âge évalués. Constatations: Les concentrations de COV dans les CPE ressemblent à celles observées dans les milieux scolaires et domestiques et, si elles reflètent les moyennes à long terme, les estimations des doses qu'ont reçu les enfants dépassaient les valeurs de référence des concentrations sans risque rajustées selon l'âge pour le benzène, le chloroforme, l'éthylbenzène et le naphtalène dans 71 %, 38 %, 56 % et 97 % des établissements, respectivement. Dans une analyse bivariée : Les niveaux de COV étaient semblables dans les établissements qui ont déclaré utiliser ou acheter des nettoyants à faible toxicité comparativement à ceux qui utilisent des nettoyants traditionnels. Toutefois, les niveaux de certains COV étaient beaucoup plus élevés dans les établissements où la fréquence de passage de la vadrouille était plus élevée, ce qui suggère des émissions de COV provenant des produits de nettoyage pour plancher.
Bello, 2010	Les tâches de nettoyage de l'évier, du miroir et de la toilette ont été simulées	Les nettoyants domestiques utilisés contenaient des composés d'ammonium quaternaire ou de l'hydroxyde de sodium.

Étude sur l'évaluation de l'exposition É.-U.[1] 2010[1]	pendant 20 minutes dans une grande salle de bain ventilée et dans une petite salle de bain non ventilée. Les produits utilisés étaient un nettoyant tout usage, un nettoyant pour le verre et un nettoyant pour salle de bain. Les composés organiques volatils totaux libérés dans l'air pendant ces tâches ont ensuite été mesurés.	Les expositions supérieures au niveau naturel ont été présentées pendant environ 20 minutes après la fin du nettoyage. La plus forte concentration d'ammoniac s'est produite pendant le nettoyage des miroirs. Les résultats indiquent donc qu'il y a une possibilité d'exposition pour toute personne qui nettoie la pièce ou entre dans la pièce peu après le nettoyage.
Quirós-Alcalá, 2016 Étude sur l'évaluation de l'exposition Washington (D.C.) Automne 2012 et 2013	Les directeurs des CPE ont d'abord été contactés par courriel et par lettre. Un questionnaire leur a été envoyé. Les directeurs ont également recueilli de l'information sur le nombre d'enfants atteints d'asthme dans chaque établissement et sur le fait de savoir si des enfants avaient eu des crises d'asthme ou des épisodes de respiration sifflante au cours des trois mois précédents. Pour pouvoir caractériser les COV dans les établissements, ils ont prélevé entre deux et cinq échantillons d'air sur 10 heures et des échantillons prélevés en temps réel par des instruments de mesure des particules à des intervalles d'une minute.	Du chloroforme (un COV qui peut provenir de produits contenant de l'eau de Javel chlorée) a été détecté dans chaque établissement. Il est important de noter qu'il peut y avoir d'autres sources de chloroforme. 92,9 % des répondants du CPE ont déclaré que l'eau de Javel chlorée était utilisée pour aseptiser l'établissement. Les surfaces désinfectées les plus fréquemment indiquées étaient les tables, les salles de bain et les chaises, mais les répondants ont aussi dit utiliser l'eau de Javel chlorée pour aseptiser les lits, les tables à langer et les jouets des enfants. Les polluants intérieurs provenant de l'eau de Javel chlorée sont des irritants respiratoires connus. Les auteurs recommandent de penser à utiliser des solutions de rechange sans eau de Javel pour la désinfection afin d'éviter d'introduire d'autres dangers dans les milieux de garde des enfants.
Études épidémiologiques		
Weinmann, 2017 Étude de cohorte prospective Allemagne 2007-2009	L'étude a évalué 2 051 jeunes adultes âgés de 19 à 24 ans qui habitaient dans deux grandes villes allemandes et ont participé à une étude dans laquelle ils autodéclaraient leur	Dans cet échantillon, 83,8 % des répondants n'ont pas déclaré qu'ils utilisaient des désinfectants. Aucune information sur les désinfectants utilisés n'a été recueillie. L'asthme a été signalé dans 5,4 % de l'échantillon :

	exposition aux vaporisateurs et aux désinfectants ménagers. Les liens entre l'exposition à des produits propres et l'asthme ou la respiration sifflante ont été étudiés.	- Une forte utilisation de désinfectants a été associée à une probabilité deux fois plus élevée d'asthme que chez les personnes qui n'utilisaient pas ces produits (RC 2,79, IC à 95 % : de 1,14 à 6,83). - Une utilisation de désinfectants de faible à moyenne a été associée à un asthme récurrent (RC 2,39, IC à 95 % : de 1,29 à 4,47). Respiration sifflante au cours des 12 derniers mois (sans lien avec le rhume) 17,1 %. Aucun lien clair n'a été établi entre les expositions et la respiration sifflante. Aucune inférence causale ne peut être tirée de ces données et d'autres évaluations de l'exposition sont donc justifiées.
Krauss-Etschmann, 2009 Étude transversale chez des enfants de 4 ans (106 Espagnols, 45 Allemands et 25 Hongrois). Espagne, Allemagne et Hongrie 2009[1]	Les enfants de quatre ans ont subi un examen médical et neurophysiologique. Pendant cette visite, les parents ont répondu à un questionnaire normalisé qui comprenait des questions sur les allergies et l'asthme dans l'enfance et les facteurs liés au mode de vie. Les données catégoriques descriptives ont fait l'objet d'une analyse χ^2. La probabilité de symptômes allergiques liés à l'utilisation de vaporisateurs dans la pièce a été évaluée dans les analyses bivariées.	Aucune information sur le désinfectant utilisé dans les pièces n'a été fournie. L'utilisation a été classée comme quotidienne, hebdomadaire, occasionnelle ou jamais. L'utilisation de désinfectants dans la pièce n'a pas été associée à des estimations d'effets plus élevés pour l'asthme, mais à des estimations d'effets beaucoup plus élevées pour la dermatite atopique et les éruptions cutanées accompagnées de démangeaisons. Aucune donnée sur le type de désinfectant n'a été indiquée.
Nickmilder, 2007 Étude transversale Suède Mars à mai 2002	L'étude a évalué la mesure dans laquelle les produits d'entretien ménager ordinaires avec javellisant influent sur le risque d'allergies et de maladies respiratoires. Un groupe de 234 écoliers âgés de 10 à 13 ans dont 78 vivaient dans une maison nettoyée avec un	Les enfants qui vivaient dans des maisons nettoyées régulièrement avec de l'eau de Javel chlorée : - avaient un risque plus faible de développer de l'asthme, ce qui était significatif si l'analyse tenait compte à la fois du diagnostic du médecin et du dépistage chez les enfants positifs; - étaient moins susceptibles d'être sensibilisés aux allergènes intérieurs, y compris aux acariens (important);

	agent de blanchiment au moins une fois par semaine. On a demandé aux parents d'enfants de remplir un questionnaire comportant un total de 38 questions.	- étaient moins susceptibles d'indiquer une respiration sifflante (non important).
Revues de la littérature		
Mendell, 2007 Revue de la littérature des études épidémiologiques É.-U.[1] Jusqu'au milieu de l'année 2004	L'étude a évalué le lien entre les émissions de produits chimiques, les émissions provenant des matériaux ou des activités liées aux émissions dans les résidences et les effets sur la respiration ou les allergies chez les enfants et les nourrissons.	Les types de matériaux et de revêtements utilisés dans les résidences, ainsi que les activités de rénovation ou de nettoyage, étaient associés aux effets sur la santé associés à l'asthme ou aux allergies chez les nourrissons ou les enfants. L'utilisation de nombreux produits nettoyants à base de produits chimiques (les femmes en utilisaient plus d'un, mais 87,4 % étaient des désinfectants et 84,8 % utilisaient de l'eau de Javel) par les mères a été mesurée par un questionnaire et la charge totale des produits chimiques dans une étude (Sherrif, 2005). Une charge totale des produits chimiques élevée était associée à une augmentation significative de la dose-réponse pour la respiration sifflante persistante chez les jeunes enfants (RR corrigé de 2,3 (IC à 95 %, de 1,2 à 4,4) et pour la respiration sifflante tardive chez les jeunes enfants (RR corrigé de 2,0 (IC à 95 %, de 0,8 à 5,2)). Aucun produit n'a été lié à la respiration sifflante chez les enfants. Ces résultats pourraient être influencés par de nombreux facteurs de confusion, et les études présentées ne permettent pas de tirer de conclusions sur une relation causale.
Slaughter, 2019 Analyse documentaire Nouvelle-Zélande[1] Janvier 1950 à juin 2018	Examen de l'intoxication à l'hypochlorite.	L'hypochlorite de sodium est un agent de blanchiment et de désinfection qu'on trouve couramment dans l'eau de Javel domestique. 110 citations ont été jugées pertinentes. Des estimations supérieures à 40 ml ou à 5 ml/kg de solutions diluées ont été suggérées comme quantités susceptibles de causer un empoisonnement corrosif ou systémique chez les enfants. Cet examen décrit plusieurs rapports de cas/séries d'enfants qui ont ingéré de l'eau de Javel. Les effets

		courants comprenaient des problèmes gastro-intestinaux mineurs, comme des nausées, des vomissements et des brûlures superficielles dans la bouche et l'œsophage. Une brève exposition de la peau à l'eau de Javel domestique entraîne normalement des effets minimes alors qu'une exposition longue ou prolongée peut causer une irritation cutanée ou une hypersensibilité.
Holm, 2019 Analyse documentaire É.-U.[1] 2018[1]	Résumé des conclusions à partir de: (1) Données d'enregistrement de l'Environmental Protection Agency sur l'efficacité des désinfectants approuvés pour une utilisation en milieu hospitalier (n = 1 907 produits, dont 529 étaient inclus). (2) Un examen de la recherche sur les toxicités et les risques pour la santé associés aux désinfectants couramment utilisés dans les établissements de garde d'enfants.	L'eau de Javel est le désinfectant le plus couramment utilisé dans les garderies. Le chloroforme, un COV, est un sous-produit de l'eau de Javel. En l'absence d'un taux de ventilation optimal, certaines études ont fait état de niveaux de chloroforme supérieurs à ceux jugés sécuritaires pour la gestion du risque de cancer. Des résultats semblables ont été indiqués pour le formaldéhyde, qui peut être un sous-produit d'un mauvais mélange de produits chimiques de nettoyage et de désinfectants. Les données sur les effets des produits de nettoyage sur les enfants sont limitées. Des études transversales ont indiqué que les enfants qui vivaient dans des maisons nettoyées avec de l'eau de Javel n'étaient pas plus susceptibles de souffrir d'asthme, tandis que d'autres ont constaté un risque accru associé à l'utilisation de vaporisateurs et de désinfectants dans la maison. Un lien entre l'utilisation de nettoyants en vaporisateur et la respiration sifflante a été signalé dans le cadre de deux études sur des nourrissons et de jeunes enfants. Les catégories de désinfectants contenant au moins un produit couvrant un vaste éventail de pathogènes comprenaient l'eau de Javel, les peroxydes, les composés d'ammoniac quaternaires et les produits combinés comprenant des composés d'ammoniac quaternaire. Risques pour la santé : Eau de Javel : irritant des voies respiratoires si elle était inhalée, elle peut libérer des COV, p. ex., du chloroforme lorsqu'elle réagit avec des matières organiques, qui sont des cancérogènes connus. L'irritation de la peau et des yeux est courante, des empoisonnements ont été signalés et une exposition

		à long terme chez les adultes a entraîné des effets respiratoires et de l'asthme. Composés d'ammonium quaternaire : risque accru d'asthme et de sensibilisation allergique indiqué. Des études ont démontré que certains de ces composés étaient mutagènes et réduisaient les taux de fécondité dans les modèles animaux. La cancérogénicité n'a pas été démontrée. Peroxydes : toxicité aiguë comprenant l'empoisonnement et l'irritation des yeux. Aucune autre donnée sur la toxicité n'a été publiée. Tous les désinfectants sont moins efficaces en présence de matières organiques.

Abréviations : CPE : Centre de la petite enfance, COV : Composés organiques volatils

Méthodes :

Une analyse quotidienne de la littérature (publiée et prépubliée) est effectuée par le groupe de science émergente de l'ASPC. L'analyse a permis de compiler la littérature sur la COVID-19 depuis le début de l'épidémie et est mise à jour quotidiennement. Les recherches pour trouver la littérature pertinente sur la COVID-19 sont menées par Pubmed, Scopus, BioRxiv, MedRxiv, ArXiv, SSRN, Research Square et sont recoupées avec la littérature de la liste de littérature COVID de l'OMS, et les centres d'information de la COVID-19 gérés par Lancet, BMJ, Elsevier et Wiley. Le résumé quotidien et les résultats complets de l'analyse sont conservés dans une base de données Refworks et une liste Excel consultable. Une recherche ciblée par mot-clé est effectuée dans ces bases de données pour identifier les citations pertinentes sur la COVID-19 et le SRAS-CoV-2. Afin de repérer des éléments de preuve publiés avant la pandémie de COVID-19, des recherches supplémentaires par mot-clé ciblé ont été effectuées dans Pubmed, en utilisant une méthode en boule de neige et en révisant des listes de référence. Les termes de recherche utilisés comprenaient : désinfecter*, chimique, sécurité, risque, enfant*. Cette synthèse contient des recherches publiées jusqu'au 5 octobre 2020. Chaque référence potentiellement pertinente a été examinée pour confirmer qu'elle comportait des données pertinentes et les données pertinentes sont extraites dans l'examen.

ANNEXE

Tableau en annexe des catégories courantes de désinfectants pour surfaces dures qui comprennent les ingrédients actifs des désinfectants utilisés dans divers milieux (domicile, public, hôpital)[1]

Catégorie (exemples)	Propriétés et utilisations	Répercussions possibles sur la santé : à plus long terme[2]	Mesures de sécurité[3]
Chlore et composés chlorés Comprend l'« eau de Javel domestique » (hypochlorite de sodium), une solution aqueuse comprenant de 5,25 % à 6,25 % d'hypochlorite de calcium solide. Autres composés conçus pour retenir le chlore plus longtemps. Comprennent le dioxyde de chlore à libération sous forme de demande, le dichloroisocyanurate de sodium et la chloramine-T.	Aucun résidu, peu coûteux, à action rapide. Rendu rapidement inactif par les matières organiques. Dilué et appliqué en surface. Ne pas mélanger avec : - Ammoniac ou produits d'entretien ménager, car le mélange produit du chlore gazeux toxique. - Solutions de formaldéhyde et d'hypochlorite, car le mélange produit un oxyde de bis(chlorométhyle) cancérogène.	Une faible incidence de toxicité grave. L'eau de Javel domestique (5,25 à 6,15 %) peut causer une irritation oculaire ou des brûlures oropharyngées, œsophagiennes et gastriques. A été associée à l'asthme et à d'autres problèmes respiratoires. Les chloramines créent des « chloramines organiques » puisqu'elles s'attachent à des matières organiques et forment des composés connus sous le nom de COV. Les études ont montré que les COV augmentent pendant le nettoyage domestique. Certains sont des cancérogènes connus (Odabasi, 2014). Aucun effet nocif n'est prévu en cas d'exposition normale et d'utilisation appropriée.	Solutions diluées d'eau de Javel domestique : Utiliser de l'eau de Javel contenant de 5,25 % à 8,25 % d'hypochlorite de sodium. Ne pas utiliser de produit javellisant si le pourcentage n'est pas dans cette fourchette ou n'est pas précisé. Assurer une ventilation adéquate tant pendant qu'après l'utilisation. S'assurer que le produit n'a pas dépassé sa date de péremption. Ne jamais mélanger l'eau de Javel domestique à de l'ammoniac ou à un autre produit nettoyant, car cela pourrait causer des émanations dont l'inhalation peut être très dangereuse. Préparer une solution d'eau de Javel en

			mélangeant : 5 cuillères à soupe (1/3 tasse) d'eau de Javel à 5,25 à 8,25 % par gallon d'eau à température ambiante ou 4 cuillères à thé d'eau de Javel à 5,25 à 8,25 % par pinte d'eau à température ambiante. Les solutions d'eau de Javel sont efficaces pour désinfecter pendant un maximum de 24 heures.
Composé d'ammonium quaternaire Comprend environ 300 homologations de produits. Le groupe I est composé de Quats hydroxyalkylés substitués. Le groupe II comprend, quant à lui, le benzyle non halogéné. Le groupe III comprend les Quats di et tri-chlorobenzyl substitués alors que le groupe IV se compose de Quats avec des substitutions inhabituelles (p. ex., chlorure d'alkyldiméthylbenzylammonium chlorure d'alkyldidécyldiméthylammonium, et chlorure de diméthylammonium dialkyle; quaternaires à deux chaînes ou dialkyles, p. ex., bromure de didécyldiméthylammonium et bromure de dioctyldiméthylammonium).	Non volatile, laisse des résidus. Est généralement approuvé pour la désinfection des surfaces et peut être utilisé sur l'équipement qui entrera en contact avec la peau. Peut être utilisé sous forme liquide ou sur une lingette.	Aucun effet à long terme sur la santé n'a été signalé : non sensibilisant au niveau de la peau, non toxique pour le développement ou la reproduction et non cancérogène ou génotoxique (Luz, 2020). Certains cas d'asthme professionnel (p. ex., chez les nettoyeurs) ont été signalés à la suite d'une exposition au chlorure de benzalkonium.	Suivre les instructions indiquées sur l'étiquette en ce qui concerne l'utilisation de tout désinfectant. Santé Canada tient compte des risques-avantages globaux associés au risque avant l'approbation, en s'assurant que les risques potentiels puissent être atténués par un étiquetage approprié.

Peroxyde d'hydrogène : Peroxygène, plusieurs désinfectants liquides contiennent du peroxyde d'hydrogène dont les concentrations varient de 6 à 25 % dans un produit chimique prémélangé prêt à l'emploi. Combinaison commune : 7,5 % de peroxyde d'hydrogène et 0,85 % d'acide phosphorique.	Laisse des résidus. Généralement approuvé pour la désinfection des surfaces. Présent dans les désinfectants, dans une teneur variant entre 3 et 9 %. Peut être utilisé sous forme liquide ou sur une lingette. Est instable et se décompose facilement.	Les données sur la cancérogénicité ne sont pas concluantes. Peut avoir des effets respiratoires.	Suivre les instructions indiquées sur l'étiquette en ce qui concerne l'utilisation de tout désinfectant. Santé Canada tient compte des risques-avantages globaux associés au risque avant l'approbation, en s'assurant que les risques potentiels puissent être atténués par un étiquetage approprié.
Phénol et dérivés du phénol Des versions plus récentes ont été créées, soit phénolique (chloroxylenol, thymol, O-Phenylphénol, triclosan, ortho-Phenylphénol ortho-benzyl-para-chlorophénol.	Laisse un résidu. Généralement approuvé pour la désinfection des surfaces. Peut être utilisé sous forme liquide ou sur une lingette.	Les résidus peuvent irriter la peau et l'absorption cutanée est la principale voie d'exposition. Un lien a été établi avec l'hyperbilirubinémie chez les nourrissons dans les pouponnières qui l'utilisent pour nettoyer les lits de bébé.	Suivre les instructions indiquées sur l'étiquette en ce qui concerne l'utilisation de tout désinfectant. Santé Canada tient compte des risques-avantages globaux associés au risque avant l'approbation, en s'assurant que les risques potentiels puissent être atténués par un étiquetage approprié.
Acide peracétique: Péracétique ou peroxyacétique	Aucun produit de décomposition nocif, augmente le pouvoir d'élimination des matières organiques, ne laisse aucun résidu, forte odeur piquante. Peut être utilisé sous forme de vaporisation liquide. Reste actif à basse température et en	Considéré comme un produit chimique peu préoccupant, à faible adsorption cutanée et aucun risque à long terme pour la santé n'a été répertorié.	Suivre les instructions indiquées sur l'étiquette en ce qui concerne l'utilisation de tout désinfectant. Santé Canada tient compte des risques-avantages globaux associés au risque avant l'approbation, en s'assurant que les risques potentiels puissent être atténués

	présence de matières organiques. Est instable lorsqu'il est dilué et doit donc être mélangé juste avant d'être utilisé. N'exige aucun rinçage.		par un étiquetage approprié.
Ortho-phtalaldéhyde (OPA ou 1,2-benzène-dicarboxaldéhyde)	N'est pas un irritant connu, sans odeur, ne nécessite pas de surveillance de l'exposition. Stable à un pH compris entre 3 et 9.	Provoque des taches sur la peau lorsqu'il transforme les protéines qui deviennent grises. A aussi été associé à l'anaphylaxie. Exposition à long terme associée à l'asthme.	Suivre les instructions indiquées sur l'étiquette en ce qui concerne l'utilisation de tout désinfectant. Santé Canada tient compte des risques-avantages globaux associés au risque avant l'approbation, en s'assurant que les risques potentiels puissent être atténués par un étiquetage approprié.
Idophores La povidone-iodine, aussi appelée polybinylpyrrolidone avec iode, est la forme la plus courante.	Peuvent être utilisés comme désinfectant de surface (mieux connu en tant qu'antiseptique). Explosent s'ils sont mélangés avec du peroxyde d'hydrogène.	Peuvent entraîner une hypothyroïdie s'ils sont ingérés en grandes quantités. Les fœtus et les nouveau-nés y sont particulièrement sensibles.	Suivre les instructions indiquées sur l'étiquette en ce qui concerne l'utilisation de tout désinfectant. Santé Canada tient compte des risques-avantages globaux associés au risque avant l'approbation, en s'assurant que les risques potentiels puissent être atténués par un étiquetage approprié.

VOC = Les composés organiques volatils (COV) sont des composés qui ont une pression de vapeur élevée, une faible solubilité dans l'eau et sont émis sous forme de gaz par certains solides ou liquides. Les COV sont libérés par un large éventail de produits, notamment les peintures, les produits de nettoyage, les pesticides, les nouveaux matériaux, les imprimantes, les marqueurs, etc. Les COV sont plus élevés à l'intérieur qu'à l'extérieur.

[1] Sources : https://www.cdc.gov/infectioncontrol/guidelines/disinfection/index.html, https://pubchem.ncbi.nlm.nih.gov/ et https://www.cdc.gov/coronavirus/2019-ncov/prevent-getting-sick/cleaning-disinfection.html

[2]Les effets sur la santé qui découlent d'une mauvaise utilisation ne sont pas indiqués. Ainsi, de ces produits ne peut être ingéré sans danger, la plupart provoquent une irritation de la peau et des lésions oculaires si le produit entre en contact avec ces surfaces. L'eau de Javel, tout comme un grand nombre de produits en spray, comporte également des avertissements en cas d'inhalation lors de l'utilisation.

[3] Précautions générales de sécurité à respecter au moment d'utiliser les désinfectants : protéger la peau et penser à porter une protection des yeux pour éviter de recevoir des éclaboussures, assurer une ventilation adéquate, ne pas utiliser plus que la quantité recommandée sur l'étiquette, utiliser de l'eau à température ambiante pour la dilution (sauf indication contraire sur l'étiquette) et éviter de mélanger différents produits chimiques.

Emerging Evidence on COVID-19

Evidence Brief of SARS-CoV-2 Contact Tracing

Introduction

What evidence exists for the strategic use of effective and efficient COVID-19 contact tracing during the pandemic?

Contact tracing is one of several public health measures (PHMs) being used to control the spread of COVID-19. When a case is identified, contact tracing may be initiated by local public health authorities to identify individuals who have potentially been exposed to the case and assess their risk of exposure. Currently in Canada, close (i.e., high risk) contacts of COVID-19 cases are required to quarantine (i.e., self-isolate) away from others for 14 days (1). It is an important, but resource-intensive activity, and during periods of high COVID-19 transmission local public health has not always had the capacity for complete contact tracing. Thus, tools or strategies to improve efficiencies in contract tracing and tools to assess tipping points in the public health capacity to perform effective contact tracing are needed. This brief highlights studies and systematic reviews on strategies for effective and efficient contact tracing during COVID-19 available up to February 10, 2021. For the purpose of this evidence brief, contact tracing is defined as the identification of people recently exposed to an infected individual in order to quarantine them with or without testing to prevent further transmission. In this review isolation refers to confirmed cases isolating to prevent transmission within or outside of their household and quarantine refers to isolation of potentially exposed contacts from the community while they complete their incubation period.

Key Points

- The ability of public health to undertake comprehensive contact tracing depends on many factors including the transmission rate in the community, the capacity of public health to undertake contact tracing, and the ability to identify infected individuals and their contacts (2). Strategies to improve contact tracing in the context of the COVID-19 pandemic were summarized in seven rapid or systematic reviews with studies up to December 2020; and two empirical and fourteen modeling studies posted November 2020 through February 10, 2021.
- People who are infected with SARS-CoV-2 can transmit the virus before developing symptoms (presymptomatic) and when they are asymptomatic, which means that contact tracing will miss infected individuals if only symptomatic cases are targeted.
    - Contact tracing strategies that relied on identifying symptomatic cases for initiating contact tracing and quarantine of contacts were shown in included models to miss a proportion of cases and thus failed to control the COVID-19 epidemic (3).

- Modeling studies showed that mass testing strategies to identify cases and conducting forward contact tracing were more effective in identifying cases and thus at controlling the spread of COVID-19 compared to contact tracing of symptomatic cases only (3-5); however, mass testing is very resource intensive in the short-term and has higher associated costs (6). For example mass testing of identified high risk populations (various healthcare workers, essential business employees, teachers and students) and contact tracing for cases in Canada was estimated to be up to $820 million per month in additional costs compared to the 70 million contact tracing activities were costing in July 2020 (7).
- Contact tracing is effective at reducing transmission of variants of concern (8).

- Minimizing the time to identify a case and notify the high risk contacts of the case is an important factor in contact tracing to minimize the potential infectious days a person is not in quarantine or isolation.
    - Several included reviews and studies suggest that timely identification of cases (within 3 days of symptom onset) and quarantine of most of the high risk contacts (~60-90% contacts needed to be traced across studies) as quickly as possible was required for a test and contact-trace strategy to be effective (5, 9-11).
- Models show that the effectiveness of contact tracing in controlling the epidemic is reduced when the prevalence of cases (and number of potential contacts) in the community exceeds public health resources.
    - The local context will determine the maximum number of cases that can be handled per day. Exceeding that capacity will result in less effective contact tracing because some cases will not be traced or there will be delays in tracing cases leading to longer time to initiate quarantine or failure to quarantine of people exposed, which may lead to more transmission (2).
- Contact tracing is one of several PHMs used to control COVID-19 which work synergistically to control the epidemic. Studies have shown that as transmission decreases and restrictive PHMs (e.g., lockdowns, closures and restricted movement) are lifted, a strong contact tracing system with sufficient capacity is needed to avoid a resurgence (5% chance of resurgence vs. <50% chance if sufficient contact tracing capacity is not in place) (12).
- Increasing efficiency and effectiveness of contact tracing using new tools and strategies was evaluated in several reviews and studies.
    - Bidirectional contact tracing (contact tracing as early as 6 days prior to symptoms) more than doubles the reduction to R_e when compared with only forward tracing (contacts of the case from 1-2 days prior to symptoms until isolation). (8, 13). However the latter requires more public health capacity.

- Bidirectional contact tracing to identify the primary case of a cluster was found to be 2-3 times more effective against the spread of SARS-CoV-2 when compared to forward contact tracing alone (23).
- Efficiency of contact tracing is improved by the use of electronic data management tools which can double the number of contacts traced and is less prone to error and data loss (14).
- Contact tracing apps have been studied and evaluated in the context of COVID-19 quickly to reach more potentially exposed individuals. As these are a new technology, most models estimated a low uptake of the apps (e.g., 50%), which resulted in a reduced R_e by 18-26% compared to public health contact tracing that resulted in a 35-53% reduction in R_e (14). Higher proportions of population uptake of automated contact-tracing apps (estimates from 56% up to 100%) resulted in improved performance of contact tracing (13, 15, 16).
- A single empirical study reported a significant decrease in R_e (from 1.3 to 0.5) after regional testing of the United Kingdom's contact tracing app that had high uptake by the majority of the population. Version 1, reported in the study, was a Bluetooth enabled proximity contact tracing app which identified probable cases with self-reported symptomatic status (17).

Overview of the Evidence

Twenty-three articles were included in this evidence brief. Systematic and rapid reviews concerning contact tracing to mitigate spread of COVID-19 accounted for seven of the cited articles (three of them in pre-print status). In addition, 16 recent articles (published in Fall 2020/Winter 2021) presented evidence on effective contact tracing strategies, two with epidemiological evidence and 14 based on modelling studies (6 of the models are pre-prints).

AMSTAR-2 tool was used to evaluate the rapid and systematic reviews (n=7) in Table 1 (18). Overall quality of the review is categorized as high, medium, low or very low quality depending on how many AMSTAR criteria were not met.

The empirical evidence (n=2) is based on observational studies aimed to evaluate contact tracing strategies, or changes in current strategies. The observational studies were at risk of many biases. Caution should be used in the interpretation of the predictive models (n=13) as they may be sensitive to the assumptions of the model and are best used to compare different scenarios, as they may not reflect a real situation or be generalizable. Most of the evidence on this topic is from predictive models.

The limitations of the evidence include a lack of empirical evidence and high reliance on the findings of modelling studies or reviews based on pre-pandemic experience.

CONTENTS

REVIEWS OF CONTACT TRACING STUDIES

Table 1: Rapid and Systematic Reviews on Contact Tracing of COVID-19 Cases (n=7)

STUDY	METHOD	KEY OUTCOMES
Overall contact tracing strategies		
Mbwogge (2020) (4) Preprint Rapid Review United Kingdom Dec 2020 AMSTAR-moderate	A rapid review included 35 articles with evidence available up to December 22, 2020 on whether mass testing and tracing would be more effective than current testing and tracing in the UK. Results were synthesized by vote counting, considering the direction of effect and degree of bias in reported outcomes.	Across 13 of the studies mass testing was more effective than symptom-based testing in 76.9% (95% CI: 46.2-95.0) of the studies, thus would improve the suppression of COVID-19 beyond the current symptom based test and trace protocol in the UK. Mass testing improves detection of asymptomatic COVID-19 cases that are not detected in a symptom-based test scheme. Across 22 studies 40.7% (95%CI: 38.8-42.5%) of cases detected would be asymptomatic and would be expected to identify 28% (95%CI: 25.9-30.2%) of asymptomatic cases in the general population and 96.6% (95%CI: 82.2-99.9%) of asymptomatic cases among long term care staff.
Girum (2020) (19) Systematic Review Ethiopia Jun 2020 AMSTAR-moderate	The review identified 22 observational (n=9) and modelling (n=13) studies providing evidence of COVID-19 prevention through contact tracing, screening, quarantine and isolation. Studies up to June 2, 2020 were included in the review. 3 studies assessed all prevention strategies, and 5 specifically assessed contact tracing effects.	Contact tracing studies: • Isolating only symptomatic patients may not contain the epidemic. • Intimate contacts have transmission rates of 40-60%, indicating household contacts of cases should quarantine. • Outbreaks may not be contained, unless high levels of tracing and quarantine are introduced. • If R_o is 2.5, more than 70% of contacts must be traced for outbreak control (20). • Using a contact trace and quarantine strategy reduces transmission 50-60% compared to mass testing or self-isolation alone 2-30% (5) (listed in Table 2).

Juneau (2020) (9) Preprint Systematic Review Quebec, Canada Jul 2020 AMSTAR- low	The review identified 32 observational (n=14) and modelling (n=18) studies concerning the effectiveness of contact tracing for COVID-19 control. All methods of contact tracing were included in the review (i.e. mobile apps, etc.). Studies were excluded if they did not consider community transmission settings or if they were not peer reviewed. The search dates are not provided in the preprint article.	Overall, the review asserts that a case must be isolated within 2-3 days of symptom onset; as well as at least 80% of their contacts quarantined, to result in no tertiary cases. Less efficient tracing and quarantine systems may slow the spread of SARS-CoV-2, but will be unable to stop the epidemic. Delays of ≥ 4 days or quarantine of less than 60% of contacts will be ineffective at controlling the epidemic.
Chung (2020) (16) Preprint Rapid Review United Kingdom May 2020 AMSTAR- very low	A rapid review of efficacy and policy of contact tracing, testing and isolation (TTI) for COVID-19 control identified 48 relevant studies. The search included publications as of May 28, 2020.	The evidence is synthesized into a suggested public health intervention strategy for Taiwan. • Public health interventions provide significant control in the absence of herd immunity for COVID-19, including contact tracing. • Test turn around of <24 hours is documented in multiple studies and is needed for quick case confirmation. • Mass testing of specific groups (i.e. healthcare workers) facilitates detection of additional cases and their contacts. • Digital tools to facilitate timely contact tracing are successfully utilized by many regions; including: cell phone based mobility, location, and apps for location, symptoms tracking and QR scans upon entry and exit of community locations. It is noted that 60-75% app usage is necessary for it to be effective against COVID-19 spread.
Digital Technology and Contact Tracing		
Anglemyer (2020) (14) Rapid review	This Cochrane rapid review conducted up to May 5, 2020 (pre-pandemic to early in pandemic) aimed to assess the benefits,	Gen pop apps: This review included 6 cohort and 6 modelling studies. Two modelling studies indicated compared to isolation alone, manual contact tracing resulted in a 35-53% reduction in R_e while digital contact tracing only reduced R_e by 18-26% across the models, the

New Zealand May 2020 AMSTAR- high	harms and acceptability of personal digital tracing solutions for identifying contacts of an identified positive case of an infectious disease.	latter assumed only 50% of the population used the app. Threats associated with privacy breaches, particularly from wearable devices were considered a possible threat. Public Health data collection apps: Having a data collection application for electronic contact tracing investigations identified 2x more contacts than paper forms during an Ebola outbreak. Another cohort reported reduced times to complete contact tracing with electronic data management system (plus they were less prone to error and data loss.) 2 cohorts reported digital systems save time and are simpler to use. Cost and internet access were barriers.
Braithwaite (2020) (15) Systematic Review United Kingdom Apr 2020 AMSTAR - medium	This systematic review on automated contact tracing, including by automating the processing of test results or symptom reports and by use of smartphone capabilities (eg, Bluetooth) to identify and notify contacts instantaneously who are at risk of infection, included articles published up to April 14-30, 2020 (pre-pandemic and early pandemic). 15 studies were included.	• No empirical evidence of the effectiveness of automated contact tracing (regarding contacts identified or transmission reduction) was identified. Four of seven included modelling studies suggested that controlling COVID-19 requires a high population uptake of automated contact-tracing apps (estimates from 56% to 95%), typically alongside other control measures. • Studies of partly automated contact tracing generally reported more complete contact identification and follow-up compared with manual systems. Automated contact tracing could potentially reduce transmission with sufficient population uptake. However, concerns regarding privacy and equity should be considered. • Automation of contact-tracing may improve the speed of quarantining contacts, which would lead to a bigger impact. Cohorts from Ebola demonstrated 69% contacts vs 39% contacts were visited and speed was reduced by 0.5- 5 hours across studies. • Resource requirements for test-based release from quarantine in the UK estimated 30-50 tests per positive case and 100000-200000 tests per day in the UK.
Qualitative Analysis of Knowledge, Attitudes and Behaviours		
Megnin-Viggars (2020) (21) Rapid review United Kingdom Jul 2020	This rapid systematic review on barriers and facilitators to engagement with contact tracing includes research up to July 15, 2020. Eleven studies were included, 6 on COVID-19, 5 on Ebola	Four themes were identified as facilitators to the uptake of, and engagement with, contact tracing: collective responsibility; personal benefit; co-production of contact tracing systems; and the perception of the system as efficient, rigorous and reliable. Participants reported that their intentions to use a contact tracing app was strongly influenced by a sense of collective responsibility (3 studies), and their desire to

AMSTAR - high	and 1 on other infectious diseases.	help reduce the deaths of others, particularly those who are vulnerable (2 studies). Many indicated it was a means to ending the pandemic and embraced their role (2 studies) even when participants had some concerns over using a contact tracing app they viewed it as the "only way out" and this collective responsibility was prioritised over personal doubts (1 study). Five themes were identified as barriers to the uptake of, and engagement with, contact tracing: privacy concerns; mistrust and/or apprehension; unmet need for more information and support; fear of stigmatization; and mode-specific challenges.

EFFECTIVENESS OF CONTACT TRACING

Table 2: Epidemiological and Modeling Studies Published Fall 2020/Winter2021 on Effective Contact Tracing Strategies (n=16)

STUDY	METHOD	KEY OUTCOMES
Epidemiological Evidence (n=2)		
Carroll (2020) (3) Contact Tracing Evaluation Ireland May – Aug 2020	The study monitors and evaluates the testing and contact tracing system in Ireland. Contacts of laboratory confirmed COVID-19 cases identified May 19 – August 2, 2020 were included (n=7272).	4586 of the 7272 contacts were tested at least once during the study period. • The attack rate of contacts was 7% (95% CI: 6.3 – 7.8%). • Symptomatic contacts testing positive on 'Day 0' was 14.6% • Asymptomatic contacts testing positive on 'Day 0' was 5.2% Symptom based criteria for contact testing at the time of identification misses >66% of secondary cases and their contacts.
Kendall (2020) (17) Contact Tracing Evaluation United Kingdom May – Jun 2020	The study assesses the impact of the test and trace system applied on the Isle of Wight, England as of May 2020. The system was introduced to Isle of Wight before being expanded to the entire UK. Version 1 of the NHS contact tracing app was implemented, which used Bluetooth to detect physically close contacts and allowed users to input cough or fever symptoms if	A significant decrease in R_e was observed after implementation of the system (from 1.3 to 0.5).

	experienced. Once symptoms were indicated, historical contacts would be notified of potential exposure and provided infection control guidance (this did not include direction to isolate or quarantine at the time).	
Modeling Analyses (n=13)		
Aleman (2021) (22) Preprint Model Canada May 2020	An agent-based model is employed to evaluate PHMs, including contact tracing, in Newfoundland on COVID-19 prevention. The model is age-stratified and considers spatial movement and comorbidities of individuals. Travel volumes of low, medium and high are modeled for comparison.	Stringent contact tracing minimized transmission of COVID-19 by 4-74x compared to no contact tracing. The model also shows that cases of COVID-19 would have overwhelmed with the contact tracing capabilities in Newfoundland without additional PHMs to control the epidemic.
Campbell (2020) (7) Economic Model Canada July 2020	5 populations were identified for strategic testing within Canada: • contacts of COVID-19 cases • acute care hospital employees • community health care workers; and both staff and residents of long-term care homes; • essential business employees with high levels of interpersonal or public contact (excluding healthcare); and • students and staff in primary and secondary schools. The testing rates of July 8-17, 2020 were used as a baseline, to compare the increased testing necessary for scenarios of strategically testing the populations identified. Testing costs considered: • direct test costs; • laboratory capacity; and • human resources for sampling, administrative scheduling/recording and contact tracing.	5 strategies were modelled and compared to the baseline (which had a monthly cost of $69.8 million): 1. Systematic tracing and testing of contacts – all provinces have lab capacity, administrative requirements increase 1.2 times and cost increase of $11.1 million per month above baseline. 2. Acute care hospital employee testing – cost of $29 million per month. 3. CHW and LTC testing – cost of $12.8 million per month. 4. Essential employees with high contacts - $321.7 million per month. 5. Students and school staff testing - $816 million per month. Lab capacity and staffing increases were all necessary in strategies 2-5. Epidemiological impacts of contact tracing were not directly modelled, and no cost-benefit analysis provided. It is hypothesized these testing costs and associated contact tracing will

		reduce downstream healthcare costs, due to transmission prevention.
Bradshaw (2021) (13) Model United States Jan 2021	A Bayesian model is used to demonstrate the effects on the COVID-19 pandemic when implementing bidirectional contact tracing, as opposed to the more common forward tracing being used in most strategies. 'Forward tracing' is informing recently exposed individuals; while bidirectional tracing additionally identifies the potential infector to allow for notification to them and their others that were potentially exposed.	Implementing bidirectional contact tracing in the model scenarios more than doubles the reduction to R_e when compared with only forward tracing. Increasing the window of contacts to be notified from 2 days presymptomatic to 6 days provided the greatest decrease in R_e. This can be replaced by smartphone exposure notification applications, but only if uptake of the app is near 100%.
Endo (2020) (23) Model United Kingdom 2021	A branching process model is used to simulate the effect of combining backward and forward contact tracing in the PHMs for COVID-19. Index cases are identified though symptom-based surveillance in both scenarios. With forward tracing subsequent exposures since the index may have been infectious are identified and quarantined. Backwards tracing identifies the primary case (infector of the index) and traces all of the primary case's exposures forwards for quarantine. The model is intended to simulate potential case detections and compare the effect on the COVID-19 cases in a community. The probability of identifying the primary case with backward tracking was set at 50 and 80% for different scenarios. The probability of identifying descendant cases from a confirmed case was varied from 0-100%; and the probability of an index case being identified by symptom surveillance was explored at 10%, 20% and 50%.	Backward tracing identifies a much larger proportion of cases, and therefore creates greater control over the spread of COVID-19 when implemented. The model found that the addition of backward tracing to the PHMs was 2-3 times more effective than forward tracing alone. The model assumes that secondary cases (from the index) were quarantined prior to becoming infectious and therefore did not result in any tertiary cases. This may under estimate the effects of backward contact tracing measures.
Bracis (2020) (24) Model	An age stratified model projects COVID-19 cases and deaths during and after a reopening period for King County, WA. Various scenarios of public	Lockdown fit a rate pC_PI of ~35% and maintaining <45% pC_PI was necessary to have reasonable control

USA Mar-Nov 2020	health interventions are presented, including variations of pre-COVID physical interaction (pC_PI) rates, testing practices, isolation and contact tracing.	of the epidemic with the testing practices as of May, 2020. The model indicated that increased testing, isolation and tracing would permit 60% pC_PI while still maintaining reasonable control. • Enhanced testing is more than 50% of symptomatic infections identified. • Contact tracing of at least 50% of contacts identifies at least 5% of asymptomatic and pre-symptomatic cases. • Random mass testing will increase identified rates of all cases 0.5 percentage points (assumes 4.5% of population tested daily).
Aleta (2020) (11) Model United States Aug 2020	Agent based model of SARS-CoV-2 transmission in Boston, MA. The model is used to analyze unmitigated spread of SARS-CoV-2, as well as with two different lockdown and release strategies; both with various levels of case detection and tracing effectiveness. Only testing, tracing and quarantine are considered, all other public health interventions are excluded from the main analyses.	The study compares scenarios that range from i) only household contacts of cases are quarantined to ii) 40% of case contacts are traced and quarantined, as well as the contacts' household members. Quarantine of the contact and their household provides a reduction in transmission sufficient to flatten the epidemic curve and prevent a second wave. The model shows that enhanced testing and contact tracing can control the COVID-19 epidemic to within healthcare capacity, even while relaxing physical distancing interventions.
Kucharski (2020) (5) Model United Kingdom Oct 2020	A quantitative model of individual-level transmission was used to simulate the effects of testing, isolation, tracing and contact reduction in household, work, school and other settings. Social contacts were modelled with data from 40,162 participants in the UK via a contact tracing app on smartphones.	In general, a large proportion of cases need to be isolated and their contacts quarantined to control the COVID-19 epidemic in the simulations. A combination of case isolation and contract tracing was found to be more effective than mass testing. Mean transmission reductions are presented for scenarios of various interventions:

		• 2% - mass testing of 5% of a population per week. • 29% - isolation of cases within their household. • 35% - isolation of cases outside of their household. • 64% - isolation of cases with quarantine of their household and manual tracing of all contacts. • 47% - isolation of cases with quarantine of their household and app-based contact tracing (assumes app use of 53%).
Ashcroft (2020) (25) Preprint Model Switzerland Dec 2020	A theoretical model is created to analyze the effectiveness of test-trace-isolate-quarantine (TTIQ) strategies to control COVID-19. Empirical distributions are used to study how the probability of detecting cases, fraction of contacts quarantined and the delay of these events effect the timing of SARS-CoV-2 transmission. The model predicts the number of secondary cases and if necessary tertiary cases that result from the index case given the circumstances.	Introducing contact tracing and contact quarantine to the mitigations is analyzed and it is found that the fraction of index cases identified and isolated has the largest effect on controlling the epidemic: • R_e = 1.5 cannot be controlled with 30% of index cases isolated, even if 100% of their contacts quarantine. Most to least effective efforts within the TTIQ Strategies: • Increase fraction of index cases identified and isolated. • Reduce time from symptom onset to isolation of index case. • Reduce time to quarantine secondary cases. • Increase the fraction of secondary cases identified and quarantined. • Extending the lookback window to identify contacts. As the R_e of the epidemic increases, it becomes increasingly difficult to flatten the epidemic curve with testing and isolation.
Bradshaw (2021) (8) Preprint	A Bayesian model presented in an earlier publication (13) is used to assess the effectiveness of various strategies of	The model R_e estimated at 1.2 to 2.0 for variant transmission, accounting for interventions already in place to reduce COVID-19 spread.

Model Germany Jan 2021	contact tracing against the B.1.1.7, P.1 and B.1.351 variants of SARS-CoV-2.	• Isolation of symptomatic cases at low compliance rates, with no contact tracing reduces R_e by 0.2-0.3; and if R_e is then ≥ 1.4, even 50% of exposures being identified successfully could move R_e below 1. • Contact tracing of 60-70% of the exposed, up to 2 days before index symptom onset produces a R_e reduction of 0.1 above isolation alone; and implementing bidirectional tracing of up to 6 days before symptom onset with 45-55% contacts successfully traced provides a similar level of mitigation. • A reduction of 0.1 or 0.2 to R_e results in case reductions over 2 months of 37-43% and 61-66%, respectively.

Stuart (2021) (10)
Preprint
 	
Model
 	
South Wales, Australia
Oct – Dec 2020
	A stochastic model is created to analyze various levels of testing, tracing and mask utilization and the resulting vulnerability to resurgences of COVID-19 in a low transmission community.	• Testing and tracing rates have a larger relative impact, particularly when there is inconsistency in community mask wearing.
		• Testing 90% of symptomatic individuals and 90% of their contacts controlled the epidemic.
		• Reducing testing rates of symptomatic individuals resulted in many times more infections (numbers for Oct 1 – Dec 31, and reflect scenario of high mask use):
		  • 90% -> ~180 cases
		  • 80% -> 2-3x increase
		  • 65% -> 8-12x increase
		  • 50% -> 30-50x increase

Amaku (2021) (26) Preprint Model Brazil Feb 2021	This quantitative model aims to evaluate the impact of contact tracing symptomatic (assumed) cases, in the absence of testing, in Sao Paulo, Brazil. Symptomatic individuals are not confirmed by testing, but isolated and traced contacts are also isolated.	The model baseline assumes no contact tracing strategy. A scenario of 5000 symptomatic individuals isolated per day, and 80% of isolated contacts are COVID-19 infections, reduces cases and deaths in the population by 80% after 60 days.

	The proportion of isolated contacts with this strategy who are actual COVID-19 infections is varied through scenarios.	A scenario of 5000 symptomatic individuals isolated per day, and 20% of isolated contacts are COVID-19 infections, reduces cases and deaths in the population by 40% and 50%, respectively after 60 days. In areas with high transmission between contacts and low availability of tests, the symptomatic contact tracing strategy can significantly impact COVID-19 spread.
Amaku (2020) (6) Model Brazil Nov 2020	A modified SEIR model is used to simulate the COVID-19 epidemic in Sao Paulo, Brazil from March through December 2020. Epidemiological data through July 18, 2020 was used to fit the model. Public health interventions reached at most a 59% reduction in contacts per individual in late March, and by August this was only 41%. Sao Paulo attempted to control the epidemic primarily through high testing rates.	Model scenarios with start dates of April, May, June, July or August 1 were run to the end of Dec 2020 to assess the effect of 1) mass testing of individuals; and 2) testing symptomatic individuals and if positive, testing of their contacts. • Mass testing (1) and strategic testing (2) were predicted to reduce cases by 90% compared to predicted case levels at the end of 2020. Mass testing would have an estimated cost of 2.25 billion USD; while strategic testing costs would be 150 million USD.
Contreras (2021) (27) Model Chile Jan 2021	A model of COVID-19 transmission in a community is used to study a test-trace-and-isolate (TTI) strategy.	The model identifies 2 tipping points between controlled and uncontrolled COVID-19 in the population: • 'Hidden' infection chains due to asymptomatic, presymptomatic, avoiders and undetected cases becomes too high; or • New infections exceed the capacity for tracing. A scenario of the hidden R_e run at 1.8 provides a stable system, but instability is introduced with an increase of the hidden R_e to 2.0. When the workload of tracing causes delays to exceed the generation time (4 days in this model) contact tracing is no longer effective.

		TTI alone cannot contain the COVID-19 epidemic due to these tipping points, and in the absence of herd immunity additional public health interventions must also be employed.
Yin (2021) (12) Preprint Model China Jan – May 2020	A quantitative model of individual-level transmission simulates the effects of testing delays, tracing and mask use in megacity populations. Spread of COVID-19 was simulated in a population of 11.2 million in Shenzhen City, China using mobile phone tracking data. The likelihood of a sporadic cases causing a COVID-19 resurgence once the city reopens, applying various public health intervention scenarios.	If the city reopens in the absence of a contact tracing system, there is less than a 50% chance of mitigating resurgence due to sporadic cases. Reopening with household contact tracing, 100% masking compliance and testing within 28 hours of symptom onset reduced the probability of a resurgence of cases to 5%. The same level of mitigation (5% resurgence) is achieved with mask compliance of 80% and testing of 40%, if tracing is expanded to include work/school contacts. This relationship holds for equivalent mitigation with decreased masking and testing, as long as contact tracing efforts are increased accordingly.

Methods:

A daily scan of the literature (published and pre-published) is conducted by the Emerging Science Group, PHAC. The scan has compiled COVID-19 literature since the beginning of the outbreak and is updated daily. Searches to retrieve relevant COVID-19 literature are conducted in Pubmed, Scopus, BioRxiv, MedRxiv, ArXiv, SSRN, Research Square and cross-referenced with the COVID-19 information centers run by Lancet, BMJ, Elsevier, Nature and Wiley. The daily summary and full scan results are maintained in a Refworks database and an excel list that can be searched. Targeted keyword searching was conducted within these databases to identify relevant citations on COVID-19 and SARS-COV-2. Search terms used included:
[(test AND (trace OR tracing OR contact)) OR (contact tracing AND review) OR mass testing OR active test] [TITLE]. Each potentially relevant reference was examined to confirm it had relevant data and relevant data was extracted into the review. Relevant systematic reviews and rapid reviews were identified and summarized and new research from Fall 2020 and Winter 2021 were also identified to update the review results. A cross analysis of studies in the reviews was not conducted. This review contains research published up to February 10, 2021.

Nouveaux éléments de preuve sur la COVID-19

Synthèse en bref sur la recherche des contacts pour le SRAS-CoV-2

Introduction

Quelles données probantes existent sur l'utilisation stratégique d'une recherche efficace et efficiente des contacts pendant la pandémie la COVID-19?

La recherche des contacts est l'une des nombreuses mesures de santé publique qui ont été utilisées pour contrôler la propagation de COVID-19. Dès qu'un cas d'infection est trouvé, les autorités locales de santé publique peuvent alors entreprendre la recherche des contacts pour déterminer toutes les personnes qui pourraient avoir été exposées à un cas et ainsi évaluer leur risque d'exposition. À l'heure actuelle, au Canada, les personnes ayant des contacts rapprochés (c.-à-d. à risque élevé) avec des cas de COVID-19 doivent être mises en quarantaine (c.-à-d. en isolement volontaire) et rester à l'écart des autres pendant 14 jours (1). Il s'agit d'un élément important, mais qui exige de nombreuses ressources, et pendant les périodes de transmission élevée de la COVID-19, la santé publique locale n'a pas toujours eu la capacité d'effectuer une recherche exhaustive des contacts. Il faut donc avoir et utiliser des outils ou des stratégies conçus pour permettre d'améliorer l'efficacité de la recherche de contacts. Il faut également avoir des outils pour évaluer les points de bascule dans la capacité de la santé publique à effectuer une recherche efficace des contacts. Cette synthèse en bref met donc en lumière les études et revues systématiques disponibles jusqu'au 10 février 2021 et portant sur des stratégies de recherche efficace et efficiente des contacts pendant la pandémie de COVID-19. Aux fins de la présente synthèse en bref, la recherche des contacts est définie comme la détermination des personnes qui ont récemment été exposées à une personne infectée pour ensuite mettre cette personne en quarantaine pour éviter la transmission, que des tests de dépistage soient effectués ou non. Dans le cadre de cette synthèse, « isolement » désigne tout isolement des cas confirmés afin de prévenir la transmission à l'intérieur ou à l'extérieur du ménage, alors que « quarantaine » désigne l'isolement de toute personne ayant potentiellement été exposée dans la collectivité avant la fin de sa période d'incubation.

Principaux points

- La capacité de la santé publique à effectuer une recherche exhaustive des contacts dépend de nombreux facteurs, notamment du taux de transmission dans la collectivité, de la capacité de la santé publique à effectuer une recherche des contacts et de sa capacité à déterminer les personnes infectées et leurs contacts (2). Les stratégies qui visent à améliorer la recherche des contacts dans le contexte de la pandémie de COVID-19 ont été résumées dans sept revues rapides ou systématiques incluant des études effectuées jusqu'en décembre 2020, deux études empiriques et quatorze études de modélisation publiées entre novembre 2020 et le 10 février 2021.

- Les personnes infectées par le SRAS-CoV-2 peuvent transmettre le virus avant qu'elles ne développent des symptômes (présymptomatiques) ainsi que lorsqu'elles sont asymptomatiques, ce qui signifie que si seuls les cas symptomatiques sont ciblés, la recherche des contacts ne permettra pas de détecter toutes les personnes infectées.
    - Parmi les modèles évalués, il a été déterminé que ceux dont les stratégies de recherche des contacts s'appuyaient uniquement sur la détermination des cas symptomatiques pour entamer la recherche et la mise en quarantaine des contacts ne tenaient pas compte d'un certain nombre de cas et ne pouvaient donc pas permettre de contrôler l'épidémie de COVID-19 (3).
    - Les études de modélisation ont montré que les stratégies qui utilisaient le dépistage de masse pour déterminer les cas et effectuer la recherche de traçage des contacts en aval étaient plus efficaces pour déterminer les cas et contrôler la propagation de la COVID-19 que la seule recherche des contacts effectuée auprès des cas symptomatiques (3-5). Toutefois, le dépistage de masse exige beaucoup de ressources à court terme et entraîne donc des coûts plus élevés (6). L'on a ainsi estimé qu'effectuer du dépistage de masse sur des populations à haut risque précises (différents travailleurs de la santé, employés d'entreprise essentiels, enseignants et étudiants) et la recherche des contacts pour les cas au Canada entraîneraient des coûts supplémentaires pouvant atteindre 820 millions de dollars par mois comparativement au montant de 70 millions associé aux activités de recherche des contacts effectuées en juillet 2020 (7).
    - La recherche des contacts est efficace pour réduire la transmission des variants préoccupants (8).
- Le fait de réduire au minimum le temps nécessaire pour déterminer un cas et en aviser les contacts à risque élevé est un élément important de la recherche des contacts qui permettra de réduire au minimum les jours d'infection potentiels pendant lesquels une personne n'est pas en quarantaine ou isolée.
    - Plusieurs des revues et des études incluses dans la présente synthèse en bref laissent entendre que la détermination des cas en temps opportun (dans les trois jours qui suivent l'apparition des symptômes) et la mise en quarantaine de la plupart des contacts à risque élevé (environ 60 à 90 % des contacts devaient être retracés d'une étude à l'autre) devait être effectuée le plus rapidement possible pour que la stratégie avec test de dépistage et recherche des contacts soit efficace (5, 9 à 11).
- Les modèles montrent que l'efficacité de la recherche des contacts dans le contrôle de l'épidémie diminue lorsque la prévalence des cas (et le nombre de contacts potentiels) dans la collectivité dépasse les ressources de santé publique disponibles.

- Le contexte local déterminera le nombre maximal de cas pouvant être traités par jour. Si cette capacité est dépassée, la recherche des contacts sera alors moins efficace, car certains cas ne pourront pas être retracés ou il y aura des retards dans la recherche, ce qui repoussera le début de la mise en quarantaine ou empêchera la mise en quarantaine de personnes exposées, ce qui, en retour, pourrait faire augmenter la transmission (2).

- La recherche des contacts est l'une des nombreuses mesures de santé publique utilisées pour contrôler la COVID-19 qui fonctionnent en synergie pour contrôler l'épidémie. Des études ont montré qu'à mesure que la transmission diminue et que les mesures de santé publique restrictives (p. ex., confinement, fermetures et déplacements restreints) sont levées, un système de recherche des contacts solide et suffisamment puissant est nécessaire pour éviter une résurgence (5 % de probabilité de résurgence par rapport à moins de 50 % si la capacité de recherche des contacts n'est pas suffisante) (12).
- L'amélioration de l'efficience et de l'efficacité de la recherche des contacts à l'aide de nouveaux outils et stratégies a été évaluée dans plusieurs revues et études.
    - La recherche bidirectionnelle des contacts (recherche des contacts jusqu'à 6 jours avant les symptômes) fait plus que doubler la réduction du R_e (taux d'exposition) lorsqu'on le compare avec la recherche de traçage des contacts en aval seulement (contacts du cas déterminés jusqu'à un ou deux jours avant l'apparition des symptômes puis jusqu'à l'isolement). (8, 13). Ce type de recherche exige cependant une plus grande capacité au niveau de la santé publique.
    - On a cependant constaté que la recherche de traçage bidirectionnelle utilisée pour déterminer le cas primaire dans une grappe était de 2 à 3 fois plus efficace contre la propagation du SRAS-CoV-2 que la recherche de traçage des contacts en aval utilisée seule (23).
    - L'efficacité de la recherche des contacts est améliorée par l'utilisation d'outils électroniques de gestion des données qui peuvent doubler le nombre de contacts suivis, en plus d'être moins sujets aux erreurs et aux pertes de données (14).
    - Les applications de recherche des contacts ont été étudiées et évaluées rapidement dans le contexte de la COVID-19 afin d'atteindre un plus grand nombre de personnes potentiellement exposées. Comme il s'agit d'une nouvelle technologie, la plupart des modèles ont estimé une faible utilisation des applications (p. ex., 50 %), ce qui a entraîné une réduction du R_e de 18 à 26 % comparativement à la recherche des contacts effectuée par la santé publique, ce qui a entraîné une réduction de 35 à 53 % du R_e (14). Des proportions plus élevées d'adoption par la population d'applications automatisées de recherche des contacts (estimations variant entre 56 % et 100 %) ont permis d'améliorer le rendement de la recherche des contacts (13, 15, 16).
    - Une seule étude empirique a fait état d'une diminution importante du R_e (qui est passé de 1,3 à 0,5) après des essais régionaux effectués avec l'application de recherche des contacts au Royaume-Uni, une application qui fut utilisée par la majorité de la population. La version 1,

mentionnée dans l'étude, était une application de recherche de contacts de proximité avec Bluetooth qui déterminait les cas probables en fonction d'un état symptomatique autodéclaré (17).

Vue d'ensemble des éléments de preuve

Vingt-trois articles ont été inclus dans cette synthèse. Les revues systématiques et les revues rapides qui portaient sur la recherche des contacts comme moyen pour atténuer la propagation de la COVID-19 représentant sept des articles cités (trois d'entre eux étant en préimpression). De plus, 16 articles récents (publiés à l'automne 2020 et à l'hiver 2021) présentaient des données probantes sur des stratégies efficaces de recherche des contacts, dont deux contaient des données épidémiologiques et 14 étaient fondés sur des études de modélisation (6 des modèles sont en préimpression).

L'outil AMSTAR-2 a été utilisé pour évaluer les revues rapides et les revues systématiques (n = 7) indiquées dans le tableau 1 (18). La qualité globale de l'examen est classée comme étant élevée, moyenne, faible ou très faible, selon le nombre de critères de l'AMSTAR qui n'ont pas été respectés.

Les données empiriques (n = 2) sont fondées sur des études d'observation visant à évaluer les stratégies de recherche des contacts ou les changements dans les stratégies actuelles. Les études d'observation risquaient de comporter de nombreux biais. Il faut faire preuve de prudence dans l'interprétation des modèles prédictifs (n = 13), car ils peuvent être sensibles aux hypothèses du modèle et sont plus adaptés pour comparer différents scénarios puisqu'ils pourraient ne pas refléter une situation réelle ou ne pas pouvoir être généralisés. La plupart des données probantes sur ce sujet proviennent de modèles prédictifs.

Les limites de la preuve comprennent un manque de preuves empiriques et une forte dépendance aux conclusions d'études de modélisation ou d'examens fondés sur l'expérience prépandémique.

TABLE DES MATIÈRES

EXAMENS DES ÉTUDES SUR LA RECHERCHE DES CONTACTS

Tableau 1 : Revues systématiques et revues rapides sur la recherche des contacts dans les cas de COVID-19 (n = 7)

ANNÉE	MÉTHODE	PRINCIPAUX RÉSULTATS
Stratégies globales de recherche des contacts		
Mbwogge (2020) (4) Prépublication Revue rapide Royaume-Uni Décembre 2020 AMSTAR – niveau modéré	La revue rapide comprenait 35 articles contenant les données probantes disponibles jusqu'au 22 décembre 2020 sur la question de savoir si le dépistage de masse et la recherche des contacts seraient plus efficaces que la méthode avec tests de dépistage et recherche des contacts actuellement utilisée au Royaume-Uni. Les résultats ont été synthétisés en comptant les votes, en tenant compte de la direction de l'effet et du degré de biais dans les résultats déclarés.	Selon 13 des études, le dépistage de masse était plus efficace que le test basé sur les symptômes dans 76,9 % des études (IC à 95 % : 46,2 à 95,0), ce qui donnerait un résultat pour la réduction de la COVID-19 supérieur à celui obtenu avec le protocole avec test basé sur les symptômes et la recherche des contacts actuellement utilisé au Royaume-Uni. Le dépistage de masse améliore la détection des cas asymptomatiques de COVID-19 qui ne sont pas détectés lors d'un test basé sur les symptômes. Dans 22 études, 40,7 % (IC à 95 % : 38,8 à 42,5 %) des cas détectés seraient asymptomatiques, ce qui veut dire qu'on s'attendrait à avoir 28 % (IC à 95 % : 25,9 à 30,2 %) de cas asymptomatiques dans la population en général et à avoir 96,6 % (IC à 95 % : 82,2 à 99,9 %) de cas asymptomatiques parmi le personnel fournissant des soins de longue durée.
Girum (2020) (19) Revue systématique Éthiopie Juin 2020 AMSTAR – niveau modéré	La revue incluait 22 études d'observation (n = 9) et de modélisation (n = 13) qui ont fourni des preuves de prévention de la COVID-19 grâce au dépistage, à la recherche de contacts, à la quarantaine et à l'isolement. Les études réalisées jusqu'au 2 juin 2020 ont été incluses dans cette revue. Trois études ont évalué toutes les stratégies de prévention alors que cinq	Étude de recherche des contacts : • Isoler uniquement les patients symptomatiques pourrait ne pas permettre de contenir l'épidémie. • Les personnes qui ont des contacts intimes ont des taux de transmission de 40 à 60 %, ce qui indique que les membres des familles qui ont été en contact avec des cas devraient être mis en quarantaine. • Les éclosions pourraient ne pas pouvoir être contenues, à moins que des niveaux élevés de recherche et de quarantaine ne soient utilisés. • Si le R_o est de 2,5, plus de 70 % des contacts doivent être inclus dans la recherche pour ainsi pouvoir lutter contre l'éclosion (20). • L'utilisation d'une stratégie de recherche des contacts et de mise en quarantaine réduit la transmission de 50 à

	ont porté spécifiquement sur les effets de la recherche des contacts.	60 % comparativement au dépistage de masse ou à la quarantaine volontaire qui ne l'a réduite que de 2 à 30 % (5) (comme cela est indiqué dans le tableau 2).
Juneau (2020) (9) Prépublication Revue systématique Québec, Canada Juillet 2020 AMSTAR – niveau faible	La revue a permis de relever 32 études d'observation (n = 14) et de modélisation (n = 18) portant sur l'efficacité de la recherche des contacts dans le contrôle de la COVID-19. Toutes les méthodes de recherche des contacts ont été incluses dans l'examen (c.-à-d., applications mobiles, etc.). Les études étaient exclues si elles ne tenaient pas compte des milieux de transmission communautaire ou si elles n'avaient pas été examinées par des pairs. Les dates de la recherche ne sont pas fournies dans l'article en préimpression.	Dans l'ensemble, la revue affirme qu'un cas doit être isolé dans les 2 à 3 jours qui suivent l'apparition des symptômes, et qu'au moins 80 % de leurs contacts doivent être mis en quarantaine pour qu'il n'y ait pas de cas tertiaires. Des systèmes de recherche des contacts et de quarantaine moins efficaces pourraient ralentir la propagation du SRAS-CoV-2, mais ne pourront pas enrayer l'épidémie. Des retards de quatre jours ou plus ou la mise en quarantaine de moins de 60 % des contacts seront inefficaces pour contrôler l'épidémie.
Chung (2020) (16) Prépublication Revue rapide Royaume-Uni Mai 2020 AMSTAR – niveau très faible	Une revue rapide portant sur l'efficacité et la politique de recherche des contacts, de tests de dépistage et d'isolement pour le contrôle de la COVID-19 a permis de relever 48 études pertinentes. La recherche a porté sur les publications disponibles jusqu'au 28 mai 2020.	Les données probantes sont résumées dans une stratégie d'intervention en santé publique suggérée pour Taïwan. • Les interventions en santé publique, incluant la recherche des contacts, permettent d'obtenir un niveau significatif de contrôle en l'absence d'immunité collective pour la COVID-19. • Un délai d'exécution des tests inférieur à 24 heures est documenté dans plusieurs études et jugé nécessaire pour obtenir la confirmation rapide d'un cas. • Le dépistage de masse dans des groupes particuliers (c.-à-d., les travailleurs de la santé) facilite la détection de cas supplémentaires et de leurs contacts. • De nombreuses régions utilisent avec succès des outils numériques pour faciliter la recherche rapide des contacts, ce qui inclut le suivi de la mobilité avec les

		téléphones cellulaires, l'emplacement et les applications de détermination de l'emplacement, le suivi des symptômes et les balayages de codes QR à l'entrée et à la sortie des lieux communautaires. Il est à noter qu'il faut que l'application soit utilisée par 60 à 75 % des gens pour qu'elle soit efficace contre la propagation de la COVID-19.
Technologie numérique et recherche des contacts		
Anglemyer (2020) (14) Revue rapide Nouvelle-Zélande Mai 2020 AMSTAR – niveau élevé	Cette revue rapide Cochrane effectuée jusqu'au 5 mai 2020 (avant la pandémie ou au début de la pandémie) visait à évaluer les avantages, les préjudices et l'acceptabilité des solutions de dépistage numérique personnel pour identifier les contacts d'un cas positif à une maladie infectieuse.	Applications pour la population en général : Cette revue comprenait six études de cohorte et six études de modélisation. Deux études de modélisation ont indiqué que, comparativement à l'isolement seul, la recherche manuelle des contacts a entraîné une réduction de 35 à 53 % du R_e, tandis que la recherche numérique des contacts n'a réduit le R_e que de 18 à 26 % dans l'ensemble des modèles (sachant que ces derniers ont présumé que l'application n'était utilisée que par 50 % de la population). Les menaces associées aux atteintes à la vie privée, en particulier pour les appareils portables, étaient vues comme une menace possible. Applications de collecte de données sur la santé publique : Pendant une éclosion d'Ebola, le fait d'avoir une application de collecte de données pour effectuer des enquêtes de recherche électronique des contacts a permis d'identifier deux fois plus de contacts que les formulaires papier. Une autre cohorte a mentionné une réduction du temps requis pour effectuer la recherche des contacts avec un système électronique de gestion des données (sans oublier que ce système était également moins sujet aux erreurs et aux pertes de données). Deux cohortes ont indiqué que les systèmes numériques permettaient de gagner du temps et étaient plus faciles à utiliser. Le coût et l'accès à Internet constituaient des obstacles.
Braithwaite (2020) (15) Revue systématique Royaume-Uni	Cette revue systématique qui porte sur la recherche automatisée des contacts, y compris le fait d'automatiser le traitement des résultats des tests ou la déclaration des symptômes et l'utilisation des	• Aucune preuve empirique de l'efficacité de la recherche automatisée des contacts (en ce qui concerne les contacts identifiés ou la réduction de la transmission) n'a été trouvée. Quatre des sept études de modélisation incluses laissaient entendre que le contrôle de la COVID-19 exigeait qu'une grande partie de la population adopte les applications automatisées de recherche des contacts (estimations variant entre 56 %

Avril 2020 AMSTAR – niveau moyen	fonctionnalités des téléphones intelligents (p. ex., Bluetooth) pour déterminer les contacts et aviser instantanément les personnes à risque d'être infectées, comprend des articles publiés jusqu'à la période du 14 au 30 avril 2020 (avant la pandémie et au début de la pandémie). Elle comprenait 15 études.	et 95 %) habituellement utilisées en parallèle avec d'autres mesures de contrôle. • Les études sur la recherche partiellement automatisée des contacts ont généralement révélé une détermination et un suivi plus complets des contacts comparativement aux systèmes manuels. La recherche automatisée des contacts pourrait réduire la transmission si une partie importante de la population y participait. Il faut toutefois tenir compte des préoccupations relatives à la protection des renseignements personnels et à l'équité. • L'automatisation de la recherche des contacts pourrait accélérer la mise en quarantaine des contacts, ce qui entraînerait des répercussions plus importantes. Les cohortes d'Ebola ont démontré un niveau de visite des contacts de 69 % comparativement à 39 % et une réduction de la vitesse variant entre 0,5 et 5 heures dans l'ensemble des études. • L'on estime les besoins en ressources pour une quarantaine basée sur un test de dépistage au Royaume-Uni à un chiffre variant entre 30 et 50 tests par cas positif et par tranche de 10 000 à 20 000 tests faits chaque jour au Royaume-Uni.
Analyse qualitative des connaissances, des attitudes et des comportements		
Megnin-Viggars (2020) (21) Revue rapide Royaume-Uni Juillet 2020 AMSTAR – niveau élevé	Cette revue systématique rapide qui porte sur les obstacles et les facteurs qui augmentent la participation à la recherche des contacts comprend des recherches publiées jusqu'au 15 juillet 2020. Elle comprend onze études, soit six sur la COVID-19, cinq sur le virus Ebola et une sur une autre maladie infectieuse.	Quatre thèmes ont été retenus comme facteurs facilitant l'adoption et l'engagement à l'égard de la recherche des contacts, soit la responsabilité collective, les avantages personnels, la coproduction des systèmes de recherche des contacts et la perception que le système est efficace, rigoureux et fiable. Les participants ont déclaré que leur intention d'utiliser l'application de recherche des contacts était fortement influencée par un sentiment de responsabilité collective (trois études) et leur désir d'aider à réduire le nombre de décès des autres personnes, en particulier celles qui sont vulnérables (deux études). Bon nombre d'entre eux ont indiqué qu'il s'agissait d'un moyen de mettre fin à la pandémie et ont assumé leurs responsabilités à cet égard (deux études), même lorsque les participants avaient certaines préoccupations quant à l'utilisation d'une application de recherche des contacts, ils jugeaient qu'elle était la « seule façon de s'en sortir » et que cette

		responsabilité collective devait être prioritaire par rapport aux doutes personnels (une étude). Cinq thèmes ont été cernés comme étant des obstacles à l'adoption et à la participation à la recherche des contacts, soit les préoccupations relatives à la protection de la vie privée, la méfiance ou l'appréhension, le besoin non satisfait d'obtenir plus d'information et de soutien, la peur de la stigmatisation et les défis propres au moyen utilisé.

EFFICACITÉ DE LA RECHERCHE DES CONTACTS

Tableau 2 : Études épidémiologiques et de modélisation publiées à l'automne 2020/hiver 2021 sur les stratégies efficaces de recherche des contacts (n = 16)

ANNÉE	MÉTHODE	PRINCIPAUX RÉSULTATS
Preuves épidémiologiques (n = 2)		
Carroll (2020) (3) Évaluation de la recherche des contacts Irlande Mai à août 2020	L'étude a surveillé et évalué le système de dépistage et de recherche des contacts en Irlande. Les contacts du laboratoire ont confirmé les cas de COVID-19 identifiés entre le 19 mai et le 2 août 2020 (n = 7 272).	De ces 7 272 contacts, 4 586 ont été testés au moins une fois pendant la durée de l'étude. • Le taux d'attaque des contacts était de 7 % (IC à 95 % : 6,3 à 7,8 %). • On a obtenu 14,6 % de contacts symptomatiques positifs au « jour 0 ». • Le test effectué sur les contacts asymptomatiques au « jour 0 » indiquait un résultat de 5,2 %. Les critères basés sur les symptômes pour la recherche des contacts lors de l'identification n'ont pas permis de détecter plus de 66 % des cas secondaires et de leurs contacts.
Kendall (2020) (17) Évaluation de la recherche des contacts Royaume-Uni	L'étude évalue l'impact du système de test de dépistage et de recherche des contacts utilisés à l'île de Wight, en Angleterre, en mai 2020. Le système a d'abord été utilisé à l'île de Wight avant d'être étendu à tout le Royaume-Uni. La version 1 de l'application de recherche des contacts	Une diminution importante du R_e a été observée après la mise en œuvre du système (passant de 1,3 à 0,5).

Mai et juin 2020	du NHS a été mise en œuvre. Elle utilisait la fonctionnalité Bluetooth pour détecter les contacts physiques étroits entre les gens et permettait aux utilisateurs d'entrer leurs symptômes, soit la toux ou la fièvre, le cas échéant. Une fois les symptômes entrés, les contacts historiques étaient alors avisés de l'exposition potentielle et l'application donnait des conseils sur la prévention des infections (n'incluait cependant pas la directive visant à s'isoler ou à se mettre en quarantaine).	
Analyses de modélisation (n = 13)		
Aleman (2021) (22) Préimpression Modèle Canada Mai 2020	Un modèle basé sur les agents a été utilisé pour évaluer les mesures de santé publique sur la prévention de la COVID-19, ce qui incluait la recherche des contacts, à Terre-Neuve-et-Labrador. Le modèle est stratifié selon l'âge et tient compte des mouvements spatiaux et des comorbidités des personnes. Des volumes de déplacements bas, moyens et élevés ont été modélisés à des fins de comparaison.	La recherche rigoureuse des contacts a réduit la transmission de la COVID-19 de 4 à 74 fois comparativement à la non-utilisation de cette recherche. Le modèle montre également si Terre-Neuve-et-Labrador n'avait pas ajouté de mesures de santé publique pour contrôler l'épidémie, la recherche des contacts aurait dépassé les capacités de la province.
Campbell (2020) (7) Modèle économique Canada Juillet 2020	Cinq populations ont été sélectionnées à des fins de tests stratégiques au Canada : • les contacts des cas de COVID-19; • les employés des hôpitaux de soins actifs; • les travailleurs des soins de santé communautaires, ainsi que le personnel et les résidents des maisons de soins de longue durée; • les employés essentiels des entreprises ayant un niveau élevé de contacts interpersonnels ou avec le public (à l'exclusion des soins de santé);	Cinq stratégies ont été modélisées et comparées à la base de référence (dont le coût mensuel était de 69,8 millions de dollars) : 1. Recherche et analyse systématiques des contacts – toutes les provinces ont la capacité de laboratoire requise, les exigences administratives augmentent de 1,2 fois et les coûts augmentent de 11,1 millions de dollars par mois par rapport au niveau de référence. 2. Tests de dépistage auprès d'employés d'hôpitaux de soins

	• les élèves et le personnel des écoles primaires et secondaires. Les taux de test obtenus entre le 8 et le 17 juillet 2020 ont été utilisés comme base de référence pour comparer l'augmentation des tests requise dans les scénarios dans lesquels les populations sélectionnées feraient l'objet d'un test de dépistage stratégique. Coûts des tests pris en compte : • coûts directs des tests; • capacité du laboratoire; • ressources humaines requises pour l'échantillonnage, l'établissement et l'enregistrement des calendriers administratifs et la recherche des contacts.	actifs – coût de 29 millions de dollars par mois. 3. Test des travailleurs des soins de santé communautaires, ainsi que du personnel et des résidents des maisons de soins de longue durée – 29 millions de dollars par mois. 4. Tests effectués chez les employés essentiels ayant un grand nombre de contacts – 321,7 millions de dollars par mois. 5. Tests effectués chez les étudiants et les membres du personnel des écoles – 816 millions de dollars par mois. La capacité de laboratoire et l'augmentation du personnel étaient toutes requises pour les stratégies 2 à 5. Les répercussions épidémiologiques de la recherche des contacts n'ont pas été modélisées directement, et aucune analyse coûts-avantages n'a été fournie. On a émis l'hypothèse que les coûts des tests et la recherche connexe des contacts réduiraient les coûts des soins de santé en aval, en raison de la prévention de la transmission.
Bradshaw (2021) (13) Modèle États-Unis Janvier 2021	Un modèle bayésien a été utilisé pour démontrer les effets sur la pandémie de COVID-19 de la mise en œuvre de la recherche de contacts bidirectionnelle, par opposition à certains types de recherche de traçage en aval plus courants, utilisés dans la plupart des stratégies. La « recherche de traçage des contacts en aval » informe les personnes récemment exposées, alors que la recherche bidirectionnelle permet également de déterminer l'agent	La mise en œuvre de la recherche bidirectionnelle des contacts dans les scénarios du modèle a fait plus que doubler la réduction de R_e par rapport à la recherche de traçage des contacts en aval seulement. Le fait d'augmenter de 2 jours dans les cas présymptomatiques à 6 jours la période pendant laquelle les contacts sont avisés a permis d'obtenir la plus grande diminution de R_e. Cette façon de faire peut être remplacée par des applications d'avis d'exposition

	infectieux potentiel et l'indique à ces personnes et aux autres personnes ayant potentiellement été exposées.	conçues pour les téléphones intelligents, mais cette façon de faire ne fonctionnera que si l'application est adoptée par presque 100 % de la population.
Endo (2020) (23) Modèle Royaume-Uni 2021	Un modèle avec processus de ramification est utilisé pour simuler l'effet que la combinaison de la recherche de traçage des contacts en amont et en aval peut avoir sur les mesures de santé publique en ce qui concerne la COVID-19. Dans les deux scénarios, les cas index sont déterminés par la surveillance basée sur les symptômes. Dans le cas des expositions avec recherche de traçage des contacts en aval, puisque le cas index peut avoir été infectieux, il est alors identifié et mis en quarantaine. La recherche de traçage des contacts en amont permet de déterminer le cas primaire (infecteur du cas index) et de retracer toutes les expositions du cas primaire en avant pour ensuite savoir qui doit se mettre en quarantaine. Le modèle vise à simuler les détections de cas possibles et à en comparer l'effet sur les cas de COVID-19 dans une collectivité. La probabilité de pouvoir déterminer le cas primaire avec la recherche de traçage des contacts en aval a été établie à 50 et à 80 % pour différents scénarios. La probabilité d'identifier les cas en amont d'un cas confirmé variait de 0 à 100 %, alors que la probabilité qu'un cas index puisse être déterminé par la surveillance des symptômes n'a atteint que 10 %, 20 % et 50 %.	La recherche de traçage des contacts en amont permet de repérer une proportion beaucoup plus grande de cas et, par conséquent, d'exercer un plus grand contrôle sur la propagation de la COVID-19 lorsqu'elle est mise en œuvre. Le modèle a révélé que l'ajout de la recherche de traçage des contacts en amont aux mesures de santé publique était de 2 à 3 fois plus efficace que la seule recherche de traçage des contacts en aval. Le modèle suppose que les cas secondaires (découlant du cas index) ont été mis en quarantaine avant de devenir infectieux et n'ont donc pas créé de cas tertiaires, ce qui pourrait donc sous-estimer les effets des mesures de recherche de traçage des contacts en amont.
Bracis (2020) (24) Modèle	Un modèle stratifié selon l'âge a été utilisé pour effectuer des prédictions du nombre de cas et de décès associés à la COVID-19 pendant et après une période de réouverture dans le comté de King, à Washington. Divers scénarios	Un taux fixe pC_PI a été établi à environ 35 % pendant le confinement et il a fallu maintenir un taux pC_PI inférieur à 45 % pour avoir un contrôle raisonnable sur l'épidémie avec les

ÉTATS-UNIS De mars à novembre 2020	d'interventions en santé publique y sont présentés, ce qui inclut les variations des taux d'interaction physique (pC_PI) avant la maladie de Lyme, les pratiques associées aux tests de dépistage, l'isolement et la recherche des contacts.	pratiques de dépistage en date de mai 2020. Le modèle indiquait qu'une augmentation du nombre de tests de dépistage, de l'isolement et de la recherche des contacts permettrait d'atteindre un taux de pC_PI de 60 % tout en conservant un contrôle raisonnable. • Les tests de dépistage améliorés ont permis de détecter plus de 50 % des infections symptomatiques. • La recherche d'au moins 50 % des contacts a permis d'identifier au moins 5 % des cas asymptomatiques et présymptomatiques. • Les tests de dépistage de masse aléatoires permettront d'augmenter les taux déterminés de tous les cas de 0,5 point de pourcentage (en supposant que 4,5 % de la population soit testée quotidiennement).
Aleta (2020) (11) Modèle États-Unis Août 2020	Modèle de transmission du SRAS-CoV-2 basé sur un agent effectué à Boston au Massachusetts. Le modèle est utilisé pour analyser la propagation non atténuée du SRAS-CoV-2, ainsi que deux stratégies de confinement et de sortie du confinement différentes, toutes deux avec divers niveaux de recherche des cas et d'efficacité du dépistage. Seuls les tests, la recherche des contacts et la quarantaine sont pris en compte. Toutes les autres interventions en santé publique ont été exclues des principales analyses.	L'étude compare différents scénarios qui vont de i) seuls les contacts du ménage de l'un des cas sont mis en quarantaine, à ii) 40 % des contacts du cas ont fait l'objet d'une recherche et ont été mis en quarantaine, tout comme les membres du ménage des contacts. La mise en quarantaine du contact et des membres de son ménage permet une réduction de la transmission suffisante pour aplanir la courbe de l'épidémie et prévenir une seconde vague. Le modèle montre qu'une amélioration dans les tests de dépistage et dans la recherche des contacts peut permettre de contrôler l'épidémie de COVID-19, en fonction du respect des capacités limites pour les soins de santé, même en réduisant

		les interventions avec distanciation physique.
Kucharski (2020) (5) Modèle Royaume-Uni Octobre 2020	Un modèle quantitatif de transmission au niveau individuel a été utilisé pour simuler les effets des tests de dépistage, de l'isolement, de la recherche des contacts et de la réduction des contacts dans les ménages, le travail, l'école et d'autres milieux. Les contacts sociaux ont été modélisés à partir des données fournies par 40 162 participants au Royaume-Uni grâce à une application de recherche de contacts sur les téléphones intelligents.	De façon générale, une grande proportion des cas doivent être isolés et leurs contacts mis en quarantaine pour contrôler l'épidémie de COVID-19 dans les simulations. On a constaté qu'une combinaison d'isolement des cas et de recherche des contacts était plus efficace que les tests de dépistage de masse. Les réductions moyennes de la transmission sont présentées pour les scénarios associés à différentes interventions : • 2 % – dépistage de masse de 5 % de la population par semaine. • 29 % – isolement des cas dans le ménage. • 35 % – isolement des cas à l'extérieur du ménage. • 64 % – isolement des cas avec mise en quarantaine du ménage et recherche manuelle de tous les contacts. • 47 % – isolement des cas avec mise en quarantaine du ménage et recherche des contacts à l'aide de l'application (suppose une utilisation des applications de 53 %).
Ashcroft (2020) (25) Prépublication Modèle Suisse Décembre 2020	Un modèle théorique a été créé pour analyser l'efficacité des stratégies avec recherche des contacts, tests de dépistage, isolement et quarantaine pour contrôler la COVID-19. Les distributions empiriques sont utilisées pour étudier la façon dont la probabilité de détection des cas, la fraction des contacts mis en quarantaine et le retard dans ces événements influent sur le moment où le SRAS-CoV-2 est transmis.	On a analysé l'ajout de la recherche des contacts et de la mise en quarantaine aux mesures d'atténuation, ce qui a permis de constater que la fraction des cas index déterminés et isolés est l'élément qui a l'effet le plus important sur le contrôle de l'épidémie : • R_e = 1,5 ne peut pas être contrôlé lorsque 30 % des cas index sont

	Le modèle prédit le nombre de cas secondaires et, au besoin, tertiaires qui découlent du cas index selon les circonstances.	isolés, même si 100 % de leurs contacts ont été mis en quarantaine. Liste des efforts, des plus efficaces aux moins efficaces dans le cadre des stratégies avec recherche des contacts, tests de dépistage, isolement et quarantaine : • Augmenter la fraction des cas index déterminés et isolés. • Réduire le temps entre l'apparition des symptômes et l'isolement du cas index. • Réduire le temps requis avant de mettre les cas secondaires en quarantaine. • Augmenter la fraction des cas secondaires déterminés et mis en quarantaine. • Prolonger la fenêtre de recherche pour déterminer les contacts. Au fur et à mesure que le R_e de l'épidémie augmente, il devient de plus en plus difficile d'aplanir la courbe de l'épidémie par les tests de dépistage et l'isolement.
Bradshaw (2021) (8) Prépublication Modèle Allemagne Janvier 2021	Un modèle bayésien présenté dans une publication antérieure (13) est utilisé pour évaluer l'efficacité de diverses stratégies de recherche des contacts par rapport aux variants B.1.1.7, P.1 et B.1.351 du SRAS-CoV-2.	Le modèle R_e a estimé la transmission des variants entre 1,2 et 2,0, en tenant compte des interventions déjà en place pour réduire la propagation de la COVID-19. • L'isolement des cas symptomatiques avec faibles taux de conformité, sans recherche des contacts, réduit le R_e de 0,2 à 0,3, ce qui donne un R_e de 1,4, même 50 % des expositions identifiées avec succès pousser le R_e a descendre sous 1. • La recherche des contacts chez 60 à 70 % des personnes exposées, jusqu'à deux jours avant l'apparition des symptômes chez le cas index, entraîne une réduction du R_e de

		0,1 pour l'isolement seulement, alors que la mise en œuvre de la recherche bidirectionnelle effectuée jusqu'à 6 jours avant l'apparition des symptômes avec une recherche de contacts variant entre 45 et 55 % a permis d'atteindre un niveau d'atténuation similaire. • Une réduction de 0,1 ou de 0,2 du R_e entraîne une réduction du nombre de cas sur deux mois de 37 à 43 % et de 61 à 66 %, respectivement.

Stuart (2021) (10)
Prépublication
 	
Modèle
 	
Galles du Sud, Australie
Octobre à décembre 2020
	Un modèle stochastique a été créé pour analyser différents niveaux d'utilisation des tests de dépistage, de la recherche des contacts et du port du couvre-visage et la vulnérabilité qui en résulte à la résurgence de la COVID-19 dans une collectivité où le niveau de transmission est faible.	• Les taux de tests de dépistage et de recherche des contacts ont une incidence relative plus importante, particulièrement lorsqu'il y a une incohérence dans le port du couvre-visage dans la collectivité.
		• Le dépistage de 90 % des personnes symptomatiques et de 90 % de leurs contacts a permis de contrôler l'épidémie.
		• La réduction des taux de dépistage chez les personnes symptomatiques a entraîné un nombre beaucoup plus grand d'infections (données pour la période du 1er octobre au 31 décembre, et reflète le scénario avec port élevé du couvre-visage) :
		  • 90 % -> ~180 cas
		  • 80 % -> de 2 à 3 fois plus
		  • 65 % -> de 8 à 12 fois plus
		  • 50 % -> de 30 à 50 fois plus

Amaku (2021) (26) Préimpression Modèle Brésil Février 2021	Ce modèle quantitatif vise à évaluer les répercussions de la recherche des contacts sur les cas symptomatiques (présumés) en l'absence de tests, à Sao Paulo, au Brésil. La proportion de personnes symptomatiques n'a pas été confirmée par des tests, mais ces dernières ont	Le modèle de référence suppose une stratégie sans recherche de contacts. Un scénario avec 5 000 personnes symptomatiques isolées par jour, dans lequel 80 % des contacts isolés sont infectés par la COVID-19, a permis de

	plutôt été isolées, tout comme leurs contacts trouvés par la recherche des contacts. La proportion de contacts isolés en raison de cette stratégie qui ont véritablement été infectés par la COVID-19 varie selon les scénarios.	réduire de 80 % les cas et les décès dans la population après 60 jours. Un scénario avec 5 000 personnes symptomatiques isolées par jour, dans lequel 20 % des contacts isolés sont infectés par la COVID-19, a permis de réduire de 40 % les cas et les décès dans la population, puis de 50 % après 60 jours. Dans les régions où la transmission est élevée entre les contacts et où peu de tests de dépistage sont disponibles, la stratégie de recherche des contacts symptomatiques peut avoir une incidence importante sur la propagation de la COVID-19.
Amaku (2020) (6) Modèle Brésil Novembre 2020	Un modèle susceptible-exposé-infectieux-retiré (modèle SEIR) modifié est utilisé pour simuler l'épidémie de COVID-19 à Sao Paulo, au Brésil, de mars à décembre 2020. Les données épidémiologiques disponibles jusqu'au 18 juillet 2020 ont été utilisées pour s'adapter au modèle. Les interventions en santé publique ont atteint une réduction maximale de 59 % des contacts par personne à la fin de mars, alors qu'en août, cette réduction n'a atteint que 41 %. Sao Paulo a tenté de contrôler l'épidémie principalement grâce à des taux de dépistage élevés.	Les scénarios des modèles débutant en avril, en mai, en juin, en juillet ou en août ont été exécutés jusqu'à la fin de décembre 2020 pour évaluer l'effet 1) des tests de dépistage de masse sur les personnes; et 2) des tests effectués sur les personnes symptomatiques qui, s'ils étaient positifs, entraînaient l'exécution de tests de dépistage sur leurs contacts. • Les tests de dépistage de masse (1) et les tests de dépistage stratégiques (2) devraient réduire les cas de 90 % par rapport aux niveaux prévus à la fin de 2020. Le coût des tests de masse était estimé à 2,25 milliards de dollars, tandis que le coût associé aux tests stratégiques atteindrait 150 millions de dollars.
Contreras (2021) (27) Modèle Chili	Un modèle de transmission de la COVID-19 dans une collectivité est utilisé pour étudier une stratégie de dépistage, de recherche de contacts et d'isolement.	Le modèle détermine 2 points de bascule entre la COVID-19 contrôlée et non contrôlée dans la population : • les chaînes d'infection « cachées » découlant de cas asymptomatiques,

Janvier 2021		présymptomatiques, évités et non détectés deviennent trop hautes; • les nouvelles infections qui dépassent la capacité de dépistage. Un scénario avec R_e caché effectué à un niveau de 1,8 donne un système stable, mais l'instabilité est introduite lorsque le R_e caché passe à 2,0. Lorsque la charge de travail de la recherche des contacts entraîne des retards supérieurs au temps de génération (4 jours dans ce modèle), la recherche des contacts n'est plus efficace. En raison de ces points de bascule, la stratégie avec tests de dépistage, recherche de contacts et isolement ne peut contenir à elle seule l'épidémie de COVID-19, et en l'absence d'immunité collective, il faut également utiliser des interventions supplémentaires en santé publique.
Yin (2021) (12) Prépublication Modèle Chine Janvier à mai 2020	Un modèle quantitatif de transmission au niveau individuel simule les effets des retards dans le dépistage, la recherche des contacts et le port de couvre-visage dans les populations des mégavilles. La propagation de la COVID-19 a été simulée dans une population de 11,2 millions d'habitants à Shenzhen City, en Chine, à l'aide de données de suivi avec téléphone mobile. La probabilité d'un cas sporadique causant une résurgence de la COVID-19 après la réouverture de la ville a exigé la mise en œuvre de différents scénarios d'intervention en santé publique.	Si la ville rouvre sans qu'un système de recherche des contacts n'ait été mis en œuvre, il y a moins de 50 % de chance que la résurgence soit atténuée en raison des cas sporadiques. Rouvrir la ville une fois que la recherche des contacts des ménages a été effectuée, que tout le monde porte un couvre-visage et après avoir obligé l'exécution de tests de dépistage dans les 28 heures suivant l'apparition des symptômes, a cependant réduit la probabilité d'une résurgence des cas à 5 %. Le même niveau d'atténuation (résurgence de 5 %) est obtenu lorsque 80 % des personnes portent un couvre-vidage et que 40 % des personnes se font test, si la recherche

		des contacts est élargie pour inclure les contacts au travail ou à l'école. Cette relation permet d'obtenir une atténuation équivalente avec une diminution du port du couvre-visage et des tests de dépistage, dans la mesure où les efforts de recherche des contacts augmentent en conséquence.

Méthodologie :

Une analyse documentaire quotidienne (ouvrages publiés et en prépublication) est effectuée par le Groupe des sciences émergentes de l'ASPC. L'analyse a compilé les ouvrages sur la COVID-19 depuis le début de l'éclosion et est mise à jour quotidiennement. Les recherches visant à extraire les ouvrages pertinents sur la COVID-19 sont menées dans Pubmed, Scopus, BioRxiv, MedRxiv, ArXiv, SSRN et Research Square, et les résultats sont recoupés avec les ouvrages figurant sur la liste de la documentation sur la COVID de l'Organisation mondiale de la Santé et des centres d'information sur la COVID-19 gérés par Lancet, BMJ, Elsevier, Nature et Wiley. Le résumé quotidien et les résultats complets de l'analyse sont conservés dans une base de données RefWorks et dans une liste Excel consultable. Une recherche ciblée par mot-clé a été effectuée dans ces bases de données pour recenser les citations pertinentes sur la COVID-19 et le SRAS-CoV-2. Les termes de recherche utilisés comprenaient :
[(test ET (trace OU tracing OU contact)) OU (contact tracing ET review) OU mass testing OU active test] [TITRE]. Chaque référence potentiellement pertinente a été examinée pour confirmer qu'elle comportait des données pertinentes, qui ont été extraites dans la revue. Les revues systématiques et les revues rapides pertinentes ont été identifiées et résumées et de nouvelles recherches datant de l'automne 2020 et de l'hiver 2021 ont également été sélectionnées pour mettre à jour les résultats de la revue. Une analyse croisée des études figurant dans les examens n'a pas été effectuée. Cette synthèse contient des recherches publiées jusqu'au 10 février 2021.

Emerging Evidence on COVID-19

Evidence Brief on Ethnicity and COVID-19

Introduction

This evidence brief aims to summarize the literature on associations of ethnicity with risk of COVID-19 infection, severity, and mortality in Canada and globally.

This evidence brief contains literature up to September 7, 2020. Ethnicity in the included studies is mostly defined by the census bureaus of the included countries and is a self-reported variable based on the individual's identification with a social/cultural group from a predefined list. For consistency in this document the main categories of reported ethnicities will be referred to as Black, White, Asian, and Hispanic. Others or more specific minority ethnic group categories e.g. East Asian, South Asian, indigenous people and Pacific Islanders were also reported and are specified in the summary tables. Please see the Appendix for a table of acronyms and additional definitions.

This review summarizes observational studies (including cohort, cross-sectional, case control and case series) analysing individual-level data where examination of ethnicity was an objective of the study rather than just a potential confounder that was used in the multivariate model. Ecological studies, studies that use aggregate data, were excluded from summarization because these studies may suffer from a high risk of bias and the results cannot be extrapolated to the individual level. In an effort to collect all the available Canadian studies and reports, grey literature and ecological studies on the Canadian population were included in this review.

Key Points

- Regarding ethnicity and COVID-19, two systematic reviews with literature up to May 15 and June 15, sixty-seven individual studies published since May 15 and four of five Canadian studies or reports were identified in the grey literature and are included in this review. There were 34 studies that assessed COVID-19 risk of infection, 31 on severity of disease and 22 studies on mortality (Table 1 & 2). Most of the research came from the USA and UK. There were two studies from France and one study from Brazil. Studies from Canada included a prepublication of an ecological study and two cross-sectional surveys and two relevant surveillance reports were identified in the grey literature (Table 3).
- This is the second version of this review. The first included a systematic review that summarized studies to May 15 and primary research published May 15 -30. This update added studies published between June 1 and Sept 7 including an additional systematic review with studies up to June 15. Analysis of studies captured in the tables and the new systematic review identified 15 studies which are marked with an asterisk (Tables 1 & 2).

Risk of Infection

- One systematic review included risk of infection and concluded across studies Blacks, Asians and Hispanics were more likely to test positive for COVID-19 compared to Whites (D. Pan, 2020).

- Twenty-nine studies examined risk of infection among different ethnic groups from people tested by RT-PCR for active infection (Table 1) and four seroprevalence studies measured risk of exposure (Table 2). Multivariable analyses with age, sex, comorbidities and socioeconomic variables attenuated associations with specific ethnicities, but in many studies the association was still significant:
    - Among twenty studies from the USA, compared to Whites, a higher risk of infection among Blacks (six adjusted and three univariate results) and Hispanics (six adjusted and six univariate results) were reported and conflicting data on Asians (two adjusted, and one univariate association and two no association results). One USA study reported a higher risk of infection among American Indians and Alaskan natives (Hatcher, 2020).
    - Fourteen studies from the UK, compared to Whites, consistently identify Black (nine adjusted results), South Asian (four adjusted results), Asian (three adjusted results) and more generally BAME groups (one adjusted and two univariate and one no association result) at higher risk of infection, whereas the results for other ethnicities were rarely reported.

COVID-19 Severity Outcomes

- Outcomes of COVID-19 severity (hospitalization, ICU admission and mechanical ventilation) were reported in two systematic reviews and thirty one studies reported associations for different ethnicities compared to Whites (Table 1).
    - For hospitalization: The systematic review reports meta-analyses of univariate associations compared to Whites for Blacks (overall countries) and for Asians (UK only), with a significantly higher magnitude association from UK studies and the adjusted analyses (age, sex and comorbidities) reported no association. Across individual studies from the USA, Blacks were found to have higher risk of hospitalization; for Asians and Hispanics there were mixed results. Mixed results from two USA studies reported on the proportion of American Indians, Alaskan Natives hospitalized (Alvarez Retamales, 2020; Karaca-Mandic, 2020). No association with Pacific Islander hospitalizations was reported in two studies (Alvarez Retamales, 2020; McPadden, 2020). In the UK, Blacks and South Asians had a higher risk of hospitalization; for Asians, mixed ethnicity or BAME groups the findings were inconsistent.
    - For ICU admission: The systematic review findings reported Asian and BAME ethnicities in UK studies were over-represented in the ICU, however the meta-analyses reported no association in adjusted analysis for Blacks, Hispanics and Asians (USA only). New studies in the USA had conflicting results for Blacks and Hispanics. In the UK, Blacks, South Asians and BAME had higher risk of admission.
    - For mechanical ventilation: Eighteen studies in the systematic review reported no association for Blacks and Hispanics, however Asians (four studies) had an association with ventilation that persisted with age and sex adjusted analysis. Few recent studies looked at the risk of ventilation by ethnicity; one from the USA reported no association for Blacks and Hispanics

and a study from the UK indicated Blacks and Asians were at increased risk compared to Whites.

- Multisystem Inflammatory Syndrome in Children (MIS-C) and ethnicity was reported in three studies one prospective cohort (ISARIC study, (Swann, 2020)) and two small case series from the UK and France (Riphagen, 2020; Toubiana, 2020). Across these studies a disproportionate number of MIS-C cases occurred in non-White ethnicities. No further analysis was conducted in these studies.

COVID-19 Mortality

- The systematic reviews reported no association with Blacks or Asians, and a protective association identified for Hispanics in univariate analyses, however the association did not persist in models adjusted for age, sex and comorbidities. An association with Asians who required mechanical ventilation due to COVID-19 was reported (4 studies). It is important to note there was high heterogeneity across studies and both reviews describe approximately 50% of studies reporting an association and the others report no association.
- In the USA and the UK twenty-two studies analysed mortality among hospitalized patients and did not report an association with ethnicity. However, when considering a population level denominator, certain ethnic groups were more likely to acquire COVID-19 disease, so proportionally they represent a higher than expected number of COVID-19 deaths. In UK studies that identified an association across all COVID-19 cases, there was an increased risk of mortality among BAME, Blacks, South Asians and Asians compared to Whites (Table 1).

Canadian studies

Despite an additional grey literature search, limited Canadian evidence was identified. Available Canadian data suggest non-White ethnicities, with the exception of East Asians, are disproportionately infected with COVID-19. The analyses largely did not adjust for comorbidities or socio-economic factors that attenuated results in other studies in this review. No Canadian data on ethnicity and hospitalizations, severity or mortality was identified.

- A cross-sectional survey designed to compare COVID-19 impacts on Black Canadians to a representative "national" sample reported a higher likelihood of COVID-19 among Black Canadians individually and among people they know. Black Canadians had a higher frequency of risk factors such as taking public transportation and having a job that requires face-to-face interactions with people. They also had a higher frequency of severe financial impacts associated with the pandemic. These data are consistent with similar studies published in the USA (Table 1).
- Toronto Public Health dashboard shows that a higher proportion of COVID-19 cases than the representation in the community was seen for Black, Hispanic, Southeast Asian, South Asian/ Indo-Caribbean and Middle Eastern ethnic groups.
- The ecological study analysed population data on number of COVID-19 cases and deaths in Canada by population level demographic information including proportion Black, proportion foreign-born,

proportion over 65 years, population density and median income. Findings from their multivariable analysis include:

- 1% increase in the proportion Black in a health unit was associated with double the case count. A 1% increase in the proportion foreign-born residents was associated with a 3% increase in the case count.
- A 1% increase in the proportion of Black residents in the health region was associated with 2.1x increase in COVID-19 death rates.

Overview of the Evidence

Seventy-four studies, including two systematic reviews published up to September 7, 2020 were included in this review. Two systematic reviews were evaluated using the AMSTAR tool, they were of moderate to high quality. One ecological study from Canada was included to allow for awareness of Canadian research, ecological studies use aggregated data for analysis, they have a high risk of bias and ecological fallacy and their findings are cannot be extrapolated to the individual level.

This review focused on studies with datasets at the individual level, this included a range of observational study designs: moderate-high quality large prospective cohorts, moderate to low quality retrospective cohorts and cross-sectional studies and low quality retrospective case series.

This literature has evolved quickly, the more recent large cohort studies have sufficient power to control for many potential confounding variables. These studies provide better estimates of the association than studies reporting crude or minimally adjusted estimates. The large cohort studies are in moderate agreement across studies and offer some confidence that future research will not change the conclusions of this review. Knowledge gaps remain on this topic, such as why some ethnic groups may be at a higher risk of infection given that confounding variables such as socio-economic factors and co-morbidities do not entirely account for this association. Potential genetic factors, related to comorbidities, ACE2 activity, pro-inflammatory cytokine response or other differences in immune system function that may be associated with the immune profile of high risk ethnic groups have been suggested, but not been explained in the literature (Tal, 2020).

CONTENTS

ETHNICITY AND COVID-19 RISK OF INFECTION, SEVERITY OF DISEASE AND MORTALITY

Two systematic reviews and sixty-one observational studies are included in the table below and report on the risk of COVID-19, hospitalizations, severe disease, ICU admission, ventilation, acute kidney injury or mortality.

The systematic reviews include studies published up to May 15 and June 15 (D. Pan, 2020; Raharja, 2020). Only 15 studies overlap the results in Table 1 and the systematic review (Raharja, 2020), the systematic review included ecological studies (results not summarized), as well as studies that did not focus on the association between ethnicity and COVID-19 were included in their meta-analyses.

Most of the research on ethnicity has come from the USA and UK, with two studies from France and Canada, and one study from Brazil (Table 1). Increasingly studies have focused on exploring why ethnicity may be associated with the risk of COVID-19 infection, severity or mortality. Potentially confounding or mediating variables included in multivariable models are age, sex, comorbidities, and socioeconomic factors. The actual variables used for socio-economic factors varied from study to study e.g. income, neighbourhood status, and other composite indices and in some studies they were more complex measures of societal factors that result in barriers to access to medical care, health seeking behaviors or other disparities. The variability in the risk factors tested in the models, and differences in the final model across studies makes direct comparison of results difficult, as seen in the meta-analyses that frequently had high between study heterogeneity. It is also notable that in studies that control for age, sex, comorbidities and socio-economic factors in their analysis, some ethnic groups are still at higher risk of COVID-19 disease.

Table 1 below lists the studies on COVID-19 infection, severity and mortality by country. A summary of their contents is briefly listed below.

- Risk of infection or likelihood of testing positive was assessed in the USA (n=18 studies), UK (n=11) and France (n=1) and one systematic review.
    - Black, Asian and Hispanic ethnicity were shown to have a higher likelihood of testing positive in one systematic review (D. Pan, 2020).
    - Sixteen studies examined testing data in the USA and analysed the probability of testing positive. There was a range of analyses and outcomes were often adjusted for a range of individual, health and socio-economic factors. Despite this, significantly more test positives (in the magnitude of 1.5-3.5 times higher risk) compared to Whites were reported for Blacks in nine studies, Hispanics in eleven studies, Asians in two studies, Native American/Alaskan in one study (Table 1).
    - Eleven studies examined testing data in the UK and reported higher probability of testing positive compared to Whites among BAME groups (3/4 studies), Blacks (seven studies), South Asians (two studies) and Asian (one study).
    - One survey of US and UK populations reported an adjusted (sex, comorbidities, BMI, smoking) higher risk of being COVID-19 positive among Black and Hispanics, not Asian or other

ethnicities compared to Whites in the USA. In the UK, different ethnicity categories were used; higher risk was reported in Black, South Asian, Chinese, Middle Eastern and Other, not East Asian or Hispanic (Lo, 2020).

- One study in France of kidney transplant recipients reported that non-white ethnicity was associated with higher odds of COVID-19 disease after adjusting for age, sex and comorbidities (Elias, 2020).

- Risk of severe disease was measured as hospitalizations, ICU admission or mechanical ventilation was reported, and across studies, mixed results were often identified. The summaries listed below have been grouped by the denominator for the sampling frame, the entire population, the number of positive COVID-19 cases or hospitalized for COVID-19, as this was considered a potential source of heterogeneity. The analysis, univariate vs. adjusted results is also a source of heterogeneity across studies as estimates adjusted for comorbidities or socio-economic factors usually resulted in the association with ethnicity attenuated towards the null.
  - For hospitalization: The systematic review reported an association with Blacks (RR: 1.68 [95%CI: 1.28-2.20], I^2=98, k=13) in univariate analysis and subgrouping by country RR UK 5.47 [95%CI: 2.51; 12.06] vs. RR USA 1.36 [95%CI: 1.08; 1.72] showed higher magnitude in the association among UK studies. In studies that adjusted for age, sex and comorbidities no association was reported. No association with Hispanics (RR: 1.00 [95%CI: 0.95-1.06], I^2=0, k=8) in the univariate analysis, but there was an association in the adjusted analysis. No association with Asians was determined overall or in adjusted analyses. However, when sub-grouped by country an association with Asians was seen in UK studies: RR UK: 2.95 [95%CI: 1.55-5.53] vs. RR USA: 0.90 [95%CI: 0.82-1.66]. No association with ICU admission and mechanical ventilation was identified in adjusted meta-analyses, except for UK studies that identified an increased risk among Asians and over-representation of BAME groups.
  - Eight USA studies provided analysis of ethnicity by severity in a population. Hospitalizations compared to Whites were higher for Blacks (n=4/4 studies), Hispanics (n=3/4), Native American/Alaskans (n=1/2), Pacific Islanders (0/2) and other ethnicities (n=1/1). Whereas in one study lower than expected hospitalization was reported for Asian ethnicity. More severe outcomes were reported for Blacks (n=2/2), Hispanic (n=2/2) and Asians (n=2/2) compared to Whites. ICU admittance was significantly more common in Blacks (n=2/3) and Hispanics (n=1/2) and ventilation was reported to be more common for Black and Hispanics in one study.
  - Ten USA studies looked at hospitalization and risk of ICU among confirmed cases of COVID-19. Hospitalizations occurs significantly more among Blacks (n=5/7 studies), Hispanics (n=3/5), Asian (n=1/2), mixed ethnicity and overall (n=1 each). There was no association with ethnicity and risk of ICU admittance among the hospitalized COVID-19 cases.

  - Two UK studies noted higher hospitalization rates for children of BAME groups compared to Whites and similarly a second study reported higher risk of hospitalization among Black and mixed ethnicity groups, but not for Asians.
  - Eight UK studies report on hospitalizations and ICU admittance among confirmed cases of COVID-19. The UK results found no association among BAME groups (n=2/2 studies) and high risk associations with Blacks (n=2/2), S. Asians (n=2/2) and Asians (n=1/1). ICU admission were also associated with BAME groups (n=4/4), South Asian (n=2/3) and Blacks (n=2/2). Higher odds of mechanical ventilation was reported for Blacks and Asians in one study.

- MIS-C, multisystem inflammatory syndrome in children, and a potential association with ethnicity was reported in three studies, two from the UK and one from France. Across these studies, higher frequency of non-white ethnicities diagnosed with MIS-C was reported; this difference was significant in the largest study.
- Mortality was reported similar to severity where the denominators were either the general population or a hospitalized population of COVID-19 cases.
  - The systematic reviews report no association with mortality for Blacks and Hispanics in adjusted analyses, and a higher risk among Asians who were mechanically ventilated compared to Whites with significant heterogeneity between studies and a notable higher mortality risk among different ethnic groups from the UK studies (Raharja, 2020).
  - Seven USA studies reported an analysis of mortality among hospitalized COVID-19 cases and ethnicity. One reported higher odds among Blacks, one reported lower odds among Hispanics and most reported no associations with Blacks (n=5), Hispanics (n=4) or all minority ethnic groups (n=1).
  - One study in the US reported mortality across all positive COVID-19 cases and found no association with Black ethnicity.
  - Seven UK studies report an analysis of mortality among hospitalized COVID-19 cases and ethnicity. An association with higher risk of mortality was reported for South Asians (n=2/3 studies), Blacks (n=1/4), Asians (n=2) and no association was reported for East Asians (n=1), Mixed ethnicity (n=2) and BAME groups (n=1).
  - Six UK studies report COVID-19 mortality across the general population. Higher associations were noted for Blacks (n=3/4 studies), South Asians (n=2/2), mixed ethnicity (n=1/2), BAME (n=1/1) and Asians (n=1/2), where the studies for Asians and mixed ethnicity were conflicting results reporting both protective and higher risk associations compared to Whites across two studies each.
  - A single study from Brazil reported an association with higher mortality among mixed and Black ethnicities.

Table 1: The association of ethnicity and risk of COVID-19 infection, severity and mortality in systematic reviews (n=2) and observational studies (n=61)

Susceptibility, Clinical Severity and Mortality associated with COVID-19		
Systematic Review		
(Raharja, 2020) preprint new	A systematic review and meta-analysis on the association between ethnicity and poor outcomes. (AMSTAR – high quality) Data up to June 15, 2020. 72 articles (13 ecological) from the USA (54), UK (15), Brazil (1) and Israel (1) were included, although the data from the later two are not presented in the results. Outcomes included mortality, hospitalization, ICU, respiratory and kidney failure. Analysis results focus on Black, Asian and Hispanic as there were very few studies for other native ethnic groups or studies outside the USA and UK. Random effects meta-analysis was conducted on quantitative outcomes in 45 studies. Studies not included in the meta-analyses were descriptively summarized. Their results are also noted if an association was identified and/or is different than the meta-analysis.	The evidence does not confirm ethnicity is an independent risk factor for poor outcomes in COVID-19 patients. Meta-analyses generally had high heterogeneity (I^2 > 60%) and where examined, adjusted analyses for age, sex and comorbidities attenuated univariate associations. Significant associations are shown below, other results of analysis are available in the paper. Hospitalization (20 studies): Compared to Whites, - Associated with Blacks (RR: 1.68 [95%CI: 1.28-2.20], I^2=98, k=13) in univariate analysis (RR UK 5.47 [95%CI: 2.51; 12.06] vs. RR USA 1.36 [95%CI: 1.08; 1.72] was significantly different). Studies that adjusted for age, sex and comorbidities report no association. - No association with Hispanics (RR: 1.00 [95%CI: 0.95-1.06], I^2=0, k=8) in the univariate analysis, but was significant in the adjusted analysis. - No association with Asians was determined overall or in adjusted analyses. However, when sub-grouped by country an association was seen in UK studies: RR UK: 2.95 [95%CI: 1.55-5.53] vs. RR USA: 0.90 [95%CI: 0.82-1.66]. ICU (18 studies): Compared to White ethnicity, - A univariate association with Blacks (RR: 1.51 [95%CI: 1.11-2.04], I^2=94, k=10) was observed, however there

		was no association after adjusted for age, sex and comorbidities. - The unadjusted and adjusted association with ICU admission not significant for Asian or Hispanic in the US. The UK studies reported an increased risk of ICU in Asians. - 5 UK studies not included in the meta-analysis, reported over-representation of BAME communities in ICU cohorts. 2 USA studies did not find an association with Blacks. Mortality (51 studies): Compared to Whites, - A protective association with overall mortality was observed across the unadjusted data: Hispanics (RR: 0.69 [95%CI: 0.57-0.84], I^2=76, k=11), however the association did not persist in models adjusted for age, sex and comorbidities. - Asians who were mechanically ventilated cases were at higher risk of mortality in four studies (RR: 1.39 [95%CI: 1.07-1.80], I^2=14, k=4). - No other associations with mortality was found in the meta-analysis conducted on overall mortality, hospitalized cases, ICU cases, mechanical ventilation cases or acute kidney injury cases and Black, Asian or Hispanic ethnicity. Mechanical Ventilation (18 studies): Compared to Whites, - An association with Asians (RR: 1.39 [95%CI: 1.07-1.80], I^2=14, k=4) was seen in the univariate and age/sex adjusted analysis.

		- No association with risk of ventilation was observed for Blacks or Hispanics, even in adjusted analysis (age, sex and comorbidities). Acute Kidney Injury (AKI) (8 studies): Compared to Whites, - No association with AKI was observed for Asians. - An association was reported for Blacks (RR: 1.35 [95%CI: 1.04-1.76], I^2= 92%, k=5) in the univariate analysis that did not persist in adjusted (age, sex and comorbidity) analysis.
(D. Pan, 2020)	A systematic review of ethnicity and clinical outcomes of COVID-19. (AMSTAR rating – medium quality: registered protocol may or may not have been done *a priori*, studies included for each outcome is not clearly reported and no discussion of heterogeneity). Data up to May 15, 2020 162 studies (80 in preprint) Supplementary files 2-6 describe each of the studies included in this SR. Searches included primary literature, clinical trials, preprints and grey literature. Analysis was descriptive and does not report the results of individual studies, number of studies or which studies contribute to each outcome. Few studies that examined ethnicity were published as of May 15, 2020.	Compared to Whites, several studies reported Blacks, Asians and Hispanics are more likely to: 1. Test positive for COVID-19 Mixed evidence was identified for 1. Hospitalization 2. Intubation 3. ICU 4. Mortality - Ethnicity and risk of infection with SARS-CoV-2: in one published study (S. de Lusignan, 2020b) Blacks were more likely to test positive and similarly in preprints higher susceptibility was reported in 14 studies for Blacks, 3 for Asians and 3 for Hispanics compared to Whites. - Hospitalization, intubation and ICU rates by ethnicity were conflicting across studies. A large cohort in the UK report higher proportion of non-white patients admitted to the ICU. - Mortality: 8 studies found no association with mortality, and others recorded an association for

		Blacks (n=6), Asian (n=3) compared to Whites. Grey literature in the US and UK are reporting higher mortality in non-White ethnicities (mainly Black and Asian).
United States (USA)		
(Petrilli, 2020)	USA, New York, multi-center health network, prospective cohort, case data up to Apr 8, follow-up to May 5. N=5279 admitted to hospital for COVID-19 COVID-19 positive tests n=5279 Hospitalizations n=2741 Hospice or death n=665 Ventilation n=647	- Risk of hospitalization among COVID-19 positive cases was significantly higher in Hispanic aOR 1.63 (95%CI 1.35-1.97) and other/mixed aOR 1.6 (95%CI 1.21 – 2.11) compared to Whites. Multivariable logistic regression adjusted for age, sex, smoking, week of outbreak and BMI.
(Goldfarb, 2020)	Single medical center, prospective cohort of pregnant women. Mar 6- May 4, 2020. 65 Hispanic (represent 18% of the population) and 127 non-Hispanic women presented with COVID-19 symptoms – not everyone was tested. No statistical analysis was performed due to sample size. Ethnicity was not shown to be a factor in this disparity which may be explained by socio-economic factors.	- Hispanic women were more likely to test positive (72%) 39/54 vs. 27% (22/82) for non-Hispanic women ($p<0.001$). This mirrored the increasing number of cases in the Hispanic population vs. non-Hispanic population in the general public after social distancing interventions were introduced. - Of those that tested positive, a similar proportion were admitted to hospital. 13/39 Hispanic and 8/22 non-Hispanic women. Of these, 5 Hispanic and 1 non-Hispanic case were admitted to ICU. No deaths.
(Bandi, 2020)	USA, Chicago, prospective cohort single hospital, pediatric COVID-19 cases. All children tested for SARS-CoV-2 were enrolled Mar 12- Apr 20, 2020. N=474 children examined, 5.2% (25) were COVID-19 positive. (n=5 children were hospitalized.) Proportion in sample: White 25.1%	- Compared to Whites, Blacks had a significantly higher positive test rate (6.8% vs. 1.7%, p=0.046). - Blacks had a higher adjusted odds aOR 3.1 (95%CI 1.23-5.34) of a positive test, adjusted age and sex. - Hispanics were similar by not significant.

	Black 43.2% Hispanic 24.7% Asian 1.5%	- Hospitalizations: 80% (20/25) were Black, which is higher than expected, but this outcome was not further analysed by the author.
(Lo, 2020) preprint new	Longitudinal survey targeting the general population in the USA and UK using an app that prompts input from users daily. Data collected March 24- May 25, 2020. All self reported. Respondents: USA = 179 873, UK= 2 234 728 Multivariable model by country: Adjusted for sex, history of diabetes, heart disease, lung disease, kidney disease, and current smoker status (each yes/no), and body mass index (17-18.4, 18.5-24.9, 25-29.9, and ≥30 kg/m2). Multivariable model combined USA and UK: also adjusted for isolation, frontline healthcare worker, community exposure to COVID-19, population density, income, and education.	- Risk of reporting a positive COVID-19 test (Odds Ratio and 95%CI): o USA: Black 2.49 (1.68-3.69), Hispanic 1.66 (1.18-2.34), Asian 1.42 (0.86-2.35) Other 1.32 (0.67-2.61). o UK: Black 1.97 (1.47-2.64), Hispanic 1.71 (0.89-3.27), South Asian 1.68 (1.43-1.97), Chinese 1.79 (1.08-2.96), East Asian 1.02 (0.55-1.87), Middle Eastern 2.10 (1.52-1.87), Other 2.10 (1.52-2.91) o USA and UK data combined compared to Whites: Blacks 1.17 (1.10-1.25), Hispanic 1.11 (1.00-1.23), Asian 1.06 (1.03-1.10), Other 1.21 (1.17-1.25) - Risk Factors: Black and Hispanic participants were more likely to be obese and have diabetes. - All ethnic minorities reported lower social isolation, were over-represented by front line health care workers and reported a higher likelihood of contact with a case of COVID-19.
(Martinez, 2020) new	Longitudinal study of the general population serviced by Johns Hopkins Health System (5 hospitals and 30 clinics) from March 11- May 25, 2020. Data represents 32 727 people tested by RT-PCR for SARS-CoV-2 (over time this increased from only high risk to all symptomatic individuals).	- The positivity rate was significantly different ($p<0.001$) across groups compared to the Hispanic ethnicity 42.6% (95% CI, 41.1%-44.1%), Whites (8.8% [95% CI, 8.4%-9.2%]), Blacks (17.6% [95% CI, 16.6%-18.3%]), or other ethnicity (17.2% [95% CI, 16.2%-18.3%]). It is unclear whether high positivity in Hispanics is due to

	Statistics: proportion positive and hospitalized was analysed by ethnic category using omnibus ANOVA with a correction for multiple comparisons.	higher prevalence of disease or lower rates of using healthcare. - Hospitalizations was lower for Hispanics (29.1% [95% CI, 27.0%-31.2%]) than Whites (40.1% [95% CI, 37.6%-42.5%]) or Blacks (41.7% [95% CI, 39.5%-43.8%]).
(Lee, 2020) preprint new	USA, retrospective cohort analysis of patient records from 12 Midwest hospitals and 60 clinics between March 4, and August 19, 2020. The primary outcome was COVID-19 severity using hospitalization within 45 days of diagnosis. 5,577 COVID-19 patients were included and 866 (n=15.5%) were hospitalized within 45 days of diagnosis. Of those hospitalized, 43.9% (n=381) were White 19.9% (n=172) were Black 18.6% (n=161) were Asian 11.8% (n=102) were Hispanic Model was adjusted for age, gender, comorbidity, relationship status, and rurality/ urbanity.	Independent of neighborhood deprivation, minority race/ethnicity of patients was associated with increased COVID-19 disease severity. - Hispanic (OR 3.8, 95% CI 2.72–5.30) - Asians (OR 2.39, 95% CI 1.74–3.29) - Blacks (OR 1.50, 95% CI 1.15–1.94)
(Hatcher, 2020) new	USA, retrospective cohort analysis of COVID-19 among the American Indian and Alaska Native (AI/AN) populations from 23 states (n=345,093). Findings on incidence of SARS-CoV-2 infection reported between January 22 and July 3, 2020 show a 3.5 times increased incidence of COVID-19 among AI/AN persons.	Cumulative incidence of COVID-19: - AI/AN persons: 594 (95%CI 203–1,740 per 100,000 AI/AN population) - White 169 (95% CI 137–209) per 100,000 white population - AI/AN had significantly higher relative risk of getting COVID-19 RR 3.5, 95%CI 1.2–10.1 compared to Whites.

(McCarty, 2020) new	USA, retrospective cohort analysis of 9 Massachusetts hospitals including 379 COVID-19 patients. Association of race/ethnicity of patients and hospitalization outcomes (i.e. in-hospital mortality, ICU admission, or mechanical ventilation).	- On multivariable analysis controlling for age, gender, obesity, cardiopulmonary comorbidities, hypertension, and diabetes, no significant differences in in-hospital mortality, ICU admission, or mechanical ventilation by race/ethnicity were found.
(Karaca-Mandic, 2020) new	USA, retrospective cohort examined the racial/ethnic prevalence of cumulative COVID-19 hospitalizations in 12 states between April 30 and June 24, 2020. The proportion of hospitalizations by ethnicity was compared to the proportion of each ethnicity in the population. Ethnicities reported on: Hispanic, White, Black, Asian, American Indian/ Alaskan Native. Data are descriptive and not adjusted.	Hospitalizations: Whites had a substantially smaller proportion hospitalized compared to their share of state population in all 12 states. - The percentage of hospitalizations among Black patients exceeded the percentage of their representative proportion of the state population in all 12 states. - Hispanic hospitalizations exceeded their representative proportion in 10 states, this was very pronounced in Virginia, Utah, and Rhode Island. - Asians hospitalized for COVID-19 were approximately equivalent or lower than their proportion in the population. - American Indians and Alaskan Native populations were reported in 8 states with large disparities in Arizona and Utah.
(Gottlieb, 2020) new	USA, retrospective case-control study conducted at Rush University Medical Center in Chicago, Illinois between March 4 and June 21, 2020, explored risk factors associated with hospitalization.	- Hispanic ethnicity was a risk factor for hospital admission (OR = 1.52, 95% CI = 1.18 to 1.92).
(Rozenfeld, 2020) new	USA, retrospective cohort study conducted between February 28 and April 27, 2020, to characterize risk factors in 34,503 patients in the Providence Health System.	Risk of SARS-CoV-2 infection compared to White patients: - Asian (OR 1.43; 95% CI 1.18–1.72, p = 0.0002) - Black (OR 1.51; 95% CI 1.25–1.83, p < 0.0001) - Hispanic (OR 2.07; 95% CI 1.77–2.41, p < 0.0001)

(McPadden, 2020) preprint new	USA, retrospective cohort study conducted at the Yale New Haven Health (YNHH) on 7,995 patients with SARS-CoV-2 between March 1 and April 30, 2020. The study assessed hospitalization and in-hospital mortality.	Race/ ethnicity with increased risk of hospitalization: - Asian (OR 1.58, 95%CI=1.02-2.41) - Black (OR 1.43, 95%CI 1.14-1.78) - Hispanic (OR 1.81, 95%CI 1.50-2.18) In the discharged population, age-adjusted, in-hospital mortality was similar among all racial and ethnic groups. In-hospital, age adjusted mortality rates: - White = 4.3% - Black = 3.3% - Hispanic = 3.4% - Asian = 4.6% - Hawaiian = 4.0% - Pacific Islander = 3.1%
(Emeruwa, 2020) new	USA, New York retrospective cohort study of women (n=100) delivering at two New York-Presbyterian–affiliated hospitals in Manhattan from March 13 through April 23, 2020. The SARS-CoV-2 infection rate per racial–ethnic group of women delivering was analyzed.	- There was a significantly higher SARS-CoV-2 infection rate among Hispanic women compared with non-Hispanic White women (18.1% vs 9.4%, P< 0.01). - The rate of positive SARS-CoV-2 infection results in non-Hispanic Black women (12.7%) was not significantly different.
(Mendy, 2020) preprint new	Retrospective cohort of hospitalized cases at the University of Cincinnati health system (4 hospitals) March 13 to May 31, 2020. N=689 cases (RT-PCR positive) Logistic regression modeling adjusted for covariates: age, sex, ethnicity, smoking, comorbidities.	- Hospitalizations (31.3% total): Adjusted analyses Black OR 2.23 (95%CI 1.41-3.53) and Hispanic OR 1.91 (95%CI 1.11-3.29) compared to Whites - Severe COVID-19: Adjusted analyses Black OR 3.15 (95%CI 1.71-5.79) and Hispanic OR 2.78 (95%CI 1.29-5.96) compared to Whites - ICU (13.2% total): Adjusted analyses Black OR 3.32 (95%CI 1.56-7.07) and Hispanic OR 3.44 (95CI 1.42-8.34) compared to Whites

		- Deaths: adjusted analysis Blacks OR 3.44 (95%CI 1.32-9.00)
(Kalyanaraman Marcello, 2020)* preprint new	Retrospective cohort, New York's public hospital system data, New York City, March 5- April 9 with follow-up to April 16, 2020. 22254 patients tested in the hospital catchment area, 13442 positive SARS-CoV-2. Black and Hispanics comprised approximately a third of the COVID-19 cases, which is an over-representation of these ethnicities compared to the NYC population. Descriptive analysis, Chi-square test used. No multivariable analysis was conducted.	- Positive Test 13442/22254 (61%). 26% Black, and 34% Hispanic. Both had significantly higher proportion of positive tests than Whites P<0.001. The higher proportion may be due to Blacks and Hispanics were more likely to present for testing at the ER rather than outpatient clinics. - Hospitalization 6248/13442 (46%). 31% Black, and 34% Hispanic. A significantly higher proportion of Blacks were hospitalized P<0.001, no association for Hispanic. - Deaths 1724/6248 (28%). 29% Black, and 31% Hispanic.
(Price-Haywood, 2020)	Retrospective cohort, Louisiana, USA, Ochsner Health system, March 1- April 11. N=3481 positive COVID-19 tests in the catchment area The population serviced by this hospital are 31% Black and 65% White. Analysis: - Multivariable logistic regression (hospitalization) adjusted by age, sex, comorbidity index score, low-income residence, public health insurance. -Survival analysis (mortality), adjusted by age, sex and comorbidity index score.	- The racial profile of positive COVID-19 tests 70.4% Black, 29.6% White. - Hospitalization (N=1382) 76.9% Black. Blacks had a higher odds OR 1.96 (95%CI 1.62-2.37) of being hospitalized. - ICU (N=474) 80.2% Black. - Mechanical Ventilation (N=364) 81.6% Black. - Death (N=326) 70.6% Black. In the survival analysis, Black race was not independently associated with mortality (HR= 1.14, 95%CI 0.88-1.49).
(Azar, 2020)*	Multihospital, retrospective cohort. San Francisco USA, patients Jan 1- Apr 8, 2020	- Hospitalization of Black 52.5% (n = 32) vs. 25.7% (n = 110) of White patients.

	Overall data: n=14036 tested for COVID-19 n=1025 COVID-19 n= 256 hospitalized n= 110 ICU	- Black case hospitalization odds was 2.7 (OR) times higher compared to White cases, multivariable model adjusted for age, gender, and sociodemographic variables. Note: Black cases were more likely to be captured at the ER in severe condition rather than in a non-ambulatory setting, which may explain this association. - ICU admittance was higher for Black cases 24.6% vs. the White cases 10.7%. - Black cases with COVID-19 lived in ZIP codes with lower income compared to all other racial and ethnic groups (p<0.001). - There was no significant difference in mortality across ethnic groups.
(Rentsch, 2020)* preprint	USA, 6 million US veterans, Feb 8- May 4. Retrospective cohort. N= 5630 COVID-19 cases from 62098 tested. Ethnicity: Whites 74%, Black 19%, Hispanic 7%. Estimates were adjusted by demographic, medical and high risk behaviours, socio economic variables.	- Tests per 1000 were higher for Blacks 16.4 (95%CI 16.2 - 16.7) and Hispanic 12.2 (95%CI 11.9 - 12.5) vs. White 9.0 (95%CI 8.9 - 9.1) - Compared to Whites, Blacks were more likely to test positive aOR 1.96 (95%CI 1.81-2.12) as were Hispanics aOR 1.73 (95%CI 1.53 – 1.96). - There was no significant difference in 30 day mortality by ethnic group among the COVID-19 cases.
(Gu, 2020)* preprint new	Retrospective cohort, Michigan USA, March 10- April 22, 2020. N= 5698 tested patients (randomly selected unmatched controls n=7211 and frequency matched controls by race, age and sex n=13351) logistic regression, adjusted for age, sex and socioeconomic characteristics.	- Risk factors for testing positive: Black test positive rate (42.6%) was significantly higher than Whites (13.7%, P<0.001) - Hospitalized Blacks 52.2% vs. Whites 39%, p<0.001 and OR 1.66 (95% CI, 1.09-2.52) - ICU Black 27% vs. Whites 14.8% p<0.001 and OR 1.52 (95%CI 0.92-2.52)

		- Mortality Blacks 5.3% vs. Whites 3.0%, p<0.12 and OR 1.17 (95%CI 0.4-3.45)
(Joseph, 2020) new	USA, single institution retrospective cohort study to study whether non-White COVID-19 patients present with increased severity on admission chest X-ray than White patients, between March 27-April 10 2020, total n=326 (210 non-White; 116 White)	- Non-White patients hospitalized with COVID-19 infection were more likely to present with higher severity of disease on admission chest X-ray than White/Non-Hispanic patients (adjusted average difference 1.6, 95% CI 0.5–2.7, p<0.01).
(Antwi-Amoabeng, 2020) preprint	Single Center, retrospective cohort study Nevada USA, n=172 COVID-19 patients Mar 12- May 8 Hispanic vs. non-Hispanic Overall outcomes: - 121 hospitalized - 28 ICU 18 died	- Significantly more Hispanics were COVID-19 cases (50.6%) than would be expected, they represent 25.7% of the population. - Mortality significantly higher in non-Hispanic group (15.3% vs. 5.8%), p=0.048. *Analysis accounting for the Hispanic group being significantly younger, fewer comorbidities, more likely to be uninsured and live in low income communities compared to the non-Hispanic group was not conducted.
(Kim, 2020)*	US COVID-NET (surveillance across 14 states): 2491 hospitalized cases March 1- May2. N=16318 COVID-19 cases n= 2491 COVID-19 cases with complete records that were discharged as of May 3, 2020 were analysed. Of these 47% White, 30% Black and 12% Hispanic. n= 798 ICU n= 420 died n=246/462 died of those receiving mechanical ventilation Multivariable logistic regression controlling for age, sex, and underlying conditions, smoking, treatment with ACE inhibitors.	Among hospitalized cases of COVID-19, ethnicity was not associated with admission to the ICU or mortality.

(Bui, 2020) new	USA, Utah outbreak investigations March 6 and June 5, 2020. Racial and ethnic composition of workplace outbreak-associated cases were compared with the overall racial and ethnic composition in each sector in Utah.	Although 24% of Utah's workforce in all 15 affected sectors identified as Hispanic or a race other than White (non-White), 73% (970 of 1,335) of workplace outbreak-associated COVID-19 cases were in persons who identified as Hispanic or non-White.
(Chamie, 2020) new	A cross-sectional study was conducted in a 16 square block area of San Francisco's Mission District April 25-28. Serology and RT-PCR testing was conducted on residents that volunteered. N=3953 tested, 40% Hispanic, 41% White, 9% Asian/Pacific Islander, 2% Black, and 7% other/mixed	- 83/3953 were RT-PCR positive, 95% of the positive individuals were Hispanic. - Prevalence among residents/workers for Hispanics: 3.9% (2.0-6.4)/10.4% (7.0-14.8) compared to other ethnicities: 0.2% (0.0-0.4) / 0.0% (0.0-2.0). - Recent infection was most likely to be identified in a Hispanic 10.1 (2.81-64.6) compared to others. - Positive Hispanics in this study were more likely to be male, work in a frontline service job, have a low income (50k) and report a COVID-19 contact.
(Ko, 2020) new	USA, cross-sectional study examined factors associated with COVID-19 hospitalizations by assessing data from 70 counties participating in the Coronavirus Disease 2019-Associated Hospitalized Surveillance Network (COVID-NET) and a population-based sample of non-hospitalized adults residing in the COVID-NET catchment area.	Risk of hospitalization by ethnicity compared to Whites: - Blacks (aRR: 4.7; 95%CI: 3.8, 5.9) - Other ethnicities (aRR: 3.5; 95%: 2.8, 4.3)
(A. Pan, 2020) preprint new	USA, Houston cross-sectional analysis conducted between March 3 and July 18, 2020, evaluated hospitalization and mortality outcomes for Blacks vs. Whites and Hispanics vs. Whites in the Greater Houston Metropolitan Area.	In a fully adjusted model, statistically significant higher likelihood of hospitalization - Blacks aOR 1·42 (95%CI 1·24–1·63) - Hispanics aOR 1·61 (95%CI 1·46–1·78) There was no association with mortality.
(Vahidy, 2020) new	USA, cross-sectional study on data being contemporaneously collected since March 5, 2020 by the Houston Methodist Hospital system on association of ethnicity and susceptibility of SARS-CoV-2 infection.	In the fully adjusted model compared to Whites, there was a higher likelihood of infection among: - Black; aOR, CI: 1.84, 1.49-2.27) - Hispanic; aOR, CI: 1.70, 1.35-2.14)

		- Asians; aOR, CI: 1.46, 1.09-1.95)
(Goyal, 2020) new	USA, cross-sectional study of 1000 children tested between March 21 and April 28, 2020 to assess association between patient ethnicity and SARS-CoV-2 infection rates.	In comparison to Whites (7.3%), minority children had higher rates of SARS-CoV-2 infection (Black: (30.0%; adjusted OR 2.3 [95% CI 1.2, 4.4]; Hispanic: 46.4%; adjusted OR 6.3 [95% CI 3.3, 11.9]).
(Alvarez Retamales, 2020) preprint new	USA, observational cross-sectional, nationwide hospital admission data taken from CDC COVID-NET on June 11, 2020 to investigate the discrepancy in hospitalization rate by race/ethnicity, 21,221 hospitalized COVID-19 patients compared to population of 328,239,523.	Significant differences in the ethnic proportion of COVID-19 cohort vs the population respectively: - White: 38% vs 60.4% - Hispanic: 19% vs 18.3% - Black: 36% vs 13.4% - Asian/Pacific Islander: 5% vs 6% - American Indian/Alaska Native: 1.6% vs 1.3% The discrepancy is greatest for Whites and Blacks: with Whites being disproportionately underrepresented and Blacks being disproportionately overrepresented in the COVID-19 cohort compared to total population.
(Gross, 2020)	USA, 28 states: Cross-sectional study up to April 21, 2020. Data from CDC was extracted by state, 28 states and NYC have racial data. Analysis adjusted for age (standardised mortality by age across race groups in each state) and meta-regression analysis was conducted to assess the association of state-level racial disparities.	- Risk of death in Black compared to the White population was aRR 3.57 (95%CI 2.84-4.48). Pennsylvania was the only state where Black risk of COVID-19 death was lower than White. - Hispanic aRR 1.88 (95%CI 1.61-2.19) times higher risk of death than white population. 12 states reported a significantly higher risk of COVID-19 deaths among Hispanic populations.
United Kingdom (UK)		
(Leeds, 2020) new	UK, NHS Trust hospital healthcare workers prospective cohort study. A staff testing programme was conducted in	- Age, sex, occupation and ethnicity are not associated with increased risk of contracting SARS-CoV-2.

	April and examined the characteristics of 991 affected healthcare workers.	
(Harrison, 2020) preprint new	Prospective cohort, England Scotland and Wales. 260 hospitals, February 6th - May 8th. N=30693 suspected and confirmed COVID-19 cases Analysis: hierarchical regression models / Cox Proportional Hazards regression, adjusted for age, sex, location	- Compared to Whites, critical care admission was more common in South Asian OR 1.28 (95%CI 1.09 - 1.52), Black OR 1.36 (95%CI 1.14 - 1.62) and other ethnic minority OR 1.29 (95%CI 1.13-1.47). - Mortality compared to Whites: South Asian HR 1.19 (95%CI 1.05 - 1.36), East Asian HR 1.00 (95%CI 0.74 - 1.35), Black HR 1.05 (95%CI 0.91 - 1.26), Other Ethnic Minority HR 0.99 (95%CI 0.89 - 1.10). - Diabetes had a significant mediation effect (17.8%, 8.9-65.7) of South Asian ethnicity on mortality.
(Williamson, 2020) new	UK NHS patient notification system, OPENSafely, for 24 million registered adults (40% population), prospective cohort. N= 12 718 279 people with ethnicity data from the general population in this cohort. Data Feb 1- May 6 was analysed (multivariable Cox proportional hazards model) for the outcome death of confirmed COVID-19 cases (n= 10 926). Adjusted by age, sex, BMI, smoking status, comorbidities, asthma, cancer, socio-economic indices, ethnicity.	- Mortality due to COVID-19: Compared to Whites, hazard ratio for black ethnicity aHR 1.48 (95%CI 1.29-1.69), South Asian ethnicity aHR 1.45 (95%CI 1.32-1.58), mixed ethnicity aHR 1.43 (95%CI 1.11-1.84) in the population. - Higher risk of death was associated with male, older age, deprivation, uncontrolled diabetes, severe asthma and other medical conditions. - Controlled for socio-economic and medical factors, ethnicity remained a strong predictor of mortality within the population.
(Razieh, 2020) new	Prospective cohort, UK Biobank Study (N= 502 543). COVID data March 16 - June 14. N=5623 tested, 1087 positive Logistic regression looking at BMI and ethnicity. Analysis adjusted for: age at test, sex, social deprivation (Townsend score), smoking status, cancer illnesses (number) and non-	- Greater risk of COVID-19 in Blacks relative to Whites was only apparent at higher BMI values (Figure 1). For example, at a BMI value of 25 kg/m2, there was no difference in risk (OR = 0.96; 95% CI: 0.61, 1.52), whereas at a BMI of 30 or 35 kg/m2, the odds of

	cancer illnesses (number), systolic blood pressure, HDL-cholesterol, total cholesterol and HbA1c	COVID-19 were 1.75 (1.24, 2.48) and 2.56 (1.63, 4.03) higher in Blacks, respectively.
(McQueenie, 2020) new	UK Biobank, prospective cohort of 502,503 participants COVID-19 Data: March 16 and May 18.	- Non-White ethnicities with multi-morbidity had nearly three times the risk [RR 2.81 (2.09-3.78)] of having COVID-19 infection compared to those of White ethnicity.
(Woolford, 2020) new	UK Biobank, prospective cohort analysis of adults admitted (n=470) with COVID-19 to Royal Oldham Hospital, UK to explore factors predicting death. COVID-19 Data: March 16- June 1 logistic regression model	Association of mortality by ethnicity compared to White - Asian [OR = 0.37, (95%CI: 0.18-0.76), p<0.01)] - Other ethnicity [OR=0.29, (95%CI: 0.10-0.88), p=0.03] - Black had no significant association with death from COVID-19 [OR = 1.18, {95%CI: 0.31-4.45), p=0.81]
(Chadeau-Hyam, 2020) new	Prospective cohort, UK, Biobank study. Test-negative case-control design modelling the risk of testing positive conditional on being tested. Data up to May 18 N=4509 tests (1325 positive COVID-19 cases) Statistics: multivariable and penalized logistic regression models Adjusted for age, sex, education, home ownership, number in household, income, healthcare worker, unemployed, smoker, obesity, comorbidities.	Risk factors for testing positive or negative: Black vs White ethnicity (OR 1.05 [1.02–1.08])
(Lassale, 2020) new	Prospective cohort, UK, Biobank study. N=340966 (640 COVID-19 cases March 16- April 26) Logistic regression to estimate risk of COVID-19 hospitalization. Adjusted for age, sex, neighbourhood deprivation, household crowding, smoking BMI, inflammation, glycated haemoglobin and mental illness.	Hospitalization compared to White: - Black OR 2.66 (95%CI 1.82, 3.91) - Asian OR 1.43 (95%CI 0.91, 2.26) - Other non-white group OR 1.41 (95%CI 0.87, 2.31) After controlling for measured factors, clear ethnic differences in risk of COVID-19 hospitalization remained. The largest attenuating factors were for socioeconomic factors.

(Raisi-Estabragh, 2020)	UK biobank (prospective cohort of >500 000 participants, recruited in 2006-2010 at age 40-69) Data Mar 16 – May 18, 2020 N= 4510 tested for COVID, 1326 positive. Analysis is restricted to within the tested cohort, the tested people in the UK are considered those with severe disease at this time.	- Multivariate logistic regression for COVID-19 positivity, non-Whites had a higher odds OR 1.59 (95%CI 1.26-1.99) compared to Whites. Adjusted for sex, ethnicity, BMI, Townsend score, and household size.
(Niedzwiedz, 2020)	UK biobank (prospective cohort of 392116 participants in England, recruited in 2006-2010 at age 40-69) Mar 16-May 3. Logistic regression model adjusted for: Initial adjustment= age, sex and assessment centre Full adjustment= Above adjustments + healthcare worker status, socioeconomic variables, lifestyle variables, medical conditions	- Compared to Whites a positive test was more likely for Blacks aRR 2.05 (95%CI 1.39–3.03, full adjustment) and south Asians aRR 2.42 (95%CI 1.75–3.36, initial adjustment). - In defined ethnic groups for risk of testing positive (initial adjustment): - Pakistani RR 3.24 (95%CI 1.73–6.07)> other south Asians RR 3.00 (95%CI 1.64-5.49)> Indian RR 1.98 (95%CI 1.26-3.09) for testing positive compared to Whites. - Black Caribbean RR 3.51 (95%CI 2.39-5.15) and Black Africans RR 3.11 (95%CI 1.97-4.91) were similar.
(Kolin, 2020) preprint	UK Biobank, (prospective cohort of >500 000 participants, recruited in 2006-2010 at age 40-69) review of the first 669 cases of COVID-19, Mar 16-data pull date not provided. Adjusted for age, sex, body-mass index, Townsend deprivation score, and history of diabetes, angina, or myocardial infarction,	Compared to White participants - Blacks aRR 3.14 (95%CI 2.28-4.31) were at a higher risk of COVID-19. - Asians s were also at higher risk of COVID-19 aRR 2.03 (95%CI 1.40-2.95). *Denominator is the Biobank cohort/population.
(Patel, 2020)	UK Biobank, (prospective cohort of 418,794 participants, recruited in 2006-2010 at age 40-69) Dates are not specified.	Both Blacks aOR 3.1 (95%CI 2.0–4.8) and Asianss2.0 (95%CI 1.2-3.1) were at increased risk of hospitalisation due to COVID-19 positive test as compared to White participants.

	Regression adjusted for age, sex and socioeconomic factors.	*Denominator is the Biobank cohort/population.
(Harman, 2020)*	Small single center cohort of children admitted with COVID-19. Prospectively identified from King's College Hospital, London, UK, between Feb 25, and April 28, 2020.	- Hospitalization: 9/12 (75%) were from Black, Asian, and minority ethnic background vs. the 39% that these ethnic backgrounds represent in the inner London area.
(Sapey, 2020) new	UK, University Hospitals Birmingham NHS Foundation Trust (UHB) retrospective cohort study on SARS-CoV-2 patients (n=2217) admitted between March 10 and April 17, 2020. South Asian ethnicity defined as Pakistani, Bangladeshi and Indian. Cox regression analysis adjusted for age, sex, deprivation and comorbidities.	- Severe disease on presentation among South Asian patients 34/137 (24.8%) vs White patients 54/483 (11.2%) p <0.0001. - ICU admissions of South Asian patients 86/410 (21.0%) vs White patients 133/1540 (8.6%), p <0.001. - Mortality comparted to Whites was aHR 1.4 (95%CI: 1.2-1.8) for South Asians. - There was no significant difference noted in survival for Blacks compared to Whites.
(Russell, 2020)* new	UK, London's Guy's Cancer Center conducted a retrospective cohort study to assess 156 cancer patients with COVID-19 diagnosis between February 29 and May 12, 2020 and their clinical characteristics associated with COVID-19 death.	- Among cancer patients with a COVID-19 diagnosis, Asians as compared to White (OR 3.73 (95%CI 1.28-10.91) had a positive statistically significant association with COVID-19 death.
(Martin, 2020) new	UK, Leicester retrospective study on COVID-19 patients at University Hospitals of Leicester NHS Trust between March 1 and April 28, 2020, and assessed factors associated with SARS-CoV-2 PCR positivity before/after lockdown.	After adjustment, compared to Whites, the odds of testing positive for other ethnicities was: - South Asian (aOR 2.44 95%CI 2.01, 2.97) - Black (aOR 2.56 95%CI 1.71, 3.84) - Other (aOR 2.53 95%CI 1.74, 3.70)
(Perez-Guzman, 2020)* new	UK, London NHS Trust retrospective cohort study assessing factors associated with mortality in 614 patients admitted between February 25 and April 5 in three large London hospitals. Patient population ethnicities:	- When adjusting for age, sex and comorbidities Black patients were at higher odds of death compared to Whites (aOR 1.69, 95%CI 1.00-2.86). - This association was stronger when further adjusting for admission severity (aOR 1.85 95% CI 1.06-3.24).

	- BAME = 40% (244) - White = 38% (235) - Unknown ethnicity = 22% (135) Analysis: logistic regression	
(Ayoubkhani, 2020) preprint new	UK, England and Wales retrospective cohort study assessing deaths occurring between March 2 and May 15, 2020, and association of deaths with ethnic minority groups. Analysis: Cox proportional hazards model.	- The fully adjusted model for females, only Black females were associated with mortality (aHR 1.29 [95% CI: 1.18 to 1.42]). - For males, COVID-19 mortality risk remained elevated for the Black (1.76 [1.29 [95% CI: 1.63 to 1.90]), Bangladeshi/Pakistani (1.35 [1.29 [95% CI: 1.21 to 1.49]) and Indian (1.30 [1.29 [95% CI: 1.19 to 1.43]) groups.
(Zakeri, 2020) preprint new	UK, South London (King's College Hospital Trust), case-control + retrospective cohort study to examine relationship between ethnicity and hospital admission and in-hospital mortality for severe COVID-19 between March 1-June 2, 2020, 872 cases, 3488 controls. Of the cases, - 48.1% were Black - 33.7% were White - 12.6% were Mixed/other - 5.6% were Asian	- Compared to Whites, admission risk was higher in Black (OR 2.28 [95%CI: 1.87-2.79]) and mixed/other patients (OR 2.66 [95%CI: 2.01-3.52]) Asians were not at higher risk of admission (OR 1.04 [95%CI: 0.72-1.48]). - In hospital mortality was not associated with Black (HR 0.84 [95%CI: 0.63-1.11]) and mixed/other ethnicities (HR 0.69 [95%CI: 0.43-1.10]). Asians had higher risk of in-hospital mortality (HR 1.54 [95%CI: 0.98-2.41]).
(Swann, 2020) preprint new	UK, multi-hospital retrospective cohort (260) in England, Wales, and Scotland from January 17-July 3, 2020, to investigate admission to ICU, mortality and multisystem inflammatory syndrome in children and adolescents (MIS-C) admitted with SARS-CoV-2 infection, n=651	- Critical care admission was associated with age younger than 1 month, age 10-14 years, and Black ethnicity. Blacks were significantly associated with admission to critical care aOR 2.82 (95% CI 1.41 to 5.57) as was other ethnicities aOR 1.91 (95%CI 1.07-3.34), and no association was identified for South Asians compared to Whites. - 11% cases were classified as MIS-C more likely to be of non-White ethnicity (64% (29/45) vs. 42% (148/355); P=0.004).

(Kakkar, 2020)* new	Retrospective cohort of adults tested (n=3018) for COVID-19 at Sheffield Teaching Hospitals, UK, January 3 - April 25, 2020. BAME 19% of Sheffield population Descriptive analysis, chi-square.	BAME vs. Whites - Test positive 95/296 vs 631/2424, p=0.026 - Hospitalized 86/95 vs. 599/631, p0.083 (not significant) - ICU 20/86 vs. 43/599 p<0.00001 - Significantly fewer tests were done on BAME population compared to their proportion in society and BAME people tested were significantly younger than Whites.
(Galloway, 2020)* new	Retrospective cohort, London UK, 2 hospitals March 1-April 17, 2020. N=1157 COVID-19 hospital admissions with positive RT-PCR for SARS-CoV-2. Analysis: Competing risks regression models, adjusted for age and sex.	- Admission to Critical Care compared to Whites: BAME ethnicity HR 1.53 (95%CI 1.12, 2.09) - Mortality compared to Whites: BAME ethnicity HR 1.19 (95%CI 0.89, 1.58) There was an association with ethnicity and more severe disease, but not mortality among hospitalized cases.
(Apea, 2020)* preprint new	Retrospective cohort, 5 hospitals, London UK, January 1-May 13. N=1996 SARS-CoV-2 cases Analysis: Logistic regression modelling of ethnicity on ICU treatment using mechanical ventilation was carried out adjusted for age and sex. Cox proportional hazards model adjusted for age and sex	Racial profile of cases 35.2% White, 27.0% Asian, 17.0% Black. - ICU admission was significant p<0.001 where 11% White, 20.1% Asian and 18.5% Black group were admitted to ICU. - Mechanical ventilation, age/sex adjusted odds compared to Whites across hospitalized cases: Asian OR 1.54 (95%CI 1.06-2.23), Black OR 1.80 (95%CI 1.20-2.71) - Mortality (30 day) Asian HR 1.49 (95%CI 1.19-1.86), Black HR 1.30 (95%CI 1.02-1.63) compared to Whites, controlling for comorbidities widened the confidence interval for ethnicity, Black p=0.09. - Mortality (90 day) Asian HR 1.46 (95%CI 1.18-1.81) compared to Whites

(Fletcher, 2020) preprint	UK, Single center retrospective cohort study. 2756 patients admitted to the Chelsea and Westminster Hospital NHS Foundation Trust, Jan 1- Apr 23. multivariable logistic regression model Note: self-reported ethnicity, many observations were unspecified leading to underpowered estimates.	- Presentation at a clinic with symptomatic COVID-19 was higher in Asians aOR 1.63 (95%CI 1.00-2.69) and other 1.70 (95%CI 1.21-2.39) compared to Whites (adjusted by age, sex and some blood biomarkers). The adjusted comparison for Black was similar, but not significant. - No association with admission to ICU and ethnicity was observed in this study. - Mortality was associated with Asians aOR 2.24 (95%CI 1.23-4.50), and similar among Blacks, but not significant.
(S. de Lusignan, 2020a) preprint	UK, Retrospective medical chart review – cross sectional study, Oxford RCGP research and surveillance centre network, Jan 28-Apr 4, 2020. COVID-19 positive cases n=587, negative test n=3215. Ethnic distribution: White n=2497 (65·7%) Asian n=152 (4·0%) Black n=58 (1·5%) Mixed, other n=81 (2·1%) Missing n=1014 (26·7%) Multivariate logistic regression.	- Compared with Whites (15.5%), the adjusted odds of a positive test were greater in Blacks (62.1%) aOR 4.75 (95%CI 2.65–8.51), adjusted by age, sex, socioeconomic deprivation, household size, urban/rural, smoking, BMI, hypertension, chronic kidney disease, diabetes, chronic heart disease.
(Wright, 2020) new	Cross-sectional data of hospital patients tested for COVID-19 March 18- April 27 in Bradford, UK. Chi-square tests.	- Mortality rates in COVID-19 cases compared to negative patients. No significant difference in mortality among White (25.4%) compared to South Asian (18.1%) in hospitalized COVID-19 cases (P=0.122). However, South Asians were significantly younger than Whites.

(Hull, 2020) preprint	UK, east London general practice dataset. Cross-sectional study of 1.2 million people in 157 practices that included n=8985 COVID-19 cases Feb 14- Apr 30, 2020. Adjusted model: age, sex, social deprivation, clinical predictors.	- The odds of SARS-COV-2 infection, fully adjusted for other variables were: South Asian aOR 1.93 (95%CI 1.83-2.04) and Black aOR 1.47 (95%CI 1.38-1.57).
(Cook, 2020)	UK, NHS staff: Cross-sectional data on health care worker deaths up to April 22, 2020 was analysed. 106 cases, 98 had patient facing roles. HCW deaths were 0.51-0.58% of deaths. No statistical analysis.	- The proportion of BAME deaths (verses their proportion in a profession) - Nurse 71% (20%) - Healthcare support worker 56% (17%) - Doctor / Dentist 94% (44%) - Other staff 29% (-)
(Riphagen, 2020)	London, UK: A small case series of children with a multisystem inflammatory syndrome that is now well recognised. 8 children were identified over 10 days mid-April 2020 in a single pediatric hospital.	- 6/8 children with this inflammatory condition were of Black ethnicity. No analysis or investigation on this potential association was undertaken in this small study.
Other countries		
(Toubiana, 2020)	Paris, France, prospective observational study of multisystem inflammatory syndrome in Children Apr 27-May 11 (follow up to May 15). 21 children median age 7.9 years (3.7-16.6)	- 57% (12/21) were Black, 3/21 were Asian. There was insufficient data in this study to explore the association, however the proportions were higher than would generally be expected based on the population demographics and what is known about Kawasaki disease in children.
(Elias, 2020) new	Paris, France, prospective cohort study of kidney transplant patients (n=1216) under active follow-up in two referral transplant centers between March 1 and April 30, 2020.	- Non-White ethnicity was independently associated with higher risk of developing COVID-19 disease: aOR= 2.17; [95% CI], 1.23 to 3.78; p=0.007)
(Baqui, 2020)*	Brazil, cross-sectional study of hospital mortality (country wide). Data from Feb 27 – May 4, 2020. N= 6882 cases with known outcomes.	- Hospital mortality was higher in mixed ethnicity aHR 1.47 (95%CI 1.33-1.58) and Blacks aHR 1.32 (95%CI 1.15-1.52) compared to Whites. Mixed ethnicity was the most influential risk factor on mortality after age.

	Racially classifies the Brazilian population in five categories (percentages as of 2010 of Brazilian population): branco (white) (47.5%), pardo (mixed ethnic) (43.4%), preto (black) (7.5%), amarelo (yellow) (1.1%) and indígena (0.4%). Cox regression analysis adjusted by age, sex, ethnic group, and comorbidities (fixed effects), with state (random effect)	

*= study is also included in (Raharja, 2020). New= Study has been published since June 1, 2020 when the first version of this review was completed. Preprint = refers to papers that have not undergone the peer-review process. BAME = Black, Asian and minority ethnic, OR= odds ratio, HR= Hazard Ratio, RR= risk ratio, 95%CI = confidence interval, I^2= measure of heterogeneity in a meta-analysis, k= number of studies.

ETHNICITY AND EXPOSURE TO COVID-19 (SEROLOGY STUDIES)

Seroprevalence and other serological investigations and associations with ethnicity were reported in five studies. Four seroprevalence studies conducted in USA on the general population, healthcare workers and pregnant women reported that there were significantly higher proportion of people seropositive among certain ethnicities: Blacks (n=3/4 studies), Hispanic (n=3), Asian (n=1/2) (Table 2). One UK study examined the dynamics of IgG antibodies to SARS-CoV-2 during acute and convalescent phases of SARS-CoV-2 infection and found that there was a difference in the magnitude of the ELISA results that may indicate during infection COVID-19 cases of non-White ethnicity may have higher viral loads (Staines, 2020). This finding requires further research to understand the significance of the difference noted in this study. Registered trials described in the systematic review included seroprevalence studies that will add to the body of information (D. Pan, 2020).

Table 2: Serology based studies on cumulative incidence and the dynamics of antibodies against SARS-COV-2 (n=5)

Reference	Study Description	Key Outcome
(Ebinger, 2020)* preprint new	USA, seroprevalence survey in a large diverse healthcare employee cohort of 6,062 adults employed in Los Angeles County. Date: May-June 2020	- The main factors significantly associated with greater odds of seropositive status were Hispanic (OR 1.80 [95% CI 1.31, 2.46], P<0.001), and Black (1.72[1.03, 2.89], P=0.04), compared to Whites.

	Analysis: multivariable-adjusted analyses of pre-existing characteristics e.g. ethnicity, age, sex, asthma, hypertension	
(Flannery, 2020) new	USA, Pennsylvania prospective cohort study conducted serological testing of 1293 parturient women at two centers in Philadelphia between April 4 and June 3, 2020, and assessed for differences among race/ethnicities among the women.	Seroprevalence rates by race/ethnicity: - Black (9.7%; 95% CI, 7.3-12.5%) - Hispanic (10.4%; 95% CI, 5.7-17.1%) - White (2.0%; 95% CI, 0.9 to 3.8%) - Asian (0.9%; 95% CI, 0.0 to 5.1%)
(Biggs, 2020) new	USA, cross-sectional study in 2 Atlanta counties between April 28 and May 3, 2020 assessing SARS-CoV-2 seroprevalence in 696 persons.	Total weighted seroprevalence rate = 2.5% (95% CI: 1.4-4.5) - Black 5.2% (95% CI: 2.9-9.1), p<0.01 compared to other ethnicities.
(Rosenberg, 2020)	New York State seroprevalence survey n=15101 adults, Apr 19-28, 2020. Estimated cumulative incidence using a post-stratification weighting to standardize to the New York population and adjustments by the antibody test characteristics.	Cumulative incidence varied significantly by ethnicity: - Hispanic 29.2% (95%CI 27.2-31.2%) - Black 20.2% (95%CI 18.1-22.3%) - Asian 12.4% (95%CI 9.4-15.4%) - Compared to Whites 8.1% (95%CI 7.4-8.7%), p<0.0001)
(Staines, 2020) preprint	Single center prospective cohort Mar 29 – May 22, London UK. 177/1785 COVID-19 cases are included. Test: COVID-19 IgG ELISA assay developed by Mologic (Bedford, UK) and manufactured by Omega (Omega Diagnostics, Cambridge UK) - 2-8% of the cases did not seroconvert.	- Non-White ethnicity was associated with a higher normalized optical density value from the ELISA than White ethnicity, mean value 1.06 vs. 0.85, p 0.035 (unpaired t-test) - Author suggests this finding may be associated with higher viral loads

*= study is also included in (Raharja, 2020). New= Study has been published since June 1, 2020 when the first version of this review was completed. Preprint = refers to papers that have not undergone the peer-review process. OR= odds ratio, 95%CI = confidence interval.

ETHNICITY AND COVID-19 IN CANADA

Limited Canadian research was identified despite a grey literature search; a preprint ecological study, two unpublished reports of surveys conducted in Canada, Indigenous Service Canada surveillance reports and Toronto Public Health's COVID-19 dashboard had relevant results addressing ethnicity and COVID-19 in Canada (Table 3). The search also identified provinces (Ontario / British Columbia) and/or health units (Toronto) collecting or planning to start collecting ethnicity data on COVID-19 cases. As of September 2020, only Toronto Public Health had an available report.

The available Canadian data suggests non-White ethnicities, with the exception of East Asians, are disproportionately infected with COVID-19 which is in agreement with other studies on risk of COVID-19 infection from other countries in this review. These studies also highlight inequalities in the social determinants of health that may be related to increased risk of COVID-19 such as housing, education, income, occupation and access to healthcare.

- A cross-sectional survey designed to compare COVID-19 impacts on Black Canadians to a representative "national" sample reported a higher likelihood of COVID-19 among Black Canadians individually and in their social circle. Canadian Blacks had a higher frequency of risk factors such as taking public transportation and having a job that requires face-to-face interactions with people. Higher frequency of severe financial impacts associated with the pandemic. These data are consistent with similar studies published in the USA (Table 1).
- Toronto Public Health dashboard shows that a higher proportion of COVID-19 cases than the representation in the community was seen for Black, Hispanic, Southeast Asian, South Asian/ Indo-Caribbean and Middle Eastern ethnic groups.
- The ecological study analysed population data on number of COVID-19 cases and deaths in Canada by population level demographic information including proportion Black, proportion foreign-born, proportion over 65 years, population density and median income. Findings from their multivariable negative binomial model include:
    - Double the case count was associated with a 1% increase in proportion Black and 3% increase in case count was associated with 1% increase in foreign born population.
    - 2.1 increase in the rate of COIVD-19 deaths was associated with a 1% increase in proportion Black in the population.

COVID-19 data focusing on Canada's indigenous population was only identified on the Indigenous Services Canada webpage and provincial webpages for Alberta, British Columbia, and Manitoba {{85811;}}. Analysis conducted at the end of July indicated that indigenous populations in Canada has reported on-reserve COVID-19 rates that were a quarter of the rate in the general population and a case fatality rate approximately one fifth that in the general population {{85811;}}. To date commentaries and news articles in CMAJ have reported successful public health

mitigation efforts by indigenous communities across Canada {{65290;}}. Indigenous populations are also more likely to live in remote communities which may protect a closed community from COVID-19, however if these communities are affected by COVID-19, they have more limited access to healthcare and are more likely be in poor socioeconomic condition (Statistics Canada, 2020). No Canadian data on ethnicity and hospitalizations, severity or mortality was identified. However publications on the relationship between ethnicity and medical conditions or socioeconomic factors identified as risk factors for severe COVID-19 disease may be useful indicators of what could be expected until COVID-19 data is available. The search identified two publications that suggested compared to Whites; Black immigrants, Indigenous people and South Asian immigrants were significantly more likely to have one or more medical conditions that have been associated with a higher risk of severe COVID-19 (Lin, 2020).

Table 3: Details of observational studies and reports conducted in Canada on the association of ethnicity and risk of COVID-19 infection (n=5)

Reference	Study information	Key Outcomes
Susceptibility, Clinical Severity and Mortality associated with COVID-19		
Canada		
(Nur, 2020) new unpublished report	An online survey (cross-sectional) was conducted June 17-30, 2020. The sample strategy was weighted by age, gender, region, ethnicity and place of birth to target a representative sample of 1500 Canadians and 400 Black Canadians (Black). N=2322 adult Canadians	COVID-19 outcomes: - Blacks were more likely to report COVID-19 symptoms and treatment (10% vs. 7% national). - Blacks were more likely have had (10% vs. 7% national) or to know someone who has had COVID-19 symptoms (28% vs. 17% national). - Commuters had higher results: they were more likely to have had (16% Black vs 12% national) and to know someone who has had COVID-19 symptoms (34% vs. 18%). - Blacks were 3x more likely to know someone who died of COVID-19 (21% vs. 8% national). Risk Factors for COVID-19 - Blacks were more likely to commute to work using public transit (25% vs. 12% national), (This has been

		shown to be an indicator for higher COVID-19 risk in other studies.). - Blacks were more likely to report frequent face-to-face requirements of their job (61% vs. 50% national). Impacts of COVID-19 - Minimal financial impact was reported in 45% of both Black and national respondents. - Black men age 45+ were more likely to report significant negative financial impact 38% vs. 22% national. - Financial confidence was lower among Black households (67% vs. 72% national).
Requested a copy of the report, not available on line. new	BC COVID-19 population survey (N=394000). (Information from news articles, Aug 14, 2020)	- Data indicate that Hispanics, West and South Asians, and Blacks were disproportionately affected by the pandemic and financially having difficulty due to lost work. - Ethnicity and access to health care was identified, where Japanese, Korean, multi-ethnic and South Asians reported difficulties.
(Toronto Public Health, 2020) new	Toronto COVID-19 by Ethno-Racial Identity and Income by Proportions surveillance dashboard. Data May 20 to August 16, 2020 24% of the ethnicity data is missing. Excludes cases in long-term care facilities. Results are descriptive and only include observations with ethnicity data.	83% of COVID-19 cases identified with an ethnic minority group compared to 52% of Toronto's population. The list below is % COVID-19 vs. % of population. - White 17% vs. 48% - Black 22% vs. 9% - Hispanic 10% vs. 3% - Southeast Asian 16% vs. 7% - South Asian or Indo-Caribbean 20% vs. 13% - Middle Eastern 11% vs. 4% - East Asian 4% vs. 13%

(Choi, 2020) preprint	Canada wide, ecological study with data up to May 5, 2020. Data sources included PHAC data, STATsCan data and crowd sourced data to compare COVID-19 cases and deaths by health unit data analysing proportion black, proportion foreign born, percent over 65 years, population density and median income as predictors. Analysis for cases and deaths respectively were conducted in a negative binomial multivariable (for over dispersed count data) model with the above predictors.	- COVID-19 infection multivariate model estimated that a 1% increase in the proportion of Black residents in a health region was associated with the doubling of COVID-19 infection rates. And a 1% increase in share of foreign-born residents was association with a 3% rise in COVID-19 infection rates. - A 1% increase in the proportion of Black residents in the health region was associated with 2.1x increase in COVID-19 death rates. An increase of 1% in the proportion of residents 65 and older were associated with a 26% increase in deaths.
{{85811;}} Surveillance report new	Surveillance Data: as of September 20, 2020 there had been 408 cases of COVID-19 in Indigenous communities' on-reserve.	As of July 31, 2020: - The percentage of Indigenous individuals living on reserve reported positive for COVID-19 is currently one-quarter the rate of the general Canadian population - The COVID-19 case fatality rate for Indigenous Peoples living on reserve is about one-fifth that of the fatality rate in the general Canadian population

New= Study has been published since June 1, 2020 when the first version of this review was completed. Preprint = refers to papers that have not undergone the peer-review process.

Methods:

A daily scan of the literature (published and pre-published) is conducted by the Emerging Science Group, PHAC. The scan has compiled COVID-19 literature since the beginning of the outbreak and is updated daily. Searches to retrieve relevant COVID-19 literature are conducted in Pubmed, Scopus, BioRxiv, MedRxiv, ArXiv, SSRN, Research Square and cross-referenced with the literature on the WHO COVID literature list, and COVID-19 information centers run by Lancet, BMJ, Elsevier and Wiley. The daily summary and full scan results are maintained in a Refworks database and an excel list that can be searched. Targeted keyword searching is conducted within these databases to identify relevant citations on COVID-19 and SARS-CoV-2. Search terms used included: racial, ethnic, ethnicity. This review contains research published up to September 7, 2020.
An augmented search for Canadian literature on ethnicity was also conducted using the indicated search terms with COVID-19 AND Canada or provinces as key terms in google and on official websites. 464 citations were captured by the search, studies were screened out for not being relevant, not primary research or systematic reviews, and not an included study design. Seventy-three studies that analyzed an association with ethnicity are included in this review. Each potentially relevant reference was examined to confirm it had relevant data and relevant data is extracted into the review.

APPENDIX:

Within the studies captured in this review ethnicity is self reported based upon a person's self-identification with one or more social groups within a list of predefined options. There were variations in the lists between countries and between studies. The table below captures the main categories of ethnicity or ethno-racial classifications and definitions used by the US and UK. In some studies there was additional granularity or classification options, those are also noted below.

Definitions:

Ethnicity: The social group a person belongs to, and either identifies with or is identified with by others, as a result of a mix of cultural and other factors including language, diet, religion, ancestry, and physical features traditionally associated with race (see race). Increasingly, the concept is being used synonymously with race but the trend is pragmatic rather than scientific.

Ethno-racial classifications refers to the administrative categorization of people along ethnic and racial lines for the purposes of statistics. This term was used by Toronto Public Health.

Ethnic Category used in the Review	Acronyms and definitions of the category.
White	Non-Hispanic White, USA definition: people with origins in Europe, the Middle East or North Africa. UK definition: British, Irish or other white background
Black	Non- Hispanic Black, African American, Black British, Black Caribbean, African, Afro-Caribbean, Haitian. USA definitions: person that have origins in any of the black racial groups of Africa. UK definition: Caribbean, African, Any other black background
Hispanic	Latino, Latinx, Latin American. Note: the US census bureau uses "Hispanic" for both Hispanic and Latinx referring to anyone born in or with ancestors from Latin America. USA definition: person of Cuban, Mexican, Puerto Rican, South or Central American, or other Spanish culture or origin, regardless of race.
Indigenous	First Nations, Inuit and Metis (Canada), American Indian and Alaska Native (USA). By definition Indigenous people refers to the original populations of North and South America.
Pacific Islander	Native Hawaiian. Refers to a person having origins Hawaii, Guam, Samoa, or other Pacific Islands.
Asian	A person having origins in any of the original peoples of the Far East, Southeast Asia, or the Indian subcontinent including, for example, Cambodia, China, India, Japan, Korea, Malaysia, Pakistan, the Philippine Islands, Thailand, and Vietnam. UK definition: Indian, Pakistani, Bangladeshi, any other Asian background
Chinese	UK definition: Chinese or any other
Mixed	UK definition: white and black Caribbean, White and Black African, White and Asian, or any other mixed background
BAME	Black Asian and minority ethnic group is a term used in many UK-based studies to denote non-White ethnicity.
Racialized communities	Refers to visible minorities and usually encompasses all people that are non-Caucasian in race or non-white in color. In Canada this may or may not include indigenous people depending on the individual report/study.
East Asians	A racialized classification for people descended from east Asian countries: China, Taiwan, Japan, Mongolia, North Korea and South Korea.

South Asian	A person whose ancestry is in the countries of the Indian subcontinent, including India, Pakistan, Bangladesh, and Sri Lanka. Indo-Caribbean was also grouped with South Asian, these are people of Indian descent that live in the Caribbean.
Southeast Asian	This is a group of mixed cultures from 11 countries Brunei, Burma (Myanmar), Cambodia, Timor-Leste, Indonesia, Laos, Malaysia, the Philippines, Singapore, Thailand and Vietnam.
Middle Eastern	Arab, Western Asian people of Middle Eastern and North African descent

Notes: Capitalization is in line with the ASA style guide for sociology research papers. United States Census Bureau definitions of ethnicity or race indicate that these are a social construct of race/ethnicity rather than a biologically based segregation. United Kingdom Census Bureau ethnicity categories.

Preuve émergente sur la COVID-19

Synthèse en bref sur l'origine ethnique et la COVID-19

Introduction

Cette synthèse en bref vise à résumer la documentation disponible sur les liens entre l'origine ethnique, le risque d'infection par la COVID-19, la gravité de l'infection et le taux de mortalité qui en découle, tant au Canada qu'à l'échelle mondiale.

Cette synthèse en bref comprend la littérature disponible jusqu'au 7 septembre 2020. L'origine ethnique mentionnée dans les études incluses dans la présente synthèse a été principalement définie par les bureaux de recensement des pays visés par les études. Elle constitue donc une variable autodéclarée, établie d'après la façon dont une personne s'identifie à un groupe social ou culturel indiqué dans une liste prédéfinie. Par souci d'uniformité, les principales catégories d'ethnies déclarées et utilisées dans la présente synthèse sont Noir, Blanc, Asiatique et Hispanique. D'autres catégories ou des catégories de groupes ethniques minoritaires plus spécifiques, p. ex., les Asiatiques de l'Est, les Asiatiques du Sud, les Autochtones et les habitants des îles du Pacifique, ont également été déclarées et sont précisées dans les tableaux sommaires. Veuillez consulter l'annexe pour voir le tableau des acronymes et certaines définitions supplémentaires.

La présente synthèse résume différentes études d'observation (y compris les études de cohortes, les études transversales, les études cas-témoins et les séries de cas) ayant analysé des données au niveau individuel lorsque l'examen de l'origine ethnique était l'un des objectifs de l'étude plutôt qu'une simple variable confusionnelle pouvant être utilisée dans le modèle multivarié. Les études écologiques qui utilisent des données agrégées ont été exclues de cette synthèse puisqu'elles peuvent présenter un risque élevé de biais et qu'il est impossible d'extrapoler les résultats au niveau individuel. Cependant, pour s'assurer de recueillir l'ensemble des études et des rapports canadiens disponibles, la littérature grise ainsi que les études écologiques sur la population canadienne ont été incluses dans la présente synthèse.

Points clés

- Pour établir le lien entre l'origine ethnique et la COVID-19, deux revues systématiques contenant la documentation disponible jusqu'au 15 mai et jusqu'au 15 juin, ainsi que soixante-sept études individuelles publiées depuis le 15 mai et quatre des cinq études ou rapports canadiens recensés dans la littérature grise ont été inclus dans la présente synthèse. De ces études, 34 ont évalué le risque d'infection au coronavirus (la COVID-19), alors que 31 portaient plutôt sur la gravité de la maladie et 22 sur la mortalité (tableaux 1 et 2). Bon nombre des recherches ont été menées aux États-Unis et au Royaume-Uni. Deux études provenant de la France et une du Brésil ont également été incluses. Les études canadiennes comprenaient une étude écologique déjà prépubliée et deux enquêtes transversales. Deux rapports de surveillance pertinents ont également été recensés dans la littérature grise (tableau 3).

- Cette synthèse en est à sa deuxième version. La première comprenait une revue systématique résumant les études diffusées jusqu'au 15 mai et des recherches originales publiées entre le 15 et le 30 mai. La présente mise à jour comprend, quant à elle, les études publiées entre le 1er juin et le 7 septembre, ce qui inclut une revue systématique supplémentaire des études publiées jusqu'au 15 juin. L'analyse des études indiquées dans les tableaux et la nouvelle revue systématique ont permis d'identifier 15 études qui sont marquées d'un astérisque (tableaux 1 et 2).

Risque d'infection

- Une revue systématique portant sur le risque d'infection a conclu que les Noirs, les Asiatiques et les Hispaniques étaient plus susceptibles que les Blancs d'obtenir un résultat positif au test de dépistage de la COVID-19 (D. Pan, 2020).
- Vingt-neuf études ont examiné le risque d'infection dans différents groupes ethniques de personnes ayant subi le test RT-PCR en raison d'une infection active (tableau 1) alors que quatre études de séroprévalence ont mesuré le risque d'exposition (tableau 2). Bien que les analyses multivariables qui incluaient l'âge, le sexe, les comorbidités et les variables socioéconomiques aient atténué les liens avec certaines ethnies en particulier, ce lien était cependant encore significatif dans de nombreuses études.
    - Parmi les 20 études réalisées aux États-Unis, un certain nombre ont indiqué un risque plus élevé d'infection chez les Noirs (six résultats corrigés et trois résultats univariés) et les Hispaniques (six résultats corrigés et six résultats univariés) que chez les Blancs, et ces études comportaient des données contradictoires sur les Asiatiques (deux résultats corrigés, un résultat avec lien univarié et deux résultats non liés). Une étude menée aux États-Unis a également révélé un risque plus élevé d'infection chez les Amérindiens et les Autochtones de l'Alaska (Hatcher, 2020).
    - Quatorze études effectuées au Royaume-Uni indiquaient systématiquement que les Noirs (neuf résultats corrigés), les Asiatiques du Sud (quatre résultats corrigés), les Asiatiques (trois résultats corrigés) et, de façon plus générale, les groupes de MECNA (Minorités Ethniques et Communautés Noire et Asiatique; un résultat corrigé, deux résultats univariés et un résultat non lié) présentaient un risque plus élevé d'infection comparativement aux Blancs, alors que les résultats pour d'autres ethnies étaient rarement déclarés.

COVID-19 Résultats relatifs à la gravité

- Les résultats en ce qui concerne la gravité de l'infection par COVID-19 (hospitalisation, admission aux soins intensifs (USI) et mise sous ventilation mécanique) figuraient dans deux revues systématiques alors que 31 études ont plutôt établi des liens entre le taux d'infection de différentes ethnies et celui des Blancs (tableau 1).
    - Hospitalisation : La revue systématique présente des méta-analyses portant sur des associations univariées qui comparent les Blancs aux Noirs (pour l'ensemble des pays) et aux Asiatiques (Royaume-Uni seulement) ainsi qu'un lien d'une ampleur significativement plus

importante pour les études britanniques et les analyses corrigées (âge, sexe et comorbidités) mentionnaient qu'il n'y avait aucune association. Les études individuelles menées aux États-Unis ont indiqué que les Noirs présentaient un risque plus élevé d'hospitalisation alors que les résultats étaient mitigés pour les Asiatiques et les Hispaniques. Deux études américaines ont, quant à elles, indiqué des résultats mitigés quant à la proportion d'Amérindiens et d'Autochtones de l'Alaska hospitalisés (Alvarez Retamales, 2020 ; Karaca-Mandic, 2020) alors que deux autres études (Alvarez Retamales, 2020 ; McPadden, 2020) n'ont révélé aucun lien avec les niveaux d'hospitalisation des habitants de l'île du Pacifique. Au Royaume-Uni, les Noirs et les Asiatiques du Sud présentaient un risque plus élevé d'hospitalisation alors que les résultats étaient incohérents pour les Asiatiques, les groupes d'ethnicité mixte ou les MECNA.

  - Admission à l'USI : Les résultats de la revue systématique indiquaient que dans les études britanniques les Asiatiques et les membres des groupes MECNA étaient surreprésentées dans les USI, alors que les méta-analyses ne rapportaient aucune association selon les analyses corrigées effectuées pour les Noirs, les Hispaniques et les Asiatiques (États-Unis seulement). De nouvelles études menées aux États-Unis ont cependant donné des résultats contradictoires pour les Noirs et les Hispaniques. Selon les études effectuées au Royaume-Uni, les Noirs, les Asiatiques du Sud et MECNA présentaient un risque plus élevé d'admission à l'USI.
  - Ventilation mécanique : Dix-huit études évaluées dans le cadre de la revue systématique n'ont indiqué aucun lien à cet égard pour les Noirs et les Hispaniques. Un lien a cependant été établi entre les Asiatiques (selon quatre études) et la ventilation, lien qui a persisté après correction de l'analyse en fonction de l'âge et du sexe. Peu d'études récentes ont tenté d'établir un lien entre l'origine ethnique et le risque de devoir utiliser la ventilation. Selon une étude américaine, aucun lien ne peut être établi ce risque et les Noirs et les Hispaniques alors qu'une étude du Royaume-Uni a indiqué que les Noirs et les Asiatiques présentaient un risque accru comparativement aux Blancs.

- Le syndrome inflammatoire multisystémique de l'enfant (SIME) et l'origine ethnique ont, quant à eux, été indiqués dans trois études, soit une cohorte prospective (étude ISARIC, (Swann, 2020)) et deux séries de cas avec des échantillons d'étude de petite taille provenant du Royaume-Uni et de la France (Riphagen, 2020 ; Toubiana, 2020). Dans l'ensemble de ces études, un nombre disproportionné de cas de SIME se sont produits dans des groupes ethniques non blancs. Aucune autre analyse n'a cependant été effectuée dans le cadre de ces études.

Taux de mortalité lié à la COVID-19

- Les revues systématiques n'ont indiqué aucun lien avec les Noirs ou les Asiatiques, même si une association protectrice a été mentionnée dans les analyses univariées pour les Hispaniques. Cette association a cependant disparu une fois les modèles corrigés en fonction de l'âge, du sexe et des comorbidités. Un lien avec des Asiatiques qui ont dû être mis sous ventilation mécanique en raison de la COVID-19 a cependant été mentionné (quatre études). Il ne faut pas oublier le haut niveau

d'hétérogénéité entre les études et le fait que les deux revues décrivent environ 50 % des études ayant établi un lien alors que les autres n'en ont déclaré aucun.

- Aux États-Unis et au Royaume-Uni, 22 études ont analysé le taux de mortalité chez les patients hospitalisés, mais aucune n'a établi de lien avec l'origine ethnique. Toutefois, lorsque l'on tient compte d'un dénominateur au niveau de la population, on peut voir que certains groupes ethniques étaient plus susceptibles de contracter la COVID-19, ce qui explique pourquoi le nombre de décès liés à l'infection au coronavirus dans ces populations est proportionnellement plus élevé que prévu. Les études britanniques effectuées sur tous les cas de COVID-19 ayant indiqué un tel lien montrent cependant un risque accru de mortalité chez les MECNA, les Noirs, les Asiatiques du Sud et les Asiatiques comparativement aux Blancs (tableau 1).

Études canadiennes

En dépit des recherches supplémentaires effectuées dans la littérature grise, nous n'avons relevé qu'un nombre limité de données canadiennes. Elles indiquent cependant que les groupes ethniques non blancs, à l'exception des Asiatiques de l'Est, ont été infectés de manière disproportionnée par la COVID-19. Dans l'ensemble, les analyses n'ont pas été corrigées en fonction de comorbidités ou de facteurs socioéconomiques ayant eu pour effet d'atténuer les résultats d'autres études incluses dans la présente synthèse. Aucune donnée canadienne sur l'origine ethnique et les hospitalisations, la gravité ou la mortalité n'a été relevée.

- Une enquête transversale conçue pour comparer les répercussions de la COVID-19 sur les Canadiens noirs à un échantillon « national » représentatif a cependant révélé une plus grande susceptibilité à la COVID-19 chez les Canadiens noirs tant au niveau individuel que parmi les personnes qu'ils connaissent. La fréquence de certains facteurs de risque liés à l'utilisation des transports en commun et au fait d'occuper un emploi exigeant des interactions en personne était plus élevée chez les Canadiens noirs. Ils étaient également plus à risque de subir de graves conséquences financières en raison de la pandémie. Ces données concordent donc avec d'autres données tirées d'études similaires publiées aux États-Unis (tableau 1).
- Le tableau de bord créé par le Bureau de santé publique de Toronto montre une proportion plus élevée de cas de COVID-19 dans les groupes ethniques composés de Noirs, d'Hispaniques, d'Asiatiques du Sud-Est, d'Asiatiques du Sud-Est/Indo-Caribéens et de Moyen-Orientaux par rapport à leur représentation dans la communauté.
- L'étude écologique a analysé les données de la population sur le nombre de cas et de décès liés à la COVID-19 au Canada en fonction de l'information démographique au niveau de la population, incluant la proportion de Noirs, la proportion de personnes nées à l'étranger, la proportion de personnes âgées de plus de 65 ans, la densité de la population et le revenu médian. Cette analyse multivariée a ainsi permis d'obtenir les résultats suivants :
    - chaque augmentation de 1 % de la proportion de Noirs dans une unité sanitaire était associée au double du nombre de cas. Chaque augmentation de 1 % de la proportion

de résidents nés à l'étranger était associée à une augmentation de 3 % du nombre de cas.

- Chaque augmentation de 1 % de la proportion de résidents noirs dans une région sanitaire était liée à une augmentation de 2,1 fois du taux de mortalité lié à la COVID-19.

Vue d'ensemble des éléments de preuve

Soixante-quatorze études, dont deux revues systématiques publiées avant le 7 septembre 2020, ont été incluses dans cette synthèse. Deux revues systématiques ont également été évaluées avec l'outil AMSTAR et ont été jugées être de qualité moyenne à élevée. Une étude écologique réalisée au Canada a été incluse pour tenir compte du contexte canadien, bien que ce type d'étude utilise des données agrégées pour l'analyse, ce qui veut dire qu'elles présentent un risque élevé de biais et de sophisme écologique et que leurs conclusions ne peuvent pas être extrapolées au niveau individuel.

La synthèse a donc principalement porté sur des études comportant des ensembles de données au niveau individuel, ce qui comprenait un éventail de plans d'étude d'observation, y compris de grandes cohortes prospectives de qualité moyenne à élevée, des cohortes rétrospectives de qualité moyenne à faible, ainsi que des études transversales et des séries de cas rétrospectives de basse qualité.

La littérature a évolué rapidement et les études plus récentes sur les grandes cohortes comportaient suffisamment de pouvoir pour contrôler de nombreuses variables potentiellement confusionnelles. Elles ont donc fourni de meilleures estimations du lien possible que les études qui font plutôt état d'estimations brutes ou ayant été légèrement corrigées. Les grandes études de cohorte concordent modérément et fournissent une certaine assurance que les recherches futures ne modifieront pas les conclusions tirées de ces études. Il subsiste cependant des lacunes dans les connaissances à cet égard, par exemple à savoir la raison pour laquelle certains groupes ethniques peuvent être plus à risque d'être infectés, sachant que certaines variables confusionnelles comme les facteurs socioéconomiques et les comorbidités n'expliquent pas entièrement cette association. Des facteurs génétiques potentiels, liés aux comorbidités, à l'activité de l'ACE2, à la réponse de cytokines pro-inflammatoires ou à d'autres différences dans la fonction du système immunitaire pouvant être associés au profil immunitaire des groupes ethniques à risque élevé ont été suggérés, mais n'ont pu être expliqués (Tal, 2020).

TABLE DES MATIÈRES

LIEN ENTRE L'ETHNICITÉ ET LE RISQUE D'INFECTION, LA GRAVITÉ DE LA MALADIE ET LE TAUX DE MORTALITÉ EN RAISON DE LA COVID-19

Deux revues systématiques et 61 études d'observation sont présentées dans le tableau ci-dessous et mentionnent le risque d'hospitalisations, de maladie grave, d'admission à l'USI, de mise sous ventilation mécanique, d'insuffisance rénale aiguë ou de mortalité en raison de la COVID-19.

Les revues systématiques incluent les études publiées jusqu'au 15 mai et au 15 juin (D. Pan, 2020 ; Raharja, 2020). Seuls les résultats de 15 études chevauchent ceux qui sont indiqués dans le tableau 1 et dans la revue systématique (Raharja, 2020). La revue systématique comprenait par ailleurs des études écologiques (résultats non résumés) et d'autres études ne portant pas sur le lien entre l'origine ethnique et la COVID-19, mais qui ont été incluses dans les méta-analyses.

Même si la majorité des recherches sur l'origine ethnique provient des États-Unis et du Royaume-Uni, deux études ont été effectuées en France et au Canada, ainsi qu'une étude menée au Brésil (tableau 1). Un nombre de plus en plus grand d'études explorait explorait pourquoi il pourrait y avoir un lien entre l'origine ethnique et le risque d'infection, de gravité ou de mortalité par la COVID-19. L'âge, le sexe, les comorbidités et les facteurs socioéconomiques sont les variables potentiellement confusionnelles ou médiatrices incluses dans les modèles multivariés. Quant aux variables réelles utilisées en ce qui concerne les facteurs socioéconomiques, elles variaient d'une étude à l'autre et incluaient notamment le revenu, l'état du quartier et d'autres indices composites. Dans certaines études cependant, les variables utilisées constituaient plutôt des mesures plus complexes associées à différents facteurs sociétaux ayant pour effet de bloquer l'accès aux soins médicaux, des comportements de recours aux soins de santé ou d'autres disparités. La variabilité des facteurs de risque utilisés dans les modèles ainsi que les différences dans le modèle final utilisé par chacune des études ne facilitent pas la comparaison directe des résultats, comme on l'a vu dans les méta-analyses qui démontraient souvent une grande hétérogénéité entre les études. Il convient également de noter que dans les études qui tiennent compte de l'âge, du sexe, des comorbidités et des facteurs socioéconomiques dans leur analyse, certains groupes ethniques présentent toujours un risque plus élevé d'infection par COVID-19.

Le tableau 1 ci-dessous énumère les études sur l'infection, la gravité et la mortalité par pays en raison de la COVID-19. Un résumé de leur contenu est présenté brièvement ci-dessous.

- Le risque d'infection ou la probabilité de résultat positif au test a été évalué aux États-Unis (n = 18 études), au Royaume-Uni (n = 11) et en France (n = 1) et dans une revue systématique.
    - Il a été démontré que les personnes d'origine ethnique noire, asiatique et hispanique étaient plus susceptibles d'obtenir un résultat positif dans une revue systématique (D. Pan, 2020).
    - Seize études ont examiné des données sur les tests réalisés aux États-Unis et analysé la probabilité de résultats positifs. L'éventail d'analyses était plutôt vaste et les résultats ont souvent été corrigés en fonction d'une fourchette de facteurs individuels, sanitaires et

socioéconomiques. Malgré cela, lorsque l'on compare leurs résultats à ceux des Blancs, les Noirs (neuf études), les Hispaniques (onze études), les Asiatiques (deux études) et les Autochtones/Alaskiens (une étude) ont obtenu un nombre significativement plus grand de résultats positifs (un risque de l'ordre de 1,5 à 3,5 fois plus grand) (tableau 1).

- Onze études ont examiné des données sur les tests au Royaume-Uni et ont indiqué une plus forte probabilité de résultats positifs aux tests comparativement aux Blancs pour les membres des groupes MECNA (3 études sur 4), les Noirs (sept études), les Asiatiques du Sud (deux études) et les Asiatiques (une étude).
- Une enquête effectuée auprès des Américains et des Britanniques a révélé que les Noirs et les Hispaniques avaient un plus grand risque corrigé (pour les facteurs comme le sexe, les comorbidités, l'IMC, le tabagisme) d'obtenir un résultat positif à la COVID-19 comparativement aux Américains blancs, alors que ce n'était pas le cas pour les Asiatiques ou les membres d'autres groupes ethniques. Au Royaume-Uni où différentes catégories ethniques ont été utilisées, utilisées, on a signalé a signalé un risque plus élevé pour les Noirs, les Asiatiques du Sud, les Chinois, les Moyen-Orientaux et les autres, mais pas chez les Asiatiques de l'Est ou les Hispaniques (Lo, 2020).
- Une étude menée en France auprès de personnes ayant reçu une greffe de rein a révélé que l'origine ethnique non blanche était associée à des probabilités plus élevées de la maladie de la COVID-19 après correction en fonction de l'âge, du sexe et des comorbidités (Elias, 2020).

- Le risque de maladie grave a été mesuré au fur et à mesure que les hospitalisations, l'admission à l'USI ou la ventilation mécanique étaient signalées, dans les différentes études, des résultats mitigés ont souvent été identifiés. Les résumés énumérés ci-dessous ont été regroupés par dénominateur pour le cadre de l'échantillonnage, soit l'ensemble de la population, le nombre de cas positifs de COVID-19 ou d'hospitalisation en raison de la COVID-19, puisqu'on jugeait qu'il s'agissait d'une source potentielle d'hétérogénéité. L'analyse, dans laquelle s'opposent les résultats univariés et les résultats corrigés, est également une source d'hétérogénéité entre les études puisque les estimations corrigées pour les comorbidités ou les facteurs socioéconomiques ont généralement entraîné l'atténuation vers le zéro en ce qui concerne les liens avec l'origine ethnique.
  - Hospitalisation : La revue systématique a indiqué un lien avec les Noirs (RR : 1,68 [IC à 95 % : de 1,28 à 2,20], I^2 = 98, k = 13) dans l'analyse univariée et les sous-groupes par pays RR R.-U. 5,47 [IC à 95 % : de 2,51 à 12,06] par rapport à RR É.-U. 1,36 [IC à 95 % : de 1,08 à 1,72] et montré un lien plus important entre les études britanniques. Dans les études qui ont été corrigées en fonction de l'âge, du sexe et des comorbidités, aucun lien n'a été signalé. L'analyse univariée n'a montré aucun lien avec les Hispaniques (RR : 1,00 [IC à 95 % : de 0,95 à 1,06], I^2 = 0, k = 8) alors que l'analyse corrigée a permis d'en établir un. Aucun lien avec les Asiatiques n'a été établi globalement ou dans les analyses corrigées. Cependant, lorsque les analyses ont été sous-regroupées par pays, on a observé un lien avec les Asiatiques dans les études britanniques : RR R.-U. : 2,95 [IC à 95 % : de 1,55 à 5,53] contre RR É.-U. : 0,90 [IC à

95 % : de 0,82 à 1,66]. Aucun lien avec l'admission à l'USI et la ventilation mécanique n'a été relevé dans les méta-analyses corrigées, sauf en ce qui concerne les études du Royaume-Uni qui ont indiqué un risque accru chez les Asiatiques et une surreprésentation des groupes MECNA.

- Huit études américaines ont fourni une analyse de l'origine ethnique selon la gravité dans une population. Comparativement aux Blancs, le nombre d'hospitalisations était plus élevé pour les Noirs (n = 4 études sur 4), les Hispaniques (n = 3 sur 4), les Amérindiens/Alaskiens (n = 1 sur 2), les habitants des îles du Pacifique (0 sur 2) et les autres groupes ethniques (n = 1 sur 1). Dans une étude, un niveau d'hospitalisation inférieur aux prévisions a été signalé pour les Asiatiques. Comparativement aux Blancs, des résultats plus graves ont été indiqués pour les Noirs (n = 2 sur 2), les Hispaniques (n = 2 sur 2) et les Asiatiques (n = 2 sur 2). L'admission aux USI était beaucoup plus fréquente chez les Noirs (n = 2 sur 3) et les Hispaniques (n = 1 sur 2), alors que dans une étude, le recours à la ventilation était plus courant chez les Noirs et les Hispaniques.
- Dix études américaines ont porté sur l'hospitalisation et le risque d'être admis à l'USI pour les cas confirmés de COVID-19. Les hospitalisations étaient beaucoup plus fréquentes chez les Noirs (n = 5 études sur 7), les Hispaniques (n = 3 sur 5), les Asiatiques (n = 1 sur 2), les personnes d'origine ethnique mixte, ainsi que globalement (n = 1 chacune). Aucun lien entre l'origine ethnique et le risque d'admission à l'USI n'a été établi pour les personnes atteintes de la COVID-19 ayant été hospitalisées.
- Deux études du Royaume-Uni ont relevé des taux d'hospitalisation plus élevés chez les enfants des groupes MECNA que chez les Blancs alors qu'une deuxième étude a indiqué un risque plus élevé d'hospitalisation chez les Noirs et les groupes ethniques mixtes, mais non chez les Asiatiques.
- Huit études du Royaume-Uni font état d'hospitalisations et d'admissions à l'USI parmi les cas confirmés de COVID-19. Les résultats obtenus au Royaume-Uni n'ont révélé aucun lien parmi les groupes de MECNA (n = 2 études sur 2) et un lien à haut risque pour les Noirs pour les Noirs (n = 2 sur 2), les Asiatiques du Sud (n = 2 sur 2) et les Asiatiques (n = 1 sur 1). L'admission à l'USI était également liée à des groupes de MECNA (n = 4 sur 4), d'Asiatiques du Sud (n = 2 sur 3) et de Noirs (n = 2 sur 2). Une étude a révélé des de plus fortes probabilités de recours à la ventilation mécanique chez les Noirs et les Asiatiques.

- Le syndrome inflammatoire multisystémique de l'enfant (SIME) et un lien potentiel avec l'origine ethnique ont été indiqués dans trois études, soit deux du Royaume-Uni et une de France. Dans l'ensemble de ces études, une fréquence plus élevée a été indiquée pour des ethnies non blanches ayant reçu un diagnostic de SIME et cette différence était significative dans la plus vaste étude.
- Le taux de mortalité était semblable à la gravité lorsque les dénominateurs étaient soit la population en général, soit une population hospitalisée en raison de COVID-19.

- Les revues systématiques ne font état d'aucun lien avec la mortalité chez les Noirs et les Hispaniques dans les analyses corrigées. Elles font cependant état d'un risque plus élevé chez les Asiatiques qui ont été mis sous ventilation mécanique comparativement aux Blancs avec une hétérogénéité significative entre les études et un risque de mortalité plus élevé notable entre les différents groupes ethniques dans les études britanniques (Raharja, 2020).
- Sept études américaines ont établi une analyse entre taux de mortalité parmi les cas de COVID-19 hospitalisés et l'origine ethnique. Une étude a indiqué de plus fortes probabilités chez les Noirs alors qu'une autre a indiqué de plus faibles probabilités chez les Hispaniques et que la plupart des études n'ont indiqué aucun lien avec les Noirs (n = 5), les Hispaniques (n = 4) ou tous les groupes ethniques minoritaires (n = 1).
- Une étude réalisée aux États-Unis a fait état de la mortalité parmi tous les cas positifs de COVID-19 sans cependant établir de lien avec l'origine ethnique noire.
- Sept études britanniques ont effectué une analyse entre taux de mortalité parmi les cas de COVID-19 hospitalisés et l'origine ethnique. Un lien avec un plus grand risque de mortalité a été indiqué pour les Asiatiques du Sud (n = 2 études sur 3), les Noirs (n = 1 sur 4), les Asiatiques (n = 2), mais aucun n'a été mentionné pour les Asiatiques de l'Est (n = 1), les groupes ethniques mixtes (n = 2) et les groupes MECNA (n = 1).
- Six études menées au Royaume-Uni font état de la mortalité liée à la COVID-19 dans l'ensemble de la population. Deux études ont établi de plus forts liens pour les Noirs (n = 3 études sur 4), les Asiatiques du Sud (n = 2 sur 2), les groupes ethniques mixtes (n = 1 sur 2), les MECNA (n = 1 sur 1) et les Asiatiques (n = 1 sur 2) alors que deux autres, portant sur les Asiatiques et les groupes ethniques mixtes, ont chacune donné des résultats contradictoires indiquant tant des liens protecteurs qu'un risque plus élevé comparativement aux Blancs.
- Une seule étude menée au Brésil a fait état d'un lien avec une mortalité plus élevée dans les groupes ethniques mixtes et noirs.

Tableau 1 : Le lien entre l'origine ethnique et le risque d'infection, la gravité de la maladie et le taux de mortalité dans les revues systémiques (n = 2) et les études d'observation (n = 61)

Référence	Renseignement sur l'étude	Principaux résultats
Susceptibilité, gravité clinique et mortalité associées à la COVID-19		
Revue systématique		
(Raharja, 2020) préimpression, nouveauté	Revue systématique et méta-analyse du lien entre l'origine ethnique et les résultats médiocres. (AMSTAR – haute qualité) Données recueillies jusqu'au 15 juin 2020. 72 articles (13 études écologiques) provenant des États-Unis (54), du Royaume-Uni (15), du Brésil (1) et d'Israël (1), ont été inclus, bien que les données des deux derniers ne figurent pas dans les résultats. Les résultats comprenaient la mortalité, l'hospitalisation, l'USI, ainsi que l'insuffisance respiratoire et rénale. Les résultats de l'analyse portent sur les Noirs, les Asiatiques et les Hispaniques, car il y a eu très peu d'études pour d'autres groupes ethniques autochtones ou d'autres études à l'extérieur des États-Unis et du Royaume-Uni. Une méta-analyse des effets aléatoires a été menée sur les résultats quantitatifs figurant dans 45 études. Les études non incluses dans les méta-analyses ont été résumées de façon descriptive. Leurs résultats sont également indiqués lorsqu'un lien a été identifié et/ou diffère de la méta-analyse.	Les données probantes ne confirment pas que l'origine ethnique est un facteur de risque indépendant pour les résultats médiocres chez les patients atteints de COVID-19. Les méta-analyses présentaient généralement une hétérogénéité élevée (I^2 > 60 %) et, lorsqu'elles ont été examinées, les analyses corrigées pour l'âge, le sexe et les comorbidités atténuaient les liens univariés. Les liens significatifs sont présentés ci-dessous et d'autres résultats d'analyse sont disponibles dans le document. Hospitalisation (20 études) : Comparativement aux Blancs, le lien avec les Noirs (RR : 1,68 [IC à 95 % : de 1,28 à 2,20], I^2 = 98, k = 13) dans l'analyse univariée (RR R.-U. 5,47 [IC à 95 % : de 2,51 à 12,06] par rapport à RR É.-U. 1,36 [IC à 95 % : de 1,08 à 1,72] était significativement différent). - Les études qui ont été corrigées en fonction de l'âge, du sexe et des comorbidités ne font état d'aucun lien. - L'analyse univariée n'a montré aucun lien avec les Hispaniques (RR : 1,00 [IC à 95 % : 0,95 à 1,06], I2 = 0, k = 8) alors que l'analyse corrigée a permis d'établir un lien significatif. - Aucun lien avec les Asiatiques n'a été établi globalement ou dans les analyses corrigées. Cependant, lorsque les analyses ont été sous-regroupées par pays, on a observé un lien dans les

		études britanniques : RR R.-U. : 2,95 [IC à 95 % : 1,55 à 5,53] contre RR É.-U. : 0,90 [IC à 95 % : 0,82 à 1,66]. USI (18 études) : comparativement aux Blancs, un lien univarié avec les Noirs (RR : 1,51 [IC à 95 % : de 1,11 à 2,04], I^2 = 94, k = 10) a été observé, mais aucun lien n'a été constaté après correction en fonction de l'âge, du sexe et des comorbidités. - Le lien non corrigé et corrigé avec l'admission à l'USI n'est pas significatif pour les Asiatiques ou les Hispaniques aux États-Unis. Les études menées au Royaume-Uni ont fait état d'un risque accru d'admission à l'USI chez les Asiatiques. - Cinq études britanniques non incluses dans la méta-analyse ont fait état d'une surreprésentation des communautés de MECNA dans les cohortes admises dans l'USI. Deux études américaines n'ont pas trouvé de lien avec les Noirs. Mortalité (51 études) : comparativement aux Blancs, une association protectrice avec la mortalité globale a été indiquée dans l'ensemble des données non corrigées : Hispaniques (RR : 0,69 [IC à 95 % : de 0,57 à 0,84], I^2 = 76, k = 11), mais ce lien a disparu dans les modèles corrigés en fonction de l'âge, du sexe et des comorbidités. - Les Asiatiques qui se sont retrouvés sous ventilation mécanique présentaient un risque de mortalité plus élevé dans quatre études (RR : 1,39 [IC à 95 % : de 1,07 à 1,80], I^2 = 14, k = 4). - Aucun autre lien avec la mortalité n'a été trouvé dans la méta-analyse effectuée en fonction de la mortalité

		globale, des cas hospitalisés, des cas à l'USI, des cas sous ventilation mécanique ou des cas de lésions rénales aiguës et l'origine ethnique noire, asiatique ou hispanique. Ventilation mécanique (18 études) : comparativement aux Blancs, un lien avec les Asiatiques (RR : 1,39[IC à 95 % : de 1,07 à 1,80], I^2 = 14, k = 4) a été indiqué dans l'analyse univariée et corrigée en fonction de l'âge et du sexe. - Aucun lien avec le risque de mise sous ventilation n'a été observé chez les Noirs ou les Hispaniques, même dans une analyse corrigée (âge, sexe et comorbidités). Insuffisance rénale aiguë (IRA) (8 études) : Comparativement aux Blancs, - Aucun lien avec l'IRA n'a été observé chez les Asiatiques. - Un lien a été signalé pour les Noirs (RR : 1,35 [IC à 95 % : de 1,04 à 1,76], I^2 = 92 %, k = 5) dans l'analyse univariée, mais a disparu dans l'analyse corrigée (âge, sexe et comorbidité).
(D. Pan, 2020)	Revue systématique de l'origine ethnique et des résultats cliniques de la COVID-19. (Cote AMSTAR – de qualité moyenne : le protocole enregistré peut ou non avoir été établi *a priori*. Les études incluses pour chacun des résultats ne sont pas indiquées de façon claire et il n'y a aucune discussion sur l'hétérogénéité). Données recueillies jusqu'au 15 mai 2020	Comparativement aux Blancs, plusieurs études ont révélé que les Noirs, les Asiatiques et les Hispaniques sont plus susceptibles d'obtenir ce qui suit : 1. Résultat positif à la COVID-19 Des preuves mixtes ont été indiquées pour les éléments suivants : 1. Hospitalisation 2. Intubation

	162 études (dont 80 en préimpression) Les fichiers supplémentaires 2 à 6 décrivent chacune des études incluses dans cette revue systématique. Les recherches incluses comprenaient de la littérature primaire, des essais cliniques, des préimpressions et de la littérature grise. L'analyse était descriptive et ne rendait pas compte des résultats des études individuelles, du nombre d'études ou des études qui contribuent à chacun des résultats. Peu d'études portant sur l'origine ethnique avaient été publiées en date du 15 mai 2020.	3. USI 4. Mortalité - Origine ethnique et risque d'infection par le SRAS-CoV-2 : une étude publiée (S. de Lusignan, 2020b) indique que les Noirs étaient plus susceptibles d'obtenir un résultat positif et, de façon similaire dans des préimpressions,, une plus grande susceptibilité a été rapportée dans 14 études pour les Noirs, 3 pour les Asiatiques et 3 pour les Hispaniques comparativement aux Blancs. - Les taux d'hospitalisation, d'intubation et d'admission à l'USI selon l'origine ethnique étaient contradictoires entre les études. Une importante cohorte au Royaume-Uni indique une proportion plus élevée de patients non blancs admis à l'USI. - Mortalité : Huit études n'ont révélé aucun lien avec la mortalité, alors que d'autres ont relevé un lien pour les Noirs (n = 6) et les Asiatiques (n = 3) comparativement aux Blancs. La littérature grise aux États-Unis et au Royaume-Uni fait état d'un taux de mortalité plus élevé chez les personnes d'origine non blanche (principalement les Noirs et les Asiatiques).
États-Unis (É.-U.)		
(Petrilli, 2020)	États-Unis, New York, réseau de santé multicentrique, cohorte prospective, données sur les cas jusqu'au 8 avril, puis suivi jusqu'au 5 mai. N = 5 279 admis à l'hôpital pour COVID-19 Tests positifs pour la COVID-19 n = 5 279 Hospitalisations n = 2 741	- Le risque d'hospitalisation parmi les cas positifs de COVID-19 était beaucoup plus élevé chez les Hispaniques RCC de 1,63 (IC à 95 %, 1,35 à 1,97) et les ethnies mixtes ou autres RCC de 1,6 (IC à 95 %, 1,21 à 2,11) que chez les Blancs. Régression logistique multivariable corrigée en fonction de l'âge, du sexe, du tabagisme, de la semaine d'éclosion et de l'IMC.

	Soins palliatifs ou décès n = 665 Ventilation n = 647	
(Goldfarb, 2020)	Un seul centre médical, cohorte prospective de femmes enceintes. Du 6 mars au 4 mai 2020. 65 Hispaniques (représentant 18 % de la population) et 127 femmes non hispaniques ont présenté des symptômes de COVID-19, mais toutes n'ont pas été testées. Aucune analyse statistique n'a été effectuée en raison de la taille de l'échantillon. L'origine ethnique n'a pas été un facteur de cette disparité qui peut s'expliquer par des facteurs socioéconomiques.	- Les femmes hispaniques étaient plus susceptibles d'obtenir un résultat positif (72 %) 39 sur 54 comparativement à 27 % (22 sur 82) pour les femmes non hispaniques (p < 0,001). Cela correspondait au nombre croissant de cas dans la population hispanique par rapport à la population non hispanique et la population en général après la mise en place des mesures de distanciation physique. - Parmi celles qui ont obtenu un résultat positif, une proportion semblable de femmes ont été admises à l'hôpital. 13 femmes hispaniques sur 39 et 8 femmes non hispaniques /22. De ce nombre, 5 femmes hispaniques et 1 femme non hispanique ont été admises à l'USI. Aucun décès.
(Bandi, 2020)	États-Unis, Chicago, cohorte prospective dans un seul hôpital, cas de COVID-19 pédiatrique. Tous les enfants testés pour le SRAS-CoV-2 ont été inscrits à l'étude qui s'est déroulée du 12 mars au 20 avril 2020. N = 474 enfants examinés, 5,2 % (25) étaient positifs à la COVID-19. (n = 5 enfants ont été hospitalisés) Proportion dans l'échantillon : Blanc 25,1 % Noir 43,2 % Hispanique 24,7 % Asiatique 1,5 %	- Comparativement aux Blancs, les Noirs affichaient un taux de résultats positifs beaucoup plus élevé (6,8 % comparativement à 1,7 %, p = 0,046). - Les Noirs avaient une cote de probabilité corrigée supérieure de 3,1 (IC à 95 %, 1,23 à 5,34) d'obtenir un test positif, après correction pour l'âge et le sexe. - Les Hispaniques ont obtenu des résultats semblables, mais ils n'étaient pas significatifs. - Hospitalisations : 80 % (20 sur 25) étaient Noirs, ce qui est plus élevé que prévu, mais l'auteur n'a pas analysé davantage ce résultat.
(Lo, 2020) préimpression, nouveauté	Enquête longitudinale ciblant la population générale aux États-Unis et au Royaume-Uni avec une application qui	- Risque d'obtenir un résultat positif au test de COVID-19 (rapport de cotes et IC 95 %) :

	invite les utilisateurs à entrer des commentaires chaque jour. Données collectées du 24 mars au 25 mai 2020. Données autodéclarées. Répondants : États-Unis = 179 873, Royaume-Uni = 2 234 728 Modèle multivariable par pays : corrigé en fonction du sexe, des antécédents de diabète, de cardiopathie, de maladie pulmonaire, de maladie rénale et de l'état actuel de fumeur (répondre oui ou non à chacune des questions) et de l'indice de masse corporelle (17 à 18,4, 18,5 à 24,9, 25 à 29,9 et 30 kg/m^2). Modèle multivarié combiné É.-U. et R.-U. – également corrigé en fonction du confinement, des travailleurs de la santé en première ligne, de l'exposition communautaire à la COVID-19, de la densité de population, du revenu et de l'éducation.	○ É.-U. : Noirs 2,49 (1,68 à 3,69), Hispaniques 1,66 (1,18 à 2,34), Asiatiques 1,42 (0,86 à 2,35) Autres 1,32 (0,67 à 2,61). ○ R.-U. : Noirs 1,97 (1,47 à 2,64), Hispaniques 1,71 (0,89 à 3,27), Asiatiques du Sud 1,68 (1,43 à 1,97), Chinois 1,79 (1,08 à 2,96), Asiatiques de l'Est 1,02 (0,55 à 1,87), Moyen-Orientaux 2,10 (1,52 à 1,87), Autres 2,10 (1,52 à 2,91). ○ Données combinées des États-Unis et du Royaume-Uni comparativement à celles des Blancs : Noirs 1,17 (1,10 à 1,25), Hispaniques 1,11 (1,00 à 1,23), Asiatiques 1,06 (1,03 à 1,10), Autres 1,21 (1,17 à 1,25). - Facteurs de risque : les Noirs et Hispaniques étaient plus susceptibles d'être obèses et de souffrir de diabète. - Toutes les minorités ethniques ont déclaré un confinement social plus faible, étaient surreprésentées dans les travailleurs de la santé en première ligne et ont déclaré une plus forte probabilité de contact avec un cas atteint de COVID-19.
(Martinez, 2020) nouveauté	Étude longitudinale de la population générale desservie par le Johns Hopkins Health System (5 hôpitaux et 30 cliniques) du 11 mars au 25 mai 2020. Les données représentent 32 727 personnes ayant subi le test RT-PCR pour le SRAS-CoV-2 (au fil du temps, le risque	- Le taux de tests positifs était significativement différent ($p < 0,001$) d'un groupe à l'autre comparativement aux Hispaniques (42,6 % [IC 95 %, 41,1 % à 44,1 %]), aux Blancs (8,8 % [IC 95 %, 8,4 % à 9,2 %]), aux Noirs (17,6 % [IC 95 %, 16,6 % à 18,3 %]) ou à une autre origine ethnique (17,2 % [IC 95 %, 16,2 % à 18,3 %]). Il n'est pas clair si le taux de tests positifs des Hispaniques est attribuable à une prévalence plus

	est passé de seulement élevé à tous les individus symptomatiques). Statistiques : la proportion de personnes ayant eu un résultat positif et ayant été hospitalisées a été analysée par catégorie ethnique à l'aide d'une analyse de variance omnibus avec correction pour les comparaisons multiples.	élevée de la maladie ou à des taux plus faibles d'utilisation des soins de santé. - Les hospitalisations étaient moins nombreuses pour les Hispaniques (29,1 % [IC 95 %, de 27,0 % à 31,2 %]) que pour les Blancs (40,1 % [IC 95 %, de 37,6 % à 42,5 %]) ou les Noirs (41,7 % [IC 95 %, de 39,5 % à 43,8 %]).
(Lee, 2020) préimpression, nouveauté	É.-U., analyse rétrospective de cohorte des dossiers des patients de 12 hôpitaux du Midwest et de 60 cliniques entre le 4 mars et le 19 août 2020. Le résultat principal portait sur la gravité de la COVID-19 établie en fonction de l'hospitalisation dans les 45 jours qui ont suivi le diagnostic. 5 577 patients atteints de COVID-19 ont été inclus et 866 (n = 15,5 %) ont été hospitalisés dans les 45 jours qui ont suivi le diagnostic. Parmi les personnes hospitalisées, 43,9 % (n = 381) étaient Blancs 19,9 % (n = 172) étaient Noirs 18,6 % (n = 161) étaient Asiatiques 11,8 % (n = 102) étaient Hispaniques Le modèle a été corrigé en fonction de l'âge, du sexe, de la comorbidité, de l'état civil et de la ruralité ou de l'urbanité de la personne.	Indépendamment de la privation du quartier, la race ou l'origine ethnique minoritaire des patients était associée à une augmentation de la gravité de la COVID-19. - Hispaniques (RC 3,8, IC 95 %, de 2,72 à 5,30) - Asiatiques (RC 2,39, IC 95 %, de 1,74 à 3,29) - Noirs (RC 1,50, IC 95 %, de 1,15 à 1,94)
(Hatcher, 2020) nouveauté	É.-U., analyse rétrospective de cohorte pour la COVID-19 dans les populations d'Amérindiens et d'Autochtones de l'Alaska de 23 États (n = 345 093). Les résultats sur l'incidence de l'infection par le SRAS-CoV-2 indiqués entre le 22 janvier et le 3 juillet 2020 montrent une incidence	Incidence cumulée de la COVID-19 : - Amérindiens et Autochtones de l'Alaska : 594 (IC 95 %, de 203 à 1 740 pour 100 000 Amérindiens et Autochtones de l'Alaska)

	3,5 fois plus élevée d'Amérindiens et Autochtones de l'Alaska atteints de la COVID-19.	- Blancs 169 (IC 95 %, de 137 à 209) pour 100 000 Blancs - Les Amérindiens et Autochtones de l'Alaska avaient un risque relatif significativement plus élevé d'être atteints de la COVID-19 (RR 3,5, IC 95 %, de 1,2 à 10,1) comparativement aux Blancs.
(McCarty, 2020) nouveauté	E.-U., analyse rétrospective de cohorte de 9 hôpitaux du Massachusetts, avec 379 patients atteints de la COVID-19. Lien entre la Race/l'origine ethnique des patients et résultats de l'hospitalisation (p. ex., mortalité à l'hôpital, admission à l'USI ou mise sous ventilation mécanique).	- Dans le cadre d'une analyse multivariable tenant compte de l'âge, du sexe, de l'obésité, des comorbidités cardiopulmonaires, de l'hypertension et du diabète, aucune différence significative n'a été observée dans la mortalité à l'hôpital, l'admission à l'USI ou la mise sous ventilation mécanique en fonction de la race ou de l'origine ethnique.
(Karaca-Mandic, 2020) nouveauté	É.-U., cohorte rétrospective qui a examiné la prévalence raciale/ethnique des hospitalisations cumulatives liées à la COVID-19 dans 12 États entre le 30 avril et le 24 juin 2020. La proportion d'hospitalisations selon l'origine ethnique a été comparée à la proportion de chaque ethnie dans la population. Origines ethniques incluses dans le rapport : Hispaniques, Blancs, Noirs, Asiatiques, Amérindiens et Autochtones de l'Alaska. Les données sont descriptives et n'ont pas été corrigées.	Hospitalisations : Le nombre de Blancs hospitalisés était significativement inférieur à la proportion de la population qu'ils représentent dans les 12 États inclus. - Le pourcentage d'hospitalisations chez les patients Noirs dépassait le pourcentage que représente cette population dans les 12 États inclus. - Les hospitalisations d'Hispaniques dépassaient la proportion de la population qu'ils représentent dans 10 États et et cette observation était très prononcée en en Virginie, en Utah et au Rhode Island. - Le nombre d'Asiatiques hospitalisés en raison de la COVID-19 était à peu près équivalent ou inférieur à la proportion qu'ils représentent dans la population. - Des Amérindiens et des Autochtones de l'Alaska ont été signalés dans huit États et parmi eux, l'Arizona et l'Utah présentaient d'importantes disparités.

(Gottlieb, 2020) nouveauté	É.-U., étude rétrospective avec cas-témoins effectuée au Rush University Medical Center de Chicago, en Illinois, entre le 4 mars et le 21 juin 2020, qui a examiné les facteurs de risque associés à l'hospitalisation.	- L'origine ethnique hispanique était un facteur de risque pour l'admission à l'hôpital (RC = 1,52, IC à 95 % = 1,18 à 1,92).
(Rozenfeld, 2020) nouveauté	É.-U., étude respective de cohorte effectuée entre le 28 février et le 27 avril 2020 afin de caractériser les facteurs de risque chez 34 503 patients du Providence Health System.	Risque d'infection par le SRAS-CoV-2 comparativement aux Blancs : - Asiatiques (RC 1,43 ; IC 95 %, de 1,18 à 1,72, p = 0,0002) - Noirs (RC 1,51 ; IC 95 %, de 1,25 à 1,83, p < 0,0001) - Hispaniques (RC 2,07 ; IC 95 %, de 1,77 à 2,41, p < 0,0001).
(McPadden, 2020) préimpression, nouveauté	É.-U., étude rétrospective de cohorte effectuée au Yale New Haven Health (YNHH) sur 7 995 patients atteints du SRAS-CoV-2 entre le 1er mars et le 30 avril 2020. L'étude a évalué l'hospitalisation et le taux de mortalité à l'hôpital.	Race/origine ethnique avec risque accru d'hospitalisation : - Asiatiques (RC 1,58, IC 95 % = 1,02 à 2,41) - Noirs (RC 1,43, IC 95 %, de 1,14 à 1,78) - Hispaniques (RC 1,81, IC 95 %, de 1,50 à 2,18) Parmi les gens qui ont pu quitter l'hôpital, la correction en fonction de l'âge et le taux de mortalité à l'hôpital étaient semblables parmi tous les groupes raciaux et ethniques. Taux de mortalité à l'hôpital, corrigé en fonction de l'âge : - Blancs = 4,3 % - Noirs = 3,3 % - Hispaniques = 3,4 % - Asiatiques = 4,6 % - Hawaïens = 4,0 % - Habitants des îles du Pacifique = 3,1 %
(Emeruwa, 2020) nouveauté	É.-U., New York : étude rétrospective de cohorte sur les femmes (n = 100) qui ont accouché dans deux hôpitaux affiliés à l'association New York-Presbyterian à Manhattan du 13 mars au 23 avril 2020. Le taux d'infection par SRAS-	- Le taux d'infection par le SRAS-CoV-2 était beaucoup plus élevé chez les femmes hispaniques que chez les femmes blanches non hispaniques (18,1 % comparativement à 9,4 %, p < 0,01).

	CoV-2 par groupe racial-ethnique de femmes ayant accouché a été analysé.	- Le taux positif d'infection au SRAS-CoV-2 chez les femmes noires non hispaniques (12,7 %) n'était pas significativement différent.
(Mendy, 2020) préimpression nouveauté	Cohorte rétrospective des cas hospitalisés dans le système de santé de l'Université de Cincinnati (4 hôpitaux) du 13 mars au 31 mai 2020. N = 689 cas (test RT-PCR positif) Modélisation de régression logistique corrigée pour les covariables: âge, sexe, origine ethnique, tabagisme, comorbidités.	- Hospitalisations (31,3 % au total) : Analyses corrigées : Noirs RC 2,23 (IC 95 %, de 1,41 à 3,53) et Hispaniques RC 1,91 (IC 95 %, de 1,11 à 3,29) comparativement aux Blancs. - COVID-19 grave : Analyses corrigées : Noirs RC 3,15 (IC 95 %, de 1,71 à 5,79) et Hispaniques RC 2,78 (IC 95 %, de 1,29 à 5,96) comparativement aux Blancs. - USI (13,2 % au total) : Analyses corrigées : Noirs RC 3,32 (IC 95 %, de 1,56 à 7,07) et Hispaniques RC 3,44 (IC 95 %, de 1,42 à 8,34) comparativement aux Blancs. - Décès : analyse corrigée Noirs RC 3,44 (IC 95 %, de 1,32 à 9,00).
(Kalyanaraman Marcello, 2020)* préimpression nouveauté	Cohorte rétrospective, données du système hospitalier public de New York, New York, du 5 mars au 9 avril, suivi jusqu'au 16 avril 2020. 22 254 patients testés dans la circonscription hospitalière, 13 442 résultats positifs au SARS-CoV-2. Les Noirs et les Hispaniques représentaient environ le tiers des cas de COVID-19, ce qui constitue une surreprésentation de ces groupes ethniques par rapport à la population de New York. Analyse descriptive, utilisation du test test du χ2 (khi carré). Aucune analyse multivariable n'a été effectuée.	- Tests positifs 13 442 sur 22 254 (61 %). 26 % de Noirs et 34 % d'Hispaniques. Tant les Noirs que les Hispaniques ont eu une proportion significativement plus élevée de tests positifs que les Blancs ($p < 0,001$). La proportion plus élevée pourrait être attribuable au fait que les Noirs et les Hispaniques étaient plus susceptibles de se présenter à l'urgence plutôt qu'en consultations externes. - Hospitalisations 6 248 sur 13 442 (46 %). 31 % de Noirs et 34 % d'Hispaniques. Une proportion significativement plus élevée de Noirs ont été hospitalisés $p < 0,001$, mais aucun lien établi pour les Hispaniques. - Décès 1 724 sur 6 248 (28 %). 29 % de Noirs et 31 % d'Hispaniques.

(Price-Haywood, 2020)	Cohorte rétrospective, Louisiane aux États-Unis, système de santé Ochsner, du 1er mars au 11 avril. N = 3 481 tests de COVID-19 positifs dans la circonscription hospitalière La population desservie par cet hôpital est composée à 31 % de Noirs et à 65 % de Blancs. Analyse : – Régression logistique multivariable (hospitalisations) corrigée en fonction l'âge, du sexe, de la cote de l'indice de comorbidité, du fait d'habiter dans une habitation habitation de loyer à faible revenu, du régime public d'assurance maladie. – Analyse de survie (mortalité), corrigée en fonction de l'âge, du sexe et de la cote de l'indice de comorbidité.	- Profil racial des tests positifs à la COVID-19 : 70,4 % de Noirs et 29,6 % de Blancs. - Hospitalisation (N = 1 382) 76,9 % de Noirs. La probabilité que les Noirs soient hospitalisés était plus élevée RC 1,96 (IC 95 %, de 1,62 à 2,37). - USI (N = 474) 80,2 % de Noirs. - Ventilation mécanique (N = 364) 81,6 % de Noirs. - Décès (N = 326) 70,6 % de Noirs. Dans l'analyse de survie, la race noire n'a pas été associée de manière indépendante à la mortalité (HR = 1,14, IC 95 %, de 0,88 à 1,49).
(Azar, 2020)*	Cohorte rétrospective multi hôpital. San Francisco aux É.-U., patients, du 1er janvier au 8 avril 2020 Données globales : n = 140 36 testés pour la COVID-19 n = 1 025 cas de COVID-19 n = 256 personnes hospitalisées n = 110 à l'USI	- Hospitalisation des noirs 52,5 % (n = 32) comparativement à 25,7 % (n = 110) pour les Blancs. - Les rapports d'hospitalisation des Noirs étaient 2,7 (RR) fois plus élevés que pour les Blancs selon un modèle multivariable corrigé en fonction de l'âge, du sexe et des variables sociodémographiques. Remarque : Les Noirs étaient plus susceptibles d'être vus à l'urgence alors qu'ils étaient dans un état grave plutôt que dans un cadre non ambulatoire, ce qui peut expliquer ce lien. - Les admissions en USI étaient plus élevées pour les Noirs (24,6 %) que pour les Blancs (10,7 %). - Les Noirs atteints de COVID-19 habitaient dans des régions où les codes postaux correspondaient à un

		revenu inférieur à celui de tous les autres groupes raciaux et ethniques (p < 0,001). - Il n'y a pas eu de différence significative dans la mortalité entre les différents groupes ethniques.
(Rentsch, 2020)* préimpression	États-Unis, 6 millions de vétérans américains, du 8 février au 4 mai. Cohorte rétrospective. N = 5 630 cas de COVID-19 sur 62 098 vétérans testés. Origine ethnique : Blancs 74 %, noirs 19 %, hispaniques 7 %. Les estimations ont été corrigées en fonction des variables démographiques, médicales et des comportements à haut risque, ainsi que des variables socioéconomiques.	- Les taux de tests pour 1 000 personnes étaient plus élevés pour les Noirs 16,4 (IC 95 %, de 16,2 à 16,7) et les Hispaniques 12,2 (IC 95 %, de 11,9 à 12,5) comparativement aux Blancs 9,0 (IC 95 %, de 8,9 à 9,1). - Comparativement rapport aux Blancs, les Noirs étaient plus susceptibles d'obtenir un résultat positif au test de dépistage RCC de 1,96 (IC 95 %, de 1,81 à 2,12), tout comme les Hispaniques 1,73 (IC 95 %, de 1,53 à 1,96). - Parmi les cas de COVID-19, il n'y avait pas de différence significative dans les taux de mortalité à 30 jours selon le groupe ethnique.
(Gu, 2020)* préimpression nouveauté	Cohorte rétrospective, Michigan aux États-Unis, du 10 mars au 22 avril 2020. N = 5 698 patients testés (témoins non appariés sélectionnés par échantillonnage aléatoire n = 7 211 et témoins appariés par fréquence selon la race, l'âge et le sexe n = 13 351) régression logistique, corrigée en fonction de l'âge, du sexe et des caractéristiques socioéconomiques.	- Facteurs de risque pour un test positif : Taux de tests positifs chez les Noirs (42,6 %) significativement plus élevé que chez les Blancs (13,7 %, p < 0,001). - Hospitalisation des noirs 52,2 % comparativement à 39 % pour les Blancs, p < 0,001 et RC 1,66 (IC 95 %, de 1,09 à 2,52). - USI pour les noirs 27 % comparativement à 14,8 % pour les Blancs, p < 0,001 et RC 1,52 (IC 95 %, de 0,92 à 2,52). - Mortalité des noirs 5,3 % comparativement à 3,0 % pour les Blancs, p < 0,12 et RC 1,17 (IC 95 %, de 0,4-3,45)
(Joseph, 2020) nouveauté	É.-U., étude rétrospective de cohorte pour un seul établissement visant à déterminer si la radiographie des poumons prise lors de l'admission des patients non Blancs	- Les patients non Blancs hospitalisés pour une infection par COVID-19 étaient plus susceptibles d'être dans un état plus grave lors de la radiographie pulmonaire prise

	atteints de la COVID-19 indique qu'ils sont dans un état plus grave que les patients Blancs,, du 27 mars au 10 avril 2020, n = 326 au total (210 non Blancs ; 116 Blancs)	au moment de l'admission que les patients Blancs/non-Hispaniques (différence moyenne corrigée de 1,6, IC 95 %, de 0,5 à 2,7, p < 0,01).
(Antwi-Amoabeng, 2020) prépublication	Étude de cohorte rétrospective pour un seul centre Nevada, aux É.-U., n = 172 patients atteints de la COVID-19, du 12 mars au 8 mai Hispaniques comparativement aux non-Hispaniques Résultats globaux : - 121 hospitalisations - 28 à l'USI 18 décès	- Les Hispaniques ont été significativement plus nombreux à être atteints de COVID-19 (50,6 %) que ce à quoi on aurait pu s'attendre puisqu'ils représentent 25,7 % de la population. - La mortalité était significativement plus élevée dans le groupe des non-Hispaniques (15,3 % comparativement à 5,8 %), p = 0,048. *L'analyse qui tient compte du fait que le groupe des Hispaniques est beaucoup plus jeune, qu'il a moins de comorbidités, qu'il est plus susceptible de ne pas avoir d'assurances et qu'il vit dans des collectivités à faible revenu que le groupe non-Hispanique n'a pas été effectuée.
(Kim, 2020)*	Réseau COVID-NET américain (surveillance couvrant 14 États) : 2 491 cas d'hospitalisation entre le 1er mars et le 2 mai. N = 16 318 cas de COVID-19 n = 2 491 cas de COVID-19 ayant des dossiers complets qui ont pu quitter l'hôpital à compter du 3 mai 2020 ont été analysés. Parmi eux, 47 % sont des Blancs, 30 % sont des Noirs et 12 % sont des Hispaniques. n = 798 à l'USI n = 420 décès n = 246 décès sur 462 parmi ceux qui ont été mis sous ventilation mécanique	Parmi les cas de COVID-19 ayant été hospitalisés, aucun lien n'a été établi entre l'origine ethnique et l'admission à l'USI ou le taux de mortalité.

	Régression logistique multivariable contrôlant l'âge, le sexe et les conditions sous-jacentes comme le tabagisme et le traitement avec les inhibiteurs de l'ECA.	
(Bui, 2020) nouveauté	É.-U., enquêtes sur l'éclosion en Utah, du 6 mars au 5 juin 2020. La composition raciale et ethnique des cas associés à une éclosion en milieu de travail a été comparée à la composition raciale et ethnique globale dans chacun des secteurs de l' Utah.	Bien que 24 % de la main-d'œuvre de l'Utah dans les 15 secteurs touchés ait été identifiée comme Hispanique ou de race autre que blanche (non-Blancs), 73 % (soit 970 sur 1 335) des cas de COVID-19 associés à une éclosion en milieu de travail étaient des personnes qui se sont identifiées comme Hispaniques ou non Blancs.
(Chamie, 2020) nouveauté	Une étude transversale a été effectuée dans un secteur comprenant 16 pâtés de maisons dans le district de Mission à San Francisco du 25 au 28 avril. Des tests sérologiques et RT-PCR ont été effectués sur des résidents qui se sont portés volontaires. N = 3 953 personnes testées, 40 % Hispaniques, 41 % Blancs, 9 % Asiatiques ou habitants des îles du Pacifique, 2 % Noirs et 7 % ethnies mixtes ou autres.	- 83 sur 3 953 ont obtenu un résultat positif lors du test RT-PCR et 95 % des personnes ayant obtenu un résultat positif étaient Hispaniques. - Prévalence parmi les résidents et travailleurs hispaniques : 3,9 % (2,0 à 6,4)/10,4 % (7,0 à 14,8) par rapport aux autres ethnies : 0,2 % (0,0 à 0,4)/0,0 % (0,0 à 2,0). - Une infection récente était plus susceptible d'être identifiée chez les Hispaniques 10,1 (2,81 à 64,6) que chez les autres ethnies. - Les Hispaniques qui ont obtenu un résultat positif lors de cette étude étaient plus susceptibles d'être des hommes, d'occuper un poste en première ligne, d'avoir un faible revenu (50 000 $) et de déclarer avoir été en contact avec une personne atteinte de COVID-19.
(Ko, 2020) nouveauté	É.-U., étude transversale qui a examiné les facteurs associés aux hospitalisations en raison de la COVID-19 en évaluant les données provenant de 70 comtés qui participaient au réseau Coronavirus Disease 2019-Associated Hospitalized Surveillance Network (COVID-NET), ainsi qu'un échantillon d'une population d'adultes	Risque d'hospitalisation par origine ethnique comparativement aux Blancs : - Noirs (RRA de 4,7, IC à 95 %, de 3,8 à 5,9). - Autres ethnies (RRA de 3,5 ; IC à 95 %, de 2,8, 4,3)

	non hospitalisés qui vivent dans la zone de couverture du réseau COVID-NET.	
(A. Pan, 2020) préimpression nouveauté	É.-U., analyse transversale effectuée à Houston entre le 3 mars et le 18 juillet 2020, qui a évalué le nombre d'hospitalisations et le taux de mortalité chez les Noirs comparativement aux Blancs et chez les Hispaniques comparativement aux Blancs dans la région métropolitaine du Grand Houston.	Dans un modèle entièrement corrigé, la probabilité d'hospitalisation plus élevée était statistiquement significative. - Noirs : RCC de 1,42 (IC 95 %, de 1,24 à 1,63). - Hispaniques : RCC de 1,61 (IC 95 %, de 1,46 à 1,78). Aucun lien n'a été établi avec le taux de mortalité.
(Vahidy, 2020) nouveauté	É.-U., étude transversale sur les données recueillies simultanément depuis le 5 mars 2020 par le système du Houston Methodist Hospital sur le lien entre l'origine ethnique et de la susceptibilité à l'infection par le SRAS-CoV-2.	Dans le modèle entièrement corrigé, la probabilité d'infection était plus élevée chez les femmes comparativement aux Blancs : - Noirs : RCC, IC de 1,84, de 1,49 à 2,27). - Hispaniques : RCC, IC de 1,70, de 1,35 à 2,14). - Asiatiques : RCC, IC de 1,46, de 1,09 à 1,95).
(Goyal, 2020) nouveauté	É.-U., étude transversale comprenant 1 000 enfants testés entre le 21 mars et le 28 avril 2020 qui a évalué le lien entre l'origine ethnique des patients et les taux d'infection par le SRAS-CoV-2.	Comparativement aux Blancs (7,3 %), les enfants des minorités avaient des taux plus élevés d'infection par le SRAS-CoV-2 (Noir : (30,0 % ; RR corrigé 2,3 [IC 95 %, de 1,2 à 4,4] ; Hispaniques : 46,4 % ; RR corrigé 6,3 [IC 95 %, de 3,3 à 11,9]).
(Alvarez Retamales, 2020) préimpression nouveauté	États-Unis, données d'observation transversales sur l'admission à l'hôpital à l'échelle nationale tirées du COVID-NET du CDC le 11 juin 2020, afin d'examiner l'écart entre le taux d'hospitalisation par race ou origine ethnique chez 21 221 patients atteints de COVID-19 et hospitalisés dans une population de 328 239 523 personnes.	Différences significatives dans la proportion ethnique de la cohorte de patients atteints de COVID-19 par rapport à la population, soit : - Blancs 38 % comparativement à 60,4 %. - Hispaniques : 19 % comparativement à 18,3 %. - Noirs : 36 % comparativement à 13,4 %. - Asiatiques et habitants des îles du Pacifique : 5 % comparativement à 6 %. - Amérindiens et Autochtones de l'Alaska : 1,6 % comparativement à 1,3 %.

		L'écart le plus marqué est entre les Blancs et les Noirs, puisque les Blancs sont sous-représentés de façon disproportionnée alors que les Noirs sont surreprésentés de façon disproportionnée dans la cohorte de patients atteints de COVID-19 par rapport à la population totale.
(Gross, 2020)	États-Unis, 28 États : étude de prévalence allant jusqu'au 21 avril 2020. Les données du CDC ont été extraites par État ; 28 États et NYC ont des données relatives à l'origine ethnique. L'analyse a été corrigée en fonction de l'âge (mortalité normalisée selon l'âge dans les groupes raciaux de chaque État) et une méta-analyse a été effectuée pour évaluer le lien avec les disparités raciales au niveau de l'État.	- Le risque de décès chez les Noirs comparativement à la population blanche était de 3,57 (IC 95 %, de 2,84 à 4,48). La Pennsylvanie était le seul État où le risque de décès lié à la COVID-19 était plus faible pour les Noirs que pour les Blancs. - Le risque de décès des Hispaniques est de 1,88 (IC 95 %, de 1,61 à 2,19) fois plus élevé que celui des Blancs. 12 États ont indiqué un risque significativement plus élevé de décès lié à COVID-19 pour les Hispaniques.
Royaume-Uni (R.-U.)		
(Leeds, 2020) nouveauté	R.-U., étude de cohorte prospective pour les travailleurs de la santé des hôpitaux du NHS Trust. Un programme de tests parmi les membres du personnel effectué en avril a examiné les caractéristiques de 991 travailleurs de la santé touchés.	- L'âge, le sexe, la profession et l'origine ethnique n'ont pas été associés à un risque accru d'avoir le SRAS-CoV-2.
(Harrison, 2020) préimpression nouveauté	Cohorte prospective, Angleterre, Écosse et Pays de Galles. 260 hôpitaux, du 6 février au 8 mai. N = 30 693 cas soupçonnés et confirmés de COVID-19 Analyse : modèles de régression hiérarchique / régression du modèle des risques proportionnels de Cox, corrigés en fonction de l'âge, du sexe, de l'emplacement.	- Comparativement aux Blancs, l'admission à l'USI était plus fréquente chez les Asiatiques du Sud RC 1,28 (IC 95 %, de 1,09 à 1,52), les Noirs RC 1,36 (IC 95 %, de 1,14 à 1,62) et les autres minorités ethniques RC 1,29 (IC 95 %, de 1,13 à 1,47). - Mortalité comparativement aux Blancs : pour les Asiatiques du Sud HR 1,19 (IC 95 %, de 1,05 à 1,36), HR 1,00 pour les Asiatiques de l'Est (IC 95 %, de 0,74 à 1,35), HR 1,05 pour les Noirs (IC 95 %, de 0,91

		à 1,26), HR 0,99 pour les autres minorités ethniques (IC 95 %, de 0,89 à 1,10). - Le diabète a eu un effet médiateur important (17,8 %, de 8,9 à 65,7) sur la mortalité des Asiatiques du Sud.
(Williamson, 2020) nouveauté	R.-U., OPENSafely, l'interface du système de notification des patients du NHS, pour 24 millions d'adultes enregistrés (soit 40 % de la population), cohorte prospective. N = 12 718 279 personnes ayant des données sur l'origine ethnique formant partie de la population générale incluse dans cette cohorte. Les données du 1er février au 6 mai ont été analysées (selon le modèle multivariable des risques proportionnels de Cox) afin d'obtenir le nombre de décès liés à des cas confirmés de COVID-19 (n = 10 926). Données corrigées en fonction de l'âge, du sexe, de l'IMC, du tabagisme, des comorbidités, de l'asthme, du cancer, des indices socioéconomiques et de l'origine ethnique.	- Mortalité due à la COVID-19 : Comparativement aux Blancs, le risque relatif pour les Noirs est de 1,48 (IC 95 %, de 1,29 à 1,69), de 1,45 (IC 95 %, de 1,32-1,58) pour les Asiatiques du Sud et de 1,43 (IC 95 %, de 1,11-1,84) pour les personnes des groupes ethniques mixtes dans la population. - Un risque plus élevé de décès était associé aux hommes, à ceux qui ont un âge plus avancé, à la privation, au diabète incontrôlé, à l'asthme grave et à d'autres problèmes médicaux. - Compte tenu des facteurs socioéconomiques et médicaux, l'origine ethnique est restée un prédicteur important de la mortalité au sein de la population.
(Razieh, 2020) nouveauté	Cohorte prospective, étude sur la biobanque du R.-U. (N = 502 543). Données sur la COVID entre le 16 mars et le 14 juin. N = 5 623 personnes testées, 1 087 résultats positifs Régression logistique sur l'IMC et l'origine ethnique. Analyse corrigée en fonction de l'âge au moment du test, le sexe, la privation sociale (indice de privation de Townsend), le tabagisme, le cancer (nombre) et les maladies autres que le cancer (nombre), la tension artérielle systolique, le cholestérol LHD, le cholestérol total et l'HbA1c.	- Le risque accru d'être atteint de la COVID-19 pour les Noirs comparativement aux Blancs n'était apparent qu'à des valeurs d'IMC plus élevées (figure 1). Par exemple, à une valeur d'IMC de 25 kg/m^2, le risque n'était pas différent (RC = 0,96 ; IC à 95 % : 0.61, 1,52), alors qu'avec un IMC de 30 ou 35 kg/m^2, le risque d'avoir la COVID-19 était respectivement 1,75 (1,24 à 2,48) et 2,56 (1,63 à 4,03) fois supérieur chez les Noirs.

(McQueenie, 2020) nouveauté	Biobanque du R.-U., cohorte prospective de 502 503 participants Données sur la COVID-19 : 16 mars et 18 mai.	- Les non-Blancs ayant de multiples facteurs de morbidité présentaient un risque d'infection par la COVID-19 près de trois fois [RR 2,81 (2,09 à 3,78)] supérieur à celui des Blancs.
(Woolford, 2020) nouveauté	Biobanque du R.-U., analyse de cohorte prospective des adultes atteints de COVID-19 (n = 470) admis au Royal Oldham Hospital visant à explorer les facteurs prédictifs de décès. Données sur la COVID-19 : Du 16 mars au 1er juin Modèle de régression logistique	Lien entre la mortalité et l'origine ethnique comparativement aux Blancs. - Asiatiques [RC = 0,37, IC 95 %, de 0,18 à 0,76), p < 0,01)]. - Autres origines ethniques [RC = 0,29 (IC 95 %, de 0,10 à 0,88, p = 0,03]. - Il n'y a eu aucun lien significatif entre l'origine ethnique des Noirs et les décès liés à la COVID-19 [RR = 1,18 {IC 95 %, de 0,31 à 4,45), p = 0,81].
(Chadeau-Hyam, 2020) nouveauté	Cohorte prospective, étude sur la biobanque du R.-U. Modèle avec cas-témoin négatif modélisant le risque de test positif à la condition d'avoir été testé. Données recueillies jusqu'au 18 mai N = 4 509 tests (1 325 cas positifs de COVID-19) Statistiques : modèles de régression logistique multivariables et pénalisés corrigés en fonction de l'âge, du sexe, de l'éducation, de l'accession à la propriété, du nombre de personnes dans le ménage, du revenu, du fait d'être un travailleur de la santé, du fait d'être au chômage, du tabagisme, de l'obésité, des comorbidités.	Facteurs de risque pour l'obtention d'un résultat positif ou négatif au test : Noirs comparativement aux Blancs (RC 1,05 [1,02 à 1,08]).
(Lassale, 2020) nouveauté	Cohorte prospective, étude sur la biobanque du R.-U. N = 340 966 (640 cas de COVID-19 du 16 mars au 26 avril) Régression logistique pour estimer le risque d'hospitalisation en raison de la COVID-19. Corrigée en fonction de l'âge, du sexe, de la privation du quartier, du surpeuplement dans le ménage, de l'IMC, du tabagisme,	Hospitalisation comparativement aux Blancs : - Noirs RC 2,66 (IC 95 %, de 1,82 à 3,91). - Asiatiques RC 1,43 (IC 95 %, de 0,91 à 2,26). - Autre groupe non-Blancs RC 1,41 (IC 95 %, de 0,87 à 2,31).

	de l'inflammation, de l'hémoglobine glyquée et de la maladie mentale.	Après avoir contrôlé les facteurs mesurés, il est resté des différences ethniques claires liées au risque d'hospitalisation en raison de la COVID-19. Les facteurs d'atténuation les plus importants ont été les facteurs socioéconomiques.
(Raisi-Estabragh, 2020)	Biobanque du R.-U. (cohorte prospective de > 500 000 participants, recrutés entre 2006 et 2010, âge variant entre 40 et 69 ans) Du 16 mars au 18 mai 2020 N = 4 510 personnes testées pour la COVID, 1 326 résultats positifs. L'analyse est limitée au sein de la cohorte testée ; les personnes testées au R.-U. sont vues comme souffrant actuellement d'une maladie grave.	- Régression logistique multivariée pour les résultats positifs au test de la COVID-19, les non-Blancs avaient une probabilité plus élevée RR 1,59 (IC 95 %, de 1,26 à 1,99) comparativement aux Blancs. Données corrigées en fonction du sexe, de l'origine ethnique, de l'IMC, de l'indice de privation de Townsend et du nombre de personnes dans le ménage.
(Niedzwiedz, 2020)	Biobanque du R.-U. (cohorte prospective de 392 116 participants en Angleterre, recrutés entre 2006 et 2010, âge variant entre 40 et 69 ans) du 16 mars au 3 mai. Modèle de régression logistique corrigé pour les éléments suivants : Correction initiale = âge, sexe et centre d'évaluation Correction complète = corrections indiquées ci-dessus + statut de travailleur de la santé, variables socioéconomiques, variables associées au mode de vie, troubles médicaux.	- Comparativement aux Blancs, il était plus probable que les Noirs RRA de 2,05 (IC 95 %, de 1,39 à 3,03, correction complète) et les Asiatiques du Sud RRA de 2,42 (IC 95 %, de 1,75 à 3,36, correction initiale) aient des résultats positifs au test. - Dans des groupes ethniques définis en fonction du risque de test positif (correction initiale) : - RR pour les Pakistanais de 3,24 (IC 95 %, de 1,73 à 6,07) > RR des Asiatiques provenant d'autres pays du Sud de 3,00 (IC 95 %, de 1,64 à 5,49) > RR des Indiens de 1,98 (IC 95 %, de 1,26 à 3,09) pour un test positif comparativement aux Blancs. - Le RR des Antillais noirs est de 3,51 (IC 95 %, de 2,39 à 5,15) et des Noirs africains de 3,11 (IC 95 %, de 1,97 à 4,91) sont similaires.

(Kolin, 2020) préimpression	Biobanque du R.-U. (cohorte prospective de > 500 000 participants, recrutés entre 2006 et 2010, âge variant entre 40 et 69 ans), examen des 669 premiers cas de COVID-19, 16 mars - date d'extraction des données non fournie. Données corrigées pour l'âge, le sexe, l'indice de masse corporelle, l'indice de privation de Townsend et les antécédents de diabète, d'angine ou d'infarctus du myocarde.	Comparativement aux Blancs - Les Noirs RRA de 3,14 (IC 95 %, de 2,28 à 4,31) présentaient un risque plus élevé d'être atteints de la COVID-19. - Les Asiatiques présentaient également un risque plus élevé d'être atteints de la COVID-19 RRA de 2,03 (IC 95 %, de 1,40 à 2,95). *Le dénominateur est la cohorte/population tirée de la Biobanque.
(Patel, 2020)	Biobanque du R.-U. (cohorte prospective de 418 794 participants, recrutés entre 2006 et 2010, âge variant entre 40 et 69 ans) Les dates ne sont pas précisées. Régression corrigée en fonction de l'âge, du sexe et des facteurs socioéconomiques.	Comparativement aux Blancs, les Noirs RRA de 3,1 (IC 95 %, de 2,0 à 4,8) et les Asiatiques 2,0 (IC 95 %, de 1,2 à 3,1) présentaient un risque accru d'hospitalisation en raison d'un test positif de COVID-19 positif. *Le dénominateur est la cohorte/population tirée de la Biobanque.
(Harman, 2020)*	Petite cohorte d'enfants admis avec la COVID-19 provenant d'un seul centre. Sélectionnés de façon prospective au King's College Hospital de Londres au R.-U., entre le 25 février et le 28 avril 2020.	- Hospitalisation : 9 sur 12 (75 %) étaient d'origine noire, asiatique ou d'une autre minorité alors qu'ils ne représentent que 39 % dans la région du centre de Londres.
(Sapey, 2020) nouveauté	R.-U., University Hospitals Birmingham NHS Foundation Trust (UHB) étude rétrospective de cohorte sur les patients atteints du SRAS-CoV-2 (n = 2 217) admis entre le 10 mars et le 17 avril 2020. L'origine ethnique asiatique du Sud est définie comme incluant les Pakistanais, les Bangladais et les Indiens. Analyse de régression du modèle des risques proportionnels de Cox corrigée en fonction de l'âge, du sexe, de la privation et des comorbidités.	- Maladie grave chez les patients asiatiques du Sud 34 sur 137 (24,8 %) comparativement aux Blancs 54 sur 483 (11,2 %) p < 0,0001. - Admissions à l'USI de patients asiatiques du Sud 86 sur 410 (21,0 %) comparativement aux patients Blancs 133 sur 1 540 (8,6 %), p < 0,001. - Mortalité HR de 1,4 (IC 95 %, de 1,2 à 1,8) pour les Asiatiques du Sud comparativement à celle des Blancs.

		- Aucune différence significative n'a été constatée dans la survie des Noirs comparativement aux Blancs.
(Russell, 2020)* nouveauté	R.-U., Guy's Cancer Center de Londres a mené une étude rétrospective de cohorte afin d'évaluer 156 patients atteints de cancer et ayant reçu un diagnostic de COVID-19 entre le 29 février et le 12 mai 2020 et les caractéristiques cliniques associées lorsque le décès était lié à la COVID-19.	- Pour les cancéreux ayant reçu un diagnostic de COVID-19, un lien positif statistiquement significatif a pu être établi avec le décès lié à la COVID-19 pour les Asiatiques comparativement aux Blancs (RC de 3,73 (IC 95 %, de 1,28 à 10,91).
(Martin, 2020) nouveauté	R.-U., étude rétrospective de Leicester sur les patients atteints de COVID-19 dans les hôpitaux universitaires du NHS Trust entre le 1er mars et le 28 avril 2020, ayant évalué les facteurs associés à un résultat positif au test PCR pour le SRAS-CoV-2 avant et après le confinement.	Après correction, comparativement aux Blancs, la probabilité d'obtenir un résultat positif était plus élevée pour d'autres ethnies : - Asiatiques du Sud (RRA de 2,44 IC 95 %, de 2,01 à 2,97). - Noirs (RRA de 2,56 IC 95 %, de 1,71 à 3,84) - Autres ethnies (RRA de 2,53 IC 95 %, de 1,74 à 3,70).
(Perez-Guzman, 2020)* nouveau	R.-U., Londres, étude rétrospective de cohorte du NHS Trust afin d'évaluer les facteurs associés à la mortalité chez 614 patients admis entre le 25 février et le 5 avril dans trois grands hôpitaux londoniens. Ethnies des patients : - MECNA = 40 % (244) - Blancs = 38 % (235) - Origine ethnique inconnue = 22 % (135) Analyse : régression logistique	- En tenant compte de l'âge, du sexe et des comorbidités, les Noirs avaient une probabilité de décès plus élevée que les blancs (RRA de 1,69, IC 95 %, de 1,00 à 2,86). - Ce lien est plus important lorsque l'on tient compte de la gravité de l'infection au moment de l'admission (RRA de 1,85 IC 95 %, de 1,06 à 3,24).
(Ayoubkhani, 2020) préimpression nouveauté	R.-U., étude de cohorte rétrospective pour l'Angleterre et le Pays de Galles afin d'évaluer les décès qui se sont produits entre le 2 mars et le 15 mai 2020, et le lien entre ces décès et les groupes ethniques des minorités.	- Le modèle entièrement corrigé pour les femmes, uniquement pour les femmes noires, a établi un lien avec la mortalité (RRA de 1,29 [IC 95 % de 1,18 à 1,42]). - Chez les hommes, le risque de mortalité lié à la COVID-19 est resté élevé chez les Noirs (1,76 [1,29 [IC 95 %]) de 1,63 à 1,90]), les Bangladais et les Pakistanais (1,35

	Analyse : Modèle des risques proportionnels de Cox.	[1,29 [95 % IC de 1,21 à 1,49]) et les Indiens (1,30 [1,29 [95 % IC de 1,19 à 1,43]).
(Zakeri, 2020) préimpression nouveauté	R.-U., Sud de Londres (King's College Hospital Trust), étude de cohorte avec cas-témoins + rétrospective afin d'examiner le lien entre l'origine ethnique, l'admission à l'hôpital et le taux de mortalité à l'hôpital en raison d'une COVID-19 grave entre le 1er mars et le 2 juin 2020, 872 cas, 3 488 cas-témoins. Parmi tous les cas, - 48,1 % étaient des Noirs, - 33,7 % étaient des Blancs, - 12,6 % étaient d'ethnies mixtes ou autres, - 5,6 % étaient des Asiatiques.	- Comparativement aux Blancs, le risque à l'admission était plus élevé pour les Noirs (RC de 2,28 [IC 95 %, de 1,87 à 2,79]) et les patients d'ethnies mixtes ou autres (RC de 2,66 [IC 95 %, de 2,01 à 3,52]). Les Asiatiques n'ont pas présenté un risque plus élevé à l'admission (RC de 1,04 [IC 95 %, de 0,72 à 1,48]). - Dans les hôpitaux, aucun lien n'a été établi entre le taux de mortalité et les Noirs (HR de 0,84 [IC 95 %, de 0,63 à 1,11]) et les ethnies mixtes ou autres (HR 0.69 [IC 95 %, de 0,43 à 1,10]). Les Asiatiques présentaient un risque plus élevé de mortalité à l'hôpital (HR de 1,54 [IC 95 %, de 0,98 à 2,41]).
(Swann, 2020) préimpression nouveauté	R.-U., cohorte rétrospective multi hôpital (260) en Angleterre, au Pays de Galles et en Écosse, du 17 janvier au 3 juillet 2020, afin d'examiner l'admission à l'USI, le taux de mortalité et le syndrome inflammatoire multisystémique de l'enfant (SIME) et de l'adolescent admis avec une infection par SRAS-CoV-2, n = 651.	- L'admission à l'USI était associée à un âge inférieur à 1 mois, à un âge variant entre 10 et 14 ans et à l'appartenance ethnique noire. Un lien significatif a été établi avec les Noirs RCC de 2,82 (IC 95 %, de 1,41 à 5,57) et avec les autres ethnies RCC de 1,91 (IC 95 %, de 1,07 à 3,34) qui ont été admis à l'USI, mais aucun lien n'a été établi pour les Asiatiques du Sud comparativement aux Blancs. - 11 % des cas ayant été classés comme SIME étaient plus susceptibles d'être d'origine ethnique autre que blanche (64 % (29 sur 45) comparativement à 42 % (148 sur 355) ; p = 0,004).
(Kakkar, 2020)* nouveau	Cohorte rétrospective d'adultes ayant subi un test pour la COVID-19 (n = 3 018) au Sheffield Teaching Hospitals, au R.-U., du 3 janvier au 25 avril 2020.	MECNA comparativement aux Blancs - Test positif : 95 sur 296 comparativement à 631 sur 2 424, p = 0,026.

	MECNA 19 % de la population de Sheffield. Analyse descriptive avec test du χ2 (khi carré).	- Hospitalisation : 86 sur 95 comparativement à 599 sur 631, p0,083 (non significatif). - USI : 20 sur 86 comparativement à 43 sur 599 p < 0,00001. - Un nombre significativement inférieur de tests a été effectué sur le groupe de MECNA comparativement au pourcentage qu'ils représentent dans la population et les personnes MECNA testées étaient significativement plus jeunes que les Blancs.
(Galloway, 2020)* nouveauté	Cohorte rétrospective, Londres au R.-U., 2 hôpitaux, du 1er mars au 17 avril 2020. N = 1 157 admissions à l'hôpital en raison du résultat positif au test RT-PCR pour le SRAS-CoV-2. Analyse : Modèles de régression des risques concurrents, corrigés en fonction de l'âge et du sexe.	- Admission à l'USI comparativement aux Blancs : MECNA HR de 1,53 (IC 95 %, de 1,12 à 2,09). - Mortalité comparativement aux Blancs : MECNA HR de 1,19 (IC 95 %, de 0,89 à 1,58). Un lien a pu être établi avec l'origine ethnique et une maladie plus grave, mais aucun lien n'a pu être établi avec le taux de mortalité parmi les cas hospitalisés.
(Apea, 2020)* préimpression nouveauté	Cohorte rétrospective, 5 hôpitaux, Londres, R.-U., du 1er janvier au 13 mai. N = 1 996 cas de SRAS-CoV-2 Analyse : Une modélisation de régression logistique portant sur l'origine ethnique et le traitement à l'USI sous ventilation mécanique a été effectuée, puis corrigée en fonction de l'âge et du sexe. Modèle des risques proportionnels de Cox corrigé en fonction de l'âge et du sexe	Profil racial des cas 35,2 % de Blancs, 27,0 % d'Asiatiques, 17,0 % de Noirs. - L'admission à l'USI était significative p < 0,001 avec 11 % de Blancs, 20,1 % d'Asiatiques et 18,5 % de Noirs admis à l'USI. - Ventilation mécanique, cotes corrigées en fonction de l'âge et du sexe comparativement aux Blancs dans les cas d'hospitalisation suivants : Asiatiques RC de 1,54 (IC 95 %, de 1,06 à 2,23), Noirs RC de 1,80 (IC 95 %, de 1,20 à 2,71). - Mortalité (dans les 30 jours) : HR de 1,49 pour les Asiatiques (IC 95 %, de 1,19 à 1,86), HR de 1,30 pour les Noirs (IC 95 %, de 1,02 à 1,63) comparativement aux Blancs. Le contrôle des comorbidités a permis d'élargir

		l'intervalle de confiance pour l'origine ethnique, p = 0,09 pour les Noirs. - Mortalité (dans les 90 jours) Asiatiques HR de 1,46 (IC 95 %, de 1,18 à 1,81) comparativement aux Blancs.
(Fletcher, 2020) préimpression	R.-U., étude de cohorte rétrospective pour un seul centre. 2 756 patients admis au Chelsea and Westminster Hospital NHS Foundation Trust, du 1er janvier au 23 avril. Modèle de régression logistique multivariable Remarque : l'origine ethnique était autodéclarée et de nombreuses observations n'étaient pas précisées ce qui a entraîné des estimations insuffisantes.	- Le nombre de personnes qui se présentaient dans des cliniques avec des symptômes de COVID-19 était plus élevé chez les Asiatiques RRA de 1,63 (IC 95 %, de 1,00 à 2,69) et les autres 1,70 (IC 95 %, de 1,21-2,39) comparativement aux Blancs (données corrigées en fonction de l'âge, du sexe et de certains biomarqueurs sanguins). La comparaison corrigée pour les Noirs était similaire, mais non significative. - Aucun lien entre l'admission à l'USI et l'origine ethnique n'a été observé dans cette étude. - Observation d'une tendance d'association de la mortalité chez les Asiatiques, avec un RRA de 2,24, et (IC 95 %, de 1,23-4,50) et un taux similaire pour les Noirs, n'était cependant pas significative.
(S. de Lusignan, 2020a) préimpression	R.-U., revue rétrospective des dossiers médicaux et étude transversale, centre de recherche et de surveillance Oxford RCGP, du 28 janvier au 4 avril 2020. Cas positifs à la COVID-19 n = 587, test négatif n = 3 215. Répartition ethnique : Blancs n = 2 497 (65,7 %) Asiatiques n = 152 (4,0 %) Noirs n = 58 (1,5 %) Ethnicité mixte, autres n = 81 (2,1 %) Informations manquantes n = 1 014 (26,7 %) Régression logistique multivariée.	- Comparativement aux Blancs (15,5 %), les cotes corrigées pour un test positif étaient plus grandes pour les Noirs (62,1 %) RCC de 4,75 (IC 95 %, de 2,65-8,51), corrigées en fonction de l'âge, du sexe, de la privation socioéconomique, de la taille du ménage, de la zone urbaine/rurale, du tabagisme, de l'IMC, de l'hypertension, de la maladie rénale chronique, du diabète, de la maladie cardiaque chronique.

(Wright, 2020) nouveauté	Données transversales sur les patients hospitalisés ayant été testés pour la COVID-19 du 18 mars au 27 avril à Bradford, R.-U. Tests du tests du χ2 (khi carré).	- Taux de mortalité associé aux cas de COVID-19 comparativement aux patients ayant obtenu un résultat négatif. Aucune différence significative dans le taux de mortalité entre les Blancs (25,4 %) et les Asiatiques du Sud (18,1 %) pour les cas hospitalisés de COVID-19 (p = 0,122). Les Asiatiques du Sud étaient cependant beaucoup plus jeunes que les Blancs.
(Hull, 2020) préimpression	R.-U., ensemble de données sur la médecine générale dans l'est de Londres. Étude transversale comptant 1,2 million de personnes dans 157 pratiques avec n = 8 985 cas de COVID-19, du 14 février au 30 avril 2020. Modèle corrigé pour l'âge, le sexe, la privation sociale, les prédicteurs cliniques.	- Les chances d'infection par le SRAS-COV-2, entièrement corrigées pour les autres variables, étaient les suivantes : Asiatiques du Sud RCC de 1,93 IC 95 %, de 1,83 à 2,04) et Noirs RCC de 1,47 (IC 95 %, de 1,38 à 1,57).
(Cook, 2020)	R.-U., personnel du NHS : Les données transversales sur le taux de décès des travailleurs de la santé jusqu'au 22 avril 2020 ont été analysées. 106 cas dont 98 interagissaient directement avec les patients. Les décès des travailleurs de la santé ont représenté de 0,51 à 0,58 % des décès. Aucune analyse statistique.	- La proportion des décès de MECNA (en proportion dans une profession) - Infirmière 71 % (20 %) - Préposés de soutien aux soins de santé 56 % (17 %) - Médecin / dentiste 94 % (44 %) - Autre 29 % (-)
(Riphagen, 2020)	Londres, R.-U., petite série de cas d'enfants atteints du syndrome inflammatoire multisystémique de l'enfant (SIME) maintenant bien reconnu. En dix jours, dans un seul hôpital pédiatrique, huit enfants ont été identifiés à la mi-avril 2020.	- 6 des 8 enfants atteints de cette maladie inflammatoire étaient Noirs. Aucune analyse ou enquête sur ce lien potentiel n'a été effectuée dans le cadre de cette petite étude.
Autres pays		
(Toubiana, 2020)	Paris en France, étude observationnelle prospective du syndrome inflammatoire multisystémique de l'enfant (SIME), du 27 avril au 11 mai (suivi jusqu'au 15 mai). 21 enfants, âge médian de 7,9 ans (entre 3,7 et 16,6 ans)	- 57 % (12 sur 21) étaient Noirs alors que 3 sur 21 étaient Asiatiques. Les données de cette étude étaient insuffisantes pour évaluer le lien, mais les proportions étaient plus élevées que ce à quoi on pourrait

		généralement s'attendre en fonction de la démographie de la population et de ce que l'on sait de la maladie de Kawasaki chez les enfants.
(Elias, 2020) nouveauté	Paris en France, étude de cohorte prospective chez des patients ayant subi une greffe de rein (n = 1 216) avec suivi actif dans deux centres de transplantation de référence entre le 1er mars et le 30 avril 2020.	- L'appartenance ethnique non blanche était liée indépendamment à un risque plus élevé de développer la COVID-19, RCC = 2,17; [95 % CI] de 1,23 à 3,78; p = 0,007).
(Baqui, 2020)*	Brésil, étude trasnversale de la mortalité dans les hôpitaux (à l'échelle du pays). Données collectées du 27 février au 4 mai 2020. N = 6 882 cas dont l'issue est connue. La classification raciale classe la population brésilienne en cinq catégories (pourcentages de la population brésilienne en 2010) : branco (Blancs) (47,5 %), pardo (ethnicité mixte) (43,4 %), preto (Noirs) (7,5 %), amarelo (Asiatiques) (1,1 %) et indígena (Autochtones) (0,4 %). Analyse de régression de Cox corrigée par âge, sexe, groupe ethnique et comorbidités (effets fixes) avec l'état (effet aléatoire).	- La mortalité à l'hôpital était plus élevée chez les personnes d'origine ethnique mixte (1,47) (IC 95 %, de 1,33 à 1,58) et chez les Noirs (1,32) (IC 95 %, de 1,15 à 1,52) comparativement aux Blancs. Après l'âge, l'appartenance ethnique mixte est le facteur de risque le plus influent sur la mortalité.

* = l'étude est également incluse dans (Raharja, 2020). Nouveauté = désigne toute étude ayant été publiée depuis le 1er juin 2020, date à laquelle la première version de cette étude a été achevée. Prépublication = désigne les articles qui n'ont pas été soumis au processus d'évaluation par les pairs. MECNA = minorités ethniques et communautés noire et asiatique, RC = rapport de cotes, HR = risque relatif, RR = rapport de risque, IC à 95 % = intervalle de confiance, I^2 = mesure de l'hétérogénéité dans une méta-analyse, k = nombre d'études.

ORIGINE ETHNIQUE ET EXPOSITION À LA COVID-19 (ÉTUDES SÉROLOGIQUES)

La séroprévalence, d'autres tests sérologiques et des liens avec l'origine ethnique ont été mentionnés dans cinq études. Quatre études de séroprévalence menées aux États-Unis sur la population en générale, les travailleurs de la santé et les femmes enceintes ont montré que la proportion de personnes séropositives était significativement plus élevée dans certaines ethnies : Noirs (n = 3 études sur 4), Hispaniques (n = 3), Asiatiques (n = 1 sur 2) (tableau 2). Une étude menée au Royaume-Uni a examiné la dynamique des anticorps IgG contre le SRAS-CoV-2 pendant

les phases aiguës et convalescentes de l'infection et constaté qu'il y avait une différence dans l'ampleur des résultats avec ELISA, pouvant indiquer que pendant l'infection par COVID-19, les non-Blancs peuvent avoir une charge virale plus élevée (Staines, 2020). Cette constatation nécessitera cependant des recherches plus poussées pour comprendre la signification de l'écart relevé dans cette étude. Les essais enregistrés décrits dans la revue systématique comprenaient des études sur la séroprévalence qui s'ajouteront au corpus d'information (D. Pan, 2020).

Tableau 2 : Études sérologiques sur l'incidence cumulative et la dynamique des anticorps contre le SRAS-COV-2 (n = 5)

Référence	Description de l'étude	Principaux résultats
(Ebinger, 2020)* préimpression nouveauté	É.-U., enquête de séroprévalence dans une vaste cohorte diversifiée d'employés du secteur de la santé, soit 6 062 adultes du comté de Los Angeles. Date : Mai à juin 2020 Analyse : analyses en fonction multivariables corrigées pour des caractéristiques préexistantes, par exemple l'origine ethnique, l'âge, le sexe, l'asthme, l'hypertension	- Comparativement aux Blancs, les Hispaniques (RC 1,80 [IC 95 %, de 1,31, 2,46], P<0,001) et les Noirs (1,72 [1,03, 2,89], P = 0,04) représentaient les principaux facteurs d'association significative à une plus grande probabilité d'être séropositif.
(Flannery, 2020) nouveauté	É.-U., étude de cohorte prospective menée en Pennsylvanie a permis d'effectuer des tests sérologiques sur 1 293 parturientes dans deux centres de Philadelphie entre le 4 avril et le 3 juin 2020, et d'évaluer les différences de race ou d'origine ethnique chez les femmes.	Taux de séroprévalence par race ou ethnie : - Noires (9,7 %; IC 95 %, de 7,3 à 12,5 %) - Hispaniques (10,4 %; IC 95 %, de 5,7 à 17,1 %) - Blanches (2,0 %; IC 95 %, de 0,9 à 3,8 %) - Asiatiques (0,9 %; IC 95 %, de 0,0 à 5,1 %)
(Biggs, 2020) nouveauté	É.-U., étude transversale menée dans deux comtés d'Atlanta entre le 28 avril et le 3 mai 2020 afin d'évaluer la séroprévalence du SRAS-CoV-2 chez 696 personnes.	Taux de séroprévalence total pondéré = 2,5 % (IC 95 %, de 1,4 à 4,5) - Noirs 5,2 % (IC 95 %, de 2,9 à 9,1), p < 0,01 comparativement aux autres ethnies.
(Rosenberg, 2020)	Enquête de séroprévalence dans l'État de New York n = 15 101 adultes, du 19 au 28 avril 2020. Estimation de l'incidence cumulée obtenue en utilisant une pondération post-stratification afin de normaliser la	L'incidence cumulée varie significativement selon l'origine ethnique : - Hispaniques : 29,2 % (IC 95 %, de 27,2 à 31,2 %). - Noirs : 20,2 % (IC 95 %, de 18,1 à 22,3 %).

	population de New York et d'apporter des correctifs à l'aide des caractéristiques du test de détection des anticorps.	- Asiatiques : 12,4 % (IC 95 %, de 9,4 à 15,4 %). - Comparativement aux Blancs 8,1 % (IC 95 %, de 7,4 à 8,7 %), p < 0,0001).
(Staines, 2020) préimpression	Cohorte prospective dans un seul centre, du 29 mars au 22 mai, Londres, R.-U. 177 cas de COVID-19 sur 1 785 sont inclus. Test : IgG du test ELISA pour la COVID-19 développé par Mologic (Bedford au R.-U.) et fabriqué par Omega (Omega Diagnostics de Cambridge au R.-U.) - 2 à 8 % des cas n'ont subi aucune séroconversion.	- L'appartenance à des non-Blancs a été associée à une valeur de densité optique normalisée d'ELISA plus élevée que celles des Blancs, valeur moyenne de 1,06 comparativement à 0,85, p 0,035 (test t non apparié) - L'auteur suggère que ce résultat pourrait être associé à des charges virales plus élevées

* = l'étude est également incluse dans (Raharja, 2020). Nouveauté = désigne toute étude ayant été publiée depuis le 1er juin 2020, date à laquelle la première version de cette étude a été achevée. Prépublication = désigne les articles qui n'ont pas été soumis au processus d'évaluation par les pairs. RC = rapport de cotes, IC 95 % = intervalle de confiance.

ORIGINE ETHNIQUE ET COVID-19 AU CANADA

Malgré une recherche dans la littérature grise, seule une quantité limitée de recherches canadiennes ont été obtenues. Ces recherches incluaient une étude écologique en préimpression, deux rapports d'enquêtes effectuées au Canada, mais non encore publiées, des rapports de surveillance de Services aux Autochtones Canada ainsi que le tableau de bord sur la COVID-19 du Bureau de santé publique de Toronto. Tous ont fourni des résultats pertinents sur l'origine ethnique et la COVID-19 au Canada (tableau 3). La recherche a également permis de déterminer quelles provinces (Ontario / Colombie-Britannique) et/ou unités de santé (Toronto) recueillent ou prévoient de commencer à recueillir des données sur l'origine ethnique des cas de COVID-19. En septembre 2020, seul le Bureau de santé publique de Toronto disposait d'un rapport.

Les données canadiennes disponibles indiquent que les groupes ethniques non Blancs, à l'exception des Asiatiques de l'Est, sont infectés de façon disproportionnée par la COVID-19, ce qui concorde avec d'autres études sur le risque d'infection par la COVID-19 menées dans d'autres pays dans le cadre de la présente synthèse. Ces études soulignent également les inégalités dans les déterminants sociaux de la santé qui peuvent être entraîner un risque accru de COVID-19, ce qui inclut le logement, l'éducation, le revenu, la profession et l'accès aux soins de santé.

- Une enquête transversale conçue pour comparer les répercussions de la COVID-19 sur les Canadiens Noirs à un échantillon « national » représentatif a cependant révélé une plus grande susceptibilité à la COVID-19 chez les Canadiens Noirs tant au niveau individuel que dans leur cercle social. La fréquence de certains facteurs de risque liés à l'utilisation des transports en commun et au fait d'occuper un emploi exigeant des interactions en personne était plus élevée chez les Canadiens Noirs. Ils étaient plus à risque de subir de graves conséquences financières en raison de la pandémie. Ces données concordent donc avec d'autres données tirées d'études similaires publiées aux États-Unis (tableau 1).
- Le tableau de bord créé par le Bureau de santé publique de Toronto montre une proportion plus élevée de cas de COVID-19 dans les groupes ethniques composés de Noirs, d'Hispaniques, d'Asiatiques du Sud-Est, d'Asiatiques du Sud/Indo-Caribéens et de Moyen-Orientaux par rapport à leur représentation dans la communauté.
- L'étude écologique a analysé les données sur le nombre de cas et de décès liés à la COVID-19 par rapport au niveau démographique de la population du Canada en fonction de plusieurs variables, incluant la proportion de Noirs, la proportion de personnes nées à l'étranger, la proportion de personnes âgées de plus de 65 ans, la densité de la population et le revenu médian. Les résultats tirés du modèle binomial négatif multivariable incluent:
    - Le doublement du nombre de cas était associé à une augmentation de 1 % de la proportion de Noirs alors que l'augmentation de 3 % du nombre de cas était associée à une augmentation de 1 % de la population de gens nés à l'étranger.
    - 2,1 fois l'augmentation du taux de mortalité des COVID-19 était, quant à elle, associée à une augmentation de 1 % de la proportion de Noirs dans la population.

Les données sur l'infection par la COVID-19 des populations autochtones du Canada provenaient de la page Web de Services aux Autochtones Canada et des pages Web provinciales de l'Alberta, de la Colombie-Britannique et du Manitoba {{85811;}}. Une analyse effectuée à la fin de juillet a révélé que les populations autochtones du Canada qui se trouvent dans les réserves ont déclaré des taux de COVID-19 correspondant au quart du taux de la population en général ainsi qu'un taux de mortalité d'environ le cinquième de celui de la population en général {{85811;}}. À ce jour, les commentaires et articles publiés dans le Journal de l'Association médicale canadienne (CMAJ)indiquent que les communautés autochtones canadiennes ont réussi dans leurs efforts visant à atténuer les répercussions sur la santé publique {{65290;}}. Les populations autochtones sont également plus susceptibles de vivre dans des collectivités éloignées qui peuvent assurer une certaine protection à une collectivité fermée contre la COVID-19, mais lorsque ces collectivités sont touchées par la COVID-19, elles n'ont alors qu'un accès limité aux soins de santé et sont plus susceptibles d'être dans une mauvaise situation socioéconomique. (Statistique Canada, 2020). Aucune donnée canadienne sur l'origine ethnique et les hospitalisations, la gravité ou la mortalité n'a été relevée. Toutefois, les publications sur le lien entre l'origine ethnique et les problèmes

médicaux ou les facteurs socioéconomiques jugés comme des facteurs de risque pouvant entraîner une forme grave de COVID-19 peuvent être des indicateurs utiles de ce à quoi on pourrait s'attendre d'ici à ce que les données sur la COVID-19 soient disponibles. La recherche a permis de trouver deux publications suggérant que, comparativement aux Blancs, les immigrants noirs, les Autochtones et les immigrants d'Asie du Sud étaient beaucoup plus susceptibles d'avoir un ou plusieurs problèmes de santé associés à un risque plus élevé d'avoir une forme grave de COVID-19 (Lin, 2020).

Tableau 3 : Détails des études et des rapports d'observation effectués au Canada sur le lien entre l'origine ethnique et le risque d'infection par la COVID-19 (n = 5)

Référence	Renseignement sur l'étude	Principaux résultats
Susceptibilité, gravité clinique et mortalité associées à la COVID-19		
Canada		
(Nur, 2020) nouveauté rapport non publié	Un sondage en ligne (transversal) a été effectué du 17 au 30 juin 2020. Il utilisait une stratégie d'échantillonnage pondérée en fonction de l'âge, du sexe, de la région, de l'origine ethnique et du lieu de naissance pour cibler un échantillon représentatif de 1 500 Canadiens et de 400 Canadiens noirs (Noirs). N = 2 322 adultes canadiens	Résultats en ce qui a trait à la COVID-19 : - Les Noirs étaient plus nombreux à déclarer des symptômes de COVID-19 et le traitement associé (10 % comparativement à 7 % à l'échelle nationale). - Les Noirs sont plus nombreux à avoir eu des symptômes de COVID-19 (10 % comparativement à 7 % à l'échelle nationale) ou à connaître quelqu'un ayant eu de tels symptômes (28 % comparativement à 17 % à l'échelle nationale). - Les banlieusards ont obtenu des résultats plus élevés, ce qui veut dire qu'ils étaient plus nombreux à avoir eu des symptômes de COVID-19 (16 % comparativement à 12 % à l'échelle nationale) ou à connaître quelqu'un ayant eu de tels symptômes (34 % comparativement à 18 % à l'échelle nationale).

		- Les Noirs étaient trois fois plus susceptibles de connaître une personne qui est décédée de la COVID-19 (21 % comparativement à 8 % à l'échelle nationale). Facteurs de risque pour la COVID-19 - Les Noirs étaient plus susceptibles de prendre les transports en commun pour se rendre au travail (25 % comparativement à 12 % à l'échelle nationale) (d'autres études ont montré qu'il s'agissait là d'un indicateur de risques plus élevés d'infection à la COVID-19). - Les Noirs sont plus nombreux à déclarer que leur emploi exige des contacts fréquents en direct (61 % comparativement à 50 % à l'échelle nationale). Répercussions de la COVID-19 - Des répercussions financières minimales ont été déclarées par 45 % des répondants Noirs et à l'échelle nationale. - Les hommes Noirs âgés de 45 ans et plus sont plus susceptibles de faire état répercussions financières négatives significatives (38 % comparativement à 22 % à l'échelle nationale) à cet égard. - La confiance financière était plus faible dans les ménages noirs (67 % comparativement à 72 % à l'échelle nationale).
Nous avons demandé une copie du rapport puisqu'il n'était pas disponible en ligne. nouveauté	Enquête sur la COVID-19 menée au sein de la population de la C.-B. (N = 394000). (Informations tirées des articles de presse au 14 août 2020)	- Les données indiquent que les Hispaniques, les Asiatiques de l'Ouest et du Sud et les Noirs ont été touchés de façon disproportionnée par la pandémie et ont éprouvé des difficultés financières en raison de la perte de leur emploi. - L'origine ethnique et l'accès aux soins de santé ont été identifiés comme sources de problèmes, lorsque les

		Japonais, les Coréens, les personnes multiethniques et les Asiatiques du Sud ont mentionné des difficultés à cet égard.
(Bureau de santé publique de Toronto, 2020) nouveauté	Tableau de bord de surveillance pour la COVID-19 à Toronto comprenant les données de proportion établies en fonction de l'identité ethnoraciale et du revenu Données recueillies du 20 mai au 16 août 2020 24 % des données sur l'origine ethnique sont manquantes. Ne comprend pas les cas de COVID-19 dans les établissements de soins de longue durée. Les résultats sont descriptifs et ne comprennent que des observations avec données sur l'origine ethnique.	83 % des cas COVID-19 signalés proviennent d'un groupe ethnique minoritaire alors qu'ils représentent 52 % de la population de Toronto. La liste ci-dessous indique le pourcentage de COVID-19 par rapport au pourcentage de population. - Blancs 17 % comparativement à 48 % - Noirs 22 % comparativement à 9 % - Hispaniques 10 % comparativement à 3 % - Asiatiques du Sud-Est 16 % comparativement à 7 % - Asiatiques du Sud ou Indo-Caribéens 20 % comparativement à 13 % - Moyen-Orientaux 11 % comparativement à 4 % - Asiatiques de l'Est 4 % comparativement à 13 %
(Choi, 2020) préimpression	Étude écologique effectuée à l'échelle du Canada, avec des données recueillies jusqu'au 5 mai 2020. Les données fournies par l'ASPC et Statistique Canada, ainsi que les données provenant de l'approche participative à grande échelle ont été utilisées pour comparer le nombre de cas et de décès liés à la COVID-19 avec les données fournies par les unités de services de santé en fonction de différents prédicteurs pour l'analyse, soit la proportion de Noirs, de personnes nées à l'étranger, le pourcentage de personnes de plus de 65 ans, la densité de la population et le revenu médian. L'analyse des cas et des décès, respectivement, a été effectuée dans un modèle multivariable binomial négatif (en raison des	- Le modèle multivarié utilisé pour évaluer l'infection à la COVID-19 a estimé qu'une augmentation de 1 % de la proportion de résidents Noirs dans une région sanitaire était liée au doublement des taux d'infection par la COVID-19. Il a également estimé qu'une augmentation de 1 % de la proportion de résidents nés à l'étranger était, quant à elle, associée à une hausse de 3 % des taux d'infection par la COVID-19. - Chaque augmentation de 1 % de la proportion de résidents noirs dans une région sanitaire était liée à 2,1 fois le taux de mortalité lié à la COVID-19. Une augmentation de 1 % de la proportion de résidents âgés de 65 ans et plus a été, quant à elle, associée à une hausse de 26 % des décès.

	données de dénombrement trop dispersées) utilisant les prédicteurs indiqués ci-dessus.	
{{85811;}} Rapport de surveillance nouveauté	Données de surveillance : au 20 septembre 2020, 408 cas de COVID-19 avaient été recensés dans les réserves des communautés autochtones.	En date du 31 juillet 2020 : - Le pourcentage d'Autochtones qui vivent dans les réserves et ont été déclarés positifs à la COVID-19 est actuellement au quart du taux observé dans la population canadienne en général. - Le taux de mortalité par COVID-19 pour les Autochtones qui vivent dans les réserves est d'environ un cinquième du taux de mortalité dans la population canadienne en général.

Nouveauté = désigne toute étude ayant été publiée depuis le 1er juin 2020, date à laquelle la première version de cette étude a été achevée.

Prépublication = désigne les articles qui n'ont pas été soumis au processus d'évaluation par les pairs.

Méthodes :

Une analyse quotidienne de la littérature (publiée et prépubliée) est effectuée par le groupe des sciences émergentes de l'ASPC. L'analyse a permis de compiler la littérature sur la COVID-19 depuis le début de l'épidémie et est mise à jour quotidiennement. La littérature est extraite de Pubmed, de Scopus, de BioRxiv, de MedRxiv, d'ArXiv, de SSRN, de Research Square et croisée avec la liste de littérature sur la COVID de l'OMS et des centres d'information sur la COVID-19 gérés par Lancet, BMJ, Elsevier et Wiley.Le résumé quotidien et les résultats complets de l'analyse sont conservés dans une base de données Refworks et une liste Excel consultable. Une recherche ciblée par mot-clé est effectuée dans ces bases de données pour identifier les citations pertinentes sur la COVID-19 et le SRAS-CoV-2. Les termes de recherche utilisés comprenaient race, ethnie et origine ethnique. Cette synthèse contient des recherches publiées jusqu'au 7 septembre 2020.
Une recherche élargie dans la littérature canadienne sur l'origine ethnique a également été effectuée en utilisant les termes de recherche indiqués avec COVID-19 ET Canada ou provinces comme termes clés dans Google et sur les sites Web officiels. 464 citations ont été saisies par la recherche; certaines études ont été éliminées, car elles n'étaient pas pertinentes, n'étaient pas des recherches primaires ou des revues systématiques ou n'incluaient pas de plan d'étude. Soixante-treize études ayant analysé un lien avec l'origine ethnique sont incluses dans cette synthèse. Chaque référence potentiellement pertinente a été examinée pour confirmer qu'elle comportait des données pertinentes et les données pertinentes sont extraites dans la revue.

ANNEXE :

Dans les études incluses dans cette synthèse, l'origine ethnique était autodéclarée selon le fait que la personne s'auto-identifie à un ou à plusieurs groupes sociaux parmi une liste d'options prédéfinies. Les listes varient d'un pays à l'autre et d'une étude à l'autre. Le tableau ci-dessous présente les principales catégories de classifications ethniques et ethnoraciales utilisées par les États-Unis et le Royaume-Uni. Certaines études comportaient d'autres options de granularité ou de classification qui sont indiquées ci-dessous.

Définitions

Origine ethnique : Groupe social auquel une personne appartient et auquel elle s'identifie ou est identifiée par d'autres, en raison d'un mélange de facteurs culturels et autres, incluant la langue, le régime alimentaire, la religion, l'ascendance et les caractéristiques physiques traditionnellement associées à la race (voir race). Le concept est de plus en plus utilisé comme synonyme de race, mais la tendance est plus pragmatique que scientifique.

Les classifications **ethnoraciales** désignent la catégorisation administrative des personnes selon des critères ethniques et raciaux à des fins statistiques. Ce terme a été utilisé par le Bureau de santé publique de Toronto.

Catégorie ethnique utilisée dans la synthèse	Acronymes et définitions de la catégorie.
Blanc	Désigne un Blanc non Hispanique. Définition des É.-U. : personne dont l'ascendance vient d'Europe, du Moyen-Orient ou de l'Afrique du Nord. Définition du R.-U. : Désigne un Britannique, un Irlandais ou toute personne dont l'ascendance est blanche.
Noir	Désigne un Noir non hispanique, un Afro-Américain, un Noir britannique, un Noir des Caraïbes, un Africain, un Afro- Caribéen ou un Haïtien. Définition des É.-U. : personne dont l'ascendance vient de l'un des groupes raciaux noirs d'Afrique. Définition du R.-U. : Désigne un Caribéen, un Africain ou toute personne dont l'ascendance est noire.
Hispanique	Latino, Latino-Américain ou Latinx. Remarque : Le Bureau du recensement des États-Unis utilise le terme « hispanique » pour désigner à la fois les personnes hispaniques et latines qui sont nées en Amérique latine ou qui ont des ancêtres provenant d'Amérique latine. Définition des É.-U. : personne dont l'ascendance est Cubaine, Mexicaine, Portoricaine, d'Amérique du Sud ou Centrale, ou de toute autre culture ou antécédence espagnole, peu importe la race.

Autochtone	Désigne les Premières Nations, les Inuits et les Métis (Canada), les Amérindiens et les Autochtones de l'Alaska (États-Unis). Par définition, les peuples autochtones désignent les premières populations d'Amérique du Nord et d'Amérique du Sud.
Habitant des îles du Pacifique	Désigne un natif d'Hawaii. Personne dont l'ascendance vient d'Hawaii, de Guam, de Samoa ou des autres îles du Pacifique.
Asiatique	Désigne toute personne originaire de l'un ou l'autre des premiers peuples de l'Extrême-Orient, de l'Asie du Sud-Est ou du sous-continent indien, y compris, par exemple, le Cambodge, la Chine, l'Inde, le Japon, la Corée, la Malaisie, le Pakistan, les îles des Philippines, la Thaïlande et le Vietnam. Définition du R.-U. : Désigne tout Indien, Pakistanais, Bangladais ou toute personne de toute autre antécédence asiatique.
Chinois	Définition du R.-U. : Désigne tout Chinois ou toute autre personne chinoise.
Mixte	Définition du Royaume-Uni : désigne toute personne blanche et noire des Caraïbes, blanche et noire d'Afrique, blanche et noire de l'Asie, ou toute autre personne ayant une antécédence mixte.
MECNA	Désigne les minorités ethniques et communautés noire et asiatique (ou « Black Asian and minority ethnic group » en anglais), un terme utilisé dans de nombreuses études au Royaume-Uni pour désigner l'origine ethnique non blanche.
Communautés raciales	Désigne les minorités visibles et englobe généralement toutes les personnes qui ne sont pas de race Caucasienne ou de couleur blanche. Au Canada, cela peut inclure ou non les Autochtones, selon le rapport ou l'étude.
Asiatique de l'Est	Constitue une classification racialisée qui désigne les personnes originaires des pays d'Asie de l'Est, soit Chine, Taïwan, Japon, Mongolie, Corée du Nord et Corée du Sud.
Asiatique du Sud	Désigne une personne dont les ancêtres proviennent des pays du sous-continent indien, y compris l'Inde, le Pakistan, le Bangladesh et le Sri Lanka. Les Indo-Caribéens, qui ont été regroupés avec les Asiatiques du Sud, sont des personnes d'origine indienne qui vivent dans les Caraïbes.
Asiatique du Sud-Est	Désigne un groupe de cultures mixtes provenant de 11 pays, soit Brunéi, Birmanie (Myanmar), Cambodge, Timor-Leste, Indonésie, Laos, Malaisie, Philippines, Singapour, Thaïlande et Vietnam.
Moyen-oriental	Désigne les Arabes et Asiatiques occidentaux d'origine moyen-orientale et nord-africaine

Remarques : La capitalisation est conforme au guide de style de l'ASA pour les documents de recherche en sociologie. Définitions de l'origine ethnique ou de la race fournies par le bureau du recensement des États-Unis. Ces définitions représentent un concept social établi d'après la race et l'origine ethnique plutôt que représenter une ségrégation fondée sur la biologie. Catégories de l'origine ethnique établies par le bureau de recensement du Royaume-Uni.

Evidence Snapshot:

Rapid Review on the Impact of School Closures and Re-openings on COVID-19 Transmission

Context

School closures were one of the earliest public health measures implemented to reduce the spread of SARS-CoV-2. The primary aim of this review was to examine the empirical evidence on the effectiveness of school closures and the impact of re-opening schools in reducing community transmission of COVID-19 and decreasing the incidence of COVID-19 in primary and secondary schools.

Key Findings

This rapid review identified 24 studies, including 5 observational studies and 19 ecological studies up to January 25, 2021. Of these, all ecological studies and one prospective cohort study assessed the impact on transmission of COVID-19 in the community, and 4 observational studies assessed the impact on in-school transmission. The key findings were:

- Most observational studies found that school closures and re-openings did not significantly impact within-school and community transmission of COVID-19.
- Findings were mixed across ecological studies that assessed the impact of school closures or re-openings (primary, secondary and/or other schools included) on the spread of COVID-19 in the community early in the pandemic during January 2020 to August 2020.
- Among these, five studies reported that school closures and re-openings did not impact community transmission of COVID-19 and that other public health measures were more effective than school closures.
- Other ecological studies attributed significant reductions in the incidence of COVID-19, the effective reproduction number, and mortality to the closure of schools.

Considerations

The evidence in this review is limited by the inconsistency in the levels of schooling included across the studies, with many of the ecological studies including other types of schools or not describing the type of schools included in their analyses. Most studies were conducted early in the pandemic therefore their findings are likely to be confounded by public health measures that were implemented simultaneously. An important knowledge gap is how the variants of concern and the rollout of COVID-19 vaccinations will impact the effectiveness of school closures or the impact of school re-opening on the spread of COVID-19.

Aperçu des éléments de preuve :

Examen rapide de l'impact des fermetures et réouvertures d'écoles sur la transmission de la COVID-19

Contexte

La fermeture des écoles a été l'une des premières mesures de santé publique mises en œuvre pour réduire la propagation du SRAS-CoV-2. L'objectif principal de cette revue était d'examiner les preuves empiriques de l'efficacité des fermetures d'écoles et de l'impact de la réouverture des écoles pour réduire la transmission communautaire de la COVID-19 et d'en diminuer son incidence dans les écoles primaires et secondaires.

Principales constatations

Cet examen rapide a permis d'identifier 24 études, dont 5 études observationnelles et 19 études écologiques jusqu'au 25 janvier 2021. Parmi celles-ci, toutes les études écologiques et une étude de cohorte prospective ont évalué l'impact sur la transmission de la COVID-19 dans la communauté, et 4 études observationnelles ont évalué l'impact sur la transmission en milieu scolaire. Les principales conclusions sont les suivantes :

- La plupart des études observationnelles ont montré que les fermetures et réouvertures d'écoles n'avaient pas d'impact significatif sur la transmission de la COVID-19 au sein d'une école et de la communauté.
- Les résultats sont mitigés dans les études écologiques qui ont évalué l'impact de la fermeture ou de la réouverture des écoles (primaires, secondaires et/ou autres écoles incluses) sur la propagation de la COVID-19 dans la communauté au début de la pandémie, entre janvier 2020 et août 2020.
- Parmi celles-ci, cinq études ont rapporté que la fermeture et la réouverture des écoles n'avaient pas d'impact sur la transmission communautaire de la COVID-19 et que d'autres mesures de santé publique étaient plus efficaces que la fermeture des écoles.
- D'autres études écologiques ont attribué à la fermeture des écoles des réductions significatives de l'incidence de la COVID-19, du nombre effectif de reproductions et de la mortalité.

Facteurs dont il faut tenir compte

Les données de cette revue sont limitées par l'incohérence des niveaux de scolarisation inclus dans les études, de nombreuses études écologiques incluant d'autres types d'écoles ou ne décrivant pas le type d'écoles incluses dans leurs analyses. La plupart des études ayant été menées au début de la pandémie, leurs résultats risquent d'être faussés par les mesures de

santé publique qui ont été mises en œuvre simultanément. Une importante lacune dans les connaissances est la façon dont les variantes de l'inquiétude et le déploiement des vaccinations pour la COVID-19 auront un impact sur l'efficacité de la fermeture des écoles ou l'impact de la réouverture de celles-ci sur la propagation de la COVID-19.

Emerging Evidence on COVID-19

Evidence Brief on the Determinants of Individual Adherence to Public Health Interventions for COVID-19

Introduction

What is the evidence on determinants of individual adherence to public health interventions to prevent COVID-19?

An individual's adherence to public health interventions such as social distancing, wearing face masks and washing hands, plays an important role in how effective these interventions will be at controlling the epidemic. This evidence brief identifies and summarizes literature until July 19, 2020 on determinants of individual adherence to public health interventions for COVID-19 to better understand the drivers and barriers of adopting recommended protective behaviors.

Key Points

- 80 studies conducted in many countries evaluated the individual adherence to protective measures against COVID-19 infection in various populations including adults, young adults, university students, children and adolescents, healthcare workers (HCWs), pregnant women, employees, and visitors to hospitals (Tables 1-5).
- Most of these studies were conducted in the initial stages of the epidemic and represent initial adoption of protective behaviours. Many studies (n=28) report better compliance among females compared to males in all age groups. There were few studies on children and adolescents, and many of these noted high compliance in these age groups with a lower compliance among children of high school age.
- Compliance varied across studies, sociodemographic factors and type of protective measure, and was frequently associated with individual knowledge and beliefs.
- Adults > 30 years old were more likely to be compliant with recommended protective behaviors in 13 studies. Other factors positively correlated to adherence in adults include: risk perception (n=7 studies), higher COVID-19 knowledge (n=5), trust in science and government (n=4), increased anxiety levels (n=3), perceived self-efficacy to adopt protective measures (n=3) and Black or Asian ethnicity (n=3).
- Non-adherence in adults was associated with psychological issues such as depression, conspiracy mentality and narcissism (n=5), as well as being a current smoker (n=3).
- In children and adolescents, factors correlated with improved adherence include father's occupation, mother's educational background, location of residence and those with an immigrant background (Chen et al., 2020; Soest, Pedersen, Bakken, & Sletten, 2020).

- Three rapid synthesis reviews were identified that included pre-pandemic literature on adherence to quarantine and individual preventative behaviors (IPC) by HCWS (Table 6).

Overview of the Evidence

Overall, 80 publications pertaining to the adherence to individual protective behaviors recommended by public health to combat the COVID-19 epidemic and the barriers and facilitators associated with these behaviors. Three rapid reviews on adherence and factors that influence adherence to public health interventions to control infectious diseases were also included, however these reviews included only studies published before the pandemic. Of the 83 publications included, 39 preprints were identified, these papers have not completed the peer-review process. The publications reporting on adherence to public health interventions are all observational studies that are at moderate/high risk of bias and thus, are considered medium-low quality. The majority of these studies use a cross-sectional study design and the outcomes are mostly self-reported, which can be biased by recall, response, and social desirability biases. While there are many studies that show similar trends, the conclusions could change with additional research.

A key knowledge gap in this research are studies that evaluate adherence over time. Most of the identified research was conducted in the early stages of the epidemic and only provide a cross-section of whether or not recommended public health behaviors were adopted. In many jurisdictions that situation has changed over time, public messaging and rules have changed with lifting and increasing intensity of different interventions. Studies that longitudinally explore the barriers and facilitators of longer term adherence to protective behaviors are needed to address both those resistant to adopting protective behaviors and the risk of dwindling adherence over time.

CONTENTS

ADHERENCE TO PUBLIC HEALTH INTERVENTIONS IN ADULTS

Fifty-eight studies evaluated adults' adherence to protective behaviors recommended by public health (Table 1). Compliance varied across studies, sociodemographic factors, and type of protective measure and was frequently associated with individual knowledge and beliefs.

- Across 24 studies, females were more likely to adhere to preventive measures than males.
- Adults > 30 years old were more likely to be compliant with recommended protective behaviors in 13 studies.
- Other factors positively correlated to adherence include: risk perception (n=7 studies), higher COVID-19 knowledge (n=5), trust in science and government (n=4), increased anxiety levels (n=3), perceived self-efficacy to adopt protective measures (n=3) and Black or Asian ethnicity (n=3).
- Non-adherence was associated with psychological issues such as depression, conspiracy mentality and narcissism (n=5), as well as being a current smoker (n=3).

Table 1. Fifty-eight studies evaluating adherence to public health measures for COVID-19 and associated factors in adults

Reference	Publication Title	Study Details	Key Outcomes
General Adult Population (18+)			
(Qian et al., 2020) *preprint*	Psychological responses, behavioral changes and public perceptions during the early phase of the COVID-19 outbreak in China: A population based cross-sectional survey	• Cross-sectional study (telephone survey conducted Feb 1-10, 2020) • 1,100 residents of Wuhan (n=510) and Shanghai (n=501) aged 18+ • Public health interventions - avoided eating out and taking public transportation, reduced visits to public places, rescheduling travel plans, increasing surface cleaning, maintaining better indoor ventilation, wearing face mask or goggles, hand-washing	• 401 (78.6%) Wuhan participants and 320 (63.9%) Shanghai participants engaged in all 6 recommended and avoidance behaviors • A high compliance rate of above 90% was observed in all other behaviors in both samples, except for increased surface cleaning • Compliance was associated with increased anxiety levels, perceived risks, and confusion about information reliability
(Wong et al., 2020) *preprint*	The role of institutional trust in preventive and treatment-seeking behaviors during the 2019 novel coronavirus	• Cross-sectional study (online survey conducted Jan 29-30, 2020) • 4,245 residents of Hubei province aged 18+	• The uptake of preventive behaviors was high in the study population • Being under quarantine (aOR=2.35, 95% CI: 1.80-3.08) and having high institutional trust score (aOR=2.23, 95% CI: 1.96-2.53)

	(2019-nCoV) outbreak among residents in Hubei, China	• Public health interventions – avoidance of social interaction, physical contact, and public space, personal protection, seeking treatment	were 2 strong significant determinants of higher preventive behavior scores • The age groups 26-35 years (aOR=1.54, 95% CI: 1.29 -1.83) and 36-45 years (aOR=1.22, 95% CI: 1.01-1.48) had significantly higher preventive behavior scores than those > 45
(Kwok et al., 2020)	Community Responses during Early Phase of COVID-19 Epidemic, Hong Kong	• Cross-sectional study (online survey conducted Jan 2020) • 1,715 residents of Hong Kong aged 18+ • Public health interventions – personal hygiene, disinfecting homes, wearing face masks, travel avoidance, social distancing	• Adoption of enhanced personal hygiene and travel avoidance was high (> 77%) and moderate (40-93%) for different types of social-distancing measures • Higher levels of adoption of social-distancing measures were associated with being female (aOR 1.31, 95% CI: 1.06-1.63, p=0.1), living in the New Territories, perceiving oneself as having a good understanding of COVID-19, and being more anxious
(Lep, Babnik, & Beyazoglu, 2020) *preprint*	The role of information credibility in emotional responses and engagement in self-protective behavior within days of the COVID-19 outbreak: A cross-sectional study	• Cross-sectional study (online survey conducted first week of Mar, 2020) • 1,717 residents of Slovenia aged 18+ • Public health interventions – avoiding crowds, frequent hand washing, avoiding touching one's face	• Perceived credibility of information received by medical professionals and scientists was linked with higher knowledge of self-protective behaviors • Knowledge is linked to higher engagement in self-protective behaviors
(Muto, Yamamoto, Nagasu, Tanaka, & Wada, 2020)	Japanese citizens' behavioral changes and preparedness against COVID-19: How effective is Japan's approach to self-restraint	• Cross-sectional study (online survey conducted Mar 26-28, 2020) • 11,342 residents of Japan aged 20+ • Public health interventions – avoiding poorly ventilated closed space, large gatherings, and	• ~ 76% of participants evaluated themselves as having taken some preventative action • Frequent handwashing was conducted by ~86% and proper coughing etiquette by 77%

preprint		conversations or shouting in close proximity, coughing etiquette	• ~20% of participants are reluctant to implement proper prevention measures. Analysis indicates those that do not follow protective behaviors are more likely to be male, younger (< 30 years old), unmarried, are in lower income household, have a drinking or smoking habit, and have a higher extraversion score.
(Shinan-Altman, 2020) *preprint*	COVID-19 precautionary behavior: The Israeli case in the initial stage of the outbreak	• Cross-sectional study (online survey conducted Mar 12-21, 2020) • 1,407 residents of Israel aged 18+ • Public health interventions – hand washing, avoiding contact with those who have symptoms	• The precautionary behavior score was relatively high among participants • Precautionary behavior was higher for females, older participants, participants with higher levels of knowledge about COVID-19, and participants with greater negative emotional reactions
(Moore, Lee, Hancock, Halley, & Linos, 2020) *preprint*	Experience with Social Distancing Early in the COVID-19 Pandemic in the United States: Implications for Public Health Messaging	• Cross-sectional study (online survey conducted Mar 14-23, 2020) • 7,355 residents of USA aged 18+ • Public health interventions – social distancing	• 39.8% reported not being compliant • The youngest group (18-31) had the lowest compliance rate (52.4%) compared to the other age groups (all > 60%; all p values < .01)
(Machida et al., 2020)	Adoption of personal protective measures by ordinary citizens during the COVID-19 outbreak in Japan	• Cross-sectional study (online survey conducted Feb 25-27, 2020) • 2,400 residents of Japan aged 20+ • Public health interventions – hand hygiene, social distancing, avoiding touching the eyes, nose and mouth, respiratory etiquette, and self-isolation	• 34.7% implemented all 5 protective measures • Prevalence of the 5 protective measures ranged from 59.8-83.8%, with the lowest being avoiding touching the eyes, nose, and mouth • Prevalence is significantly higher in women and older adults compared to men and persons < 65 (women OR: 1.57, older adults OR: 1.83, both p < 0.001)

(Williams, Armitage, Tampe, & Dienes, 2020) *preprint*	Public perceptions and experiences of social distancing and social isolation during the COVID-19 pandemic: A UK-based focus group study	• Focus group conducted online between Mar 28-Apr 4, 2020 • 27 residents of UK aged 18+ • Public health interventions – social distancing and social isolation	• All participants reported high adherence to distancing and isolation guidelines but reported seeing or hearing of non-adherence in others
(Canning, Karra, Dayalu, Guo, & Bloom, 2020) *preprint*	The association between age, COVID-19 symptoms, and social distancing behavior in the United States	• Cross-sectional study (online survey, dates conducted not reported) • 4,676 residents of USA aged 18+ • Public health interventions – social distancing	• ~52% of participants reported going out of their home the previous day (not adhering to social distancing) • Those who experienced shortness of breath have fewer close contacts, with an IRR of 0.49 (95% CI: 0.30–0.78). Having other flulike symptoms reduces the odds of going out by 0.32 (95% CI: 0.18–0.60) and the incidence rate of having close contacts by 42% (IRR = 0.58; 95% CI: 0.38–0.88). • Older people are just as likely to leave their homes as younger people, but people > 50 years had less than half the predicted number of close contacts compared to < 30 year olds
(M. Ã. Czeisler et al., 2020) *preprint*	COVID-19: public compliance with and public support for stay-at-home mitigation strategies	• Cross-sectional study (online survey conducted Apr 2-8, 2020) • 4,676 residents of USA (NY, LA) and Australia aged 18+ • Public health interventions – stay-at-home strategies	• 81.8% reported compliance with recommended quarantine or stay-at-home policies • Compliance was high in both highly-affected (US, NY) and minimally-affected regions (AU, LA)
(Pollak, Dayan, Shoham, &	Predictors of adherence to public health	• Cross-sectional study (online survey conducted Mar 28-Apr 10, 2020) • 654 residents of Israel aged 18+	• 28.7% were defined as non-adherents • Non-adherence was associated with male gender (aOR=1.54, CI 1.03– 2.31), not

Berger, 2020) *preprint*	instructions during the COVID-19 pandemic	• Public health interventions – adherence to medical instructions	having children (aOR = 1.73, 1.13–2.65), smoking (aOR = 2.27, CI 1.42–3.62), high levels of ADHD symptoms (aOR = 1.55, CI 1.07–2.25), high levels of past risk-taking behavior (aOR = 1.41, CI 1.10–1.81), current high psychological distress (aOR = 1.51, CI 1.14–2.01), low perceived risk of COVID-19 (aOR = 1.52, CI 1.22–1.89), low exposure to the instructions (aOR = 1.45, CI 1.14–1.82), and low perceived efficacy of the instructions (aOR = 1.47, CI 1.16–1.85)
(Shahnazi, Ahmadi-Livani, & Pahlavanzadeh, 2020) *preprint*	Assessing preventive health nehaviors from COVID-19 based on the health belief model (HBM) among people in Golestan province: a Cross-sectional study in northern Iran	• Cross-sectional study (online survey conducted Mar 11-16, 2020) • 750 residents of Iran aged 18+ • Public health interventions – avoiding crowded places, social distancing, hand washing, stay-at-home, cough/sneeze etiquette, touching face with hands	• Compliance ranged from 96.8% (avoiding crowded places) to 33.5% (not touching face with hands) • The mean score of preventive behavior was higher in women than men, and greater in urban dwellers than rural dwellers • A one unit increase in the standard deviation of factor scores of self-efficacy and perceived benefits increased the scores of preventive behavior by 0.22 and 0.17 units respectively • A one unit increase in the standard deviation of factor score of perceived barriers and fatalistic beliefs decreased the scores of the preventive behavior by 0.36 and 0.19 units respectively
(Lee & You, 2020)	Psychological and behavioral responses in South Korea during the early stages of	• Cross-sectional study (online survey conducted Feb 25-28, 2020) • 973 residents of South Korea aged 18+	• Participants reported always practicing hand hygiene (67.8%), always wearing a facial mask when outside (63.2%), postponing or canceling social events

	Coronavirus Disease 2019 (COVID-19)	• Public health interventions –hand washing, face masks, social distancing behaviors	(50%), avoiding crowded places (41.5%), and reducing the use of public transportation (38.7%) • Practicing precautionary behaviors is strong associated with perceived risk and response efficacy of the behavior • Specific sociodemographic variables for each behavior are provide in the study (for example, gender, education level, perceived severity, and response efficacy were positive and significant individual predictors of wearing a face mask)
(Jackson, Brown, Shahab, Steptoe, & Fancourt, 2020) *preprint*	COVID-19, smoking, and inequalities: a cross-sectional survey of adults in the UK	• Cross-sectional study (online survey conducted Mar 21-Apr 20) • 53,211 residents of the UK aged 18+ • Public health interventions – following recommendations from authorities to prevent the spread of COVID-19	• Adherence to public health interventions was generally high (96.3%, 95% CI: 96.1-96.4%) • Adherence was lower among current than never smokers (OR 0.70, 95% CI: 0.62-0.78) irrespective of education, but the association was stronger among those with post-16 qualifications
(Clements, 2020)	Knowledge and behaviors toward COVID-19 among U.S. residents during the early days of the pandemic: online questionnaire	• Cross-sectional study (online survey conducted on Mar 17, 2020) • 1,070 residents of the USA aged 18+ • Public health interventions – wearing a mask, avoiding large gatherings	• Participants who reported going to gatherings with more than 50 people, or wearing masks outside the home, were less knowledgeable about COVID-19 and younger compared to participants who did not report these activities • Participants with graduate or professional degrees had 67% greater odds of attending large gatherings and 347-641% greater odds of wearing masks outside the home, compared to those with a high school education

			• Democrats had 30% lower odds of attending large gatherings and 44% lower odds of wearing masks outside the home compared to Republicans • Black participants had 148% increased odds of wearing masks outside the home compared to white participants
(Seale et al., 2020)	COVID-19 is rapidly changing: examining public perceptions and behaviors in response to this evolving pandemic	• Cross-sectional study (online survey conducted Mar 18-24, 2020) • 1,420 residents of Australia aged 18+ • Public health interventions – 6 social distancing strategies, self-isolation, hygiene	• 84.9% of respondents reported undertaking ≥ 1 of 3 hygiene-related behaviors and 93.4% performed ≥1 of 6 avoidance-related behaviors • Adopting avoidance behaviors was associated with trust in government (aOR: 5.5, 95% CI: 3-9.0), higher perceived rating of effectiveness of behaviors (aOR: 4.3, 95% CI: 2.8-6.9), and higher levels of perceived ability to adopt social distancing strategies (aOR: 1.8, 95% CI 1.1-3.0)
(Brouard, Vasilopoulos, & Becher, 2020)	Sociodemographic and psychological correlates of compliance with the COVID-19 public health measures in France	• Cross-sectional study (online survey conducted Mar 16-17, 2020) • 1,010 residents of France aged 18+ • Public health interventions –social distancing strategies, hand hygiene, cough/sneeze etiquette, reducing travel, avoiding crowded places	• Results suggest that age is positively associated with complying with protective measures • Women are more likely to have changed their behavior compared to men • Ideological extremity is associated with a reduced adherence to public health recommendations
(Doğan & Bayraktar, 2020)	COVID-19 with a public health perspective: measures taken in Turkey and public compliance with the measures	• Cross-sectional study (survey conducted on Mar 23-27, 2020) • 178 residents of Turkey aged 18+ • Public health interventions –social distancing strategies, hand hygiene	• 97.2% washed their hands with soap and 91.6% avoided contact with people

(Y. Li, Yao, & Luo, 2020) *preprint*	Perceived stress and its impact on health behavior of Chinese residents during the epidemic of COVID-19: an internet survey	• Cross-sectional study (online survey conducted Feb 14-22, 2020) • 2,449 residents of China aged 18+ • Public health interventions –hand hygiene, wearing a mask	• As perceived stress increased, the frequency of health behaviors such as washing hands and wearing a mask decreased in turn
(Perrotta et al., 2020) preprint	Behaviors and attitudes in response to the COVID-19 pandemic: Insights from a cross-national Facebook survey	• Cross-sectional study (online survey conducted Mar 13-Apr 19, 2020) • 71,612 residents Belgium, France, Germany, Italy, Netherlands, Spain, UK, and the USA aged 18+ • Public health interventions – social distancing, hand hygiene, wearing a face mask, reduced travel	• Overall women have a higher likelihood of adopting preventive behaviors compared to men • Wearing a face mask ranges from 7% in the Netherlands to 60% in Italy • Adopting more frequent hand washing ranges from 87% in Germany to 94% in Spain • Apart from the Netherlands and the UK, women and people > 45 years show the highest adoption rates of face masks
(Cutler, Stantcheva, Alsan, & Yang, 2020) preprint	Disparities in COVID-19 reported incidence, knowledge, and behavior	• Cross-sectional study (online survey conducted Mar 29-Apr 13, 2020) • 5,198 residents of the USA aged 18+ • Public health interventions – stay-at-home and hand hygiene	• Men wash their hands 3.8 times less per 24 hours than women ($p < 0.001$) • African-American and Hispanic respondents wash their hands more frequently than white respondents in a 24 hours period ($p=.020$) • Men are more likely to leave the house frequently than are women (0.74 times, $p < 0.001$) as are African Americans compared to white respondents (0.93 times, $p < 0.001$) • Older Americans (65+) are less likely to leave their homes frequently (-0.36 times, $p =0.018$)

(Barber & Kim, 2020)	COVID-19 worries and behavior changes in older and younger men and women	• Cross-sectional study (online survey conducted Mar 23-31, 2020) • 146 younger adults (18-35) and 156 older adults (65-81) in the USA • Public health interventions – stay-at-home, hand hygiene, wearing a mask, social distancing behaviors, self-isolation	• More than 80% of participants reported washing their hands more frequently, taking more care about cleanliness, no longer shaking hands, and avoiding public places. More than 60% of participants also reported social distancing • Compared with other participants, older men endorsed the fewest number of behavior changes • Older women were the most likely to report social distancing and avoiding public places • For all participants, COVID-19 worry was related to the total number of behavior changes made regardless of age or gender
(Ha, Schensul, Lewis, & Brown, 2020) *preprint*	Early assessment of knowledge, attitudes, anxiety and behavioral adaptations of Connecticut residents to COVID-19	• Cross-sectional study (online survey conducted Mar 23-29, 2020) • 464 residents of the USA aged 21+ • Public health interventions – stay-at-home, hand hygiene, wearing a mask, social distancing behaviors, cough/sneeze etiquette, reduced travel	• Compliance ranged from 21.5% and 9.2% of participants wearing sanitary gloves and wearing a mask when going outside respectively to 96.5% avoiding public transportation, and 100% frequently washing hands, avoiding contact with people, and avoiding events and meetings with a large number of people
(Thang et al., 2020) *preprint*	Preventive behavior of Vietnamese people in response to the COVID-19 pandemic	• Cross-sectional study (online survey conducted Mar 31-Apr 6, 2020) • 2,175 residents of Vietnam aged 18+ • Public health interventions – personal (e.g., face masks, social distancing) and community (e.g., avoiding crowded places) preventive measures	• Using a 9 and 11-item score, the mean level of personal adherence to preventive measures was 7.23 ± 1.63 (range: 1-9) and community preventive measures was 9.57 ± 1.12 (range: 0-11), respectively • The least compliance (45.1%) was found for "measuring body temperature at least twice a week" and the highest for wearing a face mask when going outside (99.5%)

			• Worries about one's health, perceived adaptation of the community to the lockdown, residence in large municipalities, official sources of COVID-19 information, and having a professional role in the health sector (worker or student) were associated with higher adherence scores
(Yousef Yang, peng, Yang, & Rockett, 2020) *preprint*	Changing trends of excess self-protective behavior, and association with belief in prevention myths during the COVID-19 epidemic in China: A panel study	• Prospective longitudinal study (online survey) • 116 residents of China aged 20+ over 5 time points (Feb 5/12/19/26 and Mar 4, 2020) • Public health interventions – excess preventive behaviors (EPB) for example disinfecting clothes, excess hand washing, hoarding masks etc.	• Perceived high risk for contracting COVID-19 was positively associated with each type of selected EPB, and perception of disease severity was positively associated with disinfection of clothes and hoarding of products • Belief in the disease prevention myths (facts about disease prevention that are not true) was positively associated with disinfection of clothes and both hand washing and sanitization • Disinfection of clothes was less prevalent among females than males (OR: 0.34), and among professionals than people in other occupational groups (OR: 0.35) • Hand washing was more prevalent among females than males (OR: 3.48) and less prevalent among the married than the never married (OR: 0.43)
(S. Li, Feng, Liao, & Pan, 2020)	Internet use, risk awareness, and demographic characteristics associated with engagement in Preventive Behaviors and	• Cross-sectional study (online survey conducted Apr 10-14, 2020) • 979 residents of the USA aged 18+ • Public health interventions – wearing a face mask, washing hands, cough/sneeze etiquette, social distancing, staying home, avoiding	• Participants who received more COVID-19–related health information online reported more frequent effort to engage in all types of preventive behaviors • Compared with participants who did not have positive cases in their social circles,

	Testing: cross-sectional survey on COVID-19 in the United States	public transportation, and cleaning frequently touched surfaces	those who had immediate family members or close friends and relatives who tested positive were more likely to get tested • Overall, females, older people, married, and employed individuals more frequently engage in most types of preventive behaviors when compared to their counterparts (males, younger people, single, un-employed) • More educated participants less frequently engaged in multiple preventive behaviors • Ethnic differences were also observed in engagement with preventive behaviors. Compared with whites, African Americans and Asians more frequently wore a facemask in public and stayed at home. Americans reported more frequent effort in cleaning frequently touched surfaces than whites
(Wu, Huang, Xie, & Chen, 2020) *preprint*	People behavior changes in China during COVID-19 pandemic	• Cross-sectional study (online survey conducted Apr 26-30, 2020) • 1,048 residents of China • Public health interventions – social distancing, reduce travel, stay-at-home, wear a mask	• Nearly 80% of participants reduced their out-of-home activities (working, eating, shopping, taking public transportation, and travelling) • 92% wear a mask on the street
(Sutin et al., 2020)	Body mass index, weight discrimination, and psychological, behavioral, and interpersonal responses to the Coronavirus pandemic	• Cross-sectional study (online survey conducted mid-Mar, 2020) • 2,094 residents of the USA with different BMI • Public health interventions – preventive behaviors (e.g., hand hygiene)	• Participants who reported weight discrimination were more likely to engage in preventive behaviors • BMI was unrelated to changes in preventive behaviors

(Iorfa et al., 2020) *preprint*	COVID-19 knowledge, risk perceptions and precautionary behavior among Nigerians: A moderated mediation approach	• Cross-sectional study (online survey conducted Mar 28-Apr 4, 2020) • 1,500 residents of Nigeria aged 18+ • Public health interventions –hand hygiene, avoiding crowded places, testing, wearing a mask, cough/sneeze etiquette, avoiding touching surfaces	• Among females and males, being older, having higher COVID-19 knowledge, and higher risk perception was related to higher precautionary behavior • Females engaged in more precautionary behavior than males • Compliance varied among precautionary measures. 19% of participants reported wearing a mask, 54.4% avoided touching surfaces, 56.8% avoided crowded places, and 66.4% self-isolated
(Liu et al., 2020)	Psychological status and behavior changes of the public during the COVID-19 epidemic in China	• Cross-sectional study (online survey conducted Jan 30-Feb 3, 2020) • 608 residents of China aged 18+ • Public health interventions –hand hygiene, avoiding crowded places, wearing a mask, social distancing	• At least 70.9% of respondents took 3 or more preventive measures to avoid infection • 93.3% respondents avoided going to public places, 83.7% wore a mask and 82.4% engaged in hand hygiene • Anxiety did not appear to be related to public behavior change and preventive measures • Fewer respondents with depression or psychological abnormalities took preventive measures compared with those without depression or psychological abnormalities
(Michela & Carlucci, 2020) *preprint*	Demographic and attitudinal factors of adherence to quarantine guidelines during COVID-19: the Italian model	• Cross-sectional study (online survey conducted Mar 21-26, 2020) • 3,672 quarantined adults in Italy aged 18+ • Public health interventions –hand hygiene, social distancing, cough/sneeze etiquette, cleaning surfaces, wearing a mask, avoiding crowded places	• Respondents exhibited medium to high scores of adherence to quarantine guidelines as measured by a single interval index, with a mean of 32.59 (median= 33; SD= 5·22; range scores 0-44) • Females, being employed, risk perception and risk anxiety were associated with

			significantly higher levels of adherence ($p < 0.001$) compared to their counterparts • Healthcare professional adherence mean ($p < 0.001$) was significantly higher compared the unemployed and employed • For age, the 18-29 age group scored statistically significantly lower ($p < 0.001$) compared to other age groups. Equally, the 50-59 age group was statistically significantly higher ($p < 0.001$) in adherence scores compared to 30-39 group
(Park et al., 2020)	Americans' COVID-19 stress, coping, and adherence to CDC guidelines	• Cross-sectional study (online survey conducted Apr 7-9, 2020) • 1,015 residents of the USA aged 18+ • Public health interventions –adherence to CDC guidelines (social distancing, hand hygiene)	• The most consistent predictors of adherence to CDC guidelines were older age, female gender, and financial security (all with small effect sizes) • Overall, adherence to CDC guidelines was fairly high but varied across interventions: 95.10% avoided eating out and large gatherings, 87.2% engaged in social distancing, and 74.68% engaged in cleaning and disinfecting practices
(Plohl & Musil, 2020)	Modeling compliance with COVID-19 prevention guidelines: the critical role of trust in science	• Cross-sectional study (online survey, date conducted not reported) • 525 global participants aged 18+ • Public health interventions –hand hygiene, compliance to guidelines	• Trust in science and COVID-19 risk perception significantly and directly contribute to explaining compliance with COVID-19 prevention guidelines ($R2 = 0.265$)
(Smith et al., 2020) *preprint*	Factors associated with adherence to self-isolation and lockdown measures in the UK; a cross-sectional survey	• Cross-sectional study (online survey conducted May 6-7, 2020) • 2,240 residents of the UK aged 18+ • Public health interventions – self-isolation	• Factors associated with non-adherence to self-isolation measures included being male, less worried about COVID-19, and perceiving a smaller risk of catching COVID-19

			• 9.7% of participants reported that they or someone in their household had symptoms of COVID-19 in the last 7 days. Of these, 75.1% had left the home in the last 24 hours (non-adherent) • Adherence was also associated with having received help from someone outside the household in the last 7 days
(Haupt et al., 2020) *preprint*	Profiles of social distance compliance: psychological and situational predictors of risky behavior during COVID-19	• Cross-sectional study (online survey conducted Apr 30-May 2, 2020) • 483 residents of the US aged 18+ • Public health interventions –compliance with public health guidelines, risky behavior (e.g., attending gatherings of 5+)	• Risky activity was associated with higher extraversion, need for cognitive closure, behavior activation, and perceived resource scarcity • Risky activity was also associated with less empathy and living space access, as well as younger age • 7 different cluster profile types are constructed to explain associations between variance in risky behavior engagement and responder psychological, sociodemographic and situational factors
(Zajenkowski, Jonason, Leniarska, & Kozakiewicz, 2020)	Who complies with the restrictions to reduce the spread of COVID-19?: personality and perceptions of the COVID-19 situation	• Cross-sectional study (survey conducted Apr 14-30, 2020) • 263 residents of Poland aged 18+ • Public health interventions – compliance with public health guidelines	• Responders scoring low on agreeableness and high on aspects of the Dark Triad traits (i.e., Machiavellianism, psychopathy Factor 1, and narcissistic rivalry) were less likely to comply with public health restrictions • COVID-19 perceptions were found to account for individual differences in public health measure compliance
(Banda et al., 2020)	Knowledge and behaviors related to the	• Cross-sectional study (telephone survey conducted Apr 25-May 23, 2020)	• Use of face masks and hand sanitizers was more frequent among urban residing

preprint	COVID-19 pandemic in Malawi	• 630 residents of Malawi aged 18+ • Public health interventions – use of face masks, hand hygiene, avoiding crowds, stay-at-home	respondents (22.5%) than among rural residents (5.0%) • More than 95% of respondents reported washing their hands more frequently, and ~ 50% reported avoiding crowds. Only 1/5 rural residents and 1/4 urban residents reported staying at home
(Galasso et al., 2020) *preprint*	Gender differences in COVID-19 related attitudes and behavior: evidence from a panel survey in eight OECD countries	• Cross-sectional study (online survey conducted Mar 16-30 and Apr 15-20, 2020) • 21,649 respondents from 8 countries (Australia, Austria, France, Germany, Italy, New Zealand, UK, and US) • Public health interventions – social distancing, hand hygiene, cough/sneeze etiquette, avoiding crowded places, stay-at-home, mask and glove use	• Significant gender differences in compliance with public health rules were observed among survey participants • Public health rule compliance was markedly larger among women than among men
(Bonful et al., 2020) *preprint*	Limiting spread of COVID-19 in Ghana: compliance audit of selected transportation stations in the Greater Accra region of Ghana	• Observational study involving audits of handwashing frequency and physical distancing adherence at public transport stations (conducted Mar 27-29, 2020) • 45 sites in Ghana • Public health interventions - availability of hygiene facilities, source and cleanliness of water, number of handwashing facilities, frequency of handwashing, overcrowding at the handwashing points, social distancing, mask use and information on COVID-19 prevention	• The majority (< 80%) of audit sites did not have adequate hand wash sites, frequency of hand washing was low, and facemask use was only observed among a few passengers • Compliance with COVID-19 prevention measures was inadequate in 13 stations, basic in 16 stations, intermediate in 7 stations, and advanced in 9 stations
(M. É. Czeisler et al., 2020)	Public attitudes, behaviors, and beliefs related to COVID-19,	• Cross-sectional study (online survey conducted May 5-12, 2020)	• Of all 3 cohorts, 77.3% of adults reported self-isolating with 84.6% reporting this behavior in NYC and 83.0% in LA

	stay-at-home orders, nonessential business closures, and public health guidance – United States, New York City, and Los Angeles, May 5-12, 2020	• 3 cohorts (US=1,676, NYC=286, and LA=259) all aged 18+ • Public health intervention – self-isolation, face masks, social distancing	• 74.1% nationwide reported always or often wearing a face mask when in public, with NYC reporting 89.6% and LA 89.8% • Compliance varied significantly across respondent demographics and characteristics
(Al-Hanawi et al., 2020)	Knowledge, attitude and practice toward COVID-19 among the public in the Kingdom of Saudi Arabia: a cross-sectional study	• Cross-sectional study (online survey conducted Mar 20-24, 2020) • 3,388 residents of Saudi Arabia aged 18+ • Public health interventions - avoiding large social events and crowded places, avoiding cultural behaviors, such as shaking hands, practicing social distancing, washing hands after sneezing, coughing, nose-blowing	• The mean score for practices for COVID-19 was 4.34 (SD = 0.87, range: 0–5), indicating overall good practices • Age groups 30–39 ($\beta = 0.039$; $p < 0.001$), 40–49 ($\beta = 0.033$; $p < 0.05$), and 50–59 ($\beta = 0.051$; $p < 0.001$) were associated with better practices than the referent group (18-29) • Compared to women, men have worse practices for COVID-19 ($\beta = -0.064$; $p < 0.001$)
(Marinthe, Brown, Delouvée, & Jolley, 2020)	Looking out for myself: exploring the relationship between conspiracy mentality, perceived personal risk, and COVID-19 prevention measures	• 2 cross-sectional studies (study 1 – conducted online Mar 9, 2020; study 2 – conducted online Mar 17-23, 2020) • 762 residents (study 1 and 229 residents (study 2) of France aged 18+ • Public health interventions – Study 1 was conducted when only gatherings of more than 1,000 people were prohibited. Behaviors studied included normative prevention behaviors (kissing someone, shaking hands) and non normative prevention behaviors (talking to people, taking public transportation, going to a restaurant etc.). Study 2 was conducted during the first week	• In study 1, preventative health behaviors were measured on a 9-point scale ranging from 1= much less than before coronavirus crisis and 9=much more than before coronavirus crisis. The mean adoption of normative prevention behaviors was 6.14 (1.49 SD) and non-normative prevention behaviors was 5.3 (0.66 SD) • Study 1 demonstrated that conspiracy believers are more likely to adopt non-normative prevention behaviors, but not normative ones

		of total confinement and measured compliance with the confinement rule	• In study 2, compliance with the confinement rule was measured on a 7-point scale ranging from 1=not all, to 7=very much. The mean confinement compliance was 6.45 (0.82 SD) • Study 2 demonstrated that people with a heighted conspiracy mentality are less inclined to adopt more extreme and legal normative preventative behaviors
(Daoust, 2020)	Elderly people and responses to COVID-19 in 27 countries	• Cross-sectional study (survey started first week of Apr, 2020) • 72,417 respondents across 27 countries aged 18+ • Public health interventions - wore a face mask outside, washed hands, covered nose and mouth when sneezing or coughing, avoided contact with people who have symptoms, avoid going out in general, avoid taking public transport, social distancing, avoid crowded areas, cleaned frequently touched surfaces avoid touching objects in public	• There is no significant effect of age on one's score of compliance with COVID-19 preventive measures • The baseline level of compliance with preventive measures is quite high (score of 12/16)
(Maher, MacCarron, & Quayle, 2020)	Mapping public health responses with attitude networks: the emergence of opinion-based groups in the UK's early COVID-19 response phase	• Longitudinal study (data collected on Mar 9, 16, and 23, 2020) • 235 participants in the UK aged 18+ • Public health interventions – hand washing, avoiding contact with certain people, reducing hand shaking, avoiding touching face	• Participants reported to be 'science-sceptics' reported significantly lower behavioral compliance at (mean = 5.28, SD = 1.46) compared to those considered 'science-trusters' (mean = 5.70, SD = 1.21)
(de la Vega, Ruíz-Barquín, Boros, &	Could attitudes toward COVID-19 in Spain render men more vulnerable than women?	• 2 cross-sectional studies (online surveys, date conducted not reported) • Study 1 (n = 64) was conducted in a shopping centre in Madrid, Spain and Study 2 (n = 640) online among participants aged 18+	• Compliance was rated on an 11-point scale • Women scored higher than men in compliance with safety measures (8.06 vs. 7.46, $p < 0.001$), proper care to wash

Szabo, 2020)		• Public health interventions – compliance with safety measures and keeping at least 1.5 meters away from others in public places and wearing a mask at all times	hands (8.77 vs. 8.25, p < 0.001), keeping 1.5 meters away from others (7.16 vs. 6.56, p=0.003), and using a mask for protection (1.95 vs. 1.82, p=0.591) • Compliance with safety measures was lower in older age groups: 18-25=6.73 (1.89 SD), 26-50=7.92 (1.64 SD), and 51-72=8.08 (1.56)
(Führer et al., 2020)	COVID-19: knowledge, risk perception and strategies for handling the pandemic	• Cross-sectional study (online survey conducted Mar, 2020) • 1,048 participants from Saxony-Anhalt, Berlin and Schleswig Holstein, Germany aged 18+ • Public health interventions – keeping distance from others, restricting contacts in public spaces, restricted private contacts, avoiding travel, stopped driving tram or avoiding cafes, shopping less often, buying supply of groceries, buying supply of disinfectant, buying respirators	• The most common measures were the observance of minimum distances to others (95.6%) and the reduction of personal contacts (93.4%). Only a minority of those surveyed stated that they had inventories of food (38.3%), disinfectants (15.9%) or breathing masks (15.0%) • Among 79% of respondents who said they had taken action, 41% took action at the end of March when quarantine measures were taken in regions of Italy, while another 13% did not take any precautions until the first infections were found in their state. Only 3 respondents (0.4%) said they had already taken action in response to the spreading coverage in China
(Reuben, Danladi, Saleh, & Ejembi, 2020)	Knowledge, attitudes and practices towards COVID-19: an epidemiological survey in north-central Nigeria	• Cross-sectional study (online survey, date conducted not reported) • 589 residents of north-central Nigeria aged 18+ • Public health interventions - practicing social distancing/self-isolation, improved personal hygiene and using face mask	• 92.7% of respondents practiced social distancing/self-isolation, 96.4% improved personal hygiene, and 82.3% using face masks

(Parsons Leigh et al., 2020)	A national cross-sectional survey of public perceptions, knowledge, and behaviors during the COVID-19 pandemic	• Cross-sectional study (online survey conducted Apr 26-May 1, 2020) • 1,996 respondents from Canada aged 18+ • Public health interventions – self isolating and social/physical distancing	• 842 respondents indicated they were in self-isolation (43.4%, 95% CI: 41.2%-45.6%). • Of those who were not self-isolating (n=1,144), the vast majority (n=1,083, 95.1%, 95% CI: 93.8%-96.4%) reported that they practiced physical distancing always (n=783, 68.8%, (95% CI 66.0%-71.5%) or often (n=300, 26.3%, 95% CI 23.7%-28.9%)
(Alper, Bayrak, & Yilmaz, 2020)	Psychological correlates of COVID-19 conspiracy beliefs and preventive measures: evidence from Turkey	• Cross-sectional study (online survey, dates conducted not reported) • 1,088 residents from Turkey, median age=31 • Public health interventions – leaving the house, avoiding physical contact, avoiding touching your face, washing/disinfecting hands after time outside, avoiding sharing same environment with elders, wearing a mask, covering mouth when coughing or sneezing	• There was no conclusive evidence to suggest any meaningful relationship between conspiracy beliefs and COVID-19-related preventive measures • Female participants were significantly more likely to take preventive measures than male participants ($p < 0.001$)
(de Moura Villela, Edlaine Faria, Mendoza Lopez, Sayuri Sato, & et al., 2020) *preprint*	COVID-19 outbreak in Brazil: adherence to national preventive measures and impact on people's lives	• Cross-sectional study (survey conducted Apr 3-9, 2020) • 23,896 residents of Brazil aged 18+ • Public health interventions – hand hygiene, avoiding touching face, disinfecting cell phone, wearing a mask, cough/sneeze etiquette, physical distancing/isolation, measuring temp twice a week, staying home when experiencing symptoms	• 98.7% of respondents practiced regular handwashing and 92.6% reported adhering to the 1.5-2m physical distancing rule, but only 45.5% wore a face mask when going outside • Older age, being female, living alone, being self-employed, living in the Northeast region, having at least an undergraduate degree, being a health care worker, and having comorbidities were all independently associated with higher adherence to national prevention restrictive measures

(Xie, Campbell, & Zhang, 2020)	Working memory capacity predicts individual differences in social-distancing compliance during the COVID-19 pandemic in the United States	• Cross-sectional study (online survey conducted Mar 13-26, 2020) • 397 participants recruited between March 20-22 and 453 participants recruited between March 24-26 from the US aged 18+ • Public health intervention – held no social gathering with friends, cancelled events or plans to go to an event, stopped going to the church or attending other community activity, and had no handshakes, hugs, or kisses when greeting	• Found that working memory capacity significantly predicted individual differences in social-distancing compliance even after taking into account other mood-related covariates • Participants with higher scores in social-distancing compliance also reported leaving home less and washing their hands more • Social-distancing compliance measure was not significantly correlated with education or income levels of the participants, even though female and older participants tended to show more social-distancing compliance
(Hsu, Lin, Wang, & Jhang, 2020)	How to defend covid-19 in Taiwan? Talk about people's disease awareness, attitudes, behaviors and the impact of physical and mental health	• Cross-sectional study (survey conducted Mar 1-Apr 10, 2020) • 2,132 respondents from Taiwan aged 20+ • Public health interventions - adequate or active compliance with the epidemic prevention measures, correct naming of all prevention processes, compliance with public space regulations, wearing of masks, consultation of experts, scholars, or online media for advice, active maintenance of cleanliness at home, medical waste recycling, sharing of prevention knowledge, reminding persons of inappropriate individual behavior, active community cleaning	• Active compliance with prevention measures and wearing of masks, and sharing of prevention knowledge received the highest compliance scores • The lowest compliance scores were noted for personal and community cleaning
(Almutairi, Mustafa, Alessa, Almutairi, &	Public trust and compliance with the precautionary measures against COVID-19	• Cross-sectional study (online survey, dates conducted not reported) • 1,232 residents of Saudi Arabia aged 18+	• 657 (53.3%) respondents were considered to be practicing poor precautionary measures

Almaleh, 2020)	employed by authorities in Saudi Arabia	• Public health interventions – avoiding public gatherings, obeying night time curfew, avoiding handshakes, hand hygiene, avoiding touching eyes, nose, and mouth with hands, covers nose/mouth when sneezing/coughing, avoiding sharing personal items, using facemask, seeking medical care early, maintaining social distancing	• Precautionary measures with the highest compliance included: "obeys night time curfew" with 98.3%, "avoids public gatherings" with 91.7%, "maintains social distancing during the COVID-19 outbreak" with 89.3% • Precautionary measures with the lowest compliance included: "uses a facemask in public" with 54%, followed by "avoids touching eyes, nose, and mouth with hands" with 37.9%, and "covers nose/mouth when sneezing or coughing with a tissue" with 25.3%
General Population (All Ages)			
(Olapegba & Ayandele, 2020)	Survey data of COVID-19 related knowledge, risk perceptions and precautionary behavior among Nigerians	• Cross-sectional study (online survey conducted Mar 28-Apr 4, 2020) • 1,357 residents of Nigeria aged 15+ • Public health interventions – hand hygiene, wearing a mask, avoiding crowded places	• The majority of participants engaged in protective behaviors such as avoiding crowded places (79%), use hand sanitizer (71.19%), and avoid touching door handles and stair case railings in public spaces (75.76%)
(Shabu, Amen, & Mahmood, 2020) *preprint*	Risk perception and behavioral response to COVID-19 in Iraqi Kurdistan Region	• Cross-sectional study (online survey conducted Mar 20-26, 2020) • 976 teaching faculty and students aged 17+ • Public health interventions – avoiding sneezing/couching, touching face, nose, and eyes, avoiding large gatherings, public places, and traveling to the affected areas, staying at home, using alcohol-based disinfectants, curfew, and wearing mask/gloves	• The percent of the respondents who applied public health measures frequently or always was high for most of the behaviors, except for wearing masks and gloves, and avoiding touching face • There was a significant ($p < 0.001$) weak positive correlation between risk perception with protective behaviors
(Arp et al., 2020) *preprint*	Use of face coverings in public during the COVID-	• Cross-sectional study (direct observations conducted May 16-Jun 1, 2020)	• Females and older adults had higher odds of using face coverings

	19 pandemic: an observational study	• 3,271 residents of WI, USA across all ages (minors, young adults, adults, older adults) • Public health intervention – face mask use in a grocery store	• Shopping at high price index grocery stores was also associated with mask use • Face coverings were used by 41% of the study sample
(Stanislau Affonso de Araújo, Evaldo et al., 2020) *preprint*	Teach, and teach and teach: does the average citizen use masks correctly during daily activities? Results from an observational study with more than 12,000 participants	• Observational study (direct observations conducted Jun 17-19, 2020) • 12,588 people observed in 5 Brazilian cities (no age restriction) • Public health interventions – face mask compliance	• 45.1% of the observed population wore face masks in a correct way with a city by city range of 39.1% to 63.5% • 15.5% (12.7-18.8%) did not use masks at all • 12.9% wore masks but exposed their mouth and nose (9.9-17.6%), 12.0% exposed their nose only (7.9-16.6%), 17.8% touched their mask during use (0.0%-4.0%), and 6.5% wore poorly fitted masks (1.2%-10.7%)

ADHERENCE TO PUBLIC HEALTH INTERVENTIONS IN YOUNG ADULTS AND UNIVERSITY/MEDICAL STUDENTS

Compliance to public health interventions to control COVID-19 was high across six studies specific to young adults (aged 16-29) and university/medical students (Table 2).

- Females were more likely to engage in preventive behaviors compared to men.
- Other factors positively associated with adherence to public health interventions include access to COVID-19 related information, self-control and level of anxiety.
- Self-reported preventative behaviors were negatively correlated with risk perception and being psychologically distressed.
- Among university students, one study found that non-medical students exercised higher compliance with social restrictions while medical students practiced better hand hygiene.

Table 2. Six studies evaluating adherence to public health measures for COVID-19 in young adults and university and medical students

Reference	Publication Title	Study Details	Key Outcomes
Young Adults			
(Imtiaz, Hossain, & Khan, 2020) *preprint*	COVID-19 in Bangladesh: measuring differences in individual precautionary behaviors among young adults	• Cross-sectional study (details of survey not reported) • 350 young adults of Bangladesh aged 16-29 • Public health interventions –precautionary behavior	• The mean precautionary score was highest (26.2) for the people who had completed their postgraduate education compared to those with high school education (24.7) • Psychologically distressed people had lower mean (23.6) precautionary scores than those who were not distressed (mean=25.1), p=0.019 • Females (25.3) had higher precautionary scores than males (23.8), p=0.007 • The self-control score was found to have a significant positive association with the precautionary score
University/Medical Students			
(Taghrir, Borazjani, & Shiraly, 2020)	COVID-19 and Iranian medical students; a survey on their related-knowledge, preventive behaviors and risk perception	• Cross-sectional study (online survey conducted Feb 26-28, 2020) • 240 medical students from Iran, mean age 23.67 • Public health interventions – reducing use of public spaces, cough etiquette, hand washing, disinfecting surfaces, talking with others about preventive behaviors	• 94.2% of participants had high performance in preventive behaviors • Self-reported preventive behaviors and risk perception had a significantly negative correlation. ($r_s = -0.128$; $P < 0.05$) • As preventive behaviors increase, risk perception declines
(Yang, Bin, & He, 2020)	Opinions from the epicenter: an online survey of university students in Wuhan amidst the COVID-19 outbreak	• Cross-sectional study (online survey conducted Jan 28-30, 2020) • 8,252 university students from Wuhan, China • Public health interventions – hand hygiene, wearing a face mask, reducing outdoor activities	• There was positive behavioral compliance among the respondents. Close to 90% of participants would wear a surgical mask when going out, more than two thirds had increased the practice of hand hygiene, and almost all reduced outdoor activities

			• Those with stronger anxiety and fear tended to adopt more stringent practices of mask-wearing and hand hygiene, as a natural behavioral reaction to perceived risks
(Saddik et al., 2020) *preprint*	Increased levels of anxiety among medical and non-medical university students during the COVID-19 pandemic in the United Arab Emirates	• Cross-sectional study (online survey conducted Mar 11-21, 2020) • 1,385 medical (dental and medical) students and non-medical students from the United Arab Emirates • Public health interventions – hygienic behavior, social restrictions	• Compliance was high overall and ranged from 58% wearing gloves and masks, 77% decreasing visits to crowded places, and 85% increasing hand hygiene • Non-medical students exercised higher compliance with social restrictions while medical students practiced better hand hygiene
(Lincango-Naranjo et al., 2020) *preprint*	Paradigms about the COVID-19 pandemic: knowledge, attitudes and practices from medical students	• Cross-sectional study (online survey conducted Apr 6-20, 2020) • 309 medical students from Ecuador • Public health interventions – hand hygiene	• The majority of participants (99%) reported washing hands frequently
(Hamza, Badary, & Elmazar, 2020)	Cross-sectional study on awareness and knowledge of COVID-19 among senior pharmacy students	• Cross-sectional study (online survey conducted Apr 28-30, 2020) • 238 senior pharmacy students in Egypt • Public health interventions - avoidance of public places, masking in public, maintaining social distancing	• Females were more likely to avoid going out in crowded places and maintain social distance than males • Significant associations were noted between public masking and access of COVID-19 related information from television, as well as maintaining a 2 meter social distance and utilizing physicians' advice on COVID-19

ADHERENCE TO PUBLIC HEALTH INTERVENTIONS IN CHILDREN AND ADOLESCENTS

The adherence to protective behaviors in children and adolescents was evaluated in four studies (Table 3). Of these studies, three studies from China (n=2) and Norway (N=1) showed moderate to high compliance rates and one from India showed low compliance rates.

- Female gender was significantly associated with better hand hygiene and overall compliance with the public health interventions.
- Other factors correlated with improved adherence include father's occupation, mother's educational background, location of residence, and those with an immigrant background.
- One study found that the compliance to preventive behaviors of primary school students was generally superior to that of students in high school (Wen et al., 2020).

Table 3. Four studies evaluating adherence to public health measures for COVID-19 and associated factors in children and adolescents

Reference	Publication Title	Study Details	Key Outcomes
Children and Adolescents			
(Chen et al., 2020)	Hand hygiene, mask-wearing behaviors and its associated factors during the COVID-19 epidemic: a cross-sectional study among primary school students in Wuhan, China	• Cross-sectional study (online survey conducted Feb 16-25, 2020) • 8,569 primary school children from Wuhan, China aged 6-13 • Public health interventions – wearing face masks, hand hygiene	• 42.05% and 51.60% of the primary school students showed good hand-washing and mask-wearing behaviors, respectively • Gender (female), grade (3-6), out-going history, father's occupation, and the time filling out the survey were significantly associated with hand hygiene • Grade (5-6), mother's educational background, and residence were associated with mask-wearing
(Saurabh & Ranjan, 2020)	Compliance and psychological impact of quarantine in children and adolescents due to COVID-19 pandemic	• Cross-sectional study (interviews of parents and children, dates conducted not reported) • 121 children and adolescents in India aged 9-18 • Public health interventions – household (e.g., use separate towels) and community (social distancing) preventive measures	• Compliance with quarantine behavior varied from 25.61% (slept in a separate room by themselves) to 83.47% (did not run errands) • Overall compliance to all the behaviors was 7.43%. Compliance with all the household and community protective measures was 10.71% and 17.35%, respectively • The most difficult activity to comply with was not going out of the house to socialize (65.26%)
(Wen et al., 2020)	Knowledge, attitudes, and practices towards	• Cross-sectional study (online survey conducted Mar 2-13, 2020)	• The compliance rates for students were as follows: Reducing unnecessary outings

preprint	COVID-19 among primary and middle school students during the COVID-19 outbreak period in Beijing: an online cross-sectional survey	• 7,377 students in Beijing aged 9-18 • Public health interventions – Reducing unnecessary outings, wearing a mask outside, washing hands frequently, eating a healthy diet, avoiding public transportation, taking hygienic breathing, cleaning and disinfecting regularly, not touching face before disinfecting, taking action when symptoms occur, having rational and effective ventilation, dining separately	(97.1%), wearing a mask outside (92.5%), washing hands frequently (91.3%), eating a healthy diet (86.5%), avoiding public transportation (85.8%), taking hygienic breathing (85.4%), cleaning and disinfecting regularly (78.6%), not touching face before disinfecting (78.3%), taking action when symptoms occur (57.8%), having rational and effective ventilation (39.2%), dining separately (38.6%) • The compliance to effective preventive behaviors of primary school students was generally superior to that of students in high school
(Soest et al., 2020)	Compliance with infection control rules among adolescents in Oslo during the COVID-19 pandemic	• Cross-sectional study (survey conducted Apr 23-May 8, 2020) • 12,686 'youth' in Oslo, Norway • Public health interventions – hand washing, shaking hands, avoiding larger groups, social distancing	• The majority reported following the rules on hand washing (n = 9,915, 84%), not shaking hands/hugging (n = 8,730, 74%) and avoiding larger groups (n = 8,565, 73%). Fewer said they kept a good distance (1-2 meters) from others (n = 5,859, 50%) • The highest support for the rules was seen among girls, young people with an immigrant background, those who live in outer Oslo east

ADHERENCE TO PUBLIC HEALTH INTERVENTIONS IN HEALTHCARE WORKERS (HCWS)

Seven studies evaluated adherence to infection prevention and control protective behaviors against COVID-19 in HCWs (Table 4). Overall adherence varied across studies, healthcare settings, and by the specific behavior.

- The proportion of HCWs that engaged in hand hygiene measures ranged from 79.44% in a group of HCWs from China to 98.2% in a group of frontline doctors from Jordan.

- Two studies demonstrate that being a nurse (vs. doctor, nursing and medical staff, medical and clinical officers) was significantly associated with self-reported compliance to infection control measures. Among these HCW studies, there were conflicting results on gender as a predictor of self-reported compliance.

Table 4. Seven studies evaluating adherence to public health measures for COVID-19 and associated factors in HCWs

Reference	Publication Title	Study Details	Key Outcomes
Healthcare Workers (HCWs)			
(Suleiman et al., 2020)	Preparedness of frontline doctors in Jordan healthcare facilities to COVID-19 outbreak	• Cross-sectional study (online survey conducted Mar 23-27, 2020) • 308 frontline doctors in Jordan, mean age 30.3 ± 5.8 • Public health interventions – adherence to the PPE (Personal Protective Equipment) guidelines	• The adherence scores of these doctors were 8.4 ± 1.5 out of 10 • For example, 88% wash their scrubs, 98.1% wash their hands before seeing a patient, 93.8% avoid high fives and hand shakes, and 91.6% leave their shoes at work our outside the home
(Tamari et al., 2020)	Nationwide survey of COVID-19 prevention measures in Japanese radiotherapy departments via online questionnaire for radiation oncologists	• Cross-sectional study (online survey conducted Apr 16-23, 2020) • 184 radiation oncologists in Japan • Public health interventions – hand hygiene, use of masks/PPE, social distancing	• The majority of the respondents (81.0%) indicated that they had taken some infection control measures • There were differences in compliance between departments • 8.1% of the respondents reported that they used PPE in their radiotherapy practice and 63% engaged in proper social distanced with patients • 96.2% of participants who had direct contact with patients wore masks, and 85.3% who had no direct contact with patients wore masks
(Chatterjee et al., 2020)	Attitude, practice, behavior, and mental health impact of COVID-19 on doctors	• Cross-sectional study (online survey conducted Mar 28-Apr 6, 2020) • 152 doctors in West Bengal, India • Public health interventions – hand hygiene, use of masks/PPE	• The majority of doctors are using a surgical mask (58.6%) but only a few are using N95 masks (19.7%) • 95.4% report they are practicing regular hand hygiene but also report they mostly

			washing their hands on an as-required basis (42.8%) • Only 24.3% have access to PPE and 11.2% are actually using it
(Lai et al., 2020)	Will healthcare workers improve infection prevention and control behaviors as COVID-19 risk emerges and increases, in China?	• Cross-sectional study (survey conducted Jan 15-17, 2020) • 1,581 HCWs in China (n=1581) • Public health interventions – hand hygiene, PPE, terminal cleaning	• Overall, higher education degree, longer work years, female gender (vs. male) had significantly negative effect on the self-reported infection control compliance • Being a nurse (vs. doctors) had significant positive effects on self-reported compliance to infection control measures • Working in high risk departments were associated with increased compliance, while exposure to confirmed or suspected patients reduced infection control compliance
(Zhou, Lai, Zhang, & Tan, 2020)	Compliance measurement and observed influencing factors of hand hygiene based on COVID-19 guidelines in China	• Cross-sectional study (direct observations conducted Mar 5-7, 2020) • HCWs workers from Tongji Hospital and 17 medical groups from other provinces in China • Public health interventions – hand hygiene at 17 moments (e.g., before touching a patient, before aseptic procedure, after using toilet, etc.)	• The overall compliance for 17 moments of hand hygiene was 79.44% • The highest overall compliance was for the moment before wearing gloves (91.67%), and the lowest was the moment after touching patient surroundings (65.56%) • The overall compliance was 85% in the intensive care department, 79.18% in the non-intensive care department; 76.07% in contaminated area, 84.38% in semi contaminated area, and 84.21% in hygienic area
(Martín et al., 2020)	Prevalence of SARS-CoV-2 infection in general practitioners and nurses in primary	• Cross-sectional study (study conducted during first 2 weeks of Apr, 2020)	• The degree of compliance with preventive measures were recorded using a Likert scale of 0-10, with 0 being the lowest

	care and nursing homes in the healthcare area of León and associated factors	• 676 nurses and doctors from primary care centers and nursing homes in the Healthcare Area of León (Spain) • Public health interventions – general compliance with preventative measures	degree of exposure or compliance and 10 the highest • 31% reported high compliance with preventive measures (10 points on the survey)
(Contejean et al., 2020)	Comparing dynamics and determinants of SARS-CoV-2 transmissions among health care workers of adult and pediatric settings in central Paris	• Prospective study conducted Feb 24-Apr 10, 2020 • 336 healthcare workers in Paris, France • Public health interventions – wearing proper PPE, wearing a mask properly, avoiding public transportation, wearing a mask outside home	• The majority of workers recalled a contact without PPE with an index case. PPE was more frequently used in adult settings (56/227) vs. children settings (16/109) • Most employees declared wearing a mask always/most of the time at hospital, but 65/336 (19%) admitted removing masks during breaks in the presence of other colleagues (204/336, 61% during lunch breaks). More than half (201/336, 60%) reported using public transportation, including 112/201 (56%) over one hour per day, but less than 25% (82/334) wore mask outside home

ADHERENCE TO PUBLIC HEALTH INTERVENTIONS IN OTHER POPULATIONS

Five studies on adherence to public health measures aimed to control COVID-19 were identified in four other populations, Table 5. These other populations include pregnant women, employees, visitors to hospitals, and migrants.

Table 5. Five studies on adherence to public health measures for COVID-19 in other populations

Reference	Publication Title	Study Details	Key Outcomes
Pregnant Women			
(Yassa et al., 2020)	Near-term pregnant women's attitude toward, concern about	• Cross-sectional study (details of survey not reported) • 172 pregnant women in Turkey • Public health interventions – self quarantine	• The majority of the women (87.2%) complied with self-quarantine rules

	and knowledge of the COVID-19 pandemic		
Visitors to Hospitals			
(Gunasekaran et al., 2020) *preprint*	Prevalence and acceptance of glove wearing practice among general population when visiting high risk are during local COVID-19 outbreak	• Cross-sectional study (dates not reported) • 40 individuals entering hospitals and 30 entering wet markets in Malaysia • Public health interventions – wearing gloves and face masks	• More individuals visiting wet market (30.0%) were observed with unacceptable glove practice compared to individuals visiting the hospital (8.9%), $\chi 2$ (1) = 5.60, p=0.018 • Men were using more medical grade glove (78.8%) compared to non-medical grade glove (21.2%) while an equal amount of medical (50.0%) and non-medical grade glove (50.0%) was used among female, $\chi 2$ (1) = 6.546, p=0.011 • Glove use was higher among non-Malay (53.3%) compared to Malay (46.7%) in the hospital and glove use was higher among Malay compared to non-Malay (16.7%) visiting wet market, $\chi 2$ (1) = 10.20, p=0.001
(Sahiledengle et al., 2020) *preprint*	Hand washing compliance and COVID-19: a non-participatory observational study among hospital visitors	• Cross-sectional study (direct observations conducted Apr 27-May 3, 2020) • 1,282 individuals entering hospitals in Ethiopia • Public health interventions – hand hygiene	• Only 0.9% (95% CI: 0.4-1.4) of the participants were fully compliant with the recommended hand washing techniques • Most of the participants (47.2%, 95% CI: 44.4-49.9) had minimal compliance and 20.1% (95% CI: 17.8-22.3) were not compliant • There was no difference in the compliances between genders (0.9% vs 0.7%, P = 0.745)
Migrants			
(Mannan & Farhana, 2020)	The COVID-19 pandemic: challenges and reality of	• Cross-sectional study (survey conducted Feb 1-Mar 31, 2020)	• Only 2.74% were officially in quarantine for 14 days. Only 1.98% complied with the 14 days of personal isolation under the Health

preprint	quarantine, isolation and social distancing for the returnee migrants in Bangladesh	• 3,281 returnee migrants from 8 administrative divisions of Bangladesh aged 18+ • Public health interventions – quarantine, isolation, and social distancing for 14 days	Care Rules and only 3.38% were adhered to 14 days of social distancing • In addition to the 14 days of the health warning rule, there is also reluctance to comply with the social distance rule during the epidemic (only 5.05% compliance)
Employees			
(Wang, Yi Wong, & Ho, 2020) *preprint*	Availability of workplace policy for prevention of coronavirus disease 2019 and its relationship with personal protective behaviors: a survey of employees	• Cross-sectional study • 1,048 employees from Hong Kong • Public health interventions – hand hygiene, wearing a face mask, social distancing, household hygiene	• Compliance varied across protective measures (e.g., 77.1% reported always washing hands before meals and 51.2% reported they always avoided leaving their home) • Personal protection behaviors differed between socio-demographic subgroups in terms of age, gender, living arrangement, marital status, educational level and work status • Employees with available workplace guidelines and measures performed personal protection behaviors with higher frequency, and this association was more significant among managers/administrators and manual labourers

SYNTHESIS RESEARCH ON ADHERENCE TO PUBLIC HEALTH INTERVENTIONS

Three reviews on adherence to public health measures aimed to control infectious diseases were identified, Table 6. These reviews did not contain any specific evidence on COVID-19.

Table 6. Three reviews on adherence to public health measures for infectious diseases

Reviews			

(Webster et al., 2020)	How to improve adherence with quarantine: rapid review of the evidence	• Rapid evidence review • Search included evidence up until Jan 27, 2020 • AMSTAR: moderate quality • 14 articles included in the review • No articles specific to SARS-CoV-2	• Adherence to quarantine ranged from 0-92.8%. • Main factors associated with adherence were the knowledge people had about the disease and quarantine procedure, social norms, perceived benefits of quarantine and perceived risk of the disease
(Houghton et al., 2020)	Barriers and facilitators to healthcare workers' adherence with infection prevention and control (IPC) guidelines for respiratory infectious diseases: a rapid qualitative evidence synthesis	• Rapid qualitative evidence synthesis • Search included evidence up until Mar 26, 2020 • AMSTAR: good quality • 20 articles included in the review	• Several factors influence HCWs ability and willingness to adhere to IPC guidelines including the guideline content and how it is communicated, support from managers, workplace culture, training, physical space, access to and trust in PPE, and a desire to deliver good patient care
(Brooks, Greenberg, Wessely, & Rubin, 2020) *preprint*	Factors affecting healthcare workers' compliance with social and behavioral infection control measures during emerging infectious disease outbreaks: Rapid evidence review	• Rapid evidence review • Search included evidence up until May 4, 2020 • AMSTAR: moderate quality • 56 articles include in the review	• Staff working in emergency or ICU settings appeared more likely to comply with recommendations than those in other settings • Staff with higher levels of anxiety and higher concern about the risk of infection were more likely to comply • Negative associations were also found to hinder compliance such as observed non-compliance of colleagues, availability of PPE, perceived difficultly and effectiveness, inconvenience, and discomfort

Methods

All of the literature on COVID-19 has been compiled and organized by the Emerging Science Group of the Public Health Agency of Canada since the beginning of the outbreak. This involves a daily scan of the literature for all published and pre-published articles. Searches to retrieve relevant COVID-19 literature are conducted in PubMed, Scopus, BioRxiv, MedRxiv, ArXiv, SSRN, and Research Square. These are cross-referenced with the literature on the World Health Organization COVID literature list, and COVID-19 information centers run by Lancet, BMJ, Elsevier, and Wiley. The daily summary and full scan results are maintained in a RefWorks database and a searchable Excel file. Each article is tagged using various foci to identify the focus of the article (e.g., epidemiology, clinical data, therapeutics etc.). Targeted keyword searching is conducted within these databases to identify relevant citations on COVID-19 and SARS-COV-2. The search terms included in this review were compliance, adherence, and behavior. Each potentially relevant reference was analyzed to confirm its relevance and data was extracted into the review. This review contains research published up until July 19, 2020.

Nouveaux éléments de preuve sur la COVID-19

Note d'information sur les déterminants de l'adhésion individuelle aux interventions de santé publique pour la COVID-19

Introduction

Quelles sont les données probantes relatives aux déterminants de l'adhésion individuelle aux interventions de santé publique visant à prévenir la COVID-19?

L'adhésion d'une personne à des interventions de santé publique telles que la distanciation sociale, le port de masques faciaux et le lavage des mains, joue un rôle important dans l'efficacité de ces interventions pour contrôler l'épidémie. Cette note d'information recense et résume la littérature publiée avant le 19 juillet 2020 sur les déterminants de l'adhésion individuelle aux interventions de santé publique pour la COVID-19, afin de mieux comprendre les facteurs et les obstacles à l'adoption des comportements de protection recommandés.

Points clés

- Au nombre de 80, les études menées dans de nombreux pays ont évalué l'adhésion individuelle aux mesures de protection contre l'infection par la COVID-19 dans diverses populations, notamment chez les adultes, les jeunes adultes, les étudiants universitaires, les enfants et les adolescents, les travailleurs de la santé, les femmes enceintes ainsi que les employés et les visiteurs des hôpitaux (tableaux 1 à 5).
- La plupart de ces études ont été menées dans les premières phases de l'épidémie et représentent l'adoption initiale de comportements protecteurs. De nombreuses études (n=28) font état d'un meilleur respect des règles par les femmes par rapport aux hommes dans tous les groupes d'âge. Peu d'études ont été menées sur les enfants et les adolescents, mais bon nombre d'entre elles ont constaté un taux de conformité élevé dans ces groupes d'âge, avec un taux de conformité plus faible chez les enfants en âge de fréquenter l'école secondaire.
- La conformité varie selon les études, les facteurs sociodémographiques et le type de mesure de protection, et elle est souvent associée aux connaissances et aux croyances individuelles.
- Treize études ont révélé que les adultes de plus de 30 ans étaient plus susceptibles de respecter les comportements de protection recommandés. D'autres facteurs sont positivement corrélés à l'observance chez les adultes, notamment : la perception du risque (n=7 études), une meilleure connaissance de la COVID-19 (n=5), la confiance dans la science et le gouvernement (n=4), des niveaux d'anxiété accrus (n=3), la perception de l'auto-efficacité à adopter des mesures de protection (n=3) et l'origine ethnique noire ou asiatique (n=3).

- L'inobservance des adultes était associée à des problèmes psychologiques tels que la dépression, la mentalité de conspiration et le narcissisme (n=5), ainsi qu'au fait d'être un fumeur actuel (n=3).
- Chez les enfants et les adolescents, les facteurs corrélés à une meilleure observance comprennent la profession du père, le niveau d'éducation de la mère, le lieu de résidence et les personnes issues de l'immigration (Chen et coll., 2020; Soest, Pedersen, Bakken et Sletten, 2020).
- Trois synthèses rapides ont été recensées. Elles comprennent des documents publiés avant la pandémie qui portent sur le respect des mesures de quarantaine et les comportements préventifs individuels adoptés par les travailleurs de la santé (tableau 6).

Vue d'ensemble des éléments de preuve

Au total, 80 publications relatives à l'adoption de comportements individuels de protection recommandés par la santé publique pour lutter contre l'épidémie de COVID-19 et aux obstacles et éléments facilitants associés à ces comportements. Trois examens rapides sur l'adhésion et les facteurs qui influencent l'adhésion aux interventions de santé publique pour contrôler les maladies infectieuses ont également été inclus, mais ces examens ne comprenaient que des études publiées avant la pandémie. Sur les 83 publications incluses, 39 prétirages ont été recensés; ces articles n'ont pas été soumis au processus d'examen par les pairs. Les publications faisant état de l'adhésion aux interventions de santé publique sont toutes des études d'observation qui présentent un risque modéré/élevé de biais et sont donc considérées comme de qualité moyenne/faible. La majorité de ces études se fondent sur le modèle transversal et les résultats sont pour la plupart autodéclarés; les réponses peuvent donc être faussées par des biais de rappel, de réponse et de désirabilité sociale. Bien que de nombreuses études montrent des tendances similaires, les conclusions pourraient changer dans le cadre de recherches supplémentaires.

Les études qui évaluent l'observance au fil du temps constituent une lacune importante sur le plan des connaissances dans cette recherche. La plupart des recherches recensées ont été menées dans les premiers stades de l'épidémie et ne fournissent qu'un échantillon représentatif de l'adoption ou non des comportements recommandés par la santé publique. Dans de nombreuses juridictions, cette situation a évolué au fil du temps; les messages d'intérêt public et les règles ont changé avec la levée des différentes mesures ou le renforcement de celles-ci. Des études qui explorent longitudinalement les obstacles et les éléments qui facilitent l'adoption à long terme de comportements de protection sont nécessaires pour que l'on puisse se pencher à la fois sur les personnes qui résistent à l'adoption de comportements de protection et sur le risque de diminution de l'adhésion au fil du temps.

CONTENU

L'ADHÉSION AUX INTERVENTIONS DE SANTÉ PUBLIQUE CHEZ LES ADULTES

Cinquante-huit études ont évalué l'adoption par les adultes de comportements de protection recommandés par la santé publique (tableau 1). Le respect des mesures varie selon les études, les facteurs sociodémographiques et le type de mesure de protection, et il est souvent associé aux connaissances et aux croyances individuelles.

- Dans 24 études, les femmes étaient plus susceptibles que les hommes d'adhérer à des mesures préventives.
- Treize études ont révélé que les adultes de plus de 30 ans étaient plus susceptibles de respecter les comportements de protection recommandés.
- D'autres facteurs sont positivement corrélés à l'observance, notamment : la perception du risque (n=7 études), une meilleure connaissance de la COVID-19 (n=5), la confiance dans la science et le gouvernement (n=4), des niveaux d'anxiété accrus (n=3), la perception de l'auto-efficacité à adopter des mesures de protection (n=3) et l'origine ethnique noire ou asiatique (n=3).
- L'inobservance était associée à des problèmes psychologiques tels que la dépression, la mentalité de conspiration et le narcissisme (n=5), ainsi qu'au fait d'être un fumeur actuel (n=3).

Tableau 1. Cinquante-huit études évaluant l'adhésion aux mesures de santé publique pour lutter contre la COVID-19 et les facteurs associés chez les adultes

Référence	Titre de la publication	Description de l'étude	Principaux résultats
Population adulte générale (18+)			
(Qian et coll., 2020) *Préimpression*	Psychological responses, behavioral changes and public perceptions during the early phase of the COVID-19 outbreak in China: A population based cross-sectional survey	• Étude transversale (enquête téléphonique réalisée du 1er au 10 février 2020) • 1 100 résidents de Wuhan (n=510) et de Shanghai (n=501) âgés de 18 ans et plus • Interventions de santé publique – éviter de manger au restaurant et de prendre les transports en commun, réduire les visites dans les lieux publics, reprogrammer les plans de voyage, nettoyer plus souvent les surfaces, maintenir une meilleure ventilation intérieure, porter un masque facial ou des lunettes de protection, se laver les mains	• 401 (78,6 %) participants de Wuhan et 320 (63,9 %) participants de Shanghai ont adopté les 6 comportements recommandés et se sont abstenus d'avoir les comportements à éviter • Un taux de conformité élevé, supérieur à 90 %, a été observé pour tous les autres comportements dans les deux échantillons, à l'exception du nettoyage plus fréquent des surfaces • La conformité était associée à des niveaux d'anxiété accrus, à des risques perçus et à une confusion quant à la fiabilité de l'information
(Wong et coll., 2020) *Préimpression*	The role of institutional trust in preventive and treatment-seeking behaviors during the 2019 novel coronavirus (2019-nCoV) outbreak among residents in Hubei, China	• Étude transversale (enquête en ligne réalisée les 29 et 30 janvier 2020) • 4 245 résidents de la province d'Hubei âgés de 18 ans et plus • Interventions de santé publique – éviter l'interaction sociale, les contacts physiques et l'espace public; prévoir une protection personnelle; rechercher un traitement	• L'adoption de comportements préventifs était élevée dans la population étudiée • Le fait d'être en quarantaine (RCC=2,35; 95 % IC : 1,80 à 3,08) et le fait d'avoir un score élevé de confiance institutionnelle (RCC=2,23; 95 % IC : 1,96 à 2,53) ont été deux déterminants importants de l'augmentation des scores de comportement préventif • Les groupes d'âge de 26 à 35 ans (RCC=1,54; 95 % IC : 1,29 à 1,83) et de 36 à 45 ans (RCC=1,22; 95 % IC : 1,01 à 1,48) ont obtenu des scores de comportement préventif significativement plus élevés que ceux de plus de 45 ans

(Kwok et coll., 2020)	Community Responses during Early Phase of COVID-19 Epidemic, Hong Kong	• Étude transversale (enquête en ligne réalisée en janvier 2020) • 1 715 résidents de Hong Kong âgés de 18 ans et plus • Interventions de santé publique – avoir une bonne hygiène personnelle, désinfecter les habitations, porter un masque facial, éviter les voyages, pratiquer la distanciation sociale	• L'adoption d'une meilleure hygiène personnelle et l'évitement des voyages présentaient un pourcentage élevé (plus de 77 %) et modéré (40 à 93 %) pour différents types de mesures de distanciation sociale • Les niveaux d'adoption de mesures de distanciation sociale étaient plus élevés chez les femmes (RCC 1,31; IC 95 % : 1,06 à 1,63, p=0,1), chez les personnes vivant dans les Nouveaux Territoires, chez les personnes se percevant comme ayant une bonne compréhension de la COVID-19, et chez les personnes étant plus anxieuses
(Lep, Babnik et Beyazoglu, 2020) *Préimpression*	The role of information credibility in emotional responses and engagement in self-protective behavior within days of the COVID-19 outbreak: A cross-sectional study	• Étude transversale (enquête en ligne réalisée la première semaine de mars 2020) • 1 717 résidents de Slovénie âgés de 18 ans et plus • Interventions de santé publique – éviter les foules, se laver fréquemment les mains, éviter de se toucher le visage	• La crédibilité perçue des informations reçues par les professionnels de la santé et les scientifiques était liée à une meilleure connaissance des comportements d'autoprotection • La connaissance est liée à un engagement plus important à l'égard des comportements d'autoprotection
(Muto, Yamamoto, Nagasu, Tanaka et Wada, 2020) *Préimpression*	Japanese citizens' behavioral changes and preparedness against COVID-19: How effective is Japan's approach to self-restraint	• Étude transversale (enquête en ligne réalisée du 26 au 28 mars 2020) • 11 342 résidents du Japon âgés de 20 ans et plus • Interventions de santé publique – éviter les espaces clos mal ventilés, les grands rassemblements et les conversations ou les cris à proximité immédiate, respecter l'étiquette respiratoire	• Environ 76 % des participants ont estimé eux-mêmes avoir pris des mesures préventives • Le lavage fréquent des mains était une mesure adoptée par environ 86 % des participants et l'étiquette respiratoire par 77 % • Environ 20 % des participants sont réticents à mettre en œuvre des mesures de prévention adéquates. L'analyse indique que ceux qui n'adoptent pas de

			comportements protecteurs sont plus souvent des hommes, plus jeunes (moins de 30 ans), célibataires, font partie de ménages à faibles revenus, ont une habitude de boire ou de fumer et ont un score d'extraversion plus élevé.
(Shinan-Altman, 2020) *Préimpression*	COVID-19 precautionary behavior: The Israeli case in the initial stage of the outbreak	• Étude transversale (enquête en ligne réalisée du 12 au 21 mars 2020) • 1 407 résidents d'Israël âgés de 18 ans et plus • Interventions de santé publique – se laver les mains, éviter le contact avec les personnes qui présentent des symptômes	• Le score de comportement de précaution était relativement élevé parmi les participants • Le comportement de précaution était plus élevé chez les femmes, les participants plus âgés, les participants ayant un niveau de connaissance plus élevé sur la COVID-19 et les participants ayant des réactions émotionnelles négatives plus importantes
(Moore, Lee, Hancock, Halley et Linos, 2020) *Préimpression*	Experience with Social Distancing Early in the COVID-19 Pandemic in the United States: Implications for Public Health Messaging	• Étude transversale (enquête en ligne réalisée du 14 au 23 mars 2020) • 7 355 résidents des États-Unis âgés de 18 ans et plus • Interventions de santé publique – distanciation sociale	• 39,8 % ont déclaré ne pas se conformer aux mesures • Le groupe le plus jeune (de 18 à 31 ans) présentait le taux de conformité le plus faible (52,4 %) par rapport aux autres groupes d'âge (tous, moins de 60 %; toutes les valeurs $p < 0,01$)
(Machida et coll., 2020)	Adoption of personal protective measures by ordinary citizens during the COVID-19 outbreak in Japan	• Étude transversale (enquête en ligne menée du 25 au 27 février 2020) • 2 400 résidents du Japon âgés de 20 ans et plus • Interventions de santé publique – avoir une bonne hygiène des mains, respecter la distanciation sociale, éviter le contact avec les yeux, le nez et la bouche, respecter l'étiquette respiratoire et s'isoler volontairement	• 34,7 % ont mis en œuvre l'ensemble des 5 mesures de protection • La prévalence des cinq mesures de protection varie entre 59,8 et 83,8 %, la plus faible étant d'éviter de toucher les yeux, le nez et la bouche • La prévalence est significativement plus élevée chez les femmes et les adultes âgés que chez les hommes et les personnes de moins de 65 ans (femmes

			OU : 1,57 an, personnes plus âgées OU : 1,83, les deux p < 0,001)
(Williams, Armitage, Tampe et Dienes, 2020) *Préimpression*	Public perceptions and experiences of social distancing and social isolation during the COVID-19 pandemic: A UK-based focus group study	• Groupe de discussion mené en ligne entre le 28 mars et le 4 avril 2020 • 27 résidents du Royaume-Uni âgés de 18 ans et plus • Interventions de santé publique – respecter la distanciation sociale et l'isolement social	• Tous les participants ont indiqué qu'ils respectaient beaucoup les directives en matière de distanciation et d'isolement, mais ont déclaré avoir vu ou entendu des cas de non-respect chez d'autres personnes
(Canning, Karra, Dayalu, Guo et Bloom, 2020) *Préimpression*	The association between age, COVID-19 symptoms, and social distancing behavior in the United States	• Étude transversale (enquête en ligne, dates de réalisation non communiquées) • 4 676 résidents des États-Unis âgés de 18 ans et plus • Interventions de santé publique – distanciation sociale	• Environ 52 % des participants ont déclaré être sortis de chez eux la veille (sans respecter la distanciation sociale) • Ceux qui ont souffert d'essoufflement ont moins de contacts étroits, avec un RTI de 0,49 (IC à 95 %) : 0,30 à 0,78). Le fait d'avoir d'autres symptômes de la grippe réduit la probabilité de sortir de 0,32 (IC à 95 %) : 0.18 à 0,60) et le taux d'incidence de contacts étroits de 42 % (RTI = 0,58; IC 95 % : 0,38 à 0,88). • Les personnes âgées sont tout aussi susceptibles de quitter leur domicile que les jeunes, mais les personnes de plus de 50 ans ont eu moins de la moitié du nombre prévu de contacts étroits par rapport aux personnes de moins de 30 ans
(M. Ã. Czeisler et coll., 2020) *Préimpression*	COVID-19 : public compliance with and public support for stay-at-home mitigation strategies	• Étude transversale (enquête en ligne menée du 2 au 8 avril 2020) • 4 676 résidents des États-Unis (N.Y., L.A.) et de l'Australie âgés de 18 ans et plus	• 81,8 % ont déclaré respecter les politiques recommandées en matière de quarantaine ou pour rester à la maison • Le taux de conformité était élevé dans les régions fortement touchées (États-Unis,

		• Interventions de santé publique – adopter des stratégies pour inciter les gens à rester à la maison	New York) et dans les régions faiblement touchées (Australie, Los Angeles)
(Pollak, Dayan, Shoham et Berger, 2020) *Préimpression*	Predictors of adherence to public health instructions during the COVID-19 pandemic	• Étude transversale (enquête en ligne menée du 28 mars au 10 avril 2020) • 654 résidents d'Israël âgés de 18 ans et plus • Interventions de santé publique – respecter les instructions médicales	• 28,7 % ont été définis comme des non-adhérents • L'inobservance était associée au sexe masculin (RCC = 1,54; IC 1,03 à 2,31), au fait de ne pas avoir d'enfants (RCC = 1,73; 1,13 à 2,65), au tabagisme (RCC = 2,27; IC 1,42 à 3,62), à des niveaux élevés de symptômes de TDAH (RCC = 1,55; IC 1,07 à 2,25), à des niveaux élevés de comportements à risque antérieurs (RCC = 1,41; IC 1,10 à 1,81), à une détresse psychologique actuelle élevée (RCC = 1,51; IC 1,14 à 2,01), à un faible risque perçu de COVID-19 (RCC = 1,52; IC 1,22 à 1,89), à une faible exposition aux instructions (RCC = 1,45; IC 1,14 à 1,82) et à une faible efficacité perçue des instructions (RCC = 1,47; IC 1,16 à 1,85)
(Shahnazi, Ahmadi-Livani et Pahlavanzadeh, 2020) *Préimpression*	Assessing preventive health nehaviors from COVID-19 based on the health belief model (HBM) among people in Golestan province: a Cross-sectional study in northern Iran	• Étude transversale (enquête en ligne réalisée du 11 au 16 mars 2020) • 750 résidents de l'Iran âgés de 18 ans et plus • Interventions de santé publique – éviter les lieux bondés, respecter la distanciation sociale, se laver les mains, rester à la maison, respecter l'étiquette respiratoire, éviter de se toucher le visage avec les mains	• Le taux de conformité variait entre 96,8 % (éviter les endroits bondés) et 33,5 % (éviter de se toucher le visage avec les mains) • Le score moyen du comportement préventif était plus élevé chez les femmes que chez les hommes, et plus important chez les citadins que chez les ruraux • Une augmentation d'une unité de l'écart-type des scores factoriels « auto-efficacité » et « bénéfices perçus » a augmenté les scores de comportement

			préventif de 0,22 et 0,17 unité respectivement • Une augmentation d'une unité de l'écart-type des scores factoriels « obstacles perçus » et « croyances fatalistes » a réduit les scores du comportement préventif de 0,36 et 0,19 unité respectivement
(Lee et You, 2020)	Psychological and behavioral responses in South Korea during the early stages of Coronavirus Disease 2019 (COVID-19)	• Étude transversale (enquête en ligne menée du 25 au 28 février 2020) • 973 résidents de la Corée du Sud âgés de 18 ans et plus • Interventions de santé publique – se laver les mains, porter un masque facial, respecter la distanciation sociale	• Les participants ont déclaré qu'ils se lavaient toujours les mains (67,8 %), qu'ils portaient toujours un masque facial lorsqu'ils étaient à l'extérieur (63,2 %), qu'ils reportaient ou annulaient des événements sociaux (50 %), qu'ils évitaient les endroits bondés (41,5 %) et qu'ils réduisaient leur utilisation des transports en commun (38,7 %) • La pratique de comportements de précaution est fortement associée au risque perçu et à l'efficacité de réponse du comportement • Des variables sociodémographiques précises pour chaque comportement sont fournies dans l'étude (p. ex. le sexe, le niveau d'éducation, la gravité perçue et l'efficacité de réponse étaient des prédicteurs individuels positifs et significatifs du port d'un masque facial)
(Jackson, Brown, Shahab, Steptoe et Fancourt, 2020)	COVID-19, smoking, and inequalities: a cross-sectional survey of adults in the UK	• Étude transversale (enquête en ligne menée du 21 mars au 20 avril) • 53 211 résidents du Royaume-Uni âgés de 18 ans et plus	• L'adhésion aux interventions de santé publique était généralement élevée (96,3 %, IC à 95 %) : 96,1 à 96,4 %) • Le taux d'adhésion était plus faible chez les fumeurs actuels que chez les jeunes n'ayant jamais fumé (RC 0,70, IC à 95 %) :

Préimpression		• Interventions de santé publique – respecter les recommandations des autorités pour prévenir la propagation de la COVID-19	0,62 à 0,78) indépendamment du niveau de scolarité, mais l'association était plus forte parmi les personnes ayant obtenu des diplômes après 16 ans
(Clements, 2020)	Knowledge and behaviors toward COVID-19 among U.S. residents during the early days of the pandemic: online questionnaire	• Étude transversale (enquête en ligne réalisée le 17 mars 2020) • 1 070 résidents des États-Unis âgés de 18 ans et plus • Interventions de santé publique – porter un masque, éviter les grands rassemblements	• Les participants qui ont déclaré être allés à des rassemblements de plus de 50 personnes ou avoir porté des masques à l'extérieur de la maison étaient moins bien informés sur la COVID-19 et plus jeunes que les participants qui n'ont pas déclaré ces activités • Les participants ayant un diplôme universitaire ou professionnel étaient 67 % plus susceptibles d'assister à de grands rassemblements et de 347 à 641 % plus susceptibles de porter un masque en dehors de la maison, par rapport à ceux ayant fait des études secondaires • Les démocrates étaient 30 % moins susceptibles d'assister à de grands rassemblements et 44 % moins susceptibles de porter un masque à l'extérieur du foyer par rapport aux républicains • Les participants noirs étaient 148 % plus susceptibles de porter un masque à l'extérieur du domicile que les participants blancs
(Seale et coll., 2020)	COVID-19 is rapidly changing: examining public perceptions and behaviors in response to this evolving pandemic	• Étude transversale (enquête en ligne réalisée du 18 au 24 mars 2020) • 1 420 résidents australiens de 18 ans et plus	• 84,9 % des personnes interrogées ont déclaré avoir adopté au moins 1 des 3 comportements liés à l'hygiène et 93,4 % ont adopté au moins 1 des 6 comportements liés à l'évitement

		• Interventions de santé publique – 6 stratégies de distanciation sociale, isolement volontaire, hygiène	• L'adoption de comportements d'évitement était associée à la confiance dans le gouvernement (RCC : 5,5; 95 % IC : 3 à 9,0), une meilleure perception de l'efficacité des comportements (RCC : 4,3; 95 % IC : 2,8 à 6,9), et des niveaux plus élevés de capacité perçue à adopter des stratégies de distanciation sociale (RCC : 1,8; 95 % IC 1,1 à 3,0)
(Brouard, Vasilopoulos et Becher, 2020)	Sociodemographic and psychological correlates of compliance with the COVID-19 public health measures in France	• Étude transversale (enquête en ligne réalisée les 16 et 17 mars 2020) • 1 010 résidents de France âgés de 18 ans et plus • Interventions de santé publique – stratégies de distanciation sociale, hygiène des mains, étiquette respiratoire, réduction des déplacements, évitement des lieux bondés	• Les résultats suggèrent que l'âge est positivement associé au respect des mesures de protection • Les femmes sont plus susceptibles d'avoir changé de comportement que les hommes • L'extrémité idéologique est associée à une moindre adhésion aux recommandations de santé publique
(Doğan et Bayraktar, 2020)	COVID-19 with a public health perspective: measures taken in Turkey and public compliance with the measures	• Étude transversale (enquête menée du 23 au 27 mars 2020) • 178 résidents de la Turquie âgés de 18 ans et plus • Interventions de santé publique – stratégies de distanciation sociale, hygiène des mains	• 97,2 % se sont lavé les mains avec du savon et 91,6 % ont évité le contact avec les gens
(Y. Li, Yao et Luo, 2020) *Préimpression*	Perceived stress and its impact on health behavior of Chinese residents during the epidemic of COVID-19: an internet survey	• Étude transversale (enquête en ligne menée du 14 au 22 février 2020) • 2 449 résidents de Chine âgés de 18 ans et plus • Interventions de santé publique – hygiène des mains, port d'un masque	• À mesure que le stress perçu augmentait, la fréquence des comportements de santé comme le lavage des mains et le port d'un masque diminuait

(Perrotta et coll., 2020) Préimpression	Behaviors and attitudes in response to the COVID-19 pandemic: Insights from a cross-national Facebook survey	• Étude transversale (enquête en ligne menée du 13 mars au 19 avril 2020) • 71 612 résidents de 18 ans et plus en Belgique, en France, en Allemagne, en Italie, aux Pays-Bas, en Espagne, au Royaume-Uni et aux États-Unis • Interventions de santé publique – distanciation sociale, hygiène des mains, port d'un masque facial, réduction des déplacements	• Dans l'ensemble, les femmes sont plus susceptibles que les hommes d'adopter des comportements préventifs • Le port d'un masque facial varie de 7 % aux Pays-Bas à 60 % en Italie • L'adoption d'un lavage des mains plus fréquent va de 87 % en Allemagne à 94 % en Espagne • En dehors des Pays-Bas et du Royaume-Uni, les femmes et les personnes de plus de 45 ans affichent les taux d'adoption du masque facial les plus élevés
(Cutler, Stantcheva, Alsan et Yang, 2020) Préimpression	Disparities in COVID-19 reported incidence, knowledge, and behavior	• Étude transversale (enquête en ligne menée du 29 mars au 13 avril 2020) • 5 198 résidents des États-Unis âgés de 18 ans et plus • Interventions de santé publique – adopter une bonne hygiène des mains et rester à la maison	• Les hommes se lavent les mains 3,8 fois moins souvent dans une période de 24 heures que les femmes ($p < 0,001$) • Les répondants afro-américains et hispaniques se lavent les mains plus fréquemment que les répondants blancs au cours d'une période de 24 heures ($p=0,020$) • Les hommes sont plus susceptibles de quitter la maison fréquemment que les femmes (0,74 fois, $p < 0,001$), tout comme les Afro-Américains par rapport aux répondants blancs (0,93 fois, $p < 0,001$) • Les Américains plus âgés (65 ans et plus) sont moins susceptibles de quitter fréquemment leur domicile (-0,36 fois, $p =0,018$)
(Barber et Kim, 2020)	COVID-19 worries and behavior changes in older and younger men and women	• Étude transversale (enquête en ligne réalisée du 23 au 31 mars 2020)	• Plus de 80 % des participants ont déclaré se laver les mains plus fréquemment, faire plus attention à la propreté, ne plus serrer la main et éviter les lieux publics. Plus de

		• 146 jeunes adultes (de 18 à 35 ans) et 156 adultes plus âgés (de 65 à 81 ans) aux États-Unis • Interventions en matière de santé publique – rester à la maison, adopter une bonne hygiène des mains, porter le masque, adopter des comportements de distanciation sociale, s'isoler volontairement	60 % des participants ont également déclaré respecter la distanciation sociale • Par rapport aux autres participants, les hommes plus âgés sont ceux qui ont adopté le moins de changements de comportement • Les femmes âgées sont les plus nombreuses à déclarer respecter la distanciation sociale et éviter les lieux publics • Pour tous les participants, l'inquiétude relative à la COVID-19 était liée au nombre total de changements de comportement effectués, indépendamment de l'âge ou du sexe
(Ha, Schensul, Lewis et Brown, 2020) *Préimpression*	Early assessment of knowledge, attitudes, anxiety and behavioral adaptations of Connecticut residents to COVID-19	• Étude transversale (enquête en ligne réalisée du 23 au 29 mars 2020) • 464 résidents des États-Unis âgés de 21 ans et plus • Interventions en matière de santé publique – rester à la maison, adopter une bonne hygiène des mains, porter le masque, adopter des comportements de distanciation sociale, respecter l'étiquette respiratoire, réduire les déplacements	• Le taux de conformité variait de 21,5 % des participants portant des gants de protection et de de 9,2 % portant un masque lorsqu'ils sortaient à l'extérieur à 96,5 % évitant les transports publics et 100 % se lavant fréquemment les mains, évitant le contact avec les gens et évitant les événements et réunions avec un grand nombre de personnes
(Thang et coll., 2020) *Préimpression*	Preventive behavior of Vietnamese people in response to the COVID-19 pandemic	• Étude transversale (enquête en ligne menée du 31 mars au 6 avril 2020) • 2 175 résidents du Vietnam âgés de 18 ans et plus • Interventions de santé publique – mesures préventives personnelles (p. ex. masques faciaux, éloignement social) et communautaires (p. ex. éviter les lieux bondés)	• En utilisant un score de 9 et 11 points, le niveau moyen d'adhésion personnelle aux mesures préventives était de 7,23 ± 1,63 (étendue : 1 à 9) et les mesures préventives communautaires étaient de 9,57 ± 1,12 (étendue : 0 à 11), respectivement

			• Le taux de conformité le plus faible (45,1 %) a été constaté pour « la mesure de la température corporelle au moins deux fois par semaine » et le plus élevé pour le port d'un masque facial lors de sorties à l'extérieur (99,5 %) • Les inquiétudes concernant la santé, la perception de l'adaptation de la communauté au confinement, le fait de vivre dans de grandes municipalités, les sources officielles d'information sur la COVID-19 et le fait d'avoir un rôle professionnel dans le secteur de la santé (travailleur ou étudiant) ont été associés à des scores d'adhésion plus élevés
(Yousef Yang, peng, Yang et Rockett, 2020) *Préimpression*	Changing trends of excess self-protective behavior, and association with belief in prevention myths during the COVID-19 epidemic in China: Une étude de panel	• Étude longitudinale prospective (enquête en ligne) • 116 résidents de la Chine âgés de 20 ans et plus à 5 moments dans le temps (5/12/19/26 février et 4 mars 2020) • Interventions de santé publique – comportements préventifs excessifs, par exemple désinfection des vêtements, lavage excessif des mains, accumulation de masques, etc.	• La perception d'un risque élevé de contracter la COVID-19 était positivement associée à chaque type de comportement préventif excessif sélectionné, et la perception de la gravité de la maladie était positivement associée à la désinfection des vêtements et à l'accumulation de produits • La croyance dans les mythes sur la prévention des maladies (faits sur la prévention des maladies qui ne sont pas vrais) a été positivement associée à la désinfection des vêtements ainsi qu'au lavage et à la désinfection des mains • La désinfection des vêtements était moins répandue chez les femmes que chez les hommes (CR : 0,34), et parmi les professionnels que chez les personnes

			appartenant à d'autres groupes professionnels (CR : 0,35) • Le lavage des mains était plus fréquent chez les femmes que chez les hommes (CR : 3,48) et moins fréquents chez les personnes mariées que chez les personnes jamais mariées (CR : 0,43)
(S. Li, Feng, Liao et Pan, 2020)	Internet use, risk awareness, and demographic characteristics associated with engagement in Preventive Behaviors and Testing: cross-sectional survey on COVID-19 in the United States	• Étude transversale (enquête en ligne réalisée du 10 au 14 avril 2020) • 979 résidents des États-Unis âgés de 18 ans et plus • Interventions de santé publique – porter un masque facial, se laver les mains, respecter l'étiquette respiratoire, respecter la distanciation sociale, rester à la maison, éviter les transports en commun et nettoyer les surfaces fréquemment touchées	• Les participants qui ont reçu plus d'information en ligne sur la santé liée à la COVID-19 ont déclaré faire plus souvent des efforts pour adopter tous les types de comportements préventifs • Par rapport aux participants qui n'ont pas eu de cas positifs dans leur entourage, ceux dont des membres de la famille immédiate ou des amis et parents proches ont reçu un diagnostic positif sont plus susceptibles de se faire dépister • Dans l'ensemble, les femmes, les personnes âgées, les personnes mariées et les personnes ayant un emploi adoptent plus fréquemment la plupart des types de comportements préventifs que leurs homologues (hommes, jeunes, célibataires, sans emploi) • Des participants plus instruits étaient moins souvent engagés dans de multiples comportements préventifs • Des différences ethniques ont également été observées en ce qui concerne l'adoption de comportements préventifs. Par rapport aux Blancs, les Afro-Américains et les Asiatiques portent plus

			fréquemment un masque en public et restent à la maison. Les Américains ont signalé des efforts plus fréquents que les Blancs pour nettoyer les surfaces fréquemment touchées
(Wu, Huang, Xie et Chen, 2020) *Préimpression*	People behavior changes in China during COVID-19 pandemic	• Étude transversale (enquête en ligne réalisée du 26 au 30 avril 2020) • 1 048 résidents de la Chine • Interventions de santé publique – respecter la distanciation sociale, réduire les déplacements, rester à la maison, porter un masque	• Près de 80 % des participants ont réduit leurs activités hors du domicile (travailler, manger, faire des courses, prendre les transports en commun et voyager) • 92 % portent un masque dans la rue
(Sutin et coll., 2020)	Body mass index, weight discrimination, and psychological, behavioral, and interpersonal responses to the Coronavirus pandemic	• Étude transversale (enquête en ligne réalisée à la mi-mars 2020) • 2 094 résidents des États-Unis ayant un IMC différent • Interventions de santé publique – comportements préventifs (p. ex. l'hygiène des mains)	• Les participants qui ont signalé une discrimination liée au poids étaient plus susceptibles d'adopter des comportements préventifs • L'IMC n'était pas lié aux changements de comportements préventifs
(Iorfa et coll., 2020) *Préimpression*	COVID-19 knowledge, risk perceptions and precautionary behavior among Nigerians: A moderated mediation approach	• Étude transversale (enquête en ligne menée du 28 mars au 4 avril 2020) • 1 500 résidents du Nigeria âgés de 18 ans et plus • Interventions de santé publique – adopter une bonne hygiène des mains, éviter les endroits bondés, se faire tester, porter le masque, respecter l'étiquette respiratoire, éviter de toucher les surfaces	• Chez les femmes et les hommes, le fait d'être plus âgés, d'avoir une meilleure connaissance de la COVID-19 et une perception plus élevée du risque était lié à un comportement plus prudent • Les femmes adoptent un comportement plus prudent que les hommes • Le respect des mesures de précaution varie. 19 % des participants ont déclaré porter un masque, 54,4 % ont évité de toucher les surfaces, 56,8 % ont évité les endroits bondés et 66,4 % se sont isolés volontairement

(Liu et coll., 2020)	Psychological status and behavior changes of the public during the COVID-19 epidemic in China	• Étude transversale (enquête en ligne réalisée du 30 janvier au 3 février 2020) • 608 résidents de Chine âgés de 18 ans et plus • Interventions de santé publique – adopter une bonne hygiène des mains, éviter les lieux bondés, porter le masque, respecter la distanciation sociale	• Au moins 70,9 % des personnes interrogées ont pris 3 mesures préventives ou plus pour éviter l'infection • 93,3 % des personnes interrogées évitent d'aller dans les lieux publics, 83,7 % portent un masque et 82,4 % se lavent les mains • L'anxiété ne semble pas être liée au changement de comportement du public et aux mesures préventives • Moins de répondants souffrant de dépression ou d'anomalies psychologiques ont pris des mesures préventives par rapport à ceux qui n'en souffraient pas
(Michela et Carlucci, 2020) *Préimpression*	Demographic and attitudinal factors of adherence to quarantine guidelines during COVID-19: the Italian model	• Étude transversale (enquête en ligne menée du 21 au 26 mars 2020) • 3 672 adultes de 18 ans et plus mis en quarantaine en Italie • Interventions de santé publique – avoir une bonne hygiène des mains, respecter la distanciation sociale, respecter l'étiquette respiratoire, nettoyer les surfaces, porter le masque, éviter les lieux bondés	• Les répondants ont obtenu des scores de moyens à élevés en matière de respect des directives de quarantaine, mesurés par un indice d'intervalle unique, avec une moyenne de 32,59 (médiane = 33; ET = 5 22; étendue : 0 à 44) • Chez les femmes, le fait d'être employées, la perception du risque et l'anxiété liée au risque étaient associés à des niveaux d'observance beaucoup plus élevés ($p < 0,001$) comparativement à leurs homologues • La moyenne de l'observance chez les professionnels de la santé ($p < 0,001$) était significativement plus élevée que celle des chômeurs et des salariés • En ce qui concerne l'âge, la tranche des 18 à 29 ans a obtenu un score

			statistiquement inférieur ($p < 0,001$) par rapport aux autres tranches d'âge. De même, le groupe des 50 à 59 ans a obtenu des scores d'observance statistiquement plus élevés ($p < 0,001$) que le groupe des 30 à 39 ans
(Park et coll., 2020)	Americans' COVID-19 stress, coping, and adherence to CDC guidelines	• Étude transversale (enquête en ligne menée du 7 au 9 avril 2020) • 1 015 résidents des États-Unis âgés de 18 ans et plus • Interventions de santé publique – respect des directives du CDC (distanciation sociale, hygiène des mains)	• Les prédicteurs les plus cohérents du respect des directives du CDC étaient l'âge, le sexe féminin et la sécurité financière (tous avec un effet de faible ampleur) • Dans l'ensemble, le respect des directives du CDC était assez élevé, mais variait selon les interventions : 95,10 % évitent de manger au restaurant et se rendre dans les grands rassemblements, 87,2 % s'engagent dans des pratiques de distanciation sociale et 74,68 % adoptent des pratiques de nettoyage et de désinfection
(Plohl et Musil, 2020)	Modeling compliance with COVID-19 prevention guidelines: the critical role of trust in science	• Étude transversale (enquête en ligne, date de réalisation non communiquée) • 525 participants mondiaux âgés de 18 ans et plus • Interventions de santé publique – hygiène des mains, respect des directives	• La confiance dans la science et la perception du risque lié à la COVID-19 contribuent de manière significative et directe à expliquer le respect des directives de prévention de la COVID-19 ($R2 = 0,265$)
(Smith et coll., 2020) *Préimpression*	Factors associated with adherence to self-isolation and lockdown measures in the UK; a cross-sectional survey	• Étude transversale (enquête en ligne réalisée les 6 et 7 mai 2020) • 2 240 résidents du Royaume-Uni âgés de 18 ans et plus • Interventions de santé publique – isolement volontaire	• Les facteurs associés au non-respect des mesures d'isolement volontaire sont notamment le fait d'être un homme, d'être moins préoccupé par la COVID-19 et de percevoir un risque moindre de contracter la COVID-19

			• 9,7 % des participants ont déclaré qu'eux-mêmes ou un membre de leur foyer avaient eu des symptômes de COVID-19 au cours des 7 derniers jours. Parmi ceux-ci, 75,1 % avaient quitté le domicile au cours des dernières 24 heures (inobservance) • L'observance était également associée au fait d'avoir reçu de l'aide d'une personne extérieure au ménage au cours des 7 derniers jours
(Haupt et coll., 2020) *Préimpression*	Profiles of social distance compliance: psychological and situational predictors of risky behavior during COVID-19	• Étude transversale (enquête en ligne réalisée du 30 avril au 2 mai 2020) • 483 résidents des États-Unis âgés de 18 ans et plus • Interventions de santé publique – respecter les directives de santé publique, éviter les comportements à risque (p. ex. participation à des rassemblements de plus de 5 personnes)	• L'activité à risque était associée à une extraversion plus élevée, à un besoin de fermeture cognitive, à l'activation du comportement et à la perception d'une pénurie de ressources • L'activité à risque était également associée à une moindre empathie et à un accès plus restreint à l'espace de vie, ainsi qu'à un âge plus précoce • Sept différents types de profils de grappes sont créés pour expliquer les associations entre la variance dans l'adoption de comportements à risque et les facteurs psychologiques, sociodémographiques et situationnels des répondants
(Zajenkowski, Jonason, Leniarska et Kozakiewicz, 2020)	Who complies with the restrictions to reduce the spread of COVID-19?: personality and perceptions of the COVID-19 situation	• Étude transversale (enquête menée du 14 au 30 avril 2020) • 263 résidents de Pologne âgés de 18 ans et plus • Interventions de santé publique – respect des lignes directrices en matière de santé publique	• Les répondants ayant obtenu un score faible pour le caractère agréable et élevé pour certains aspects des traits de la triade noire (c.-à-d. le machiavélisme, la psychopathie Facteur 1 et la rivalité narcissique) étaient moins susceptibles de

			respecter les restrictions de santé publique • Les perceptions de la COVID-19 expliquent les différences individuelles dans le respect des mesures de santé publique
(Banda et coll., 2020) *Préimpression*	Knowledge and behaviors related to the COVID-19 pandemic in Malawi	• Étude transversale (enquête téléphonique réalisée du 25 avril au 23 mai 2020) • 630 résidents du Malawi âgés de 18 ans et plus • Interventions de santé publique – utiliser un masque facial, avoir une bonne hygiène des mains, éviter les foules, rester à la maison	• L'utilisation de masques faciaux et de désinfectants pour les mains était plus fréquente parmi les répondants résidant en milieu urbain (22,5 %) que parmi ceux résidant en milieu rural (5,0 %) • Plus de 95 % des personnes interrogées ont déclaré se laver les mains plus fréquemment et environ 50 % ont déclaré éviter les foules. Seuls 1/5 des résidents ruraux et 1/4 des résidents urbains ont déclaré rester à la maison
(Galasso et coll., 2020) *Préimpression*	Gender differences in COVID-19 related attitudes and behavior: evidence from a panel survey in eight OECD countries	• Étude transversale (enquête en ligne réalisée du 16 au 30 mars et du 15 au 20 avril 2020) • 21 649 répondants de 8 pays (Australie, Autriche, France, Allemagne, Italie, Nouvelle-Zélande, Royaume-Uni et États-Unis) • Interventions de santé publique – respecter la distanciation sociale, avoir une bonne hygiène des mains, respecter l'étiquette respiratoire, éviter les endroits bondés, rester à la maison, utiliser des masques et des gants	• Des différences significatives entre les sexes en matière de respect des règles de santé publique ont été observées parmi les participants à l'enquête • Le respect des règles de santé publique était nettement plus important chez les femmes que chez les hommes
(Bonful et coll., 2020) *Préimpression*	Limiting spread of COVID-19 in Ghana: compliance audit of selected transportation	• Étude d'observation comprenant des vérifications de la fréquence du lavage des mains et du respect de la distanciation physique dans les stations de transport en commun (menée du 27 au 29 mars 2020)	• La majorité (moins de 80 %) des sites de vérification ne disposaient pas d'emplacements adéquats pour le lavage des mains, la fréquence de lavage des

	stations in the Greater Accra region of Ghana	• 45 sites au Ghana • Interventions de santé publique – disponibilité des installations d'hygiène, source et propreté de l'eau, nombre d'installations de lavage des mains, fréquence du lavage des mains, surpopulation dans les points de lavage des mains, distanciation sociale, utilisation de masques et information sur la prévention de la COVID-19	mains était faible et le port du masque n'a été observé que chez quelques passagers • Le respect des mesures de prévention de la COVID-19 était insuffisant dans 13 stations, de base dans 16 stations, intermédiaire dans 7 stations, et avancée dans 9 stations
(M. É. Czeisler et coll., 2020)	Public attitudes, behaviors, and beliefs related to COVID-19, stay-at-home orders, nonessential business closures, and public health guidance – United States, New York City, and Los Angeles, May 5-12, 2020	• Étude transversale (enquête en ligne réalisée du 5 au 12 mai 2020) • 3 cohortes (É.-U.=1 676, N.Y.=286, et L.A.=259) toutes âgées de 18 ans et plus • Intervention de santé publique – isolement volontaire, masques faciaux, distanciation sociale	• Sur les 3 cohortes, 77,3 % des adultes ont déclaré s'isoler, 84,6 % à New York et 83,0 % à Los Angeles • 74,1 % des personnes interrogées dans l'ensemble du pays ont déclaré porter toujours ou souvent un masque facial lorsqu'elles sont en public, 89,6 % à New York et 89,8 % à Los Angeles • Le respect des mesures varie considérablement en fonction de la démographie et des caractéristiques des répondants
(Al-Hanawi et coll., 2020)	Knowledge, attitude and practice toward COVID-19 among the public in the Kingdom of Saudi Arabia: a cross-sectional study	• Étude transversale (enquête en ligne réalisée du 20 au 24 mars 2020) • 3 388 résidents de l'Arabie saoudite âgés de 18 ans et plus • Interventions de santé publique – éviter les grands événements sociaux et les lieux bondés, éviter les comportements culturels tels que la poignée de main, respecter la distanciation sociale, se laver les mains après un éternuement, une toux et après s'être mouché	• Le score moyen pour les pratiques de lutte contre la COVID-19 était de 4,34 (ET = 0,87, étendue : 0 à 5), indiquant l'adoption de bonnes pratiques en général • Les groupes d'âge de 30 à 39 ans (β = 0,039; pβ = 0,033; pβ = 0,051; p • Par rapport aux femmes, les hommes ont de moins bonnes pratiques pour éviter la propagation de la COVID-19 (β = −0,064; p

(Marinthe, Brown, Delouvée et Jolley, 2020)	Looking out for myself: exploring the relationship between conspiracy mentality, perceived personal risk, and COVID-19 prevention measures	• Deux études transversales (étude 1 – réalisée en ligne le 9 mars 2020; étude 2 – réalisée en ligne du 17 au 23 mars 2020) • 762 résidents (étude 1) et 229 résidents (étude 2) de France âgés de 18 ans et plus • Interventions de santé publique – L'étude 1 a été menée alors que seuls les rassemblements de plus de 1 000 personnes étaient interdits. Les comportements étudiés comprenaient des comportements de prévention normatifs (embrasser quelqu'un, lui serrer la main) et des comportements de prévention non normatifs (parler aux gens, prendre les transports en commun, aller au restaurant, etc.) L'étude 2 a été menée pendant la première semaine de confinement total et a mesuré le respect de la règle de confinement	• Dans l'étude 1, les comportements de santé préventifs ont été mesurés sur une échelle de 9 points allant de 1 = beaucoup moins qu'avant la crise du coronavirus à 9 = beaucoup plus qu'avant la crise du coronavirus. L'adoption moyenne de comportements de prévention normatifs était de 6,14 (1,49 ET) et de comportements de prévention non normatifs de 5,3 (0,66 ET) • L'étude 1 a démontré que les personnes qui croient à une conspiration sont plus susceptibles d'adopter des comportements de prévention non normatifs, mais pas des comportements de préventions normatifs • Dans l'étude 2, le respect de la règle de confinement a été mesuré sur une échelle de 7 points allant de 1=pas du tout à 7= beaucoup. Le taux moyen de respect des mesures de confinement était de 6,45 (0,82 ET) • L'étude 2 a démontré que les personnes ayant une forte mentalité de conspiration sont moins enclines à adopter des comportements préventifs normatifs plus extrêmes et légaux
(Daoust, 2020)	Elderly people and responses to COVID-19 in 27 countries	• Étude transversale (l'enquête a débuté la première semaine d'avril 2020) • 72 417 répondants dans 27 pays, âgés de 18 ans et plus • Interventions de santé publique – porter un masque facial à l'extérieur, se laver les mains,	• L'âge n'a pas d'effet significatif de l'âge sur le score de conformité aux mesures préventives de lutte contre la COVID-19 • Le niveau de base du respect des mesures préventives est assez élevé (score de 12/16)

		se couvrir le nez et la bouche lorsqu'on éternue ou qu'on tousse, éviter le contact avec les personnes qui présentent des symptômes, éviter de sortir en général, éviter de prendre les transports en commun, respecter la distanciation sociale, éviter les endroits bondés, nettoyer les surfaces fréquemment touchées, éviter de toucher des objets en public	
(Maher, MacCarron et Quayle, 2020)	Mapping public health responses with attitude networks: the emergence of opinion-based groups in the UK's early COVID-19 response phase	• Étude longitudinale (données recueillies les 9, 16 et 23 mars 2020) • 235 participants au Royaume-Uni âgés de 18 ans et plus • Interventions de santé publique – se laver les mains, éviter le contact avec certaines personnes, réduire les poignées de mains, éviter de toucher le visage	• Les participants qui ont déclaré être « sceptiquesà l'égard de la science » ont fait état d'une conformité comportementale significativement plus faible (moyenne = 5,28; ET = 1,46) que les personnes considérées comme « ayant confiance dans la science » (moyenne = 5,70; ET = 1,21)
(de la Vega, Ruíz-Barquín, Boros et Szabo, 2020)	Could attitudes toward COVID-19 in Spain render men more vulnerable than women?	• 2 études transversales (enquêtes en ligne, date de réalisation non communiquée) • L'étude 1 (n = 64) a été menée dans un centre commercial à Madrid, en Espagne, et l'étude 2 (n = 640) a été menée en ligne parmi des participants âgés de 18 ans et plus • Interventions de santé publique – respecter les mesures de sécurité et maintenir une distance d'au moins 1,5 mètre par rapport aux autres dans les lieux publics et porter un masque à tout moment	• Le respect des mesures a été évalué sur une échelle de 11 points • Les femmes ont obtenu un score plus élevé que les hommes en ce qui concerne les mesures de sécurité (8,06 contre 7,46; p < 0,001), le lavage des mains (8,77 contre 8,25; p < 0,001), le maintien d'une distance de 1,5 mètre par rapport aux autres (7,16 contre 6,56; p=0,003) et l'utilisation d'un masque de protection (1,95 contre 1,82; p=0,591) • Le respect des mesures de sécurité était plus faible dans les tranches d'âge plus élevées : 18 à 25=6,73 (1,89 ET), 26 à 50=7,92 (1,64 ET) et 51 à 72=8,08 (1,56)

(Führer et coll., 2020)	COVID-19 : knowledge, risk perception and strategies for handling the pandemic	• Étude transversale (enquête en ligne réalisée en mars 2020) • 1 048 participants de Saxe-Anhalt, Berlin et Schleswig-Holstein, en Allemagne, âgés de 18 ans et plus • Interventions de santé publique – se tenir à distance des autres, limiter les contacts dans les espaces publics, limiter les contacts privés, éviter les déplacements, cesser de prendre le tramway ou éviter les cafés, faire les courses moins souvent, faire des provisions, acheter du désinfectant, acheter des respirateurs	• Les mesures les plus courantes sont le respect des distances minimales par rapport aux autres (95,6 %) et la réduction des contacts personnels (93,4 %). Seule une minorité des personnes interrogées ont déclaré avoir des stocks de nourriture (38,3 %), de désinfectants (15,9 %) ou de masques respiratoires (15,0 %) • Sur 79 % de personnes interrogées qui ont déclaré avoir pris des mesures, 41 % ont agi à la fin mars lorsque des mesures de quarantaine ont été prises dans certaines régions d'Italie, tandis que 13 % n'ont pris aucune précaution avant que les premières infections ne soient découvertes dans leur État. Seuls 3 répondants (0,4 %) ont déclaré avoir déjà pris des mesures en réponse à la propagation étendue en Chine
(Reuben, Danladi, Saleh et Ejembi, 2020)	Knowledge, attitudes and practices towards COVID-19: an epidemiological survey in north-central Nigeria	• Étude transversale (enquête en ligne, date de réalisation non communiquée) • 589 résidents du centre-nord du Nigeria âgés de 18 ans et plus • Interventions de santé publique – pratique de la distanciation sociale/isolement volontaire, amélioration de l'hygiène personnelle et utilisation d'un masque facial	• 92,7 % des répondants ont pratiqué la distanciation sociale/isolement volontaire, 96,4 % ont amélioré leur hygiène personnelle et 82,3 % ont utilisé des masques faciaux
(Parsons Leigh et coll., 2020)	A national cross-sectional survey of public perceptions, knowledge, and behaviors during the COVID-19 pandemic	• Étude transversale (enquête en ligne réalisée du 26 avril au 1er mai 2020) • 1 996 répondants du Canada âgés de 18 ans et plus • Interventions de santé publique – isolement volontaire et distanciation sociale/physique	• 842 répondants ont indiqué qu'ils se sont isolés volontairement (43,4 %, IC 95 %) : 41,2 % à 45,6 %). • Parmi ceux qui ne se sont pas isolés volontairement (n=1 144), la grande majorité (n=1 083, 95,1 %, IC 95 %) : 93,8

			à 96,4 %) ont déclaré qu'ils pratiquaient la distanciation physique toujours (n=783; 68,8 % (IC 95 % 66,0 à 71,5 %) ou souvent (n=300, 26,3 %, IC 95 % 23,7 à 28,9 %)
(Alper, Bayrak et Yilmaz, 2020)	Psychological correlates of COVID-19 conspiracy beliefs and preventive measures: evidence from Turkey	• Étude transversale (enquête en ligne, dates de réalisation non communiquées) • 1 088 résidents de Turquie, âge médian = 31 ans • Interventions de santé publique – quitter la maison, éviter les contacts physiques, éviter de se toucher le visage, se laver/désinfecter les mains après une sortie à l'extérieur, éviter de partager le même environnement avec des personnes âgées, porter un masque, se couvrir la bouche lorsqu'on tousse ou éternue	• Il n'y a pas eu de preuve concluante suggérant une relation significative entre les croyances de conspiration et les mesures préventives liées à la COVID-19 • Les participantes étaient significativement plus susceptibles de prendre des mesures préventives que les participants (p < 0,001)
(de Moura Villela, Edlaine Faria, Mendoza L opez, Sayuri Sato et coll., 2020) *Préimpressi on*	COVID-19 outbreak in Brazil: adherence to national preventive measures and impact on people's lives	• Étude transversale (enquête menée du 3 au 9 avril 2020) • 23 896 résidents du Brésil âgés de 18 ans et plus • Interventions de santé publique – avoir une bonne hygiène des mains, éviter de se toucher le visage, désinfecter le téléphone portable, porter un masque, respecter l'étiquette respiratoire, respecter la distanciation physique/isolement, prendre sa température deux fois par semaine, rester à la maison en cas de symptômes	• 98,7 % des personnes interrogées se lavent régulièrement les mains et 92,6 % déclarent respecter la règle de distanciation physique de 1,5 à 2 m, mais seulement 45,5 % portent un masque facial lorsqu'ils sortent • Le fait d'être âgé, d'être une femme, de vivre seul, d'être travailleur indépendant, de vivre dans la région du Nord-Est, d'avoir au moins un diplôme de premier cycle, d'être un travailleur de la santé et le fait d'avoir des comorbidités étaient tous indépendamment associés à une plus grande adhésion aux mesures nationales de prévention et de restriction
(Xie, Campbell et	Working memory capacity predicts	• Étude transversale (enquête en ligne menée du 13 au 26 mars 2020)	• On a constaté que la capacité de mémoire de travail permettait de prédire de

Zhang, 2020)	individual differences in social-distancing compliance during the COVID-19 pandemic in the United States	• 397 participants recrutés entre le 20 et le 22 mars et 453 participants recrutés entre le 24 et le 26 mars aux États-Unis, âgés de 18 ans et plus • Intervention de santé publique – pas de rassemblement avec des amis, annulation d'événements ou de projets de participation à un événement, pas de visite à l'église ni de participation à d'autres activités communautaires, et pas de poignée de main, d'accolade ou de baiser lors de la salutation	manière significative les différences individuelles en matière de respect de la distanciation sociale, même en tenant compte d'autres covariables liées à l'humeur • Les participants ayant obtenu des scores plus élevés en matière de respect de la distanciation sociale ont également déclaré quitter moins souvent la maison et se laver davantage les mains • La mesure du respect de la distanciation sociale n'a pas été significativement corrélée avec le niveau de scolarité ou de revenu des participants, même si les femmes et les participants plus âgés avaient tendance à montrer un plus grand respect de la distanciation sociale
(Hsu, Lin, Wang et Jhang, 2020)	How to defend covid-19 in Taiwan? Talk about people's disease awareness, attitudes, behaviors and the impact of physical and mental health	• Étude transversale (enquête menée du 1er mars au 10 avril 2020) • 2 132 répondants de Taïwan âgés de 20 ans et plus • Interventions de santé publique – respect adéquat ou actif des mesures de prévention des épidémies, dénomination correcte de tous les processus de prévention, respect de la réglementation relative aux espaces publics, port de masques, consultation d'experts, d'universitaires ou de médias en ligne pour obtenir des conseils, maintien actif de la propreté à domicile, recyclage des déchets médicaux, partage des connaissances en matière de prévention, rappel des	• Le respect actif des mesures de prévention et le port de masques, ainsi que le partage des connaissances en matière de prévention ont obtenu les meilleurs scores de conformité • Les scores de conformité les plus faibles ont été relevés pour le nettoyage sur les plans personnel et communautaire

		comportements individuels inappropriés, nettoyage actif au sein de la communauté	
(Almutairi, Mustafa, Alessa, Almutairi et Almaleh, 2020)	Public trust and compliance with the precautionary measures against COVID-19 employed by authorities in Saudi Arabia	• Étude transversale (enquête en ligne, dates de réalisation non communiquées) • 1 232 résidents de l'Arabie saoudite âgés de 18 ans et plus • Interventions de santé publique – éviter les rassemblements publics, respecter le couvre-feu nocturne, éviter les poignées de main, avoir une bonne hygiène des mains, éviter de se toucher les yeux, le nez et la bouche avec les mains, se couvrir le nez et la bouche lorsqu'on éternue ou qu'on tousse, éviter de partager des objets personnels, porter un masque facial, se faire soigner tôt, maintenir une distance sociale	• 657 (53,3 %) des répondants ont été considérés comme appliquant de mauvaises mesures de précaution • Les mesures de précaution les plus respectées comprenaient : « respecte le couvre-feu nocturne » avec 98,3 %, « évite les rassemblements publics » avec 91,7 %, « maintient une distance sociale pendant l'épidémie de COVID-19 » avec 89,3 % • Les mesures de précaution les moins respectées comprenaient : « utilise un masque facial en public » avec 54 %, suivie de « évite de toucher les yeux, le nez et la bouche avec les mains » avec 37,9 %, et de « couvre le nez et la bouche lorsqu'il éternue ou tousse avec un mouchoir » avec 25,3 %
Population générale (tous âges)			
(Olapegba et Ayandele, 2020)	Survey data of COVID-19 related knowledge, risk perceptions and precautionary behavior among Nigerians	• Étude transversale (enquête en ligne menée du 28 mars au 4 avril 2020) • 1 357 résidents du Nigeria âgés de 15 ans et plus • Interventions de santé publique - avoir une bonne hygiène des mains, porter un masque, éviter les lieux bondés	• La majorité des participants ont adopté des comportements de protection, comme éviter les endroits bondés (79 %), utiliser du désinfectant pour les mains (71,19 %) et éviter de toucher les poignées de porte et les rampes d'escalier dans les espaces publics (75,76 %)
(Shabu, Amen et Mahmood, 2020)	Risk perception and behavioral response to COVID-19 in Iraqi Kurdistan Region	• Étude transversale (enquête en ligne menée du 20 au 26 mars 2020) • 976 enseignants et étudiants âgés de 17 ans et plus	• Le pourcentage de personnes interrogées qui appliquent fréquemment ou toujours des mesures de santé publique est élevé pour la plupart des comportements, à l'exception du port du masque et de

Préimpression		• Interventions de santé publique : éviter d'éternuer ou de tousser, éviter de se toucher le visage, le nez et les yeux, éviter les grands rassemblements et les lieux publics, éviter de se rendre dans les zones touchées, rester chez soi, utiliser des désinfectants à base d'alcool, respecter le couvre-feu et porter un masque ou des gants	gants et du fait d'éviter de se toucher le visage • Il y avait une corrélation positive faible et significative ($p < 0,001$) entre la perception du risque et les comportements de protection
(Arp et coll., 2020) *Préimpression*	Use of face coverings in public during the COVID-19 pandemic: an observational study	• Étude transversale (observations directes effectuées du 16 mai au 1er juin 2020) • 3 271 résidents du Wisconsin aux États-Unis, de tous âges (mineurs, jeunes adultes, adultes, personnes âgées) • Intervention de santé publique – utilisation d'un masque facial dans une épicerie	• Les femmes et les personnes âgées sont plus susceptibles d'utiliser des couvre-visage • Les achats dans les épiceries où les prix sont élevés ont également été associés à l'utilisation de masques • 41 % des personnes faisant partie de l'échantillon d'étude ont utilisé des couvre-visage
(Stanislau Affonso de Araújo, Evaldo et coll., 2020) *Préimpression*	Teach, and teach and teach: does the average citizen use masks correctly during daily activities? Results from an observational study with more than 12,000 participants	• Étude d'observation (observations directes effectuées du 17 au 19 juin 2020) • 12 588 personnes observées dans 5 villes brésiliennes (pas de restriction d'âge) • Interventions de santé publique – respect du port de masques faciaux	• 45,1 % de la population observée portait un masque facial de manière correcte, l'étendue ville par ville étant de 39,1 % à 63,5 % • 15,5 % (12,7 à 18,8 %) n'ont pas du tout utilisé de masques • 12,9 % portaient un masque, mais exposaient leur bouche et leur nez (9,9 à 17,6 %), 12,0 % exposaient leur nez uniquement (7,9 à 16,6 %), 17,8 % touchaient leur masque pendant l'utilisation (0,0 à 4,0 %) et 6,5 % portaient un masque mal ajusté (1,2 à 10,7 %)

ADHÉSION AUX INTERVENTIONS DE SANTÉ PUBLIQUE CHEZ LES JEUNES ADULTES ET LES

ÉTUDIANTS UNIVERSITAIRES/MÉDECINE

La conformité aux interventions de santé publique pour contrôler la propagation de la COVID-19 était élevée dans six études visant précisément les jeunes adultes (16 à 29 ans) et les étudiants universitaires/médecine (tableau 2).

- Les femmes sont plus susceptibles d'adopter des comportements préventifs que les hommes.
- D'autres facteurs sont positivement associés à l'adhésion aux interventions de santé publique, notamment l'accès à l'information sur la COVID-19, la maîtrise de soi et le niveau d'anxiété.
- Les comportements préventifs signalés ont été négativement corrélés à la perception du risque et à la détresse psychologique.
- Parmi les étudiants universitaires, une étude a révélé que les étudiants qui n'étaient pas en médecine respectaient davantage les restrictions sociales, tandis que les étudiants en médecine pratiquaient une meilleure hygiène des mains.

Tableau 2. Six études évaluant l'adhésion aux mesures de santé publique pour lutter contre la COVID-19 chez les jeunes adultes et les étudiants universitaires/médecine

Référence	Titre de la publication	Description de l'étude	Principaux résultats
Jeunes adultes			
(Imtiaz, Hossain et Khan, 2020) *Préimpression*	COVID-19 in Bangladesh: measuring differences in individual precautionary behaviors among young adults	• Étude transversale (détails de l'enquête non communiqués) • 350 jeunes adultes du Bangladesh âgés de 16 à 29 ans • Interventions de santé publique – comportement de précaution	• Le score moyen de précaution était le plus élevé (26,2) pour les personnes ayant terminé leurs études supérieures par rapport à celles ayant fait des études secondaires (24,7) • Les personnes en détresse psychologique avaient des scores de précaution moyens (23,6) plus faibles que ceux des personnes qui n'étaient pas en détresse (moyenne=25,1), p=0,019 • Les femmes (25,3) ont obtenu un score de précaution plus élevé que les hommes (23,8), p=0,007

			• Il a été constaté que le score de maîtrise de soi était significativement associé au score de précaution
Étudiants universitaires/médecine			
(Taghrir, Borazjani et Shiraly, 2020)	COVID-19 and Iranian medical students; a survey on their related-knowledge, preventive behaviors and risk perception	• Étude transversale (enquête en ligne menée du 26 au 28 février 2020) • 240 étudiants en médecine d'Iran, âge moyen 23,67 ans • Interventions de santé publique – réduire l'utilisation des espaces publics, respecter l'étiquette respiratoire, se laver les mains, désinfecter les surfaces, discuter avec d'autres des comportements préventifs	• 94,2 % des participants ont obtenu de bons résultats en matière de comportements préventifs • Les comportements préventifs et la perception du risque signalés par les personnes interrogées ont une corrélation négative significative. (rs = -0,128; P < 0,05) • La perception du risque diminue à mesure que les comportements préventifs augmentent
(Yang, Bin et He, 2020)	Opinions from the epicenter: an online survey of university students in Wuhan amidst the COVID-19 outbreak	• Étude transversale (enquête en ligne réalisée les 28 et 30 janvier 2020) • 8 252 étudiants universitaires de Wuhan, Chine • Interventions de santé publique – hygiène des mains, port d'un masque facial, réduction des activités de plein air	• Il y avait une conformité comportementale positive chez les répondants. Près de 90 % des participants portaient un masque chirurgical lors de leurs sorties, plus des deux tiers avaient renforcé la pratique de l'hygiène des mains et presque tous avaient réduit les activités de plein air • Les personnes plus anxieuses et effrayées avaient tendance à adopter des pratiques plus strictes en matière de port de masque et d'hygiène des mains, en réaction naturelle aux risques perçus
(Saddik et coll., 2020) *Préimpression*	Increased levels of anxiety among medical and non-medical university students during the COVID-19	• Étude transversale (enquête en ligne réalisée du 11 au 21 mars 2020) • 1 385 étudiants en médecine (dentaire et médecine) et étudiants d'autres programmes des Émirats arabes unis	• Le taux de conformité était globalement élevé et variait entre 58 % pour le port de gants et de masques, 77 % pour la diminution des visites dans les lieux très fréquentés et 85 % pour l'amélioration de l'hygiène des mains

	pandemic in the United Arab Emirates	• Interventions de santé publique – comportement hygiénique, restrictions sociales	• Les étudiants d'autres programmes que la médecine respectaient mieux les restrictions sociales, tandis que les étudiants en médecine avaient une meilleure hygiène des mains
(Lincango-Naranjo et coll., 2020) *Préimpression*	Paradigms about the COVID-19 pandemic: knowledge, attitudes and practices from medical students	• Étude transversale (enquête en ligne réalisée du 6 au 20 avril 2020) • 309 étudiants en médecine d'Équateur • Interventions de santé publique – hygiène des mains	• La majorité des participants (99 %) ont déclaré se laver fréquemment les mains
(Hamza, Badary et Elmazar, 2020)	Cross-sectional study on awareness and knowledge of COVID-19 among senior pharmacy students	• Étude transversale (enquête en ligne réalisée du 28 au 30 avril 2020) • 238 étudiants en pharmacie en Égypte • Interventions de santé publique – éviter les lieux publics, porter le masque en public, maintenir la distance sociale	• Les femmes sont plus susceptibles que les hommes d'éviter de sortir dans des endroits bondés et de maintenir une distance sociale • Des associations significatives ont été notées entre le port du masque en public et l'accès à l'information sur la COVID-19 à partir de la télévision, ainsi que le maintien d'une distance sociale de 2 mètres et l'utilisation des conseils des médecins sur la COVID-19

ADHÉSION AUX INTERVENTIONS DE SANTÉ PUBLIQUE CHEZ LES ENFANTS ET LES ADOLESCENTS

Le respect des comportements de protection chez les enfants et les adolescents a été évalué dans quatre études (tableau 3). Parmi ces études, trois études réalisées en Chine (n=2) et en Norvège (N=1) ont montré des taux de conformité modérés à élevés et une étude réalisée en Inde a montré des taux de conformité faibles.

- Le sexe féminin a été associé de manière significative à une meilleure hygiène des mains et au respect général des interventions de santé publique.

- Parmi les autres facteurs en corrélation avec une meilleure observance, citons la profession du père, le niveau d'éducation de la mère, le lieu de résidence et les personnes issues de l'immigration.
- Une étude a montré que le respect des comportements préventifs des élèves de l'école primaire était généralement supérieur à celui des élèves du secondaire (Wen et coll., 2020).

Tableau 3. Quatre études évaluant l'adhésion aux mesures de santé publique pour lutter contre la COVID-19 et les facteurs associés chez les enfants et les adolescents

Référence	Titre de la publication	Description de l'étude	Principaux résultats
Enfants et adolescents			
(Chen et coll., 2020)	Hand hygiene, mask-wearing behaviors and its associated factors during the COVID-19 epidemic: a cross-sectional study among primary school students in Wuhan, China	• Étude transversale (enquête en ligne menée du 16 au 25 février 2020) • 8 569 élèves de l'école primaire de Wuhan, en Chine, âgés de 6 à 13 ans • Interventions de santé publique – port de masques faciaux, hygiène des mains	• 42,05 % et 51,60 % des élèves de l'école primaire ont montré de bons comportements en matière de lavage des mains et de port de masque, respectivement • Le sexe (féminin), l'année d'études (3e à 6e), les antécédents de sortie, la profession du père et le temps passé à remplir l'enquête ont été associés de manière significative à l'hygiène des mains • L'année d'études (5e à 6e), le niveau d'éducation de la mère et le lieu de résidence étaient associés au port du masque
(Saurabh et Ranjan, 2020)	Compliance and psychological impact of quarantine in children and adolescents due to COVID-19 pandemic	• Étude transversale (entretiens avec les parents et les enfants, dates de réalisation non communiquées) • 121 enfants et adolescents de 9 à 18 ans en Inde • Interventions de santé publique – mesures préventives au niveau des ménages (par exemple, utilisation de serviettes distinctes) et de la communauté (distanciation sociale)	• Le respect du comportement de quarantaine varie de 25,61 % (ont dormi seuls dans une chambre séparée) à 83,47 % (n'ont pas fait de courses) • Le respect global de tous les comportements était de 7,43 %. Le respect de toutes les mesures de protection des ménages et de la communauté était de 10,71 % et 17,35 %, respectivement

			• L'activité la plus difficile à respecter était de ne pas sortir de la maison pour socialiser (65,26 %)
(Wen et coll., 2020) *Préimpression*	Knowledge, attitudes, and practices towards COVID-19 among primary and middle school students during the COVID-19 outbreak period in Beijing: an online cross-sectional survey	• Étude transversale (enquête en ligne menée du 2 au 13 mars 2020) • 7 377 étudiants de 9 à 18 ans à Pékin • Interventions de santé publique – Réduire les sorties inutiles, porter un masque à l'extérieur, se laver fréquemment les mains, avoir une alimentation saine, éviter les transports en commun, respirer de manière hygiénique, nettoyer et désinfecter régulièrement, ne pas se toucher le visage avant de désinfecter, agir lorsque des symptômes apparaissent, avoir une ventilation rationnelle et efficace, manger séparément	• Les taux de conformité pour les étudiants étaient les suivants : Réduire les sorties inutiles (97,1 %), porter un masque à l'extérieur (92,5 %), se laver fréquemment les mains (91,3 %), avoir une alimentation saine (86,5 %), éviter les transports en commun (85,8 %), respirer de manière hygiénique (85,4 %), nettoyer et désinfecter régulièrement (78,6 %), ne pas se toucher le visage avant de désinfecter (78,3 %), agir lorsque les symptômes se manifestent (57,8 %), avoir une ventilation rationnelle et efficace (39,2 %), manger séparément (38,6 %) • Le respect de comportements préventifs efficaces par les élèves de l'école primaire était généralement supérieur à celui des élèves du secondaire
(Soest et coll., 2020)	Compliance with infection control rules among adolescents in Oslo during the COVID-19 pandemic	• Étude transversale (enquête menée du 23 avril au 8 mai 2020) • 12 686 « jeunes » à Oslo, Norvège • Interventions de santé publique – se laver les mains, se serrer la main, éviter les grands groupes, respecter la distanciation sociale	• La majorité d'entre eux ont déclaré suivre les règles concernant le lavage des mains (n = 9 915, 84 %), ne pas se serrer la main/se serrer dans les bras (n = 8 730, 74 %) et éviter les grands groupes (n = 8 565, 73 %). Moins nombreux sont ceux qui ont déclaré avoir gardé une bonne distance (1 à 2 mètres) par rapport aux autres (n = 5 859, 50 %) • Le soutien le plus important à l'égard des règles a été constaté chez les filles, les jeunes issus de l'immigration et ceux qui vivent dans la périphérie est d'Oslo

ADHÉSION AUX INTERVENTIONS DE SANTÉ PUBLIQUE CHEZ LES TRAVAILLEURS DE LA SANTÉ

Sept études ont évalué l'adhésion aux comportements de prévention et de contrôle des infections contre la COVID-19 chez les travailleurs de la santé (tableau 4). L'adhésion globale varie selon les études, les établissements de santé et les comportements spécifiques.

- La proportion de travailleurs de la santé qui ont pris des mesures d'hygiène des mains allait de 79,44 % dans un groupe de travailleurs de la santé de Chine à 98,2 % dans un groupe de médecins de première ligne de Jordanie.
- Deux études démontrent que le fait d'être infirmière (par opposition à médecin, personnel infirmier et médical, agents médicaux et cliniques) était significativement associé à la conformité autodéclarée aux mesures de contrôle des infections. Parmi ces études sur les travailleurs de la santé, les résultats sont contradictoires en ce qui concerne le sexe en tant que prédicteur de la conformité déclarée.

Tableau 4. Sept études évaluant l'adhésion aux mesures de santé publique pour lutter contre la COVID-19 et les facteurs associés chez les travailleurs de la santé

Référence	Titre de la publication	Description de l'étude	Principaux résultats
Travailleurs de la santé			
(Suleiman et coll., 2020)	Preparedness of frontline doctors in Jordan healthcare facilities to COVID-19 outbreak	• Étude transversale (enquête en ligne réalisée du 23 au 27 mars 2020) • 308 médecins de première ligne en Jordanie, âge moyen 30,3 ± 5,8 • Interventions de santé publique – respect des directives relatives aux EPI (équipements de protection individuelle)	• Les scores d'adhésion de ces médecins étaient de 8,4 ± 1,5 sur 10 • Par exemple, 88 % des personnes interrogées lavent leur blouse, 98,1 % se lavent les mains avant de voir un patient, 93,8 % évitent les « tape m'en cinq » et les poignées de main, et 91,6 % laissent leurs chaussures au travail ou en dehors de la maison
(Tamari et coll., 2020)	Nationwide survey of COVID-19 prevention measures in Japanese radiotherapy departments via online	• Étude transversale (enquête en ligne réalisée du 16 au 23 avril 2020) • 184 radio-oncologues au Japon • Interventions de santé publique – hygiène des mains, utilisation de masques/EPI, distanciation sociale	• La majorité des personnes interrogées (81,0 %) ont indiqué avoir pris certaines mesures de lutte contre l'infection • Il y a eu des différences de conformité entre les services

	questionnaire for radiation oncologists		• 8,1 % des personnes interrogées ont déclaré utiliser des EPI dans leur pratique de la radiothérapie et 63 % ont pris une distance sociale appropriée avec les patients • 96,2 % des participants qui ont eu un contact direct avec les patients portaient un masque, et 85,3 % qui n'ont pas eu de contact direct avec les patients portaient un masque
(Chatterjee et coll., 2020)	Attitude, practice, behavior, and mental health impact of COVID-19 on doctors	• Étude transversale (enquête en ligne menée du 28 mars au 6 avril 2020) • 152 médecins au Bengale occidental, en Inde • Interventions de santé publique – hygiène des mains, utilisation de masques/EPI	• La majorité des médecins utilisent un masque chirurgical (58,6 %), mais seuls quelques-uns utilisent des masques N95 (19,7 %) • 95,4 % déclarent qu'ils pratiquent une hygiène des mains régulière, mais déclarent également qu'ils se lavent principalement les mains en fonction des besoins (42,8 %) • Seuls 24,3 % ont accès à l'EPI et 11,2 % l'utilisent réellement
(Lai et coll., 2020)	Will healthcare workers improve infection prevention and control behaviors as COVID-19 risk emerges and increases, in China?	• Étude transversale (enquête menée du 15 au 17 janvier 2020) • 1 581 travailleurs de la santé en Chine (n=1581) • Interventions de santé publique – hygiène des mains, EPI, nettoyage des terminaux	• Dans l'ensemble, un diplôme d'études supérieures, des années de travail plus longues, le sexe féminin (par rapport au sexe masculin) ont eu un effet négatif significatif sur le respect des mesures de lutte contre les infections autodéclarées • Le fait d'être infirmière (par opposition aux médecins) a eu des effets positifs significatifs sur l'autodéclaration de la conformité aux mesures de lutte contre les infections • Le fait de travailler dans des services à haut risque était associé à une meilleure

			conformité, tandis que l'exposition à des patients confirmés ou suspectés réduisait la conformité au contrôle des infections
(Zhou, Lai, Zhang et Tan, 2020)	Compliance measurement and observed influencing factors of hand hygiene based on COVID-19 guidelines in China	• Étude transversale (observations directes effectuées du 5 au 7 mars 2020) • Travailleurs de l'hôpital de Tongji et de 17 groupes médicaux d'autres provinces de Chine • Interventions de santé publique – hygiène des mains à 17 moments (par exemple, avant de toucher un patient, avant une procédure aseptique, après être allé aux toilettes, etc.)	• La conformité globale pour 17 moments liés à l'hygiène des mains était de 79,44 % • La conformité globale la plus élevée était associée au moment précédant le port de gants (91,67 %), et la plus faible au moment après avoir touché l'environnement du patient (65,56 %) • La conformité globale était de 85 % dans le service des soins intensifs, 79,18 % dans le service des soins non intensifs, 76,07 % dans la zone contaminée, 84,38 % dans la zone semi-contaminée et 84,21 % dans la zone hygiénique
(Martín et coll., 2020)	Prevalence of SARS-CoV-2 infection in general practitioners and nurses in primary care and nursing homes in the healthcare area of León and associated factors	• Étude transversale (étude menée pendant les deux premières semaines d'avril 2020) • 676 infirmières et médecins de centres de soins primaires et de maisons de retraite dans la zone de soins de santé de León (Espagne) • Interventions de santé publique – respect général des mesures préventives	• Le degré de conformité aux mesures préventives a été enregistré sur une échelle de Likert de 0 à 10, 0 étant le degré d'exposition ou de conformité le plus faible et 10 le plus élevé • 31 % ont déclaré un taux élevé de respect des mesures préventives (10 points dans l'enquête)
(Contejean et coll., 2020)	Comparing dynamics and determinants of SARS-CoV-2 transmissions among health care workers of adult and pediatric settings in central Paris	• Étude prospective réalisée du 24 février au 10 avril 2020 • 336 travailleurs de la santé à Paris, France • Interventions de santé publique – porter un EPI approprié, porter un masque correctement, éviter les transports en commun, porter un masque à l'extérieur du domicile	• La majorité des travailleurs ont rappelé un contact sans EPI avec un cas index. Les EPI ont été plus souvent utilisés dans des environnements d'adultes (56/227) que dans des environnements d'enfants (16/109) • La plupart des salariés ont déclaré porter un masque toujours/la plupart du temps à

			l'hôpital, mais 65/336 (19 %) ont admis enlever leur masque pendant les pauses en présence d'autres collègues (204/336, 61 % pendant les pauses déjeuner). Plus de la moitié (201/336, 60 %) ont déclaré utiliser les transports en commun, dont le 112/201 (56 %) plus d'une heure par jour, mais moins de 25 % (82/334) portaient un masque en dehors de chez eux

L'ADHÉSION AUX INTERVENTIONS DE SANTÉ PUBLIQUE DANS D'AUTRES POPULATIONS

Cinq études sur l'adhésion aux mesures de santé publique visant à contrôler la COVID-19 ont été recensées dans quatre autres populations, tableau 5. Ces autres populations comprennent les femmes enceintes, les employés, les visiteurs des hôpitaux et les migrants.

Tableau 5 Cinq études sur l'adhésion aux mesures de santé publique pour lutter contre la COVID-19 dans d'autres populations

Référence	Titre de la publication	Description de l'étude	Principaux résultats
Femmes enceintes			
(Yassa et coll., 2020)	Near-term pregnant women's attitude toward, concern about and knowledge of the COVID-19 pandemic	• Étude transversale (détails de l'enquête non communiqués) • 172 femmes enceintes en Turquie • Interventions de santé publique – autosurveillance	• La majorité des femmes (87,2 %) ont respecté les règles d'autodiscipline
Visiteurs dans les hôpitaux			
(Gunasekaran et coll., 2020) *Préimpression*	Prevalence and acceptance of glove wearing practice among general population when visiting high risk are during local COVID-19 outbreak	• Étude transversale (dates non communiquées) • 40 personnes fréquentant les hôpitaux et 30 fréquentant les marchés traditionnels de produits frais en Malaisie • Interventions de santé publique – port de gants et de masques	• On a observé un plus grand nombre de personnes fréquentant le marché traditionnel de produits frais (30,0 %) qui n'avaient pas de bonnes pratiques pour le port de gants par rapport aux personnes visitant l'hôpital (8,9 %), $\chi 2$ (1) = 5,60, p=0,018

			• Les hommes utilisent davantage de gants de qualité médicale (78,8 %) que de gants de qualité non médicale (21,2 %), tandis que les femmes utilisent autant de gants de qualité médicale (50,0 %) que de gants de qualité non médicale (50,0 %), $\chi 2$ (1) = 6 546, p=0,011 • L'utilisation de gants était plus élevée chez les non-Malais (53,3 %) que chez les Malais (46,7 %) à l'hôpital et l'utilisation de gants était plus élevée chez les Malais que chez les non-Malais (16,7 %) dans le marché traditionnel de produits frais, $\chi 2$ (1) = 10,20, p=0,001
(Sahiledengle et coll., 2020) *Préimpression*	Hand washing compliance and COVID-19: a non-participatory observational study among hospital visitors	• Étude transversale (observations directes effectuées du 27 avril au 3 mai 2020) • 1 282 personnes entrant dans les hôpitaux en Éthiopie • Interventions de santé publique – hygiène des mains	• Seulement 0,9 % (95 % IC : 0,4 à 1,4) des participants ont pleinement respecté les techniques de lavage des mains recommandées • La plupart des participants (47,2 %, 95 % IC : 44,4 à 49,9) présentaient une conformité minimale et 20,1 % (95 % IC : 17,8 à 22,3) n'étaient pas conformes • Il n'y a pas de différence dans les conformités entre les sexes (0,9 % contre 0,7 %, P = 0,745)
Migrants			
(Mannan et Farhana, 2020) *Préimpression*	The COVID-19 pandemic: challenges and reality of quarantine, isolation and social distancing	• Étude transversale (enquête menée du 1er février au 31 mars 2020) • 3 281 migrants de retour de 8 divisions administratives du Bangladesh âgés de 18 ans et plus	• Seulement 2,74 % ont été officiellement en quarantaine pendant 14 jours. Seulement 1,98 % ont respecté les 14 jours d'isolement personnel prévus par les règles de soins de santé et seulement 3,38 % ont

	for the returnee migrants in Bangladesh	• Interventions de santé publique – quarantaine, isolement et distanciation sociale pendant 14 jours	respecté les 14 jours de distanciation sociale • En plus des 14 jours prévus dans la règle d'avertissement sanitaire, il y a aussi une réticence à respecter la règle de la distanciation sociale pendant l'épidémie (seulement 5,05 % s'y sont conformés)
Employés			
(Wang, Yi Wong et Ho, 2020) *Préimpression*	Availability of workplace policy for prevention of coronavirus disease 2019 and its relationship with personal protective behaviors: a survey of employees	• Étude transversale • 1 048 employés de Hong Kong • Interventions de santé publique – hygiène des mains, port d'un masque facial, distanciation sociale, hygiène domestique	• La conformité varie selon les mesures de protection (par exemple, 77,1 % ont déclaré se laver toujours les mains avant les repas et 51,2 % ont déclaré qu'ils évitaient toujours de quitter leur domicile) • Les comportements en matière de protection personnelle diffèrent selon les sous-groupes sociodémographiques en termes d'âge, de sexe, de conditions de vie, de situation matrimoniale, de niveau d'éducation et de statut professionnel • Les employés disposant de directives et de mesures sur le lieu de travail ont eu plus souvent des comportements de protection personnelle, et cette association était plus importante chez les directeurs/administrateurs et les travailleurs manuels

RECHERCHE DE SYNTHÈSE SUR L'ADHÉSION AUX INTERVENTIONS DE SANTÉ PUBLIQUE

Trois examens sur le respect des mesures de santé publique visant à contrôler les maladies infectieuses ont été recensés, au tableau 6. Ces examens ne contenaient pas de preuves précises sur la COVID-19.

Tableau 6 Trois études sur le respect des mesures de santé publique pour les maladies infectieuses

Référence	Titre de la publication	Description de l'étude	Principaux résultats
Revues			
(Webster et coll., 2020)	How to improve adherence with quarantine: rapid review of the evidence	• Examen rapide des données probantes • Les recherches ont porté sur des données probantes recueillies jusqu'au 27 janvier 2020 • AMSTAR : qualité modérée • 14 articles sont inclus dans l'examen • Aucun article propre au SRAS-CoV-2	• Le respect de la quarantaine varie de 0 à 92,8 %. • Les principaux facteurs associés à l'adhésion étaient les connaissances des personnes sur la maladie et la procédure de quarantaine, les normes sociales, les avantages perçus de la quarantaine et le risque perçu lié à la maladie
(Houghton et coll., 2020)	Barriers and facilitators to healthcare workers' adherence with infection prevention and control (IPC) guidelines for respiratory infectious diseases: a rapid qualitative evidence synthesis	• Synthèse rapide de données probantes qualitatives • Les recherches ont porté sur des données probantes recueillies jusqu'au 26 mars 2020 • AMSTAR : bonne qualité • 20 articles sont inclus dans l'examen	• Plusieurs facteurs influencent la capacité et la volonté des travailleurs de la santé de respecter les directives de CPI, notamment le contenu des directives et la manière dont elles sont communiquées, le soutien des responsables, la culture du lieu de travail, la formation, l'espace physique, l'accès et la confiance dans les EPI et le désir de fournir de bons soins aux patients
(Brooks, Greenberg, Wessely et Rubin, 2020) *Préimpression*	Factors affecting healthcare workers' compliance with social and behavioral infection control measures during emerging infectious disease outbreaks: Examen rapide des données probantes	• Examen rapide des données probantes • Les recherches ont porté sur des données probantes recueillies jusqu'au 4 mai 2020 • AMSTAR : qualité modérée • 56 articles sont inclus dans l'examen	• Le personnel travaillant dans les situations d'urgence ou dans les unités de soins intensifs semble plus enclin à respecter les recommandations que celui travaillant dans d'autres contextes • Le personnel plus anxieux et plus préoccupé par le risque d'infection était plus enclin à se conformer • Il a également été constaté que des associations négatives entravaient le respect des règles, comme le non-respect observé de la part des collègues, la disponibilité des EPI, la perception de la difficulté et de l'efficacité, les désagréments et l'inconfort

Méthodes

Toute la littérature sur la COVID-19 a été compilée et classée par le Groupe des sciences émergentes de l'Agence de la santé publique du Canada depuis le début de l'épidémie. Cela suppose une recension quotidienne de la littérature pour tous les articles publiés et prépubliés. Les recherches pour trouver de la littérature pertinente sur la COVID-19 sont menées dans PubMed, Scopus, BioRxiv, MedRxiv, ArXiv, SSRN et Research Square. Elles sont mises en correspondance avec les publications figurant sur la liste de littérature de l'Organisation mondiale de la santé au sujet de la COVID et les centres d'information COVID-19 gérés par Lancet, BMJ, Elsevier et Wiley. Le résumé quotidien et les résultats complets de la recension sont conservés dans une base de données Refworks et un fichier Excel qui peut être consulté. Chaque article est étiqueté en fonction de divers critères permettant de déterminer le thème central de l'article (p. ex. épidémiologie, données cliniques, thérapeutique, etc.) Une recherche ciblée par mot-clé est effectuée dans ces bases de données pour y relever des citations pertinentes sur la COVID-19 et le SARS-CoV-2. Les termes de recherche inclus dans cet examen étaient la conformité, l'adhésion et le comportement. Chaque référence potentiellement pertinente a été analysée pour confirmer sa pertinence, et des données ont été extraites et incluses dans la recension de la littérature. Cette revue contient des recherches publiées jusqu'au 19 juillet 2020.

Emerging Evidence on COVID-19

Evidence Brief on Age-Dependent Transmission

Introduction

What is the evidence for age-dependent transmission of SARS-CoV-2?

It is important to establish whether there are differences in the potential to transmit SARS-CoV-2 among children of different age groups (preschool 0-4 years old, primary school 5-11 years old, intermediate 12-13 years old and high school 14-19 years old) compared to adults. This evidence brief is an update to the June 22, 2020 version and includes COVID-19 literature up to July 20, 2020 that measures age-dependent transmission or estimates transmission scenarios among children of different age groups such as in school.

Key Points

- Empirical evidence suggests that a low proportion of SARS-CoV-2 cases occur in children <19 years old. Of the cases in children, a large proportion may be asymptomatic, but they are still capable of transmitting the virus (Table 1).
- Few contact tracing or outbreak studies have reported children <19 years old as the index case (Table 1). However, there are instances where an infected child has passed SARS-CoV-2 to an adult or another child. Most studies conclude that children have not been the main drivers of transmission of SARS-CoV-2 to date.
- One study estimated the relative infectivity of children to adults to be 85% (65-110%). However, few children were the index case in the household outbreaks investigated, which resulted in the study being underpowered (Dattner et al., 2020). In a systematic review, pooled odds ratio of being an infected contact in children compared with adults for all contact tracing studies was reported as 0.44 (0.29, 0.69) (Viner et al., 2020).
- Viral load in symptomatic children was shown to be the same as adults in three studies of symptomatic COVID-19 cases (Table 2).
- Six publications use mathematical models to investigate the impact of relaxing intervention measures by targeting different age groups on the epidemic (Table 1).
    - Re-opening schools: the most recent model examines the risk of opening schools in a low transmission vs. high community transmission scenario, indicating opening schools in low transmission scenarios along side other public health interventions did not result in a large spike in cases. Two other mathematical models demonstrate that allowing younger children (pre-school and primary school aged) to return to school would have the smaller impact on the basic reproduction number (R0) , whereas the return of secondary school grades will have

the greatest impact (Di Domenico, Pullano, Sabbatini, Boëlle, & Colizza, 2020; Keeling et al., 2020).

- Of the three models that analyzed lifting interventions by age groups, results suggest that relaxing measures by age group could reduce the impact of COVID-19. Specifically, releasing younger individuals (0-19) from strict lockdown can lead to lower overall fatality rates compared to the simultaneous release of all individuals after a lockdown (Castilho, Gondim, & Marchesin, 2020; Zhao & Feng, 2020).

Overview of the Evidence

The evidence for age-dependent transmission of SARS-CoV-2 has been directly and indirectly explored in a number of predictive models. These models are based on scenarios and are parameterized using observational data from the outbreak; caution should be exercised in using these findings, as the extent to which the results can be generalized to the local context is variable.

Empirical evidence from surveillance, estimates of transmission and descriptions of transmission clusters or outbreaks are obtained from data collected during retrospective outbreak investigations, which have a moderate to high risk of bias. Many studies identified in this brief are in preprint format and have not completed a peer-review process. There is some evidence that may allow estimation of transmission rates among child age groups compared to adults, this evidence is accumulating rapidly and there is a high probability that estimates or conclusions will change as additional evidence becomes available.

CONTENTS

EVIDENCE OF AGE-DEPENDANT TRANSMISSION AND TRANSMISSION POTENTIAL

The age distribution of COVID-19 cases has shown strong age dependence with fewer cases documented in children, and few transmission events attributed to transmission from an infected child. In this updated review, several studies were added from cluster investigations and school community investigations conducted in countries in Asia, Europe, Australasia, North America and South America that add a significant update to this review.

It is hypothesized that the apparent age-dependence we see in epidemiological data may have several contributing factors including that children may be less susceptible to infection and/or are less prone to showing clinical symptoms when infected. Several studies in Table 1 provide evidence that a significantly lower proportion of children are infected with SARS-CoV-2 compared to adult populations, that children are less susceptible to SARS-CoV-2 infection than adults and that they may be less likely to have symptoms. This susceptibility appears to increase between 10 and 20 years old. Models like the one by Davies et al. show the impact of different rates of transmission by age and the impact of assumptions around how readily asymptomatic or paucisymptomatic transmission occurs (Davies et al., 2020).

Contact tracing studies in Table 1, such as the results from South Korea, agree that children are infrequently identified as the index case or a contact in cluster investigations. However, a unique finding of this study was that the few 10-19 year old index cases had a high rate of transmission (18.6%) compared to their household contacts (Park et al., 2020). Speculation around this increase in transmission includes that children in this age group are taller, and can contaminate more shared air with adults and that they may be less likely to adhere to optimal personal hygiene behaviors. Across other studies a child <18 years old is rarely implicated as the index case in a family or non-household cluster (Table 1).

Similarly, there were seven investigations within school communities. Even though cases were identified in the school, most were not attributed to transmission at school and instead were attributed to transmission from a family member at home. Two of the school investigations from Chile and France reported very high seroprevalence after school closures (Fontanet, Tondeur et al., 2020; Torres et al., 2020). The study in France was in one of the epicenters of an outbreak, and was thought to have been going on for approximately 3 weeks before the school closed. The results were high seroprevalence across all age groups in this investigation (Fontanet, Tondeur et al., 2020). The study from a school community in Santiago Chile indicated that the there was high prevalence among the preschool teachers and parents due to meetings that had taken place in the first few weeks of schools opening (Torres et al., 2020).

Table 1: Twenty-three studies that inform age-dependent factors of COVID-19 transmission including predictive models (n=2), contact tracing studies (n=10), school/daycare studies of transmission (n=7), synthesis research on age related transmission (n=4)

Reference	Title	Study Description	Key Outcomes
Predictive Models of age-dependent transmission			
(Davies et al., 2020)	Age-dependent effects in the transmission and control of COVID-19 epidemics	Dynamic transmission models were fit to a range of available data on the age distribution of reported cases, and 2studies that looked for infections among close contacts, to estimate the age-specific susceptibility to SARS-CoV-2 infection and the age-specific fraction of infections that develop full clinical symptoms of COVID-19. Data from China, Italy, Japan, Singapore, Canada and South Korea was used. The model examined epidemiological evidence to better understand whether children have lower susceptibility to infection, lower propensity to show clinical symptoms or both. The model accounting for both fit the data best.	• Susceptibility to SARS-CoV-2 infection in <20 yo is approximately half that of adults aged over 20 years. Relative susceptibility to infection was 0.40 (0.25-0.57) in 0-9 yo vs. 0.88 (0.70-0.99) in 60-69 yo. • Clinical symptoms manifest in 21% (95% credible interval: 12–31%) of infections in 10-19 yo, rising to 69% (57–82%) of infections in >70 yo. • Results were consistent across countries and intervention contexts. • These results show that interventions targeting schoolchildren may be less effective than for other respiratory infections. • Age-structure of a population is important for estimating the burden of SARS-CoV-2. • A comparison of COVID-19 vs. influenza in 3 cities with different age structures indicates that school closures delay the COVID-19 peak 1-6 days and decreased it by 10-19% vs. 10-89 days and 17-35% for influenza.
(Lau, Grenfell, Nelson, & Lopman, 2020)	Characterizing super-spreading events and age-specific infectivity of COVID-19 transmission in Georgia, USA	Individual-level spatiotemporal mechanistic framework to statistically integrate case data with geo-location data and aggregate mobility data, enabling a more granular understanding of the transmission dynamics of COVID-19. Data: March 1- May 3, the analysis included the 5 most infected counties with n=9559 COVID-19 cases with demographic information.	• They did not look at children as a separate age group because there were not enough observations. Younger children seem to be less susceptible to SARS-CoV-2. • We estimate that the infected children and adults <60 yo may be 2.38 [1.30, 3.51] times more transmissible than infected elderly (>=60 yo), and the former may be the main driver of super-spreading.

Surveillance / Contact Tracing Data			
(Park et al., 2020) *new*	Contact tracing during Coronavirus Disease outbreak, South Korea, 2020	Summary of S. Korea's retrospective cluster investigations from Jan 20- Mar 27 59073 contacts of 5706 COVID-19 cases were traced. RT-PCR was used to determine COVID-19 status. They did not test asymptomatic contacts and had different thresholds for testing household vs. non-household contacts. Age category: # index/# contacts traced 0–9: 29 (0.5%)/ 237 (0.4%) 10–19: 124 (2.2%)/ 457 (0.8%) 20–29: 1695 (29.7%)/ 15810 (26.8%) 30–39: 668 (11.7%)/ 8,636 (14.6%) 40–49: 807 (14.1%)/ 9709 (16.4%) 50–59: 1107 (19.4%)/ 11353 (19.2%) 60–69: 736 (12.9%)/ 8490 (14.4%) 70–79: 338 (5.9%)/ 2,389 (4.0%) >80: 202 (3.5%) / 1992 (3.4%) • Index and contracts in the 20-29 year group and the 50-59 year group represented the larges age categories identified as the index case and traced for COVID-19 infection. In this study, the index case was the first case to be identified in time since they could not confirm who transmitted to whom.	• Overall: o 11.8% (95% CI 11.2%–12.4%) of household contacts were infected o 1.9% (95% CI 1.8%–2.0%) of non-household contacts were infected. • Index case age category: positive/N (%, 95% CI) in household contacts. 0–9: 3/57 (5.3%,1.3–13.7) 10–19: 43/231 (18.6%,14.0–24.0) 20–29: 138/12393 (1.1%, 0.9–1.3) 30–39: 70/7,407 (0.9%, 0.7–1.2) 40–49: 206/1749 (11.8%, 10.3–13.4) 50–59: 300/2045 (14.7%, 13.2–16.3) 60–69: 177/1039 (17.0%, 14.8–19.4) 70–79: 86/477 (18.0%, 14.8–21.7) ≥80: 50/348 (14.4%, 11.0–18.4) o Note transmission from a 10-19 year old index case to household contacts was significantly higher that other younger age groups. • Index case age category: positive/N (%, 95% CI) in non-household contacts. 0–9: 2/180 (1.1%, 0.2–3.6) 10–19: 2/226 (0.9%, 0.1–2.9) 20–29: 138/12393 (1.1%, 0.9–1.3) 30–39: 70/7,407 (0.9%, 0.7–1.2) 40–49: 161/7960 (2.0%, 1.7–2.3) 50-59: 166/9308 (1.8%, 1.5–2.1) 60–69: 215/7451 (2.9%, 2.5–3.3) 70–79: 92/1912 (4.8%, 3.9–5.8) • ≥80: 75/1,644 (4.6%, 3.6–5.7)
(Van Der Hoek et al., 2020)	[De rol van kinderen in de transmissie van	Data from the Dutch surveillance system Osiris was analysed up to May 11, 2020.	• 0.9%, 369/42788 confirmed COVID-19 cases in the Netherlands have been 0-18 yo.

new	SARS-CoV-2] in Dutch	This is preliminary data and the study is on going. Family cluster investigations were prospective enrolment at first confirmed case between March 23 and April 16. N=54 families Note: schools were closed during this study period.	○ 0-3 yo, 74 cases ○ 4-11 yo, 38 cases ○ 12-18 yo, 257 cases • There was no difference between Ct values of children or adults. • Results of a transmission pair analysis indicated 21 cases of parent to child transmission and 2 cases of child-to-child transmission within a household. • None of the 43 contacts of 10 COVID-19 cases under 18 yo developed infections compared to adults where secondary transmission was 8.3%. • In the family investigations, children were less likely to report symptoms in the last 14 days (67%) vs. adults (91%) or have specific respiratory symptoms (25% vs. 78%) • Seroconversion at 2-3 weeks post initial investigation: ○ 1-5 yo, 21% (3/14) ○ 6-11 yo, 13% (4/31) ○ 12-17 yo, 32% (12/38) ○ 18-45 yo, 31% (11/35) ○ >45 yo, 43% (13/30) • The study concluded that children can become infected, but they do not appear to contribute as much to transmission as adults.
(Sun et al., 2020) *new*	Children infected with SARS-CoV-2 from family clusters	Analysis of 74 children admitted to a Wuhan hospital Jan 28- Mar3. Cases were confirmed by RT-PCR.	• In all pediatric cases at least one adult family member was infected before the children in the household.
(Somekh et al., 2020) *new*	The role of children in the dynamics of intra family Coronavirus 2019 spread in densely populated area	Bnei Brak, Israel, which is one of the most crowded cities in the world and the city with the highest rates of children per family in Israel.	• 13 family clusters were investigated. ○ 12/13 index cases were adults exposed at the synagogue, holiday feast, work or unknown in 50%. ○ 1/13 was 14.5 yo that was exposed at Yeshiva.

		Children 0–19 years of age comprise 50% of the 200,000 population. The average number of children in a family is 4.57.
		In each family cluster all members were tested by RT-PCR
			• RT-PCR positive cases within these clusters included [relative risk of being positive compared to >18yo]
			  ○ >18 yo: 58.3%, 21/36
			  ○ 5-17 yo: 32.5%, 13/40 [0.61, 95%CI 0.39–0.96, p=0.037]
			  ○ 0-4 yo: 11.8%, 2/18 [0.47, 95%CI 0.30–0.71, p<0.002]
			• The study concludes they could not show a dominant role for children in transmission of SARS-CoV-2 even in a densely populated city with a high proportion of children.

(Dattner et al., 2020) *new*	The role of children in the spread of COVID-19: Using household data from Bnei Brak, Israel, to estimate the relative susceptibility and infectivity of children	Data from Bnei Brak up to May 2 was used for analysis. Epidemiological cluster investigations of 637 households were included. Estimates were generated from a stochastic dynamic model.	• Most index cases were adults. • Adults had a higher risk of being infected than children (44% vs. 25%). • Children under 1 yo had a higher risk of being infected compared to those aged 1-4 yo. • Their model estimates that children may have a lower infectivity compared to adults. Relative infectivity 85% (65-110%). Few child index cases meant this estimate is underpowered.
(Lavezzo et al., 2020) p*reprint*	Suppression of COVID-19 outbreak in the municipality of Vo, Italy	Two population surveys were conducted to collect nasopharyngeal swabs from 2,812 and 2,343 in the municipality of Vo, Italy.	• No infections were detected in either survey in 234 tested children ranging from 0-10 yo, despite 13 of them living in the same household as infected people. Based on household secondary infection rate positive children were expected.
(Zhang et al., 2020)	Changes in contact patterns shape the dynamics of the COVID-19 outbreak in China	Contact surveys were conducted in two cities: Wuhan and Shanghai. The surveys were conducted from Feb 1 to Feb 10. The dataset included 1245 contacts in Wuhan and 1296 in Shanghai.	• Susceptibility to SARS-CoV-2 infection increased with age. Young individuals (aged 0-14 yo) had a lower risk of infection than individuals aged 15-64 yo {OR = 0.34 [95% confidence interval (CI): 0.24 to 0.49], p < 0.0001}.

(Mizumoto, Omori, & Nishiura, 2020) *preprint*	Age specificity of cases and attack rate of novel coronavirus disease (COVID-19)	Summarized Japan's cases up to March 7. 313 domestically acquired cases from 2496 close contacts that were investigated.	• The attack rate was low among children (male 7.2%, female 3.0%) compared to adults which peaked in the 50-59 age group (22.23%, 21.9%). As these were all exposed or symptomatic-suspected COVID-19 samples, it appears that the risk of disease given exposure is low among children.
(Bi et al., 2020)	Epidemiology and transmission of COVID-19 in 391 cases and 1286 of their close contacts in Shenzhen, China: a retrospective cohort study	Summary of case data from Jan 14 to Feb 12, 2020, the Shenzhen Center for Disease Control and Prevention. There were 391 SARS-CoV-2 cases and 1286 close contacts identified through symptomatic surveillance and contact tracing.	• Transmission from a child to adult was not documented. • The authors conclude that children had a similar risk of infection as adults. However, there are few observations and large uncertainty in the data for the child age categories. • Contact-based (exposed) testing results by age: 0-9= 14.9%, 10-19= 5.7%, 20-59= 10.3-17.2%. • Symptom-based testing results by age: 0-9 & 10-19= 2.1%, 20-59=7.9-24.3%.
(Danis et al., 2020)	Cluster of Coronavirus Disease 2019 (COVID-19) in the French Alps, February 2020	Ski Chalet outbreak in the French Alps February 2020. The index case spread SARS-CoV-2 to 11 people at the chalet during a 4 day stay.	• A pediatric case in this outbreak visited 3 different schools while symptomatic and no secondary cases were caused by this case.
School and Daycare Investigations			
(Yung et al., 2020) *new*	Novel coronavirus 2019 transmission risk in educational settings	Case reports of cases that attended daycare and secondary school from contact tracing studies in February and March in Singapore. Schools were not closed in Singapore, but they cancelled extracurricular activities, staggered breaks, and cohorted children. A strict cleaning protocol was also implemented. Daycares with a positive case closed for 14 days.	• 3 incidents are reported: ○ A 12 year old and a 5 year old were identified through contact tracing of an adult case they had contact with. None of the 8 symptomatic contacts at the secondary school or 34 in the preschool tested SARS-CoV-2 positive by RT-PCR. ○ The 3rd cluster was an adult staff member at a preschool. Up to 16 staff members were infected. 77 children (8 symptomatic) all tested negative.

			The 23% of children not swabbed did not develop symptoms.
(National Centre for Immunisation Research and Surveillance, 2020) *new*	COVID-19 in schools – the experience in NSW	In New south Wales between March and Mid-April 9 students and 9 staff from 15 different schools were diagnosed with SARS-CoV-2 infection. 735 students and 128 staff were close contacts.	• 2 children were potential secondary cases. • Most of the cases and observations were from high schools (12 cases/ 695 contacts). 235 contacts received RT-PCR tests and 75 received serology tests 30 days post exposure. One serology test was positive. • 1/263 close contact (53 tested) was identified from all the close contacts of 6 cases across 5 primary schools.
(Heavey, Casey, Kelly, Kelly, & McDarby, 2020) *new*	No evidence of secondary transmission of COVID-19 from children attending school in Ireland, 2020	The retrospective epidemiological investigations here targeted any case that had attended schools as a student or employee prior to school closures (Mar 12) in Ireland. Only symptomatic contacts were tested.	• 3 adults and 3 children had 1155 contacts between school, sports, music (woodwind instruments) and choir practice. • Only 1 transmission event was detected, this occurred outside of school between 2 infected adults and a susceptible adult.
(Armann et al., 2020) *new*	Anti-SARS-CoV-2 IgG antibodies in adolescent students and their teachers in Saxony, Germany (SchoolCoviDD19): very low seroprevalence and transmission rates	Seroprevalence survey conducted in eastern Saxony Germany among 13 secondary schools (grade 8-11) May 25- June 30, 2020. Anti-SARS-CoV-2 IgG were assessed using 3 assays starting with Diasorin Liaison, Abbott Diagnostics and Euroimmun to confirm results. 1538 students and 507 teachers participated in this study. The community PCR confirmed prevalence was 0.15% (based on surveillance data).	• Overall seroprevalence was 0.6% o Students 0.7%, 12/1538 (5 had confirmed COVID-19 and 22 had family members with confirmed COVID-19) o Teachers 0.2%, 1/507 (2 had family members with confirmed COVDI-19) • No clusters of cases were identified even from schools with COVID-19 cases prior to lockdown (March 13). • This paper concludes that students and teachers do not seem to play a crucial role in driving SARS-CoV-2.
(Fontanet et al., 2020) *new*	SARS-CoV-2 infection in primary schools in northern France	Retrospective cohort in France. Serological tests and questionnaire data were collected April 28-30 to measure exposure among	• Infection attack rate (IAR), no difference between groups (P = 0.29) o Students (primary school 6-11 yo) 45/510 (8.8%) o Teachers 3/42 (7.1%)

		primary school families and staff from February/March 2020. Before school closures Feb 14 there were 3 infected students.	○ Non-teaching staff 1/28 (3.6%) ○ Parents 76/641 (11.9%) ○ Relatives 14/119 (11.8%) • Familial clustering of cases was documented by the high proportion of antibodies among parents (61.0% versus 6.9%; P <0.0001) and relatives s (44.4% versus 9.1%; P = 0.002) of infected pupils. • Asymptomatic cases were reported in 41.4% of children and 9.9% of adults. Only 2 adults were hospitalized in this study group.
(Torres et al., 2020) *new*	SARS-CoV-2 antibody prevalence in blood in a large school community subject to a COVID-19 outbreak: a cross-sectional study	Santiago Chile outbreak March 12 (10 days after schools opened). 52 cases from a large school community (K-12, N=2950) were identified. The school was closed and the community was quarantined. Seroprevalence survey was conducted May 4-19 of all students and staff. Test used: The Novel Coronavirus (2019-nCoV) IgG/IgM Test Kit (Colloidal gold) from Genrui Biotech Inc, China, High school students had a significantly lower seropositivity (p=0.01) than other students. Among seropositive cases 40% (95%CI: 30-50%) of students and 18% (95%CI: 8-34%) of staff reported no symptoms.	• N=1009 students, 235 staff were included in the study ○ Preschool 12.3% (95%CI 7.8-18.6), N=147 ○ Elementary 10.8% (7.81-14.7), 286 ○ Middle School 11.9% (8.81-15.9), 295 ○ High School 5.7% (3.6-8.9), 281 ○ Teachers 20.6% (14.7-27.6), 165 ○ Support Staff 7.1% (2.4-15.9), 70 • Students had a higher seropositivity than staff p=0.003. • The primary school had higher seropositive staff and analysis of contact rates indicated children with more contacts were more likely to be seropositive. • Sources with the greatest likelihood of possible contagion in students were: a home caregiver (OR: 27.9), a household relative (OR: 5.4), a classmate (OR: 3.2), and teacher (OR: 2.2) This study attributes the age distribution to preschool parent-teacher meetings.
(Fontanet, Tondeur et al., 2020) *preprint, new*	Cluster of COVID-19 in northern France: a retrospective	After 2 cases from a high school were identified in Oise France, part of the epicenter, a retrospective seroepidemiology study was conducted March 30- April 4th to	• 452/661 participants reported symptoms. • 10 participants were hospitalized (9 were SARS-CoV-2 seropositive) and there were no deaths. Serology Results: • 171/661 had antibodies

	closed cohort study	investigate the pupils, teaches and non-teaching staff serology levels.
		Response rate was 37%, this low level of participation may reflect a bias in the sample.
		They also sampled a nearby blood bank for comparison.
			• IAR of 25.9% (95%CI; 22.6-29.4)
			  ○ Pupils = 38.3%
			  ○ Teachers = 43.4%
			  ○ Non-teaching staff = 59.3%
			  ○ Parents = 11.4%
			  ○ Siblings = 10.2%
			• IFR 0% (one-sided 97.5% CI:0 - 2.1).
			• Hospitalization rate 5.3% (95%CI: 2.4 –9.8).
			• The blood donor samples had seropositive rates of (3.0%, 95%CI = 1.1- 6.4).
			• Based on the epidemiological information there appears to have been an outbreak at this high school from the last week of January to mid-February when schools closed.

Synthesis Research			

(Li et al., 2020)	The role of children in transmission of SARS-CoV-2: a rapid review	Rapid Review (search date Apr30):
		Evidence for four categories:
		1) studies reporting documented cases of SARS-CoV-2 transmission by infected children;
		2) studies presenting indirect evidence on the potential of SARS-CoV-2 transmission by (both symptomatic and asymptomatic) children;
		3) studies reporting cluster outbreaks of COVID-19 in schools; and,
		4) studies estimating the proportions of children infected by SARS-CoV-2.
			• 16 studies included
			• Conclusions:
			  ○ Case series and outbreak reports detailing transmission in children are few. Those studies which are available demonstrate that transmission by children is possible but do not quantify the likelihood of transmission in children compared to adults.
			  ○ There is little evidence on transmission dynamics in school settings. Given the current paucity of data, further investigation and close monitoring will be essential where schools have re-opened and in settings where schools have remained open.
			  ○ Children are infected, but perhaps less frequently than adults.

(Ludvigsson, 2020a)	Children are unlikely to be the main drivers of the COVID-19 pandemic: a systematic review	Systematic review up to May 12, (no protocol, data extraction or quality assessment = low quality). The authors screened 600 papers to identify key papers for the review.	• Children make up a small percentage of cases across studies. • Children tend to have milder disease. • Children are rarely the index case in household transmission events. • Even asymptomatic children have viral loads, but opening daycares and schools is unlikely to have an impact on the bigger picture of mortality.
(Viner et al., 2020) *preprint*	Susceptibility to and transmission of COVID-19 amongst children and adolescents compared with adults: a systematic review and meta-analysis	Rapid systematic review up to May 16. Includes 18 studies on contact tracing and population screening. The analysis dichotomized age at <20 yo.	• Pooled odds ratio of being an infected contact in children compared with adults for all contact tracing studies was 0.44 (0.29, 0.69). • There was heterogeneity across countries in terms of the proportion of children infected. • There is weak evidence that children and young people play a lesser role in transmission of SARS-CoV-2 at a population level.
(Zhu et al., 2020)	Children are unlikely to have been the primary source of household SARS-CoV-2 infections	A review of the literature up to March 31. They looked for evidence of the role of children in transmission of SARS-CoV-2.	• 3/31 clusters investigated had a pediatric index case. This suggests that children are not the primary source of household transmission.

IAR= Infection Attack Rate, IFR= Infection fatality rate, CI= confidence interval.

One of the hypotheses suggested to explain why children seem to transmit SARS-CoV-2 less frequently than adults is that their viral load may be lower. Three studies were included in this review, two used RT-PCR cycle counts to estimate viral load and the third cultured virus from RT-PCR positive samples. All three studies (Table 2) sampled only symptomatic cases, and all agreed that the viral load was not different from adults.

Two case studies (Table 2) of several SARS-CoV-2 infected children failed to detect transmission to their caregivers, with the possible exception of an infant who may or may not have been the index case in her family.

Studies measuring the proportion of SARS-CoV-2 infection in children have consistently reported lower infection prevalence compared to adults regardless of whether the sampling frame is targeted at potentially exposed, high risk populations or targeted at the general population (Desmet et al., 2020; Gudbjartsson et al., 2020; Johansen et al., 2020; Ludvigsson, 2020b)

Table 2: Nine studies that describe viral load (n=3) and proportion of SARS-CoV-2 by age group or SARS-CoV-2 case studies (n=2) of transmission and synthesis of research (n=1) on children

Reference	Title	Study Description	Key Outcomes
Viral Load in Samples from Symptomatic Cases of Different Age Groups			
(Baggio et al., 2020) *preprint, new*	SARS-CoV-2 viral load in the upper respiratory tract of children and adults with early acute COVID-19	Switzerland, single center cross-sectional study of viral load among children and adults tested within 5 days of symptom onset by RT-PCR. Data collected March 10-May 26. N=405	• Viral load in log10 RNA copies/mL, o Child (0-11 yo): 6.13 ± 2.02 (range 3.06-9.21) o Adolescent (12-19 yo): 5.85 ± 2.32 (range 2.36-9.42) o Young adult (20-45 yo): 5.91 ± 1.88 (range 2.37-9.39) o Adult (>45 yo): 6.33 ± 2.05 (range 2.49-9.39) • No correlation between viral load and age was found in this study.
(L'Huillier, Torriani, Pigny, Kaiser, & Eckerle, 2020) *new*	Culture-competent SARS-CoV-2 in nasopharynx of symptomatic neonates, children, and adolescents	Switzerland, case series of 23 children. They cultured SARS-CoV-2 from the upper respiratory tract samples between Jan 25- Mar 31. 23/638 patients <16 years were SARS-CoV-2 positive. Samples were collected a median of 2 days post symptom onset.	• 12/23 children had virus that could be cultured. o Median viral RNA load (VRL) at diagnosis was 3.0×10^6 copies/mL o Mean VRL 4.4×10^8 [IQR 6.9×10^3–4.4×10^8] copies/mL o Peak VRL 5.3×10^9 copies/mL • The data show that viral load at diagnosis is comparable to that of adults, and that symptomatic children of all ages shed infectious virus in early acute illness.

(Jones et al., 2020)	An analysis of SARS-CoV-2 viral load by patient age	Jan 1 to Apr 26 virology laboratories at Charité, Berlin screened 59,831 patients for COVID-19 infection, 3,712 (6.2%) with a positive real-time RT-PCR result.
		School groups: kindergarten (ages 0-6), grade school (ages 7-11), high school (ages 12-19), university (ages 20-25), adult (26-45 years), and mature (age over 45).
			• Although there were fewer children tested than adults, the proportion positive:
			  ○ By 10 year blocks,
			  ▪ 1-10 yo=2.25%
			  ▪ 11-20 yo=3.9%
			  ▪ adult age groups 4.96-6.25%
			  ▪ elderly 7.8-10.69%
			  ○ By school group,
			  ▪ kindergarten =2.10%
			  ▪ grade school =2.57%
			  ▪ high school 4.13%
			  ▪ university 5.82%
			  ▪ adults 5.27%
			  ▪ mature adults 7.56%
			• Viral load was reported to be not significantly different across age groups by the author.
			• The viral load was back translated to: 43k 1-10 yo, 63k 11-20 yo, 183k 21-30 yo, 164k 31-40 yo. P=0.008 by kurkal-wallis test.

Case studies			
(Wongsawat et al., 2020)	Risk of novel coronavirus 2019 transmission from children to caregivers: a case series	This study reports on 3 cases in children in Thailand. The children were exposed by an infected family member.	• Caregivers of the mildly sick children did not develop an infection to SARS-CoV-2.
(Cai et al., 2020)	A case series of children with 2019 novel coronavirus infection: clinical and epidemiological features	Case series of pediatric cases. N=10 describes the clinical course of each case. One case may have transmitted to her parents, although it is plausible that she had a shorter incubation period.	• A 3 month old infant that became ill with COVID-19 prior to her parents. They were from Wuhan and exposure of the infant is unknown.

Only Report on Proportion of Children Infected with SARS-CoV-2			
(Gudbjartsson et al., 2020)	Spread of SARS-CoV-2 in the Icelandic population	This study describes the results of two sampling techniques in Iceland. 1) symptom/contact history and 2) population screening.	• Targeted testing of children: (<10 years) 38/564 positive (6.7%) vs. older ages 1183/8635 (13.7%). There was a gradual increase in the proportion that tested positive between 10 and 20 years. • The population screening group detected 0/848 children positive vs. 100/12232 (0.8% 95%CI 0.7-1.0) in older ages groups, this is despite the school remaining open in Iceland. • Children in Iceland had lower positive tests compared to other age groups despite not closing their schools.
(Johansen et al., 2020)	Infection prevention guidelines and considerations for paediatric risk groups when reopening primary schools during COVID-19 pandemic, Norway, April 2020	Summary of a risk assessment and IPC guidelines developed by the Norwegian Institute for Public Health. Data up to May 11	• 8135 COVID-19 cases in Norway o 0-5 yo 0.9%, n=72 o 6-13 yo 2.0%, n=162 o 14-19 yo 4.2%, n=341 o >19 yo 93%, n=7560 • The rest of the document includes guidelines for school re-opening.
(Desmet et al., 2020)	No SARS-CoV-2 carriage observed in children attending daycare centers during the first weeks of the epidemic in Belgium	An on-going study in Belgium of nasopharyngeal carriage in daycare children was on-going at the start of the epidemic. From March 2-12 samples collected across 8 daycare centers were tested for SARS-CoV-2.	• 0/84 positive samples from children age 6 months to 30 months. • There was no evidence of SARS-CoV-2 transmission at these daycare facilities.
Synthesis Research			

(Ludvigsson, 2020b)	Systematic review of COVID-19 in children show milder cases and a better prognosis than adults	A systematic review of COVID-19 in children including evidence (45 papers) up to March 18.	• The proportion of cases that were <19 yo was small across countries. In China 2% (n=44672 cases) were 0-19 yo. Italian reported 1.2% (n=22 512 cases) were children. This is consistent with SARS where 6.9% of cases were children and none died (Caselli & AricÃ², 2020).

THE IMPACT OF RELAXING INTERVENTION MEASURES BY TARGETING DIFFERENT AGE GROUPS

Six publications use mathematical models to investigate the impact of relaxing intervention measures by targeting different age groups on the epidemic (Table 1). In the context of re-opening schools, two mathematical models demonstrate that allowing younger children (pre-school and primary school aged) to return to school would have the smaller impact on R, whereas the return of secondary school grades will have the greatest impact (Di Domenico et al., 2020; Keeling et al., 2020). A more recent model examines several European countries and estimates that countries with low transmission and high intensity interventions for controlling the epidemic can fully reopen schools, however if community transmission is high, then care should be taken to re-open schools slowly (Stage, Shingleton, Ghosh, & et al., 2020).

Of the three models that analyzed lifting interventions by age groups, results suggest that relaxing measures by age group could reduce the impact of COVID-19. Specifically, releasing younger individuals (0-19) from strict lockdown would result in lower overall fatality rates compared to the simultaneous release of all individuals after a lockdown (Castilho et al., 2020; Zhao & Feng, 2020).

Table 3: Six publications that investigate the impact of relaxing intervention measures by targeting different age groups on the epidemic.

Reference	Publication Title	Study Description	Key Outcomes
Returning to School			
(Stage et al., 2020)	Shut and re-open: the role of schools in the spread of COVID-19 in Europe	Investigates the effect of school closure and subsequent reopening on the transmission of COVID-19, by considering Denmark, Norway, Sweden, and German states as case studies.	• The effect of school closure on growth rate of the epidemic has a noticeable reduction in the growth rate approximately 9 days after implementation. • Large-scale reopening of schools while controlling or suppressing the epidemic appears feasible in

			countries such as Denmark or Norway, where community transmission is generally low. • School reopening can contribute to significant increases in the growth rate in countries like Germany, where community transmission is relatively high.
(Keeling et al., 2020) *preprint*	The impact of school reopening on the spread of COVID-19 in England	Using an SEIR model, eight strategies for reopening primary and secondary schools in England starting on June 1 were analyzed.	• The study predicts that reopening schools with half class sizes, or that is focused on younger children is unlikely to push R above 1, although there is noticeable variation between the regions of the country. • Since older children have a greater number of social contacts and therefore a greater potential for transmission, reopening secondary schools results in larger increases in case burden compared to only reopening primary schools. • The more year groups allowed to return to school at one time, the greater the effect on R, with the return of secondary school grades having the greatest impact.
(Di Domenico et al., 2020) *preprint*	Expected impact of reopening schools after lockdown on COVID-19 epidemic in Île-de-France	This stochastic discrete age-structured epidemic model was used to assess the impact of reopening schools in the Île-de-France region of France after the withdrawal of lockdown scheduled for May 11. Authors explore several scenarios of partial, progressive, or full school reopening combined with moderate social distancing interventions and large-scale tracing, testing, and isolation.	• Results indicate that reopening all schools on this date would lead to a 2nd wave similar to the 1st and overwhelm the ICU system. • If just pre-schools and primary schools opened and middle/high schools reopen 1 month later following a progressive protocol, the ICU capacity would not be overwhelmed and would reach at most 72% capacity (95% CI: 55-83%). • There is no difference in the epidemic risk if pre-school and primary schools are reopened promptly or progressively, allowing full attendance for the younger children.

			• Full attendance for middle and high school students is not recommended.
Lifting Interventions by Age Group			
(Castilho et al., 2020) *preprint*	Assessing the efficiency of different control strategies for the Coronavirus (COVID-19) epidemic	This SEIR model was used to explore four different strategies to lift interventions in Brazil. These strategies based on age groups were analyzed using 3 age classes: children (0 to 19), adults (20 to 59), and elderly (60 to 100). The strategies include: 1) splitting the effort equally among the 3 groups, 2) stronger isolation (x2) of the elderly compared to infants/adults, 3) stronger isolation (x2) of infants/adults compared to the elderly, 4) stronger isolation (x2) of adults compared to infants/elderly.	• Results indicate that stronger isolation of the elderly compared to children and adults is the best strategy. • All other options result in 7.5% more deaths. • Authors also found that social distancing among adults has the greatest impact on R0.
(Scala, Flori, & Spelta, 2020) *preprint*	Between geography and demography: key interdependencies and exit mechanisms for COVID-19	This SIOR model analyzed the impact of mobility restrictions and age-based lockdowns in Italy during the outbreak.	• The most intensively interacting age-class are the young (0-19) and the old (70+). Mitigation strategies geared towards these two classes can produce a significant impact on diffusion rates in the post-lock down phase.
(Zhao & Feng, 2020) *preprint*	Staggered release policies for COVID-19 control: costs and benefits of sequentially relaxing restrictions by age	This SEIR model investigated the impact of sequential timing of relaxing restrictions across age groups in reducing health risks from COVID-19.	• Results show that releasing the least vulnerable group of a population before other groups will reduce the overall number of deaths. • A properly constructed sequential release of age-defined subgroups (young, middle-aged, old) from strict lockdown can lead to lower overall fatality rates compared to the simultaneous release of all individuals after a lockdown.

			• However, the timing of each step of the staggered release is very important. For example, releasing the middle-aged group too soon after releasing the young group would cause a drastic increase infections and deaths.

OTHER EVIDENCE SYNTHESIS PRODUCTS CONDUCTED TO LOOK AT TRANSMISSION AMONG DIFFERENT AGE GROUPS.

The synthesis products below were identified during our search. These products are part of the grey literature and inform the topic of transmission of SARS-CoV-2 in select age groups.

Table 3: Synthesis products that are up to date or evergreen and present information on transmission in different age groups.

Reference	Publication Title	Study Description	Key Outcomes
Rapid Review			
NCCMT Rapid Review	Rapid review: what is the specific role of daycares and schools in COVID-19 transmission?	Updated July 9, 2020 1. What is known about the likelihood of transmission of COVID-19 amongst children and adults in daycare and schools and among children to their household members? 2. What is known about likelihood of transmission of COVID-19 by infants, toddlers, and school-aged children to others in other settings?	• 23 publications are summarized that show some potential transmission of SARS-CoV-2 among children of different ages. No transmission among young daycare age children was identified. • A potential outbreak in a high school is described, however the results are based on serology 6 weeks after schools closed in an epicenter.
COVID-Explained	COVID-19 and children: our crowd-sourced data	Updated July 8, 2020. Researchers and students at Brown, MIT, Harvard, Mass General and elsewhere crowd sourcing data on COVID-19 in daycares and camps in the USA.	• They report 970 daycare settings with 27234 students and a total of 42 cases (0.15%). Among staff infections were 106/9587 (1.01%). • There is also information from camps.

Methods:

A daily scan of the literature (published and pre-published) is conducted by the Emerging Science Group, PHAC. The scan has compiled COVID-19 literature since the beginning of the outbreak and is updated daily. Searches to retrieve relevant COVID-19 literature are conducted in Pubmed, Scopus, BioRxiv, MedRxiv, ArXiv, SSRN, Research Square and cross-referenced with the literature on the WHO COVID literature list, and COVID-19 information centers run by Lancet, BMJ, Elsevier and Wiley. The daily summary and full scan results are maintained in a Refworks database and an Excel list that can be searched. Targeted keyword searching is conducted within these databases to identify relevant citations on COVID-19 and SARS-CoV-2. Search terms used included: age-dependent, children and transmission. This review contains research published up to July 20, 2020. Each potentially relevant reference was examined to confirm it had relevant data and relevant data is extracted into the review.

Prepared by: Lisa Waddell and Tricia Corrin. Emerging Science Group, PHAC. phac.emergingsciencesecretariat-secretariatdessciencesemergentes.aspc@canada.ca

Nouveaux éléments de preuve sur la COVID-19

Note d'information sur la transmission en fonction de l'âge

Introduction

Quelles sont les preuves de la transmission du SRAS-CoV-2 en fonction de l'âge?

Il est important de déterminer s'il existe des différences dans le potentiel de transmission du SRAS-CoV-2 entre les enfants de différents groupes d'âge (préscolaire 0 à 4 ans, école primaire 5 à 11 ans, intermédiaire 12 à 13 ans et secondaire 14 à 19 ans) par rapport aux adultes. Cette note d'information est une mise à jour de la version du 22 juin 2020 et inclut la littérature sur la COVID-19 jusqu'au 20 juillet 2020 qui mesure la transmission en fonction de l'âge ou estime les scénarios de transmission parmi les enfants de différents groupes d'âge, comme à l'école.

Points clés

- Les données empiriques suggèrent qu'une faible proportion des cas de SRAS-CoV-2 survient chez les enfants de moins de 19 ans. Parmi les cas chez les enfants, une grande partie d'entre eux peuvent être asymptomatiques, mais ils sont toujours capables de transmettre le virus (tableau 1).
- Peu d'études sur les contacts ou les épidémies ont rapporté des enfants de moins de 19 ans comme cas index (tableau 1). Toutefois, il existe des cas où un enfant infecté a transmis le SRAS-CoV-2 à un adulte ou à un autre enfant. La plupart des études concluent que les enfants n'ont pas été les principaux vecteurs de transmission du SRAS-CoV-2 à ce jour.
- Une étude a estimé que l'infectiosité relative des enfants par rapport aux adultes était de 85 % (65 à 110 %). Cependant, peu d'enfants ont été le cas index dans les foyers étudiés, ce qui a entraîné une sous-estimation de l'étude (Dattner et coll., 2020). Dans une revue systématique, le rapport de cotes mis en commun pour être un contact infecté chez les enfants par rapport aux adultes pour toutes les études de recherche des contacts a été rapporté comme étant de 0,44 (0,29; 0,69) (Viner et coll., 2020).
- La charge virale chez les enfants symptomatiques s'est révélée être la même que celle des adultes dans trois études de cas symptomatiques de COVID-19 (tableau 2).
- Six publications utilisent des modèles mathématiques pour étudier l'impact de l'assouplissement des mesures d'intervention en ciblant différentes tranches d'âge sur l'épidémie (tableau 1).
    - Réouverture des écoles : le modèle le plus récent examine le risque d'ouverture des écoles dans un scénario de faible transmission par rapport à un scénario de forte transmission communautaire, indiquant que l'ouverture des écoles dans des scénarios de faible transmission parallèlement à d'autres interventions de santé publique n'a pas entraîné une forte hausse des

cas. Deux autres modèles mathématiques démontrent que le retour à l'école des enfants plus jeunes (en âge préscolaire et primaire) aurait un impact plus faible sur le taux de reproduction de base (R0), tandis que le retour aux études secondaires aurait l'impact le plus important (Di Domenico, Pullano, Sabbatini, Boëlle et Colizza, 2020; Keeling et coll., 2020).

- Sur les trois modèles qui ont analysé la levée de mesures par groupes d'âge, les résultats suggèrent que l'assouplissement des mesures par groupe d'âge pourrait réduire l'impact de la COVID-19. Plus précisément, la libération de jeunes individus (0 à 19 ans) après un confinement strict peut entraîner un taux de mortalité global plus faible que la libération simultanée de tous les individus après un confinement (Castilho, Gondim et Marchesin, 2020; Zhao et Feng, 2020).

Vue d'ensemble des éléments de preuve

Les preuves de la transmission du SRAS-CoV-2 en fonction de l'âge ont été directement et indirectement explorées dans un certain nombre de modèles prédictifs. Ces modèles sont fondés sur des scénarios et sont paramétrés à partir des données d'observation de l'épidémie; il convient d'utiliser ces résultats avec prudence, car la mesure dans laquelle ils peuvent être généralisés au contexte local est variable.

Les preuves empiriques issues de la surveillance, des estimations de la transmission et des descriptions des groupes de transmission ou des foyers sont obtenues à partir des données recueillies lors d'enquêtes rétrospectives sur les foyers, qui présentent un risque de biais modéré à élevé. De nombreuses études recensées dans ce dossier sont en version préliminaire et n'ont pas fait l'objet d'un processus d'évaluation par les pairs. Certains éléments peuvent permettre d'estimer les taux de transmission parmi les groupes d'âge des enfants par rapport aux adultes, ces éléments s'accumulent rapidement et il est fort probable que les estimations ou les conclusions changent à mesure que d'autres éléments deviennent disponibles.

CONTENU

PREUVES DE LA TRANSMISSION EN FONCTION DE L'ÂGE ET DU POTENTIEL DE TRANSMISSION

La répartition par âge des cas de COVID-19 a montré une forte dépendance à l'âge, avec moins de cas documentés chez les enfants, et peu d'événements de transmission attribués à la transmission à partir d'un enfant infecté. Dans cette mise à jour, plusieurs études ont été ajoutées à partir d'enquêtes sur les grappes et les communautés scolaires menées dans des pays d'Asie, d'Europe, d'Australasie, d'Amérique du Nord et d'Amérique du Sud, qui apportent une mise à jour importante à cette revue.

On suppose que l'apparente dépendance de l'âge que nous constatons dans les données épidémiologiques peut avoir plusieurs facteurs contributifs, notamment le fait que les enfants peuvent être moins sensibles à l'infection et/ou sont moins enclins à présenter des symptômes cliniques lorsqu'ils sont infectés. Plusieurs études du tableau 1 montrent qu'une proportion nettement plus faible d'enfants sont infectés par le SRAS-CoV-2 par rapport aux populations adultes, que les enfants sont moins susceptibles d'être infectés par le SRAS-CoV-2 que les adultes et qu'ils sont peut-être moins susceptibles d'avoir des symptômes. Cette susceptibilité semble augmenter entre 10 et 20 ans. Des modèles comme celui de Davies et coll. montrent l'impact des différents taux de transmission selon l'âge et l'impact des hypothèses concernant la facilité avec laquelle la transmission asymptomatique ou paucisymptomatique se produit (Davies et coll., 2020).

Les études de recherche de contacts du tableau 1, telles que les résultats de la Corée du Sud, s'accordent à dire que les enfants sont rarement identifiés comme cas index ou comme contact dans les enquêtes par grappes. Cependant, une conclusion unique de cette étude était que les quelques cas index âgés de 10 à 19 ans avaient un taux de transmission élevé (18,6 %) par rapport à leurs contacts familiaux (Park et coll., 2020). Les spéculations autour de cette augmentation de la transmission incluent le fait que les enfants de ce groupe d'âge sont plus grands, qu'ils peuvent contaminer davantage l'air partagé avec les adultes et qu'ils sont moins susceptibles d'adhérer à des comportements d'hygiène personnelle optimaux. Dans d'autres études, un enfant de moins de 18 ans est rarement impliqué comme cas index dans un groupe familial ou non familial (tableau 1).

De même, il y a eu sept enquêtes au sein des communautés scolaires. Même si des cas ont été recensés à l'école, la plupart n'ont pas été attribués à une transmission à l'école, mais à une transmission par un membre de la famille à la maison. Deux des enquêtes scolaires menées au Chili et en France ont fait état d'une séroprévalence très élevée après la fermeture des écoles (Fontanet, Tondeur et coll., 2020; Torres et coll., 2020). L'étude en France a été menée dans l'un des épicentres d'une épidémie, et aurait duré environ 3 semaines avant la fermeture de l'école. Les résultats ont montré une séroprévalence élevée dans tous les groupes d'âge de cette enquête (Fontanet, Tondeur et coll., 2020). L'étude d'une communauté scolaire de Santiago au Chili a indiqué qu'il y avait une forte prévalence parmi les enseignants et les parents des écoles maternelles en raison des réunions qui avaient eu lieu au cours des premières semaines d'ouverture des écoles (Torres et coll., 2020).

Tableau 1 : Vingt-trois études qui informent sur les facteurs de transmission de la COVID-19 en fonction de l'âge, y compris des modèles prédictifs (n=2), des études de recherche de contacts (n=10), des études de transmission en milieu scolaire/garderie (n=7), des recherches de synthèse sur la transmission liée à l'âge (n=4)

Référence	Titre	Description de l'étude	Principaux résultats
Modèles prédictifs de transmission en fonction de l'âge			
(Davies et coll., 2020)	Age-dependent effects in the transmission and control of COVID-19 epidemics	Des modèles dynamiques de transmission ont été adaptés à une série de données disponibles sur la répartition par âge des cas déclarés et à deux études qui ont recherché les infections parmi les contacts proches, afin d'estimer la sensibilité par âge à l'infection par le SRAS-CoV-2 et la fraction par âge des infections pour lesquelles des symptômes cliniques complets de COVID-19 sont développés. Des données de la Chine, de l'Italie, du Japon, de Singapour, du Canada et de la Corée du Sud ont été utilisées. Le modèle a examiné les données épidémiologiques pour mieux comprendre si les enfants sont moins sensibles à l'infection, moins enclins à présenter des symptômes cliniques ou les deux. Le modèle qui tient compte des deux correspond le mieux aux données.	• La sensibilité à l'infection par le SRAS-CoV-2 chez les moins de 20 ans est environ la moitié de celle des adultes âgés de plus de 20 ans. La sensibilité à l'infection était de 0,40 (0,25 à 0,57) chez les 0 à 9 ans contre 0,88 (0,70 à 0,99) chez les 60 à 69 ans. • Les symptômes cliniques se manifestent dans 21 % des cas (intervalle crédible de 95 % : 12 à 31 %) des infections chez les 10 à 19 ans, passant à 69 % (57 à 82 %) des infections chez les personnes âgées de plus de 70 ans. • Les résultats sont cohérents d'un pays à l'autre et d'un contexte d'intervention à l'autre. • Ces résultats montrent que les interventions ciblant les écoliers peuvent être moins efficaces que pour d'autres infections respiratoires. • La structure par âge d'une population est importante pour estimer la charge du SRAS-CoV-2. • Une comparaison entre les cas de COVID-19 et de grippe dans trois villes ayant des structures d'âge différentes indique que les fermetures d'écoles retardent le pic de COVID-19 de 1 à 6 jours et le réduisent de 10 à 19 %, contre 10 à 89 jours et 17 à 35 % pour la grippe.
(Lau, Grenfell, Nelson et Lopman, 2020)	Characterizing super-spreading events and age-specific infectivity of COVID-19	Cadre mécaniste spatio-temporel au niveau individuel pour intégrer statistiquement les données de cas avec les données de géolocalisation et les données de mobilité agrégées, permettant une compréhension	• Ils n'ont pas considéré les enfants comme un groupe d'âge distinct, faute d'observations suffisantes. Les jeunes enfants semblent être moins sensibles au SRAS-CoV-2. • Nous estimons que les enfants et les adultes infectés de moins de 60 ans peuvent être des vecteurs de

	transmission in Georgia, USA	plus granulaire de la dynamique de transmission de la COVID-19. Données : Du 1er mars au 3 mai, l'analyse a inclus les 5 comtés les plus infectés (n=9 559 cas de COVID-19) avec des informations démographiques.	transmission 2,38 [1,30; 3,51] fois plus élevés que les personnes âgées infectées (>=60 ans), et que les premiers peuvent être le principal facteur de la super-diffusion.
Surveillance/Données de recherche des contacts			
(Park et coll., 2020) *nouveau*	Contact tracing during Coronavirus Disease outbreak, South Korea, 2020	Résumé des enquêtes en grappes rétrospectives menées en Corée du Sud du 20 janvier au 27 mars; 59 073 contacts de 5 706 cas de COVID-19 ont été retracés. La RT-PCR a été utilisée pour déterminer le statut de COVID-19. Ils n'ont pas testé les contacts asymptomatiques et avaient des seuils différents pour tester les contacts domestiques et non domestiques. Catégorie d'âge : # index/# contacts tracés 0 à 9 : 29 (0,5 %)/237 (0,4 %) 10 à 19 : 124 (2,2 %)/457 (0,8 %) 20 à 29 : 1695 (29,7 %)/15 810 (26,8 %) 30 à 39 : 668 (11,7 %)/8 636 (14,6 %) 40 à 49 : 807 (14,1 %)/9709 (16,4 %) 50 à 59 : 1107 (19,4%)/11 353 (19,2%) 60 à 69 : 736 (12,9 %)/8490 (14,4 %) 70 à 79 : 338 (5,9 %)/2 389 (4,0 %) >80 : 202 (3,5 %)/1992 (3,4 %) • L'index et les personnes ayant contracté le virus dans les groupes des 20 à 29 ans et des 50 à 59 ans représentaient les plus grandes catégories d'âge identifiées comme cas index et ayant été tracées pour l'infection à la COVID-19.	• Dans l'ensemble : o 11,8 % (95 % IC, 11,2 % à 12,4 %) des contacts familiaux étaient infectés o 1,9 % (95 % IC, 1,8 % à 2,0 %) des contacts non domestiques ont été infectés. • Catégorie d'âge du cas index : positive/N (%, IC 95 %) dans les contacts du ménage. 0 à 9 : 3/57 (5,3 %,1,3 à 13,7) 10 à 19 : 43/231 (18,6 %,14,0 à 24,0) 20 à 29 : 138/12 393 (1,1 %, 0,9 à 1,3) 30 à 39 : 70/7 407 (0,9 %, 0,7 à 1,2) 40 à 49 : 206/1 749 (11,8 %, 10,3 à 13,4) 50 à 59 : 300/2 045 (14,7 %, 13,2 à 16,3) 60 à 69 : 177/1 039 (17,0 %, 14,8 à 19,4) 70 à 79 : 86/477 (18,0 %, 14,8 à 21,7) ≥80 : 50/348 (14,4 %, 11,0 à 18,4) o Il convient de noter que la transmission d'un cas index de 10 à 19 ans aux contacts du ménage était significativement plus élevée que pour les autres groupes d'âge plus jeunes. • Catégorie d'âge des cas index : positive/N (%, IC 95 %) dans les contacts hors du ménage. 0 à 9 : 2/180 (1,1 %, 0,2 à 3,6) 10 à 19 : 2/226 (0,9 %, 0,1 à 2,9) 20 à 29 : 138/12 393 (1,1 %, 0,9 à 1,3) 30 à 39 : 70/7 407 (0,9 %, 0,7 à 1,2)

		Dans cette étude, le cas index a été le premier cas à être identifié à temps, car ils ne pouvaient pas confirmer qui avait transmis à qui.	40 à 49 : 161/7 960 (2,0 %, 1,7 à 2,3) 50-59 : 166/9 308 (1,8 %, 1,5 à 2,1) 60 à 69 : 215/7 451 (2,9 %, 2,5 à 3,3) 70 à 79 : 92/1 912 (4,8 %, 3,9 à 5,8) • ≥80 : 75/1 644 (4,6 %, 3,6 à 5,7)
(Van Der Hoek et coll., 2020) *nouveau*	[De rol van kinderen in de transmissie van SARS-CoV-2] en hollandais	Les données du système de surveillance néerlandais Osiris ont été analysées jusqu'au 11 mai 2020. Il s'agit de données préliminaires et l'étude est en cours. Les enquêtes sur les grappes familiales étaient des inscriptions prospectives lors du premier cas confirmé entre le 23 mars et le 16 avril. N=54 familles Note : les écoles ont été fermées pendant cette période d'étude.	• 0,9 %, 369/42 788 cas confirmés de COVID-19 aux Pays-Bas touchaient des personnes âgées de 0 à 18 ans. o 0 à 3 ans, 74 cas o 4 à 11 ans, 38 cas o 12 à 18 ans, 257 cas • Il n'y avait aucune différence entre les valeurs de Ct des enfants et des adultes. • Les résultats d'une analyse des paires de transmission ont indiqué 21 cas de transmission de parent à enfant et 2 cas de transmission d'enfant à enfant au sein d'un ménage. • Aucun des 43 contacts de 10 cas de COVID-19 de moins de 18 ans n'a développé d'infection par rapport aux adultes où la transmission secondaire était de 8,3 %. • Dans les enquêtes familiales, les enfants ont moins tendance à signaler des symptômes au cours des 14 derniers jours (67 %) que les adultes (91 %) ou à présenter des symptômes respiratoires spécifiques (25 % contre 78 %) • Séroconversion à 2 ou 3 semaines après l'enquête initiale : o 1 à 5 ans, 21 % (3/14) o 6 à 11 ans, 13% (4/31) o 12 à 17 ans, 32% (12/38) o 18 à 45 ans, 31% (11/35) o >45 ans, 43 % (13/30)

			• L'étude a conclu que les enfants peuvent être infectés, mais qu'ils ne semblent pas contribuer autant à la transmission que les adultes.
(Sun et coll., 2020) *nouveau*	Children infected with SARS-CoV-2 from family clusters	Analyse de 74 enfants admis dans un hôpital de Wuhan du 28 janvier au 3 mars. Les cas ont été confirmés par RT-PCR.	• Dans tous les cas pédiatriques, au moins un membre adulte de la famille a été infecté avant les enfants du ménage.
(Somekh et coll., 2020) *nouveau*	The role of children in the dynamics of intra family Coronavirus 2019 spread in densely populated area	Bnei Brak, Israël est l'une des villes les plus peuplées du monde et la ville qui a le taux le plus élevé d'enfants par famille en Israël. Les enfants de 0 à 19 ans représentent 50 % des 200 000 habitants. Le nombre moyen d'enfants dans une famille est de 4,57. Dans chaque grappe familiale, tous les membres ont été testés par RT-PCR	• 13 grappes familiales ont été étudiées. o 12/13 cas index étaient des adultes ayant été exposés à la synagogue, lors d'un repas en période de fête, au travail ou à un endroit inconnu dans 50 % des cas. o 1/13 des cas avaient 14,5 ans et ont été exposés à la yeshiva. • Les cas de RT-PCR positifs dans ces grappes comprenaient [risque relatif d'être positif par rapport aux personnes >18 ans] o >18 ans : 58,3 %, 21/36 o 5 à 17 ans : 32,5 %, 13/40 [0,61, 95 %CI 0,39 à 0,96, p=0,037] o 0 à 4 ans : 11,8 %, 2/18 [0,47, 95%CI 0,30 à 0,71, p<0,002] • L'étude conclut qu'ils n'ont pas pu montrer un rôle dominant des enfants dans la transmission du SRAS-CoV-2, même dans une ville très peuplée où la proportion d'enfants est élevée.
(Dattner et coll., 2020) *nouveau*	The role of children in the spread of COVID-19: Using household data from Bnei Brak, Israel, to estimate the relative	Les données de Bnei Brak recueillies jusqu'au 2 mai ont été utilisées pour l'analyse. Des enquêtes épidémiologiques par grappes de 637 ménages ont été incluses. Les estimations ont été générées à partir d'un modèle dynamique stochastique.	• La plupart des cas index étaient des adultes. • Les adultes ont un risque plus élevé d'être infectés que les enfants (44 % contre 25 %). • Les enfants de moins de 1 an ont un risque plus élevé d'être infectés que ceux âgés de 1 à 4 ans. • Leur modèle estime que les enfants peuvent avoir une infectiosité plus faible que les adultes. Infectiosité

	susceptibility and infectivity of children		relative 85 % (65 à 110 %). Le peu de cas index d'enfants signifie que cette estimation est sous-évaluée.
(Lavezzo et coll., 2020) *préimpression*	Suppression of COVID-19 outbreak in the municipality of Vo, Italy	Deux enquêtes de population ont été menées pour recueillir des prélèvements nasopharyngés auprès de 2 812 et 2 343 personnes dans la municipalité de Vo, en Italie.	• Aucune infection n'a été détectée dans les deux enquêtes chez 234 enfants testés âgés de 0 à 10 ans, bien que 13 d'entre eux vivent dans le même foyer que des personnes infectées. D'après le taux d'infection secondaire des ménages, on s'attendait à ce que les enfants soient positifs.
(Zhang et coll., 2020)	Changes in contact patterns shape the dynamics of the COVID-19 outbreak in China	Des enquêtes de contact ont été menées dans deux villes : Wuhan et Shanghai. Les enquêtes ont été menées du 1er au 10 février. L'ensemble de données comprenait 1 245 contacts à Wuhan et 1 296 à Shanghai.	• La vulnérabilité à l'infection par le SRAS-CoV-2 augmente avec l'âge. Les jeunes individus (0 à 14 ans) ont un risque d'infection plus faible que les individus âgés de 15 à 64 ans {CR = 0,34 [intervalle de confiance (IC) de 95 %] : 0,24 à 0,49], p < 0,000 1}.
(Mizumoto, Omori et Nishiura, 2020) *Préimpression*	Age specificity of cases and attack rate of novel coronavirus disease (COVID-19)	Résumé des cas au Japon jusqu'au 7 mars. 313 cas d'infections contractées au pays auprès de 2 496 contacts étroits qui ont fait l'objet d'une enquête.	• Le taux d'attaque était faible chez les enfants (7,2 % chez les hommes, 3,0 % chez les femmes) par rapport aux adultes qui ont atteint un pic dans la tranche d'âge des 50 à 59 ans (22,23 %, 21,9 %). Comme il s'agissait de tous les échantillons COVID-19 exposés ou suspectés d'être symptomatiques, il semble que le risque de maladie, compte tenu de l'exposition, soit faible chez les enfants.
(Bi et coll., 2020)	Epidemiology and transmission of COVID-19 in 391 cases and 1286 of their close contacts in Shenzhen, China: a retrospective cohort study	Résumé des données sur les cas du 14 janvier au 12 février 2020, au Centre de contrôle et de prévention des maladies de Shenzhen. Il y a eu 391 cas de SRAS-CoV-2 et 1 286 contacts étroits identifiés grâce à la surveillance symptomatique et à la recherche des contacts.	• La transmission d'un enfant à un adulte n'a pas été documentée. • Les auteurs concluent que les enfants présentent un risque d'infection similaire à celui des adultes. Cependant, il y a peu d'observations et une grande incertitude dans les données pour les catégories d'âge des enfants.

			• Résultats des tests par contact (exposition) selon l'âge : 0 à 9= 14,9 %, 10 à 19= 5,7 %, 20 à 59= 10,3 à 17,2 %. • Résultats des tests basés sur les symptômes par âge : 0 à 9 et 10 à 19= 2,1 %, 20 à 59=7,9 à 24,3 %.
(Danis et coll., 2020)	Cluster of Coronavirus Disease 2019 (COVID-19) in the French Alps, February 2020	Février 2020 : flambée épidémique au chalet de ski dans les Alpes françaises. Le cas index a propagé le SRAS-CoV-2 à 11 personnes au chalet pendant un séjour de 4 jours.	• Un cas pédiatrique dans cette épidémie a visité 3 écoles différentes alors que ce cas était symptomatique et qu'aucun cas secondaire n'a été causé par ce cas.
Enquêtes sur les écoles et les garderies			
(Yung et coll., 2020) *nouveau*	Novel coronavirus 2019 transmission risk in educational settings	Rapports de cas de personnes ayant fréquenté une garderie et une école secondaire dans le cadre d'études de recherche de contacts en février et mars à Singapour. Les écoles n'ont pas été fermées à Singapour, mais elles ont annulé les activités parascolaires, échelonné les pauses et regroupé les enfants. Un protocole de nettoyage strict a également été mis en place. Les garderies ayant un cas positif ont fermé pendant 14 jours.	• 3 incidents sont signalés : o Un enfant de 12 ans et un enfant de 5 ans ont été identifiés grâce à la recherche d'un cas d'adulte avec lequel ils ont été en contact. Aucun des 8 contacts symptomatiques de l'école secondaire ou des 34 de l'école maternelle n'a été testé positif au SRAS-CoV-2 par RT-PCR. o La troisième grappe était un membre adulte du personnel d'une école maternelle. Jusqu'à 16 membres du personnel ont été infectés. 77 enfants (8 symptomatiques) ont tous reçu un résultat négatif au test. Les 23 % d'enfants qui n'ont pas fait l'objet d'un prélèvement n'ont pas développé de symptômes.
(National Centre for Immunisation Research and Surveillance, 2020)	COVID-19 in schools – the experience in NSW	En Nouvelle-Galles-du-Sud, entre mars et la mi-avril, 9 élèves et 9 membres du personnel de 15 écoles différentes ont été diagnostiqués comme étant atteints d'une infection par le SRAS-CoV-2.	• 2 enfants étaient des cas secondaires potentiels. • La plupart des cas et des observations provenaient d'écoles secondaires (12 cas/695 contacts). 235 contacts ont reçu des tests RT-PCR et 75 ont reçu des tests sérologiques 30 jours après l'exposition. Un test sérologique s'est avéré positif.

nouveau		735 étudiants et 128 membres du personnel étaient des contacts étroits.	• 1/263 contacts étroits (53 testés) ont été identifiés parmi tous les contacts étroits de 6 cas dans 5 écoles primaires.
(Heavey, Casey, Kelly, Kelly et McDarby, 2020) *nouveau*	No evidence of secondary transmission of COVID-19 from children attending school in Ireland, 2020	Les enquêtes épidémiologiques rétrospectives ont ciblé ici tout cas ayant fréquenté des écoles en tant qu'étudiant ou employé avant la fermeture des écoles (12 mars) en Irlande. Seuls les contacts symptomatiques ont été testés.	• 3 adultes et 3 enfants ont eu 1 155 contacts entre l'école, le sport, la musique (instruments à vent en bois) et la pratique de la chorale. • Un seul cas de transmission a été détecté; il s'est produit en dehors de l'école entre deux adultes infectés et un adulte sensible.
(Armann et coll., 2020) nouveau	Anti-SARS-CoV-2 IgG antibodies in adolescent students and their teachers in Saxony, Germany (SchoolCoviDD19): very low seroprevalence and transmission rates	Enquête de séroprévalence menée en Saxe orientale, en Allemagne, auprès de 13 écoles secondaires (de la 8e à la 11e année) du 25 mai au 30 juin 2020. Les IgG anti-SARS-CoV-2 ont été évalués à l'aide de 3 tests, en commençant par Diasorin Liaison, Abbott Diagnostics et Euroimmun pour confirmer les résultats. 1 538 étudiants et 507 enseignants ont participé à cette étude. La PCR communautaire a confirmé une prévalence de 0,15 % (sur la base des données de surveillance).	• La séroprévalence globale était de 0,6 % o Étudiants 0,7 %, 12/1 538 (5 avaient une COVID-19 confirmée et 22 avaient des membres de leur famille avec une COVID-19 confirmée) o Enseignants 0,2 %, 1/507 (2 avaient des membres de leur famille avec une COVDI-19 confirmée) • Aucune grappe de cas n'a été identifiée, même dans les écoles ayant des cas de COVID-19 avant le confinement (13 mars). • Ce document conclut que les étudiants et les enseignants ne semblent pas jouer un rôle crucial dans la lutte contre le SRAS-CoV-2.
(Fontanet et coll., 2020) nouveau	SARS-CoV-2 infection in primary schools in northern France	Retrospective cohort in France. Des tests sérologiques et des données de questionnaires ont été recueillis du 28 au 30 avril pour mesurer l'exposition des familles et du personnel des écoles primaires à partir de février/mars 2020. Avant la fermeture des écoles le 14 février, il y avait 3 élèves infectés.	• Taux d'attaque de l'infection (TAI), aucune différence entre les groupes (P = 0,29) o Élèves (école primaire 6-11 ans) 45/510 (8,8 %) o Enseignants 3/42 (7,1 %) o Personnel non enseignant 1/28 (3,6 %) o Parents 76/641 (11,9 %) o Famille 14/119 (11,8 %) • Le regroupement des cas en grappes familiales a été documenté par la forte proportion d'anticorps chez

			les parents (61,0 % contre 6,9 %; P < 0,000 1) et les proches (44,4 % contre 9,1 %; P = 0,002) des élèves infectés. • Des cas asymptomatiques ont été signalés chez 41,4 % des enfants et 9,9 % des adultes. Seuls deux adultes ont été hospitalisés dans ce groupe d'étude.
(Torres et coll., 2020) nouveau	SARS-CoV-2 antibody prevalence in blood in a large school community subject to a COVID-19 outbreak: a cross-sectional study	Foyer d'éclosion à Santiago au Chili, le 12 mars (10 jours après l'ouverture des écoles). 52 cas provenant d'une grande communauté scolaire (K-12, N=2 950) ont été identifiés. L'école a été fermée et la communauté a été mise en quarantaine. Une enquête de séroprévalence a été menée du 4 au 19 mai auprès de l'ensemble des étudiants et du personnel. Test utilisé : La trousse de test IgG/IgM (or colloïdal) du nouveau coronavirus (2019-nCoV) de Genrui Biotech Inc, Chine Les élèves du secondaire ont eu une séropositivité significativement plus faible (p=0,01) que les autres élèves. Parmi les cas séropositifs, 40 % (95 % IC : 30 à 50 %) des étudiants et 18 % (95%CI : 8 à 34 %) du personnel n'ont pas signalé de symptômes.	• N=1 009 étudiants, 235 membres du personnel ont été inclus dans l'étude o Préscolaire 12,3 % (95 % IC 7,8 à 18,6), N=147 o Primaire 10,8 % (7,81 à 14,7), 286 o Intermédiaire 11,9 % (8,81 à 15,9), 295 o Secondaire 5,7 % (3,6 à 8,9), 281 o Enseignants 20,6 % (14,7 à 27,6), 165 o Personnel de soutien 7,1 % (2,4 à 15,9), 70 • Les étudiants avaient une séropositivité plus élevée que le personnel p=0,003. • La séropositivité était plus élevée chez le personnel de l'école primaire et l'analyse des taux de contact indiquait que les enfants ayant plus de contacts étaient plus susceptibles d'être séropositifs. • Les sources présentant la plus grande probabilité de contagion possible chez les étudiants étaient : une aide à domicile (CR : 27,9), un parent du ménage (CR : 5,4), un camarade de classe (CR : 3,2), et un professeur (CR : 2,2) Cette étude attribue la répartition selon l'âge aux réunions parents-professeurs dans les écoles maternelles.
(Fontanet, Tondeur et coll., 2020) préimpression, nouveau	Cluster of COVID-19 in northern France: a retrospective	Après l'identification de deux cas dans un lycée de l'Oise, en France, qui fait partie de l'épicentre, une étude rétrospective de séroépidémiologie a été menée du 30 mars au 4 avril pour étudier les niveaux	• 452/661 participants ont déclaré des symptômes. • 10 participants ont été hospitalisés (9 étaient séropositifs pour le SRAS-CoV-2) et il n'y a eu aucun décès. Résultats de la sérologie : • 171/661 avait des anticorps

	étude de cohorte fermée	sériques des élèves, des enseignants et du personnel non enseignant. Le taux de réponse était de 37 %; ce faible niveau de participation peut refléter un biais dans l'échantillon. Ils ont également prélevé des échantillons dans une banque de sang voisine pour les comparer.	• TAI de 25,9 % (95%CI; 22,6 à 29,4) o Élèves = 38,3 % o Enseignants = 43,4 % o Personnel non enseignant = 59,3 % o Parents = 11,4 % o Frères et sœurs = 10,2 % • TLI 0 % (CI unilatéral 97,5 % : 0 à 2,1). • Taux d'hospitalisation 5,3 % (95 % IC : 2,4 à 9,8). • Les échantillons des donneurs de sang ont eu des taux de séropositivité de (3,0 %, 95 % IC = 1,1 à 6,4). • D'après les informations épidémiologiques, il semble qu'il y ait eu une épidémie dans ce lycée entre la dernière semaine de janvier et la mi-février, lorsque les écoles ont fermé.
Recherche de synthèse			
(Li et coll., 2020)	The role of children in transmission of SARS-CoV-2: a rapid review	Examen rapide (date de recherche : 30 avril) : Preuves pour quatre catégories : 1) études faisant état de cas documentés de transmission du SRAS-CoV-2 par des enfants infectés; 2) études présentant des preuves indirectes du potentiel de transmission du SRAS-CoV-2 par des enfants (tant symptomatiques qu'asymptomatiques); 3) études signalant des flambées de COVID-19 en grappes dans les écoles; et 4) études estimant les proportions d'enfants infectés par le SRAS-CoV-2.	• 16 études ont été réalisées • Conclusions : o Les séries de cas et les rapports d'épidémies détaillant la transmission chez les enfants sont peu nombreux. Les études disponibles démontrent que la transmission par les enfants est possible, mais ne quantifient pas la probabilité de transmission chez les enfants par rapport aux adultes. o Il existe peu de données sur la dynamique de la transmission en milieu scolaire. Étant donné le manque actuel de données, il sera essentiel de mener des enquêtes plus approfondies et d'assurer un suivi étroit dans les cas où les écoles ont rouvert et dans les milieux où les écoles sont restées ouvertes. o Les enfants sont infectés, mais peut-être moins fréquemment que les adultes.

(Ludvigsson, 2020a)	Children are unlikely to be the main drivers of the COVID-19 pandemic: a systematic review	Examen systématique jusqu'au 12 mai, (pas de protocole, extraction de données ou évaluation de la qualité = faible qualité). Les auteurs ont passé en revue 600 articles afin d'isoler les articles clés pour l'examen.	• Les enfants représentent un faible pourcentage des cas dans l'ensemble des études. • Les enfants ont tendance à avoir des effets moins graves de la maladie. • Les enfants sont rarement le cas index dans les événements de transmission des ménages. • Même les enfants asymptomatiques ont une charge virale, mais l'ouverture de garderies et d'écoles n'aura probablement pas d'impact sur le tableau général de la mortalité.
(Viner et coll., 2020) *Préimpression*	Susceptibility to and transmission of COVID-19 amongst children and adolescents compared with adults: a systematic review and meta-analysis	Examen systématique rapide jusqu'au 16 mai. Comprend 18 études sur la recherche des contacts et le dépistage de la population. L'analyse a dichotomisé l'âge à <20 ans.	• Le rapport de cotes cumulé d'être un contact infecté chez les enfants par rapport aux adultes pour toutes les études de recherche des contacts était de 0,44 (0,29; 0,69). • Il y avait une hétérogénéité entre les pays en termes de proportion d'enfants infectés. • Il n'existe que peu de preuves que les enfants et les jeunes jouent un rôle moindre dans la transmission du SRAS-CoV-2 au niveau de la population.
(Zhu et coll., 2020)	Children are unlikely to have been the primary source of household SARS-CoV-2 infections	Une revue de la littérature jusqu'au 31 mars. Ils ont cherché des preuves du rôle des enfants dans la transmission du SRAS-CoV-2.	• 3/31 des grappes étudiées comptaient un cas index pédiatrique. Cela suggère que les enfants ne sont pas la principale source de transmission au sein des ménages.

TAI = taux d'attaque de l'infection, TLI = taux de létalité de l'infection, IC = intervalle de confiance.

L'une des hypothèses avancées pour expliquer pourquoi les enfants semblent transmettre le SRAS-CoV-2 moins fréquemment que les adultes est que leur charge virale pourrait être plus faible. Trois études ont été incluses dans cette revue, deux ont utilisé des cycles de RT-PCR pour estimer la charge virale et la troisième a cultivé le virus à partir d'échantillons positifs RT-PCR. Les trois études (tableau 2) n'ont porté que sur des cas symptomatiques, et toutes ont convenu que la charge virale n'était pas différente de celle des adultes.

Deux études de cas (tableau 2) de plusieurs enfants infectés par le SRAS-CoV-2 n'ont pas permis de détecter la transmission à leurs soignants, à l'exception peut-être d'un nourrisson qui peut ou non avoir été le cas index dans sa famille.

Les études mesurant la proportion d'infection par le SRAS-CoV-2 chez les enfants ont systématiquement fait état d'une prévalence d'infection inférieure à celle des adultes, que la base d'échantillonnage soit destinée aux populations potentiellement exposées et à haut risque ou à la population générale (Desmet et coll., 2020; Gudbjartsson et coll., 2020; Johansen et coll., 2020; Ludvigsson, 2020b)

Tableau 2 : Neuf études qui décrivent la charge virale (n=3) et la proportion de cas de SRAS-CoV-2 par groupe d'âge ou des études de cas de transmission du SRAS-CoV-2 (n=2) et synthèse des recherches (n=1) sur les enfants

Référence	Titre	Description de l'étude	Principaux résultats
Charge virale dans les échantillons provenant de cas symptomatiques de différentes tranches d'âge			
(Baggio et coll., 2020) *préimpression, nouveau*	SARS-CoV-2 viral load in the upper respiratory tract of children and adults with early acute COVID-19	Suisse, étude transversale à centre unique de la charge virale chez les enfants et les adultes testés dans les 5 jours suivant l'apparition des symptômes par RT-PCR. Données recueillies du 10 mars au 26 mai. N=405	• Charge virale en log10 copies d'ARN/mL, o Enfant (0 à 11 ans) : 6,13 ± 2,02 (étendue 3,06 à 9,21) o Adolescent (12 à 19 ans) : 5,85 ± 2,32 (étendue 2,36 à 9,42) o Jeune adulte (20 à 45 ans) : 5,91 ± 1,88 (étendue 2,37 à 9,39) o Adulte (>45 ans) : 6,33 ± 2,05 (étendue 2,49 à 9,39) • Aucune corrélation entre la charge virale et l'âge n'a été trouvée dans cette étude.
(L'Huillier, Torriani, Pigny, Kaiser et Eckerle, 2020) *nouveau*	Culture-competent SARS-CoV-2 in nasopharynx of symptomatic neonates, children, and adolescents	Suisse, série de cas de 23 enfants. Ils ont cultivé le SRAS-CoV-2 à partir d'échantillons des voies respiratoires supérieures entre le 25 janvier et le 31 mars. 23/638 patients <16 ans avaient obtenu un résultat positif pour le SRAS-CoV-2. Les échantillons ont été prélevés en moyenne deux jours après l'apparition des symptômes.	• 12/23 enfants avaient un virus qui pouvait être cultivé. o La charge médiane d'ARN viral (VRL) au moment du diagnostic était de $3,0 \times 10^6$ copies/mL o VRL moyen $4,4 \times 10^8$ [EI $6,9 \times 10^3$, $4,4 \times 10^8$] copies/mL o VRL de pointe $5,3 \times 10^9$ copies/mL • Les données montrent que la charge virale au moment du diagnostic est comparable à celle des adultes, et que les enfants symptomatiques

			de tous âges éliminent le virus infectieux au début de la phase aiguë de la maladie.
(Jones et coll., 2020)	An analysis of SARS-CoV-2 viral load by patient age	Du 1er janvier au 26 avril, les laboratoires de virologie Charité, à Berlin, ont examiné 59 831 patients pour une infection à la COVID-19, dont 3 712 (6,2 %) ont obtenu un résultat positif en RT-PCR en temps réel. Groupes scolaires : maternelle (0 à 6 ans), école primaire (7 à 11 ans), école secondaire (12 à 19 ans), université (20 à 25 ans), adultes (26 à 45 ans) et adultes (plus de 45 ans).	• Bien qu'il y ait moins d'enfants testés que d'adultes, la proportion est positive : o Par blocs de 10 ans, ▪ 1 à 10 ans=2,25 % ▪ 11 à 20 ans=3,9 % ▪ groupes d'âge adulte 4,96 à 6,25 % ▪ personnes âgées 7,8 à 10,69 % o Par groupe scolaire, ▪ Maternelle =2,10 % ▪ École primaire =2,57 % ▪ École secondaire = 4,13 % ▪ Université = 5,82 % ▪ Adultes = 5,27 % ▪ Adultes matures = 7,56 % • Selon l'auteur, la charge virale n'est pas significativement différente d'un groupe d'âge à l'autre. • La charge virale a été à nouveau traduite : 43k 1 à 10 ans, 63 k 11 à 20 ans, 183 k 21 à 30 ans, 164 k 31 à 40 ans. P=0,008 par le test de kurkal-wallis.
Études de cas			
(Wongsawat et coll., 2020)	Risk of novel coronavirus 2019 transmission from children to caregivers: a case series	Cette étude fait état de 3 cas d'enfants en Thaïlande. Les enfants ont été exposés par un membre de la famille infecté.	• Les personnes qui s'occupaient des enfants légèrement malades n'ont pas développé d'infection au SRAS-CoV-2.
(Cai et coll., 2020)	A case series of children with 2019	Série de cas pédiatriques. N=10 décrit l'évolution clinique de chaque cas. Un cas peut avoir été	• Un bébé de 3 mois qui est tombé malade de la COVID-19 avant ses parents. Ils étaient de

	novel coronavirus infection: clinical and epidemiological features	transmis à ses parents, bien qu'il soit plausible qu'elle ait eu une période d'incubation plus courte.	Wuhan et l'exposition du nourrisson est inconnue.
Seul rapport sur la proportion d'enfants infectés par le SRAS-CoV-2			
(Gudbjartsson et coll., 2020)	Spread of SARS-CoV-2 in the Icelandic population	Cette étude décrit les résultats de deux techniques d'échantillonnage en Islande. 1) les symptômes/antécédents de contact et 2) le dépistage de la population.	• Tests ciblés sur les enfants : (<10 ans) 38/564 positifs (6,7 %) contre 1183/8635 plus âgés (13,7 %). La proportion de personnes ayant obtenu un résultat positif au test a augmenté progressivement entre 10 et 20 ans. • Le groupe de dépistage de la population a détecté 0/848 enfants positifs contre 100/12 232 (0,8 % IC 95 % 0,7 à 1,0) dans les groupes d'âge plus âgés, et ce malgré le fait que l'école reste ouverte en Islande. • En Islande, les enfants ont eu moins de tests positifs que les autres groupes d'âge, bien que les écoles n'aient pas été fermées.
(Johansen et coll., 2020)	Infection prevention guidelines and considerations for paediatric risk groups when reopening primary schools during COVID-19 pandemic, Norway, April 2020	Résumé d'une évaluation des risques et des lignes directrices de CPI élaborées par l'Institut norvégien de la santé publique. Données jusqu'au 11 mai	• 8 135 cas de COVID-19 en Norvège o 0 à 5 ans 0,9 %, n=72 o 6 à 13 ans 2,0 %, n=162 o 14 à 19 ans 4,2 %, n=341 o >19 ans 93 %, n=7 560 • Le reste du document comprend des lignes directrices pour la réouverture des écoles.
(Desmet et coll., 2020)	No SARS-CoV-2 carriage observed in	Une étude en cours en Belgique sur le portage nasopharyngé chez les enfants en garderie était en cours au début de l'épidémie. Du 2 au	• 0/84 échantillons positifs d'enfants âgés de 6 mois à 30 mois. • Il n'y avait aucune preuve de transmission du SRAS-CoV-2 dans ces garderies.

	children attending daycare centers during the first weeks of the epidemic in Belgium	12 mars, des échantillons recueillis dans 8 garderies ont été testés pour le SRAS-CoV-2.	
Recherche de synthèse			
(Ludvigsson, 2020b)	Systematic review of COVID-19 in children show milder cases and a better prognosis than adults	Une revue systématique de la COVID-19 chez les enfants, y compris des données probantes (45 articles) jusqu'au 18 mars.	• La proportion de cas de moins de 19 ans était faible dans tous les pays. En Chine, 2 % (n=44 672 cas) étaient âgés de 0 à 19 ans. Les Italiens ont déclaré que 1,2 % (n=22 512 cas) étaient des enfants. Cela correspond au SRAS où 6,9 % des cas étaient des enfants et aucun n'est mort (Caselli & AricÃ², 2020).

L'IMPACT DE L'ASSOUPLISSEMENT DES MESURES D'INTERVENTION EN CIBLANT DIFFÉRENTES TRANCHES D'ÂGE

Six publications utilisent des modèles mathématiques pour étudier l'impact de l'assouplissement des mesures d'intervention en ciblant différentes tranches d'âge sur l'épidémie (tableau 1). Dans le contexte de la réouverture des écoles, deux modèles mathématiques démontrent que le retour à l'école des enfants plus jeunes (en âge préscolaire et primaire) aurait un impact plus faible, tandis que le retour aux études secondaires aurait l'impact le plus important (Di Domenico, et coll., 2020; Keeling et coll., 2020). Un modèle plus récent examine plusieurs pays européens et estime que les pays où la transmission est faible et où les interventions visant à contrôler l'épidémie sont très intensives peuvent rouvrir complètement les écoles, mais si la transmission communautaire est élevée, il faut alors s'assurer de rouvrir les écoles lentement (Stage, Shingleton, Ghosh et coll., 2020).

Sur les trois modèles qui ont analysé la levée de mesures par groupes d'âge, les résultats suggèrent que l'assouplissement des mesures par groupe d'âge pourrait réduire l'impact de la COVID-19. Plus précisément, la libération de jeunes individus (0 à 19 ans) après un confinement strict entraînerait un taux de mortalité global plus faible que la libération simultanée de tous les individus après un confinement (Castilho et coll., 2020; Zhao et Feng, 2020).

Tableau 3 : Six publications qui étudient l'impact de l'assouplissement des mesures d'intervention en ciblant différentes tranches d'âge sur l'épidémie.

Référence	Titre de la publication	Description de l'étude	Principaux résultats
Retour à l'école			
(Stage et coll., 2020)	Shut and re-open: the role of schools in the spread of COVID-19 in Europe	Étudie l'effet de la fermeture et de la réouverture ultérieure des écoles sur la transmission de la COVID-19, en considérant le Danemark, la Norvège, la Suède et les États allemands comme des études de cas.	• L'effet de la fermeture des écoles sur le taux de croissance de l'épidémie se traduit par une réduction sensible du taux de croissance environ 9 jours après la mise en œuvre. • La réouverture à grande échelle des écoles tout en contrôlant ou en supprimant l'épidémie semble possible dans des pays comme le Danemark ou la Norvège, où la transmission communautaire est généralement faible. • La réouverture des écoles peut contribuer à une augmentation significative du taux de croissance dans des pays comme l'Allemagne, où la transmission communautaire est relativement élevée.
(Keeling et coll., 2020) *Préimpression*	The impact of school reopening on the spread of COVID-19 in England	À l'aide d'un modèle SEIR, huit stratégies de réouverture des écoles primaires et secondaires en Angleterre à partir du 1er juin ont été analysées.	• L'étude prévoit que la réouverture des écoles dont les classes sont à moitié pleines ou qui s'adressent à des enfants plus jeunes ne fera probablement pas passer la cote R au-dessus de 1, bien qu'il y ait des variations notables entre les régions du pays. • Comme les enfants plus âgés ont un plus grand nombre de contacts sociaux et donc un plus grand potentiel de transmission, la réouverture des écoles secondaires entraîne une augmentation plus importante de la charge de travail par rapport à la seule réouverture des écoles primaires. • Plus le nombre de groupes d'âge autorisés à retourner à l'école en même temps est élevé, plus

			l'effet sur la cote R est important, le retour des niveaux de l'école secondaire ayant le plus grand impact.
(Di Domenico et coll., 2020) *Préimpression*	Expected impact of reopening schools after lockdown on COVID-19 epidemic in Île-de-France	Ce modèle stochastique discret d'épidémie structurée par âge a été utilisé pour évaluer l'impact de la réouverture des écoles dans la région Île-de-France, en France, après la levée du confinement prévue pour le 11 mai. Les auteurs explorent plusieurs scénarios de réouverture partielle, progressive ou totale de l'école, combinés à des interventions modérées de distanciation sociale et à un dépistage, un suivi et un isolement à grande échelle.	• Les résultats indiquent que la réouverture de toutes les écoles à cette date entraînerait une 2e vague similaire à la 1re et submergerait le système des USI. • Si seules les écoles maternelles et primaires ouvraient et que les collèges et lycées rouvraient un mois plus tard en suivant un protocole progressif, la capacité de l'ICU ne serait pas dépassée et atteindrait au maximum 72 % de sa capacité (95 % IC : 55 à 83 %). • Il n'y a pas de différence dans le risque d'épidémie si les écoles maternelles et primaires sont rouvertes rapidement ou progressivement, permettant la pleine fréquentation des plus jeunes enfants. • Il n'est pas recommandé aux élèves des collèges et des lycées d'assister à tous les cours.
Levée des interventions par groupe d'âge			
(Castilho et coll., 2020) *Préimpression*	Assessing the efficiency of different control strategies for the Coronavirus (COVID-19) epidemic	Ce modèle SEIR a été utilisé pour explorer quatre stratégies différentes pour lever les interventions au Brésil. Ces stratégies basées sur les groupes d'âge ont été analysées en utilisant 3 classes d'âge : les enfants (0 à 19 ans), les adultes (20 à 59 ans) et les personnes âgées (60 à 100 ans). Les stratégies comprennent : 1) la répartition de l'effort à parts égales entre les 3 groupes, 2) un isolement plus rigoureux (x2) des personnes âgées par rapport aux enfants/adultes,	• Les résultats indiquent que la meilleure stratégie consiste à isoler davantage les personnes âgées par rapport aux enfants et aux adultes. • Toutes les autres options entraînent 7,5 % de décès en plus. • Les auteurs ont également constaté que la distance sociale entre les adultes a le plus grand impact sur le R0.

		3) un isolement plus rigoureux (x2) des nourrissons/adultes par rapport aux personnes âgées, 4) un isolement plus rigoureux (x2) des adultes par rapport aux nourrissons et aux personnes âgées.	
(Scala, Flori et Spelta, 2020) *Préimpression*	Between geography and demography: key interdependencies and exit mechanisms for COVID-19	Ce modèle SIOR a analysé l'impact des restrictions de mobilité et du confinement selon l'âge en Italie pendant l'épidémie.	• Les classes d'âge qui interagissent le plus intensément sont les jeunes (0 à 19 ans) et les personnes âgées (70+). Les stratégies d'atténuation axées sur ces deux classes peuvent avoir un impact significatif sur les taux de diffusion dans la phase de post-confinement.
(Zhao et Feng, 2020) *Préimpression*	Staggered release policies for COVID-19 control: costs and benefits of sequentially relaxing restrictions by age	Ce modèle SEIR a étudié l'impact du calendrier séquentiel de l'assouplissement des restrictions dans les différents groupes d'âge sur la réduction des risques sanitaires liés à la COVID-19.	• Les résultats montrent que le fait de déconfiner le groupe le moins vulnérable d'une population avant les autres groupes réduira le nombre total de décès. • Une libération séquentielle correctement construite de sous-groupes définis par âge (jeunes, personnes d'âge moyen, personnes âgées) d'un confinement strict peut conduire à un taux de mortalité global plus faible que la libération simultanée de tous les individus après un confinement. • Toutefois, le calendrier de chaque étape du déconfinement échelonné est très important. Par exemple, si l'on déconfine le groupe d'âge moyen trop tôt après avoir déconfiné le groupe jeune, cela entraînerait une augmentation drastique du nombre d'infections et de décès.

AUTRES PRODUITS DE SYNTHÈSE EVIDENCE RÉALISÉS POUR EXAMINER LA TRANSMISSION ENTRE DIFFÉRENTS GROUPES D'ÂGE.

Les produits de synthèse ci-dessous ont été recensés au cours de notre recherche. Ces produits font partie de la littérature grise et nous informent sur le thème de la transmission du SRAS-CoV-2 dans certaines tranches d'âge.

Tableau 3 : Des produits de synthèse actualisés ou évolutifs qui présentent des informations sur la transmission dans différentes tranches d'âge.

Référence	Titre de la publication	Description de l'étude	Principaux résultats
Examen rapide			
Examen rapide du CCNMO	Examen rapide : quel est le rôle spécifique des garderies et des écoles dans la transmission de la COVID-19?	Mis à jour le 9 juillet 2020 1. Que sait-on sur la probabilité de transmission de la COVID-19 chez les enfants et les adultes dans les garderies et les écoles et des enfants aux membres de leur ménage? 2. Que sait-on sur la probabilité de transmission de la COVID-19 par les nourrissons, les tout-petits et les enfants d'âge scolaire à d'autres personnes dans d'autres contextes?	• 23 publications sont résumées; elles montrent une certaine transmission potentielle du SRAS-CoV-2 chez les enfants de différents âges. Aucune transmission parmi les jeunes enfants en âge d'aller à la garderie n'a été observée. • Une épidémie potentielle dans une école secondaire est décrite, mais les résultats sont basés sur la sérologie obtenue 6 semaines après la fermeture des écoles dans un épicentre.
Explication de la COVID	La COVID-19 et les enfants : nos données participatives	Mis à jour le 8 juillet 2020. Les chercheurs et les étudiants de Brown, du MIT, de Harvard, de Mass General et d'ailleurs se pressent pour obtenir des données sur la COVID-19 dans les garderies et les camps aux États-Unis.	• Ils font état de 970 garderies accueillant 27 234 élèves et d'un total de 42 cas (0,15 %). Quant aux infections chez le personnel, on observe 106 cas sur 9587 (1,01 %). • Il y a aussi des informations provenant des camps.

Méthodologies

Une recension quotidienne de la littérature (publiée et prépubliée) est effectuée par le Groupe des sciences émergentes de l'ASPC. Cette recension a permis de compiler la littérature sur la COVID-19 depuis le début de l'épidémie et est mise à jour quotidiennement. Les recherches pour trouver de la littérature pertinente sur la COVID-19 sont menées dans Pubmed, Scopus, BioRxiv, MedRxiv, ArXiv, SSRN, Research Square et sont mises en correspondance avec les publications figurant sur la liste de littérature de l'OMS au sujet de la COVID, et les centres d'information sur la COVID-19 gérés par Lancet, BMJ, Elsevier et Wiley. Le résumé quotidien et les résultats complets de la recension sont conservés dans une base de données Refworks et une liste Excel qui peut être consultée. Une recherche ciblée par mot-clé est effectuée dans ces bases de données pour y relever des citations pertinentes sur la COVID-19 et le SARS-CoV-2. Les termes de recherche utilisés sont notamment : selon l'âge, enfants et transmission. Cette revue contient des recherches publiées avant le 20 juillet 2020. Chaque référence potentiellement pertinente a été examinée pour confirmer qu'elle comportait des données pertinentes, lesquelles ont été extraites et incluses dans la recension de la littérature.

Emerging Evidence on COVID-19

Evidence Brief of Pregnancy and Severity of COVID-19

Introduction

Are pregnant women at higher risk of severe COVID-19 disease than non-pregnant women of reproductive age?

Pregnant women are potentially a vulnerable population, and may be expected to experience different symptoms and disease outcomes compared to the general population due to physiological changes during pregnancy. The objective of this evidence brief was to summarize studies conducted on COVID-19 related outcomes among pregnant women to assess whether there is evidence indicating their COVID-19 disease outcomes are more severe than the general population. This brief focused on COVID-19 disease outcomes and did not summarize birth outcomes or neonate outcomes, and includes studies published up to July 13, 2020.

Key Points

- Studies looking at severity of COVID-19 disease among pregnant women compared to non-infected pregnant women or non-pregnant COVID-19 cases present variable results that are not comparable from one study to the next due to their study design.
- Prospective studies of pregnant women in the population find a low proportion of women were infected with COVID-19 during the initial stage of the epidemic (note this was not compared to infection in the general population). Many COVID-19 positive pregnant women were asymptomatic at the time of enrollment, which ranged from first trimester visits to delivery. Many of these studies report close to zero hospitalizations or severe outcomes (Table 1).
- Prospective and retrospective case series report on a spectrum of COVID-19 disease severity outcomes in pregnant women, with significant heterogeneity across estimates between studies and within the systematic review meta-analyses (Table 2 & 3). Most of these studies did not indicate that the proportions reported were higher or different from the general population. A summary of the range in proportions reported across studies for each outcome is listed below:
    - Severe COVID-19 disease: 5.3% - 26.1%
    - Critical COVID-19 disease: 1.4% - 5%
    - Mortality: 0 – 2.0% / ICU mortality: 15.4%
    - Hospitalized for COVID-19: 0% - 28%
    - Oxygen therapy among hospitalized COVID-19 cases: 7% - 32%
    - ICU overall COVID-19 cases: 2% -10%
    - Mechanical Ventilation overall COVID-19 cases: 2 - 3.4% / ICU: 11 - 61.5%

    - ECMO overall COVID-19 cases: 0.03% - 2.3%
    - Induction of delivery due to COVID-19 disease: 9% - 19.0%
- One study based on USA surveillance data reported that the adjusted risk ratio for hospitalizations among pregnant women during the beginning of the epidemic was 5.4 times that of non-pregnant women of reproductive age (Ellington et al., 2020). This study also reported higher adjusted relative risk of ICU admission 1.5 times and mechanical ventilation 1.7 times, but no difference in the adjusted relative risk of mortality. This data could not distinguish hospitalizations for COVID-19 from other reasons for hospital admission (e.g., pregnancy-related treatment, or labor and delivery, which are common during pregnancy), thus it is unknown what proportion of the risk of hospitalization between pregnant and non-pregnant women can be attributed to pregnancy versus a possible increased risk due to COVID-19 during pregnancy.
- Another large hospital dataset from New York, USA compared the hospitalization rates of weeks one and four of the epidemic between pregnant women [RR 14.81 (95%CI 2.07-107.38) N=3064] and total hospitalizations [RR 46.99 (95% CI, 36.72-60.15) N=21980] (Tekbali et al., 2020). The study concludes that the increase in risk of the general population being hospitalized was more than for pregnant women in the first month of the epidemic. However, without a measure of excess hospitalizations due to COVID-19, these results are difficult to interpret.
- A study from China, documented that pregnant women were more likely to be admitted to the hospital sooner and with more mild symptoms compared to non-pregnant COVID-19 cases, which may bias outcomes such as hospitalization when comparing pregnant women to non-pregnant populations (Wang, Wang, & Xiong, 2020).
- There was no association with COVID-19 status and spontaneous abortion in the first trimester (S. Cosma et al., 2020b).
- There was some indication that women in the third trimester are more likely to have clinical symptoms and be diagnosed with pneumonia related to SARS-CoV-2 infection compared to those in the first trimester (Crovetto et al., 2020).
- Risk factors for severe COVID-19 disease among pregnant women included age>35, comorbidities and/or obesity (Table 2 & 3) (Cohen, Vignaux, & Jacquemard, 2020; Khalil et al.; Vivanti et al., 2020).

Overview of the Evidence

A range of retrospective and prospective case series and cohorts, case-control studies, cross-sectional data from surveillance and systematic reviews of relevant outcomes were identified, and provide evidence for this review. Retrospective observational studies, case reports and case series are considered to have a high risk of bias. The case-control study in this review did not have a large enough sample size to detect a difference between groups. The prospective studies and cohort designs have moderate to low risk of bias. Included

systematic reviews were evaluated using the AMSTAR quality assessment tool, and only reviews of moderate and high quality were summarized as those of low quality were missing key methodological steps. Those systematic reviews that were also evaluated by McMaster Plus are noted along with their quality score.

A large amount of heterogeneity across studies was identified for most outcomes that relate to severity of COVID-19 in pregnant women. This is likely due to variation in where and how the observations were collected, as well as the wide variability in sample size.

CONTENTS

OBSERVATIONAL STUDIES

Observational study data that has exposed and unexposed, diseased and healthy individuals in the sampling frame are needed to address the question of whether pregnant women are at higher risk of severe COVID-19 disease. Recent research from the USA and surveillance data from the CDC (July 16, 2020) suggest that pregnant women are at higher risk of hospitalization (3381/10156), ICU admission (160/3302) and mechanical ventilation (63/2856), but their risk for death is the same. These conclusions are supported by an MMWR paper based on the same surveillance data, in which the authors analyzed COVID-19 outcomes for all women of reproductive age (Ellington et al., 2020). Their analysis reports significantly higher adjusted risk ratios for hospitalization, ICU admittance and mechanical ventilation among women who are pregnant, controlling for age, ethnicity and presence of comorbidities. However, due to the nature of this dataset it is unknown if hospitalization, ICU or mechanical ventilation were due to COVID-19 disease, or due to conditions related to pregnancy.

Another large hospitalizations dataset from New York in the beginning of the epidemic compared the hospitalization rates of pregnant women vs. total hospitalizations (Tekbali et al., 2020). They report that the increased risk of hospitalization for pregnant women over the first four weeks of the epidemic in New York was lower [RR 14.81 (95%CI 2.07-107.38) N=3064] than for the rest of the population [RR 46.99 (95% CI, 36.72-60.15) N=21980] (Tekbali et al., 2020). This analysis did not control for any potential confounders and the results imply that the increased risk of hospitalization was lower during the first four weeks of the epidemic for pregnant women compared to the general population. However, the reasons for this difference were not explored. Another study from China documented that pregnant women were more likely to be admitted to the hospital sooner and with more mild symptoms compared to non-pregnant COVID-19 cases

(Wang et al., 2020). During pregnancy women may be admitted to the hospital for several reasons that would be unrelated to COVID-19 (e.g., to deliver, for pregnancy related complications and illness) which makes it difficult to interpret the high relative risk for hospitalization presented by (Ellington et al., 2020) or the lower increase in risk of hospitalization for pregnant women in the first four weeks of the epidemic in New York (Tekbali et al., 2020).

Several studies prospectively enrolled pregnant women attending the first trimester visit, a third trimester visit, or at delivery during the pandemic. Enrolled women were screened for SARS-CoV-2 infection and the impact of COVID-19 infection was evaluated compared to non-infected pregnant women (S. Cosma et al., 2020a; S. Cosma et al., 2020b; Fassett et al., 2020; Mohr-Sasson et al., 2020; Ruggiero, Somigliana, Tassis, & et al., 2020). There was no evidence that COVID-19 infection is associated with spontaneous abortions [RR 1.28 (95%CI 0.53-3.08)] in first trimester pregnancies (S. Cosma et al., 2020b). Two studies reported infected first trimester pregnancies were largely asymptomatic and none were hospitalized (S. Cosma et al., 2020a; Crovetto et al., 2020). Serological evidence of exposure to SARS-CoV-2 in first trimester and third trimester women report risk of exposure is the same, and that women in the third trimester were more likely to be hospitalized (0% vs. 9%) and treated for pneumonia (0% vs. 4.2%) (Crovetto et al., 2020). Post-partum complications resulting in re-admittance to the hospital was reported to be significantly higher in COVID-19 positive cases 12.9% (N=70) compared to non-COVID-19 controls 4.5% (N=605), p<0.001 (Prabhu et al., 2020). Other studies conclude that most infected pregnant women are not at higher risk of hospitalization compared to non-infected pregnant women (Fassett et al., 2020; Mohr-Sasson et al., 2020). In one study, there was no evidence of an association with COVID-19 status among pregnant women and other risk factors (e.g., age and comorbidities) (Ruggiero et al., 2020).

There were few deaths recorded among the observational studies (Table 1-3) of pregnant women. One study of USA surveillance data concluded that mortality was the same among pregnant and non-pregnant women with COVID-19 of reproductive age (Ellington et al., 2020).

Table 1: Observational studies (cohorts, case control studies), N=10 published June 8- July 10*, that compared pregnant COVID-19 cases to severity outcomes in the general population or severe outcomes in non-infected pregnant groups.

				N=91412 (8207 pregnant)	admission for pregnancy-related treatment or procedures (e.g., delivery).) ICU aRR 1.5 (95%CI 1.2-1,8) Mechanical Ventilation aRR 1.7 (95%CI 1.2-2.4) Mortality : pregnant 0.2% and control 0.2% aRR 0.9 (95%CI 0.5-1.5) *Adjusted for comorbidities, age, ethnicity
(S. Cosma et al., 2020a)	Italy	Apr 16 – Jun 4	1st trimester	Prospective cohort – consecutive pregnant women (n=138) attending their 12 week appointment at a single hospital	Prevalence 10.1% 14/138 (8 seropositive, 6 RT-PCR) None of the patients were hospitalized or treated for pneumonia associated with COVID-19
(Prabhu et al., 2020)	USA	Mar 22-Apr 27	> 20 weeks	Prospective cohort- women (n=675) admitted for delivery at 3 New York hospitals	COVID-19 cases 10.4% (70/675), 55 asymptomatic Readmission for postpartum complication COVID-19 12.9% vs. control 4.5%, p<0.001 ICU 1 No woman had mechanical ventilation No maternal deaths
(Fassett et al., 2020)	USA	Apr 6- May 11	3rd trimester	Prospective Cohort – women (N=3963) admitted to delivery at the KPSC hospitals in southern California	Prevalence COVID-19: 0.43%; 95% CI 0.23-0.63%, (17/3923) All COVID-19 cases were asymptomatic on admission
(Tekbali et al., 2020)	USA	Mar 2- Mar 29	NR	Analysis of the COVID-19 cases collected from a 14 hospital database.(N=21980 admissions of which 3064 were pregnant)	Over the four week period the relative risk of hospital admission for COVID-19 increased: Pregnant: RR 14.81 (95%CI 2.07-107.38) All hospital admissions : RR 46.99 (95% CI, 36.72-60.15) Study does not try to adjust for age or other confounders/risk factors. It is also discussed that reproductive age women are younger and less likely to be symptomatic or get tested, and most of the

					admissions for pregnant women were for labor and delivery
(Mohr-Sasson et al., 2020)	Israel	NR	3rd trimester	Case-control study comparing 11 pregnant COVID-19 cases with 25 age-matched non-pregnant controls. This study was underpowered	Hospitalization 7/11 pregnant vs. 20/25 controls p=0.29, lower admission rate, but not significant Noted clinical measures of severity that were different in the COVID-19 group: • Lymphocyte count to WBC was significantly reduced in the pregnant group compared to the controls [13.6% (4.5–19.3) vs. 26.5% (15.7–29.9); p=0.003, • pCO2 was significantly lower [39 (31–43 vs.46 (45–57); p=0.004] • base excess was significantly elevated [(−2.9)[(−7.9) − (−1.7)] vs. 0.4(0.05–2); p=0.004]
(Crovetto et al., 2020) *Preprint*	Spain	Apr 14- May 5	1st Trimester (N=372) and 3rd trimester (N=502)	Cohort of pregnant women (N=874) at their first trimester appointment or delivery. Serology, and a questionnaire collected data on previous COVID-19 status	Seropositivity to SARS-CoV-2 were the same in 1st trimester (14.3%) and 3rd trimester patients (14.1%), the authors concluded there is no difference in susceptibility between 1st and 3rd trimester. Hospital admission for COVID-19 was 0% and 9.9% for 1st and 3rd trimester. Severity of COVID-19, 1st vs. 3rd trimester Asymptomatic 70.4% vs. 52.1% Mild: 29.6% vs. 43.7% Pneumonia 0% vs. 4.2% There were higher proportions of symptomatic infections in the 3rd trimester, which is in line with other studies where a high proportion are in the 3rd trimester.

(S. Cosma et al., 2020b)	Italy	Feb 22- May 21	1st trimester	Case control study comparing spontaneous abortion and COVID-19 status	Cumulative incidence of COVID-19 between the cases (11/100, 11%) and the controls (12/125, 9.6%) (p=0.73) was the same. Logistic regression analysis confirmed that COVID-19 was not an independent predictor of abortion (1.28, 95%CI 0.53-3.08).
(RUGGIERO et al., 2020)	Italy	Apr 7 – May 6	3rd trimester	Cohort of all women delivering (N=315) at an obstetrics hospital in Milan	COVID-19 8.9%, 95%CI: 6.2–12.5%, 28/315 There was no difference between the COVID-19 group and the control group in terms of risk factors or disease outcomes.
(Wang et al., 2020)	China	Dec 8 – Apr 1	NR	Retrospective study of 30 pregnant COVID-19 cases and 42 non-pregnant COVID-19 cases in Wuhan	Pregnant women were admitted to the hospital earlier (0.25 vs. 11.00 days; P<0.001), and with milder symptoms. The proportion of asymptomatic pregnant women were 26.7% vs. 0% among non-pregnant COVID-19 cases.

* The most recent systematic review on this topic searched the literature up to June 8, 2020 and is described in Table 2.
aRR= adjusted risk ratio, RR= risk ratio

SYSTEMATIC REVIEWS

There were 38 studies that identified as a systematic review, meta-analysis, scoping review, rapid review or umbrella review and had outcomes on severity of COVID-19 in pregnant women. Only nine of these were considered of moderate or high quality with most reviews failing to describe *a priori* development of a protocol and to a lesser extent other key components of conducting synthesis research.

Studies included in the systematic reviews vary depending on search date, inclusion and exclusion criteria. Most included studies are case reports and case series with some of the newer ones also identifying case control studies. Meta-analysis or raw data on the proportions of hospitalization, severe/critical COVID-19, ICU admission, oxygen therapy, mechanical ventilation and death are reported in the systematic reviews and most have a significant amount of heterogeneity across studies (Table 2). A comparable proportion in a non-pregnant population was not reported in most reviews as the data is based largely on case series. Sources of heterogeneity likely include the selection procedure for inclusion in a study, e.g., prospective enrollment, retrospective medical records, or just a summary of a couple of cases without details of selection. There is also likely

variation depending on the spectrum of COVID-19 severity, outpatient clinic vs. hospital case selection, admittance to labor and delivery or hospitalized for COVID-19.

Table 2: Summary of the findings of systematic reviews evaluated to be of moderate or high quality (9/38) using the AMSTAR quality assessment tool with outcomes relevant to severity of COVID-19 in pregnant women.

Reference	Study Design	Quality (AMSTAR)	# Studies/ Observations/ Details	Key Outcomes
Systematic Review				
(Khalil et al., 2020)	Systematic Review and meta-analysis. Search data June 8, 2020.	High	17 studies with > 15 observations (86 included in qualitative summary) global/ 25676 pregnancies/ most women were in the 3rd trimester or post partum	Asymptomatic: 253/1205, 14.5% (5.6–32.5%), I^2=97.0% Prevalence of Risk Factors across samples: • Obesity 509/1725, 38.2% (23.6–55.4%), I^2=97% • Any co-morbidity 252/776, 32.5% (29.3–35.8%), I^2=0% ICU: 159/1591, 7% (95%CI 4-11), I^2=82% Oxygen Support: 295/1623, 18.2% (9.8–31.1%), I^2=95.5% Mechanical Ventilation 92/1680, 3.4% (1.5–7.7%), I^2=90.2% ECMO 13/1896, 0.7% (0.4–1.2%), I^2=0.0% Mortality 43/2650, 0.9% (0.3–2.9%), I^2=84.4% Deliver due to COVID-19 related reason: 95/497, 19.0% (8.9–36.0%), I^2=89.4% - ICU in pregnant women with COVID-19 was ~7% across studies for pregnant women, which is higher than 4.2% (CDC COVID-19 Response Team, 2020) reported by USA surveillance data for the reproductive age group. - ICU admittance was associated with older age (>35) and comorbidities (p<0.05). Trimester of pregnancy, ethnicity and obesity did not explain the heterogeneity in ICU or maternal death.
(Trippella et al., 2020)	Systematic Review. Search	Moderate	37 (China and Other countries)/275	Oxygen therapy: 36/275 (13%) ICU: 10/275 (4%) Mechanical ventilation: 5/275 (2%)

	date April 18, 2020. Includes epidemiological studies, case reports	(9/10 McMaster Plus)	pregnancies, 239 deliveries	ECMO: 1/275 (0.03%) Mortality: 1/275 (0.03%) The majority of pregnant women had mild or moderate disease with a low incidence of severe complications and low mortality rates.
(Huntley et al., 2020)	Systematic Review. Reports of >10 observations. Search date April 29, 2020. Includes mainly case reports and case series.	High (9/10 McMaster Plus)	13 (China, US, Italy, Data Jan-Apr 4)/538 pregnancies % 438 deliveries	Mild COVID-19: 86.1% (81.5–89.7) Severe COVID-19: 15.3% (11.1–20.8) ICU admission: 3.0% (95% CI 1.6–5.9, 8/263) Critical disease: 1.4% (95% CI 0.5–4.1, 3/209) Deaths: 0% (95% CI 0.0–1.1, 0/348) Approximately 1 in 3 pregnant women with SARS-CoV-2 had a comorbidity across studies.
(Juan et al., 2020)	Systematic Review. Search date April 20, 2020. Includes 9 case series and 15 case reports.	Moderate (8/10 McMaster Plus)	24 (China, Australia, Canada, France, Korea, Iran, Italy, Sweden, Turkey, USA)/324 pregnancies/ maternal age 20-44 and gestational age 5-41 weeks	Severe pneumonia 0-14% across studies, most admitted to ICU One case series from Iran of severe COVID-19 pregnant women had 7 death/9 ICU admitted cases on mechanical ventilation. This review also summarizes comorbidities and reports the frequency to be similar to the general population.
(Gao, Ye, & Zhang, 2020) *Preprint*	Systematic Review. Search Date April 16,	Moderate	14 (China, USA)/ 236 pregnancies	Pregnant Women Severe case or death MA: 12%, 95%CI: 0.03~0.20, I^2 =0%, P=0.006 Co-morbidities MA: 33%, 95%CI: 0.21~0.44, I^2=70%, P=0.000

	2020. Only studies with >5 observations. Includes case reports, case series and observational studies			
(Smith et al., 2020)	Systematic Review. Search date March 28, 2020 Includes: case series and 1 controlled before and after study design.	Moderate (8/10 McMaster Plus)	9 (China)/ 92 pregnancies	Hospitalized:34.7%, 32/92 Oxygen therapy: 28.1%, 9/32 hospitalized ICU: 3.1%, 1/32 hospitalized Mortality: 0/32 Many pregnant women captured across these studies were asymptomatic and afebrile at presentation. Lymphopenia: 66.7% (similar to SARS 67% and MERS 50%) and was NOT associated with worse prognosis in pregnant women. ICU and mortality for pregnant women with SARS-CoV-2 appears lower than for SARS (15-18%/30%) and MERS (25-27%/ 60%)
(Yang, Wang, Zhu, & Liu, 2020)	Systematic Review. Search date March 26, 2020 Includes case reports, case series and 1 case control.	Moderate	18/114 pregnancies	Severe/Critical: 5.3%, 6/114 ECMO 0.9%: 1/114 The only case-control study suggested no differences in preeclampsia, gestational diabetes mellitus, and premature rupture of membrane between COVID-19 and non-COVID-19 groups. In general, the clinical characteristics of pregnant women are similar to those of non-pregnant adults
(Gajbhiye, Modi, & Mahale, 2020) *Preprint*	Systematic Review. Search Date May 3, 2020.	Moderate	50 (china, USA, Iran, Australia, Canada, Korea, Honduras, Jordan, Spain, Peru, Sweden,	ICU with mechanical ventilation: 11% Oxygen therapy: 24% ECMO: 2.3%, 10/441 Deaths: 2.0%, 9/441

	Includes case series, case reports.		Turkey, Italy, Portugal, Switzerland, India)/ 441 pregnancies, 387 deliveries/ 95% of the women were in the 3rd trimester

High	17/ 21 SARS, 11 MERS, 41 COVID-19 pregnancies	Hospital stay >15 days: COVID-19 (50% [95%CI -0·19-1·19], p>0·05) MERS: (80% [95%CI 0·45-1·15], p<0·05) Fatality Rate COVID-19: 0% MERS: 40% ([95%CI -0·03-0·83], p>0·05) SARS: 25% ([95%CI 0·01-0·49], p<0·05)

CASE SERIES

Case series and case reports are the most common study design used to describe COVID-19 impacts on pregnancy. As this review question was about whether there is more severe COVID-19 disease among pregnant women we targeted new case series with more than 30 observations. There were 16 case reports published between June 8-July 10 that were excluded by this cut point.

Table 3: Case series (>30 women) published June 8- July 10 summarizing the probability of severe outcomes in pregnant COVID-19 cases.

Reference	Country	Dates	Trimester	Study Design	Key outcomes
Primary Research					

(Cohen et al., 2020)}	France	Not specified	1-3 (27 weeks median, range 4-34)	Survey of pregnant women with COVID-19 in France (self-identified) N=194. Only data on RT-PCR confirmed cases was analysed, N= 88. Recruitment bias	Hospitalization 18/88 (20%) Severe disease with oxygen therapy 6/88 (7%) Uterine contractions 15/88 (2 severe) Delivery: 14/88 (1 severe) Severe disease was seen in older women p=0.009., higher BMI p=0.002, and those with diabetes (50% vs. 5%) p=0.006
(Vivanti et al., 2020)	France	Mar 12- Apr 13	14 weeks and 2 days postpartum	Retrospective multicenter review of medical records (N=100)	Hospitalized 52/100 ICU 10/100 Oxygen therapy 32/100 Risk factors for hospitalization: - BMI high vs. lower p=0.003 - Not significant were maternal age, gestational age, parity, and comorbidities.
(Sentilhes et al., 2020)	France	Mar 1- Apr 3	NR	Retrospective case series of all pregnant women with COVID-10 (N=54) in Strasbourg	Oxygen therapy 24.1%, 13/54 Mechanical ventilation in 3/13 ECMO 1/13 Medically indicated premature birth (>37 weeks) due to severe COVID-19: 5/54
(Lokken, Walker, & Adams Waldorf, 2020)	USA	Jan21- Apr 17	2nd trimester (N=20), 3rd trimester (N=23)	Retrospective Case series of pregnant women with hospital entries for COVID-19 (N=46) in Washington State hospitals	Severe 15%, 6/46 (all overweight or with comorbidities) Hospitalization: 16%, 7/46 ICU 1/46
(Khoury et al., 2020)	USA	Mar 13 – Apr 12	Term	Prospective cohort of COVID-19 cases (N=241) that gave birth across 5 New York medical centers	Asymptomatic 42.1%, 102/241 Mild 26.5%,, 64/241 Severe 26.1%, 63/241 Critical 5%, 12/241 ICU 7.1%, 17/241 Mechanical ventilation 3.7%, 9/241 Deaths 0%

					Risk Factors: BMI was associated with severity p=0.001
(Blitz et al., 2020)	USA	Mar 1- May 6	NR	Case Series of COVID-19 confirmed cases in pregnant women (N=462) in 10 hospitals in New York state	Severe or critical 15.2% 70/462 ICU 18.6%, 13/70 Deaths 15.4%, 2/13 (and overall) Invasive mechanical ventilation 61.5%, 8/13 5 emergency deliveries were performed in the ICU cases prior to invasive mechanical ventilation due to COVID-19 symptoms.
(San-Juan et al., 2020)	Spain	Mar 5- Apr 6	2nd trimester (N=9), 3rd trimester (N=22)	Retrospective cohort, patients enrolled at diagnosis (N=52)	COVID-19 pneumonia was diagnosed in 61.5%, 32/54 Oxygen therapy 56%,18/32 ARDS 25%, 8/32 ICU 6.4%, 2/32 Mortality 0/32

* The most recent systematic review on this topic searched the literature up to June 8, 2020 and is described in Table 2.

Methods:

A daily scan of the literature (published and pre-published) is conducted by the Emerging Science Group, PHAC. The scan has compiled COVID-19 literature since the beginning of the outbreak and is updated daily. Searches to retrieve relevant COVID-19 literature are conducted in Pubmed, Scopus, BioRxiv, MedRxiv, ArXiv, SSRN, Research Square and cross-referenced with the literature on the WHO COVID literature list, and COVID-19 information centers run by Lancet, BMJ, Elsevier and Wiley. The daily summary and full scan results are maintained in a refworks database and an excel list that can be searched. Targeted keyword searching is conducted within these databases to identify relevant citations on COVID-19 and SARS-COV-2. Search terms used included: pregnancy or pregnant or maternal
This review contains research published up to July 14, 2020
Each potentially relevant reference was examined to confirm it had relevant data and relevant data is extracted into the review.

Preuve émergente sur la COVID-19

Synthèse en bref des données probantes sur la grossesse et la gravité de la COVID-19

Introduction

Les femmes enceintes ont-elles un risque plus élevé d'être atteintes d'une forme grave de COVID-19 que les femmes non enceintes en âge de procréer?

Les femmes enceintes représentent une population potentiellement vulnérable et l'on peut s'attendre à ce qu'elles présentent des symptômes et une évolution de la maladie différents de ceux de la population en général en raison des changements physiologiques qu'elles vivent pendant la grossesse. L'objectif de cette synthèse en bref vise à faire synthétiser les études sur l'évolution de la COVID-19 chez les femmes enceintes afin d'évaluer s'il existe des données probantes indiquant que l'évolution de cette maladie est plus grave chez ces femmes que dans la population en général. Ce document porte sur l'évolution de la COVID-19, mais n'inclut aucune donnée de synthèse en ce qui concerne l'issue de la grossesse ou l'évolution de la maladie chez les nouveau-nés, et comprend des études publiées jusqu'au 13 juillet 2020.

Points clés

- Les études portant sur la gravité de la COVID-19 chez les femmes enceintes comparativement aux femmes enceintes non infectées ou aux femmes non enceintes atteintes de la COVID-19 présentent des résultats variables non comparables d'une étude à l'autre en raison du plan de chacune des études.
- Des études prospectives sur les femmes enceintes révèlent qu'une faible proportion de ces femmes ont été infectées par la COVID-19 pendant la première phase de l'épidémie (à noter que cela n'a pas été comparé au taux d'infection dans la population en général). Les femmes qui se sont inscrites aux études en étaient à différentes étapes de leur grossesse allant des premières visites pendant le premier trimestre à l'accouchement et bon nombre d'entre elles étaient positives à la COVID-19 et asymptomatiques. Bon nombre de ces études font état de presque zéro hospitalisation ou évolution grave (tableau 1).
- Les séries de cas prospectifs et rétrospectifs indiquent un spectre de gravité de l'infection associée à la COVID-19 chez les femmes enceintes, avec une hétérogénéité importante entre les estimations découlant des études et les méta-analyses de la revue systématique (tableaux 2 et 3). La plupart de ces études n'indiquaient pas que les proportions déclarées étaient plus élevées que dans la population en général ou différentes de celles-ci. Voici un résumé de l'éventail de proportions déclarées dans les études pour chaque résultat découlant de l'évolution de la maladie :

  - Maladie grave associée à la COVID-19 : entre 5,3 % et 26,1 %
  - Maladie très grave associée à la COVID-19 : entre 1,4 % et 5 %
  - Mortalité : entre 0 % et 2,0 %/mortalité pendant le séjour dans les USI : 15,4 %
  - Hospitalisation en raison de la COVID-19 : entre 0 % et 28 %
  - Oxygénothérapie utilisée parmi les cas d'infection à la COVID-19 ayant exigé une hospitalisation : entre 7 % et 32 %
  - Taux global de COVID-19 dans les USI : entre 2 % et 10 %
  - Taux global de COVID-19 ayant exigé l'utilisation d'un ventilateur mécanique : entre 2 % et 3,4 %/dans les USI : entre 11 % et 61,5 %
  - Taux global de COVID-19 ayant exigé une ECMO : entre 0,03 % et 2,3 %
  - Accouchement provoqué en raison de la COVID-19 : entre 9 % et 19,0 %
- Une étude fondée sur des données de surveillance aux États-Unis a révélé que le risque relatif ajusté pour les hospitalisations chez les femmes enceintes au début de l'épidémie était 5,4 fois supérieur à celui des femmes non enceintes en âge de procréer (Ellington et coll., 2020). Cette étude a également indiqué un risque relatif ajusté 1,5 fois supérieur pour l'admission aux soins intensifs et 1,7 fois supérieur pour le ventilateur mécanique, mais aucune différence dans le risque relatif ajusté de mortalité. Ces données n'ont pas permis de faire une distinction entre les hospitalisations en raison de la COVID-19 et des autres motifs d'admission à l'hôpital (p. ex., traitements liés à la grossesse, au travail et à l'accouchement, qui sont courants pendant la grossesse). On ne sait donc pas quelle proportion du risque d'hospitalisation chez les femmes enceintes et celles qui ne le sont pas peut être attribuée à la grossesse plutôt qu'à un risque accru possible en raison de la COVID-19 pendant la grossesse.
- Un autre grand ensemble de données provenant des hôpitaux de New York, aux États-Unis, a comparé les taux d'hospitalisation pendant les semaines un et quatre de l'épidémie chez les femmes enceintes [RRA de 14,81 (2,07 à 107,38, IC à 95 %) N=3 064] aux hospitalisations totales [RRA de 46,99 (36,72 à 60,15, IC à 95 %)) N=21 980] (Tekbali et coll., 2020). L'étude a conclu que l'augmentation du risque d'hospitalisation dans la population en général était supérieure à celle des femmes enceintes pendant le premier mois de l'épidémie. Toutefois, sans éléments permettant de mesurer les hospitalisations supplémentaires associées à la COVID-19, ces résultats sont difficiles à interpréter.
- Une étude menée en Chine a révélé que les femmes enceintes étaient plus susceptibles d'être admises plus tôt à l'hôpital et de présenter des symptômes plus bénins que les femmes non enceintes atteintes de COVID-19, ce qui peut fausser les résultats comme en ce qui concerne les hospitalisations, lorsqu'on compare les femmes enceintes aux populations non enceintes (Wang, Wang et Xiong, 2020).
- Il n'y avait aucun lien entre le fait d'être atteinte de COVID-19 et l'avortement spontané au cours du premier trimestre (S. Cosma et coll., 2020b).
- Selon certaines indications, les femmes qui en sont à leur troisième trimestre sont plus susceptibles d'avoir des symptômes cliniques et de recevoir un diagnostic de pneumonie liée à une infection par le SRAS-CoV-2 que celles qui en sont à leur premier trimestre (Crovetto et coll., 2020).

- Les facteurs de risque de maladie grave liée à la COVID-19 chez les femmes enceintes comprenaient l'âge (> 35 ans), les comorbidités ou l'obésité (tableaux 2 et 3) (Cohen, Vignaux et Jacquemard, 2020; Khalil et coll.; Vivanti et coll., 2020).

Vue d'ensemble des éléments de preuve

Un éventail de séries de cas et de cohortes rétrospectives et prospectives, d'études cas-témoins, de données transversales provenant de la surveillance et de l'examen systématique de l'évolution pertinente de la maladie a été établi et fournit des données probantes pour cet examen. Les études d'observation rétrospectives, les rapports de cas et les séries de cas sont jugés présenter un risque élevé de biais. La taille de l'étude cas/témoins de cette étude n'était pas assez grande pour permettre de déceler une différence entre les groupes. Les études prospectives et les cohortes présentent un risque modéré à faible de biais. Les examens systématiques inclus ont été évalués à l'aide de l'outil d'évaluation de la qualité AMSTAR, et seuls les examens de qualité moyenne et élevée ont été résumés puisque ceux de faible qualité ne comportaient pas d'étapes méthodologiques clés. Les examens systématiques ayant également été évalués par McMaster Plus sont mentionnés, avec leur cote de qualité.

Les études ont révélé une grande hétérogénéité en ce qui concerne l'évolution et la gravité de la COVID-19 chez les femmes enceintes. Cette homogénéité est probablement attribuable aux variations liées à l'endroit et à la façon dont les observations ont été notées, ainsi qu'à la grande variabilité dans la taille des échantillons.

CONTENU

ÉTUDES D'OBSERVATION

Des données d'études d'observation sur des femmes exposées et non exposées, malades et en santé dans la base d'échantillonnage sont nécessaires pour déterminer si les femmes enceintes sont plus à risque de contracter une forme grave de la COVID-19. Les données des recherches récentes menées aux États-Unis et les données de surveillance du CDC (16 juillet 2020) suggèrent que les femmes enceintes sont plus à risque d'être hospitalisées (3 381/10 156), d'être admisses aux soins intensifs (160/3 302) et de devoir être mises sous ventilateur mécanique (63/2 856), mais que leur risque de décès est le même. Ces conclusions sont

appuyées par un document du MMWR fondé sur les mêmes données de surveillance, dans lequel les auteurs ont analysé l'évolution de la COVID-19 chez l'ensemble des femmes en âge de procréer (Ellington et coll., 2020). Leur analyse révèle un taux de risque ajusté beaucoup plus élevé en ce qui concerne l'hospitalisation, l'admission aux soins intensifs et le recours au ventilateur mécanique chez les femmes enceintes, compte tenu de l'âge, de l'origine ethnique et de la présence de comorbidités. Toutefois, en raison de la nature de cet ensemble de données, on ne sait pas si l'hospitalisation, le séjour aux soins intensifs ou le recours au ventilateur mécanique étaient attribuables à la COVID-19 ou à des problèmes liés à la grossesse.

Un autre important ensemble de données sur les hospitalisations émanant de New York au début de l'épidémie comparait les taux d'hospitalisation des femmes enceintes par rapport au nombre total d'hospitalisations (Tekbali et coll., 2020). Il indiquait que le risque accru d'hospitalisation des femmes enceintes pendant les quatre premières semaines de l'épidémie à New York était plus faible [RRA de 14,81 (2,07 à 107,38, IC à 95 %)) N=3 064] que pour le reste de la population [RR 46,99 (36,72 à 60,15, IC à 95 %)) N=21 980] (Tekbali et coll., 2020). Cette analyse n'a cependant pas pu contrôler certaines variables confusionnelles et ses résultats sous-entendent que le risque accru d'hospitalisation était plus faible chez les femmes enceintes pendant les quatre premières semaines de l'épidémie que dans la population en général. Toutefois, les raisons de cette différence n'ont pas été examinées. Une autre étude menée en Chine a révélé que les femmes enceintes étaient plus susceptibles d'être admises à l'hôpital plus tôt avec des symptômes plus bénins comparé aux femmes non enceintes atteintes de COVID-19.

(Wang et coll., 2020). Pendant la grossesse, les femmes ont pu être admises à l'hôpital pour différentes raisons sans lien avec la COVID-19 (par exemple, pour accoucher, en raison de complications et de maladies liées à la grossesse), ce qui rend difficile l'interprétation du risque relatif élevé d'hospitalisation présenté par (Ellington et coll., 2020) ou la plus faible augmentation du risque d'hospitalisation des femmes enceintes pendant les quatre premières semaines de l'épidémie à New York (Tekbali et coll., 2020).

Pendant la pandémie, plusieurs études ont inscrit de manière prospective des femmes enceintes qui allaient à l'hôpital dans le cadre d'un rendez-vous pendant le premier trimestre ou le troisième trimestre ou au moment de leur accouchement. Ces femmes ont été soumises à un dépistage de l'infection par le SRAS-CoV-2 et les répercussions de l'infection par COVID-19 a ont été évalué par rapport aux femmes enceintes non infectées (S. Cosma et coll., 2020a; S. Cosma et coll., 2020b; Fassett et coll., 2020; Mohr-Sasson et coll., 2020; Ruggiero, Somigliana, Tassis et coll., 2020). Il n'a pas été démontré que l'infection par COVID-19 était associée à des avortements spontanés [RRA de 1,28 (0,53 à 3,08, IC à 95 %))] pendant le premier trimestre de la grossesse (S. Cosma et coll., 2020b). Deux études ont indiqué que les femmes infectées, qui en étaient au premier trimestre, étaient en grande partie asymptomatiques et qu'aucune n'avait été hospitalisée (S. Cosma et coll., 2020a; Crovetto et coll., 2020). Les signes sérologiques de l'exposition au SRAS-CoV-2 pendant le premier et le troisième trimestre indiquent que le risque d'exposition était le même et que les femmes qui en étaient au troisième trimestre étaient plus susceptibles d'être hospitalisées (0 % c. 9 %) et traitées pour une pneumonie (0 % c. 4,2 %) (Crovetto et coll., 2020). Les complications post-partum ayant entraîné une réadmission à l'hôpital ont été signalées comme étant significativement plus élevées chez les femmes ayant

été déclarées positives à la COVID-19 par rapport aux femmes témoins non atteintes de COVID-19 dans une proportion de 12,9 % (N=70) et de 4,5 % (N=605), p< 0,001 respectivement (Prabhu et coll., 2020). D'autres études ont conclu que bon nombre des femmes enceintes infectées ne présentaient pas de risque d'hospitalisation plus élevé que les femmes enceintes non infectées (Fassett et coll., 2020; Mohr-Sasson et coll., 2020). Dans une étude, aucune preuve n'a pu établir de lien entre la situation liée à la COVID-19 chez les femmes enceintes et d'autres facteurs de risque (par exemple, l'âge et les comorbidités) (Ruggiero et coll., 2020).

Peu de décès ont été enregistrés dans les études d'observation (tableau 1-3) chez les femmes enceintes. Une étude avec données de surveillance aux États-Unis a conclu que le taux de mortalité était le même chez les femmes enceintes et non enceintes en âge de procréer atteintes de COVID-19 (Ellington et coll., 2020).

Tableau 1 : Études d'observation (cohortes, études de comparaison avec témoins), N=10 publiées entre le 8 juin et le 10 juillet* ayant comparé les cas de femmes enceintes atteintes de COVID-19 à la gravité de la maladie dans la population en général ou à des infections graves parmi les groupes de femmes enceintes non infectées.

Recherche originale					
(Ellington et coll., 2020)	États-Unis	22 janvier au 7 juin	Non précisé	Échantillon représentatif des données de surveillance Données représentant 50 États Femmes de 15 à 44 ans dont la COVID-19 a été confirmée N=91 412 (8 207 étaient enceintes)	Hospitalisation : femmes enceintes 31,5 %, groupe de contrôle 5,8 % RRA de 5,4 (5,1 à 5,6, IC à 95 %) (Aucune donnée permettant de faire une distinction entre les hospitalisations en raison de circonstances liées à la COVID-19 (par exemple, aggravation de l'état respiratoire) et les admissions à l'hôpital pour un traitement ou des procédures liés à la grossesse (par exemple, l'accouchement).) RRA de 1,5 dans les USI (1,2 à 1,8, IC à 95 %) RRA de 1,7 avec le ventilateur mécanique (1,2 à 2,4, IC à 95 %) Mortalité : femmes enceintes 0,2 % et groupe de contrôle 0,2 % avec RRA de 0,9 (0,5 à 1,5, IC à 95 %) *Ajusté pour les comorbidités, l'âge, l'ethnicité
(S. Cosma et coll., 2020a)	Italie	16 avril au 4 juin	1er trimestre	Cohorte prospective - femmes enceintes (n=138)	Prévalence de 10,1 % 14/138 (8 séropositives, 6 RT-PCR)

				qui se présentent à leur visite à 12 semaines de grossesse dans un seul hôpital	Aucune des patientes n'a été hospitalisée ou traitée pour une pneumonie associée à la COVID-19
(Prabhu et coll., 2020)	États-Unis	22 mars au 27 avril	> 20 semaines	Cohorte prospective - femmes (n=675) admises pour accoucher dans 3 hôpitaux de New York	10,4 % (70/675) de cas de COVID-19, 55 asymptomatiques Réadmission pour complications post-partum 12,9 % de COVID-19 contre 4,5 %, p<0,001 pour le groupe de contrôle USI 1 Aucune femme n'a eu besoin du ventilateur mécanique Aucun décès maternel
(Fassett et coll., 2020)	États-Unis	6 avril au 11 mai	3e trimestre	Cohorte prospective - femmes (N=3 963) admises pour accoucher dans les hôpitaux du KPSC en Californie du Sud	Prévalence de COVID-19 : 0,43 %; IC à 95 % 0,23 à 0,63 %, (17/3 923) Tous les cas de COVID-19 étaient asymptomatiques lors de leur admission
(Tekbali et coll., 2020)	États-Unis	2 mars au 29 mars	N.d.	Analyse des cas de COVID-19 tirée d'une base de données de 14 hôpitaux (N=21 980 admissions, dont 3 064 femmes enceintes)	Pendant cette période de quatre semaines, le risque relatif d'admission à l'hôpital pour la COVID-19 a augmenté : Enceinte : RRA de 14,81 (2,07 à 107,38, IC à 95 %) Toutes les admissions à l'hôpital : RRA de 46,99 (36,72 à 60,15, IC à 95 %) L'étude n'a pas essayé d'ajouter les données en fonction de l'âge ou d'autres facteurs de confusion ou de risque. Il est également mentionné que les femmes en âge de procréer étaient plus jeunes et moins susceptibles de présenter des symptômes ou de se faire dépister, et que la plupart des femmes enceintes se présentaient à l'hôpital parce qu'elles étaient en plein travail et pour accoucher.

(Mohr-Sasson et coll., 2020)	Israël	N.d.	3e trimestre	Étude cas-témoins comparant 11 cas de COVID-19 chez des femmes enceintes avec groupe témoin de 25 femmes non enceintes appariées par âge. Cette étude ne comportait pas suffisamment de candidates.	Hospitalisation 7/11 femmes enceintes contre 20/25 dans le groupe témoins p=0,29, soit un taux d'admission plus faible, mais non significatif Mesures cliniques de gravité distinctes en ce qui concerne le groupe de femmes atteintes de COVID-19 : • la numération lymphocytaire par rapport au nombre de globules blancs était sensiblement inférieure dans le groupe de femmes enceintes par rapport au groupe témoin [13,6 % (4,5 à 19,3) contre 26,5 % (15,7 à 29,9); p=0,003, • la pCO2 était nettement inférieure [39 (31 à 43 contre 46 (45 à 57); p=0,004] • l'excès de base était nettement élevé [(-2,9) [(-7,9) à (-1,7)] par rapport à 0,4 (0,05 à 2); p=0,004]
(Crovetto et coll., 2020) *Prépublication*	Espagne	14 avril au 5 mai	1er trimestre (N=372) et 3e trimestre (N=502)	Cohorte de femmes enceintes (N=874) lors de leur rendez-vous au premier trimestre ou de leur accouchement. Sérologie, et un questionnaire a permis de recueillir des données sur leur situation précédente liée à la COVID-19	La séropositivité au SRAS-CoV-2 étant la même au 1er trimestre (14,3 %) et au 3e trimestre (14,1 %), les auteurs ont conclu qu'il n'y a pas de différence de susceptibilité entre le 1er et le 3e trimestre. L'admission à l'hôpital pour des raisons liées à la COVID-19 était de 0 % et de 9,9 % pour les 1er et 3e trimestres respectivement. Gravité de la COVID-19 entre le 1er et le 3e trimestre Asymptomatique : 70,4 % contre 52,1 % Bénigne : 29,6 % contre 43,7 % Pneumonie : 0 % contre 4,2 % Les proportions d'infections symptomatiques étaient plus élevées pendant le troisième trimestre, ce qui est conforme à d'autres études dans

					lesquelles une proportion plus élevée avait été remarquée pendant le troisième trimestre.
(S. Cosma et coll., 2020b)	Italie	22 février au 21 mai	1er trimestre	Étude cas/témoins visant à comparer les avortements spontanés et la situation liée à la COVID-19	L'incidence cumulée de COVID-19 entre les cas (11/100, 11 %) et les témoins (12/125, 9,6 %) (p=0,73) était la même. L'analyse de régression logistique a confirmé que la COVID-19 n'était pas un prédicteur indépendant de l'avortement (1,28, IC à 95 % 0,53 à 3,08).
(RUGGIERO et coll., 2020)	Italie	7 avril au 6 mai	3e trimestre	Cohorte comprenant toutes les femmes qui accouchent (N=315) dans un hôpital obstétrique de Milan	COVID-19 : 8,9 %, 6,2 à 12,5 %, IC à 95 %, 28/315 Il n'y avait aucune différence entre le groupe de femmes atteintes de la COVID-19 et le groupe témoin en ce qui concerne les facteurs de risque ou d'évolution de la maladie.
(Wang et coll., 2020)	Chine	8 décembre au 1er avril	N.d.	Étude rétrospective de 30 cas de COVID-19 chez des femmes enceintes et de 42 cas de COVID-19 chez des femmes non enceintes à Wuhan	Les femmes enceintes ont été admises à l'hôpital plus tôt (0,25 contre 11,00 jours; P<0,001), avec des symptômes plus légers. La proportion de femmes enceintes asymptomatiques était de 26,7 % contre 0 % pour les cas de COVID-19 chez les femmes non enceintes.

* L'étude systématique la plus récente à ce sujet a examiné la littérature publiée jusqu'au 8 juin 2020 et est décrite dans le tableau 2.

RRA= ratio de risque ajusté, RR= ratio de risque

REVUES SYSTÉMATIQUES

38 études ont été identifiées comme étant des revues systématiques, une méta-analyse, une revue exploratoire, une revue rapide ou une revue d'ensemble et incluaient de l'information sur la gravité de la COVID-19 chez les femmes enceintes. Seules neuf de ces études ont été jugées de qualité moyenne ou élevée, la plupart ne décrivant pas le développement *a priori* d'un protocole et, dans une moindre mesure, d'autres éléments clés de la recherche de synthèse.

Les études incluses dans les revues systématiques varient en fonction de la date de recherche, ainsi que des critères d'inclusion et d'exclusion. La plupart des études incluses sont des exposés de cas de cas et des séries de cas, alors que certaines des plus récentes ont également mentionné des études de comparaison avec les témoins. Les méta-analyses ou les données brutes sur les proportions d'hospitalisation, d'état grave ou sévère associé à la COVID-19, d'admission en USI, de recours à l'oxygénothérapie, d'utilisation du ventilateur mécanique et de décès sont indiqués dans les revues systématiques et bon nombre démontrent une grande hétérogénéité entre les études (tableau 2). Une proportion comparable dans une population de femmes non enceintes n'a pas été signalée dans la plupart des études, puisque les données sont fondées en grande partie sur des séries de cas. Les sources d'hétérogénéité comprennent probablement la procédure de sélection pour l'inclusion dans une étude, par exemple, l'inscription prospective, les dossiers médicaux rétrospectifs ou un simple résumé de quelques cas, sans détails sur la sélection. Il est également probable qu'il y ait des variations dans le spectre de gravité de la COVID-19, de la sélection des cas en clinique externe ou à l'hôpital, de l'admission en raison du travail et de l'accouchement ou de l'hospitalisation liée à la COVID-19.

Tableau 2 : Résumé des conclusions des revues systématiques évaluées comme étant de qualité moyenne ou élevée (9/38) à l'aide de l'outil d'évaluation de la qualité AMSTAR avec des résultats pertinents en ce qui concerne la gravité de la COVID-19 chez les femmes enceintes.

Revue systématique				
(Khalil et coll., 2020)	Revue systématique et méta-analyse. Recherche de données effectuée le 8 juin 2020.	Élevée	17 études avec > 15 observations (86 ont été incluses dans le résumé qualitatif) global/25 676 grossesses/la plupart des femmes étaient au 3e trimestre ou en post-partum	Asymptomatiques : 253/1 205, 14,5 % (5,6 à 32,5 %), I^2=97,0 % Prévalence des facteurs de risque dans les échantillons : • Obésité : 509/1 725, 38,2 % (23,6 à 55,4 %), I^2=97 % • Toute comorbidité : 252/776, 32,5 % (29,3 à 35,8 %), I^2=0 % USI : 159/1 591, 7 % (4 à 11, IC à 95 %), I^2=82 % Oxygénothérapie : 295/1 623, 18,2 % (9,8 à 31,1 %), I^2=95,5 % Ventilateur mécanique : 92/1 680, 3,4 % (1,5 à 7,7 %), I^2=90,2 %

				ECMO : 13/1 896, 0,7 % (0,4 à 1,2 %), I^2=0,0 % Mortalité : 43/2 650, 0,9 % (0,3 à 2,9 %), I^2=84,4 % Accouchement pour toute raison liée à la COVID-19 : 95/497, 19,0 % (8,9 à 36,0 %), I^2=89,4 % - Les femmes enceintes atteintes de COVID-19 qui ont dû être hospitalisées dans l'USI étaient d'environ 7 % dans l'ensemble des études sur les femmes enceintes, ce qui est supérieur aux taux de 4,2 % (CDC COVID-19 Response Team, 2020) indiqué par les données de surveillance des États-Unis pour le groupe en âge de procréer. - L'admission en USI était associée à un âge plus avancé (>35 ans) et à des comorbidités (p<0,05). Le trimestre, l'ethnicité et l'obésité n'expliquent pas l'hétérogénéité en ce qui concerne l'USI ni le décès de la mère.
(Trippella et coll., 2020)	Revue systématique. Date de la recherche : 18 avril 2020. Comprend des études épidémiologiques, des exposés de cas	Modérée (9/10 McMaster Plus)	37 (Chine et autres pays)/275 grossesses, 239 accouchements	Oxygénothérapie : 36/275 (13 %) USI : 10/275 (4 %) Ventilateur mécanique : 5/275 (2 %) ECMO: 1/275 (0,03 %) Mortalité : 1/275 (0,03 %) La majorité des femmes enceintes étaient atteintes d'une forme bénigne ou modérée de la maladie avec faible incidence de complications graves et faible taux de mortalité.
(Huntley et coll., 2020)	Revue systématique.	Élevée	13 (Chine, États-Unis, Italie, données pour janvier à	Bénin : 86,1 % (81,5 à 89,7) Grave : 15,3 % (11,1 à 20,8)

	Rapports sur >10 observations. Date de la recherche : 29 avril 2020. Comprend principalement des exposés de cas et des séries de cas.	(9/10 McMaster Plus)	avril 4)/538 grossesses 438 accouchements	Admission à l'USI : 3,0 % (1,6 à 5,9, IC à 95 %, 8/263) Maladie grave : 1,4 % (0,5 à 4,1, IC à 95 %, 3/209) Décès : 0 % (0,0 à 1,1, IC à 95 %, 0/348) Entre les études, environ une femme enceinte sur trois atteinte du SRAS-CoV-2 présentait une comorbidité.
(Juan et coll., 2020)	Revue systématique. Date de la recherche : 20 avril 2020. Comprend 9 séries de cas et 15 exposés de cas.	Modérée (8/10 McMaster Plus)	24 (Chine, Australie, Canada, France, Corée, Iran, Italie, Suède, Turquie, États-Unis)/324 grossesses/âge de la mère de 20 à 44 ans et âge gestationnel de 5 à 41 semaines	Pneumonie sévère de 0 à 14 % selon les études, la plupart des femmes ayant été admises à l'USI Une série de cas en Iran de femmes enceintes atteintes d'une grave infection à la COVID-19 a entraîné 7 décès/9 cas admis à l'USI sous ventilateur mécanique. Cette revue résume également les comorbidités et indique que leur fréquence est similaire à celle de la population en général.
(Gao, Ye et Zhang, 2020) *Prépublication*	Revue systématique. Date de la recherche : 16 avril 2020. Uniquement les études comportant plus de 5 observations. Comprend des exposés de cas, des séries de cas et des études d'observation.	Modérée	14 (Chine, États-Unis)/236 grossesses	Femmes enceintes Cas grave ou décès MA : 12 %, 0,03~0,20, IC à 95 % I^2 =0 %, P=0,006 Comorbidités MA : 33%, 0,21~0,44, IC à 95 % I^2=70 %, P=0,000

(Smith et coll., 2020)	Revue systématique. Date de la recherche : 28 mars 2020 Comprend : des séries de cas et un plan d'étude avant/après.	Modérée (8/10 McMaster Plus)	9 (Chine)/92 grossesses	Hospitalisation : 34,7 %, 32/92 Oxygénothérapie : 28,1 %, 9/32 hospitalisées USI : 3,1 %, 1/32 hospitalisées Mortalité : 0/32 De nombreuses femmes enceintes prises en compte dans ces études étaient asymptomatiques et afébriles lors de la présentation. Lymphopénie : 66,7 % (comme le SRAS 67 % et le MERS 50 %) et n'était PAS associé à un pronostic plus défavorable chez les femmes enceintes. Le séjour à l'USI et la mortalité des femmes enceintes atteintes du SRAS-CoV-2 semblent plus faibles que pour le SRAS (15 à 18 %/30 %) et le MERS (25 à 27 %/60 %)
(Yang, Wang, Zhu et Liu, 2020)	Revue systématique. Date de la recherche : 26 mars 2020 Comprend des exposés de cas, des séries de cas et une comparaison avec les témoins.	Modérée	18/114 grossesses	Grave/critique : 5,3 %, 6/114 ECMO 0,9 % : 1/114 La seule étude cas/témoins n'a révélé aucune différence en ce qui concerne la prééclampsie, le diabète sucré de la grossesse et la rupture prématurée des membranes entre les groupes de femmes atteintes ou non de COVID-19. En général, les caractéristiques cliniques des femmes enceintes sont similaires à celles des femmes adultes non enceintes.

SÉRIE DE CAS

Les séries de cas et les exposés de cas constituent le modèle d'étude le plus couramment utilisé pour décrire les effets de la COVID-19 sur la grossesse. Comme cette revue visait à savoir si la COVID-19 était plus grave chez les femmes enceintes, nous avons ciblé de nouvelles séries de cas comportant plus de 30 observations. Seize exposés de cas publiés entre le 8 juin et le 10 juillet ont été exclus en fonction de ce point de découpage.

Tableau 3 : Série de cas (>30 femmes) publiée entre le 8 juin et le 10 juillet résumant la probabilité de résultats graves dans les cas de COVID-19 chez les femmes enceintes.

* L'étude systématique la plus récente à ce sujet a examiné la littérature publiée jusqu'au 8 juin 2020 et est décrite dans le tableau 2.

Méthodes :

Une analyse quotidienne de la littérature (publiée et prépubliée) est effectuée par le groupe des sciences émergentes de l'ASPC. L'analyse a permis de compiler la littérature sur la COVID-19 depuis le début de l'épidémie et est mise à jour quotidiennement. Les recherches pour trouver la littérature pertinente sur la COVID-19 sont menées par Pubmed, Scopus, BioRxiv, MedRxiv, ArXiv, SSRN, Research Square et sont recoupées avec la littérature de la liste de littérature COVID de l'OMS, et les centres d'information de la COVID-19 gérés par Lancet, BMJ, Elsevier et Wiley. Le résumé quotidien et les résultats complets de l'analyse sont conservés dans une base de données Refworks et une liste Excel consultable. Une recherche ciblée par mot-clé est effectuée dans ces bases de données pour identifier les citations pertinentes sur la COVID-19 et le SRAS-COV-2. Termes de recherche utilisés comprennent : pregnancy ou pregnant ou maternal
Cet examen contient les recherches publiées jusqu'au 14 juillet 2020
Chaque référence potentiellement pertinente a été examinée pour confirmer qu'elle comportait des données pertinentes et les données pertinentes sont extraites dans l'examen.

Emerging Evidence on COVID-19

Evidence Brief on SARS-CoV-2 Variants of Concern and Transmission in Children

Introduction

What is the global evidence on whether SARS-CoV-2 variants of concern (VOCs) have changed transmission in children and transmission patterns in schools?

Several SARS-CoV-2 variants of concern (VOCs) have been identified since December 2020. As of March 26, 2021, these included B.1.1.7, B.1.351, P.1 (1) and B.1.429 (2) which have acquired enhanced infectivity and transmissibility. The new variants have quickly spread to many countries globally and are being intensely studied to understand their clinical and epidemiological impacts. This evidence brief identifies and summarizes the existing evidence up to March 26, 2021 on transmission of the VOCs in children and the impact on in-school transmission.

Key Points

- Web-scraped media data of school related COVID-19 outbreaks across Canada indicate that an increasing number of VOC related school outbreaks have been reported from January to March 2021.
- Overall, nine studies were identified COVID-19 VOC transmission in children. Of these, five focused only on transmission of VOCs in children, three assessed transmission patterns in schools and one study evaluated both (Tables 1 and 2). Currently, all studies focused on B.1.1.7 transmission patterns in children in the UK during November 2020 to January 2021 as the proportion of cases associated with B.1.1.7 increased steadily from the end of November onward (3).
- Five studies found that B.1.1.7 does not disproportionately affect children (<11 years old) and youth (11-19 years old). The increased transmissibility of the variant is observed in both adults and children, which suggested that the variant is not particularly adapted to any age group. A modelling study as well as epidemiological evidence of B.1.1.7 transmission in the UK identified that VOC transmission was not driven by children.
    - A single study reported that there were increased cases of B.1.1.7 in children and youth <20 years compared to older adults (> 70 years). However, schools remained open

during the community lockdown, which would result in school-age children having higher contact rates and risk of being exposed compared to adults over 70 years (4).

- Among children and young people hospitalized, there was no evidence of more severe disease (e.g., requiring ventilation support) with B.1.1.7 infection. This suggested that clinical course does not differ appreciably.
- Evidence identified that transmission in school-aged children was strongly correlated with the level of community transmission.
    - None of the studies estimated the likelihood of school outbreaks associated with VOCs compared to the original SARS-CoV-2 variant.
    - There was no evidence identified that schools were playing a large role in driving B.1.1.7 transmission in the community (5).
    - There was a reduction of cases in children and youth following school closures which may be due to both a reduction in cases and a reduction in testing of this age group. Reopening schools are expected to increase the proportion of VOC cases in children relative to the level of VOC community transmission (6, 7).
    - There was insufficient evidence to quantify the effect of VOC transmission in schools compared to transmission in the wider community.
- A single report in the UK estimated that children under ten are about half as likely as adults to transmit the B.1.1.7 variant. Thus, while secondary attack rates from B.1.1.7 cases in children increased 30-50%, the secondary attack rates for VOC child cases were still half that seen in VOC adult cases (3). This finding is similar to the original SARS-CoV-2 variant attack rates.
- Predictive models indicate that the stringency of public health measures other than school closures, particularly with a more transmissible VOC, is the most important determinant of the epidemic trajectory and that schools being open or closed has minimal impact on the epidemic course overall.

Overview of Evidence

Eight studies pertaining to transmission of VOC B.1.1.7 in children and patterns of transmission in schools were included in this review. The studies reporting transmission in children were mainly observational with the majority being retrospective cohort studies exploring the B.1.1.7 variant transmission in the UK during fall 2020 to early winter 2021. There was also one surveillance data

analysis, one prevalence study and two predictive models. The predictive models were focused on variant transmission and school closures.

A formal risk of bias assessment was not conducted. These observational studies are moderate to high risk of bias due to the retrospective nature of the study design and whether the sample is representative of the population and sufficiently large to obtain generalizable results. The retrospective studies obtained surveillance data in children from large national databases while others focused on small numbers of cases in a specific setting. In addition, due to the nature of the study designs these studies may be at higher risk for missing information bias, selection biases and confounding.

Quantitative predictive models were included. These do not identify actual outcomes of strategies that have been tested, but rather present a range of plausible outcomes within the theoretical scenarios being studied. Their results are useful to compare different options as part of a decision-making process, however the results need to be interpreted with caution as the models will vary on their assumptions, input values based on the epidemic period and region specific parameters used.

A key knowledge gap in this research is the lack of high-quality studies of transmission of VOCs in children and transmission patterns in schools. Although current evidence from a small number of studies on B.1.1.7 reports similar findings, there is the possibility that conclusions could change with further research. There is limited evidence evaluating the severity and clinical course of treatment and further studies that follow these outcomes closely in children are needed. Furthermore, studies of the effects from other VOCs are needed to provide understanding about the role these variants have in transmission of SARS-CoV-2 in children and school settings. Additional evidence is also needed on the clinical epidemiology of VOCs in children. Further research is also needed to investigate whether VOC transmission in schools have a different epidemiology than the original SARS-CoV-2 variant and may need re-evaluation of public health measures in this setting.

CONTENTS

COVID-19 CANADIAN SCHOOL OUTBREAKS

A summary of data on the number of school related outbreaks in Canada that included two or more people are summarized in Figure 1. The proportion of outbreaks associated with VOCs increased between January and March 2021. While this data is imperfect, it provides a snapshot of the proportion of school-based outbreaks attributed to VOCs up to the end of March 2021.

The data in Figure 1 is based on webscraping media reports conducted by the Outbreak Response Unit in CIRID and has the following caveats:

- Due to the volume of school outbreaks and the limited information provided about them by some jurisdictions, the database includes only school outbreaks that are referenced in the media, and not those reported by public health in these provinces, for both original strain and VOC-associated outbreaks.
- Unnamed schools are not captured in the webscraping database.
- Therefore, the total number of outbreaks in schools in the webscraping database is likely an underestimate for both original strain and VOC-associated outbreaks.
- The reported date represents the date the outbreak was declared if available, otherwise it represents the earliest date the outbreak was reported in the media.

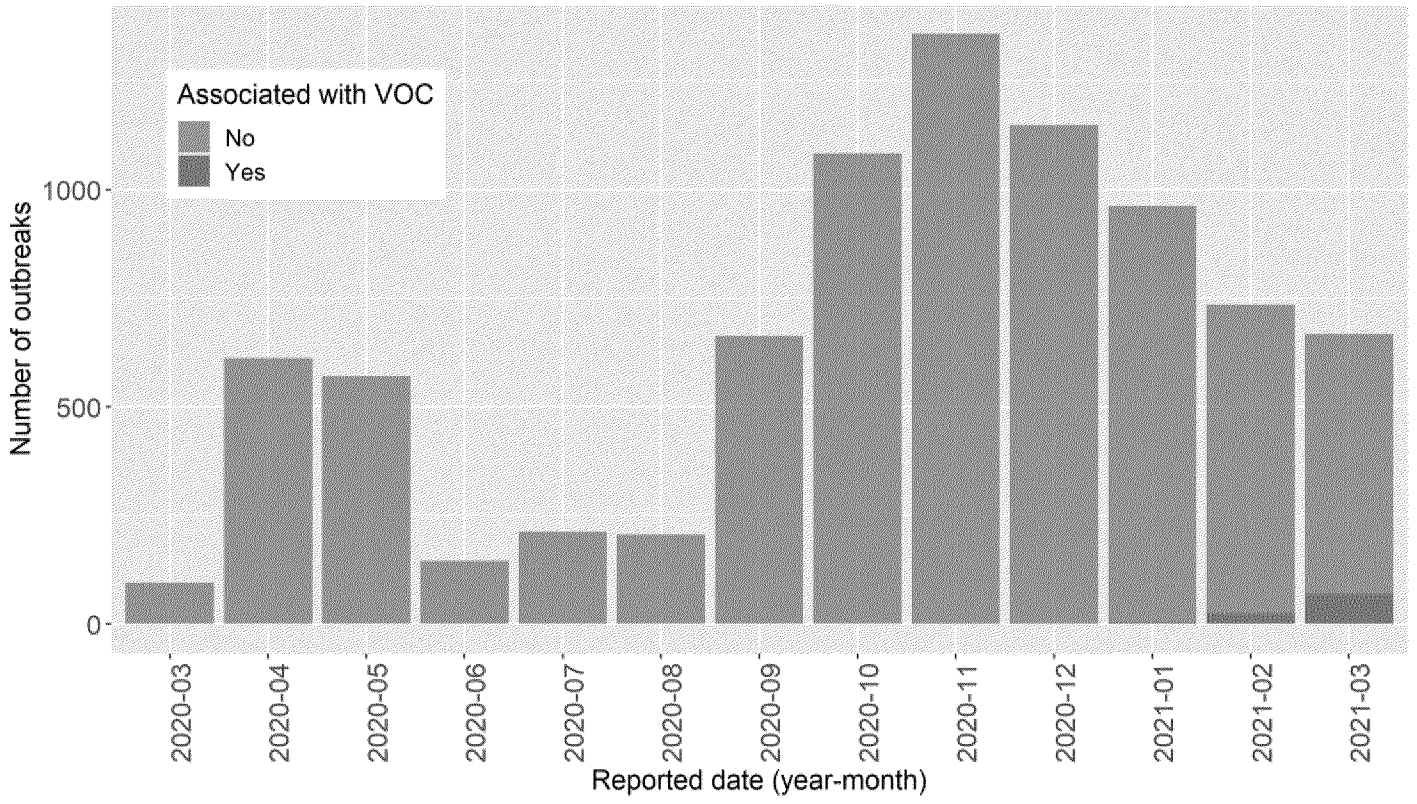

Figure 1: Outbreaks in Canadian schools reported by the media between March 2020 and March 2021

COVID-19 VOC TRANSMISSION IN CHILDREN

The current research has only evaluated the impact of B.1.1.7 on transmission and severity of disease in children in six studies (Table 1). All the studies detail outcomes of B.1.1.7 transmission in children from the UK during November 2020 to January 2021.

- Five studies found that B.1.1.7 does not disproportionately transmit more in children compared to adults (3, 8-11). The increased transmissibility of the variant is observed in both adults and children.
    - Transmission of B.1.1.7 in children correlated strongly with community transmission (5, 9, 10).
    - S-gene target failure (SGTF), which serves as a proxy for B.1.1.7 cases, was studied in adults and children and no difference in SGTF mean excess growth rates between children up to high school (5% (95% CI 1-8%)) and adults (6% (95% CI 4-9%)) were reported (10). This suggested that there are increased VOC infections compared to the original SARS-CoV-2 variant. However, the growth is similar in both children and adults. Furthermore, this study found no evidence that VOC transmission was driven by children (10).
    - A single report in the UK found that children under ten are about half as likely to transmit the B.1.1.7 variant compared to adults >20 years. Although, secondary attack rates from B.1.1.7 cases in children increased 30-50%, the secondary attack rates in VOC child cases were still half that seen in VOC adult case, similar to the original SARS-CoV-2 variant attack rates (3).
    - A modelling study found that data did not support a hypothesis that children were more susceptible to infection from VOCs than the original SARS-CoV-2 variant (11).
- A single study reported that there were increased cases of B.1.1.7 in children <20 years compared to older adults (>70 years old). The authors identified that given the community was in lockdown, but the schools were open, the children had a higher contact rate and risk of being exposed than the older adults (4).
- Two studies evaluated severity of disease in children:
    - One study found no evidence of more severe disease having occurred in children and young people during November 2020 to January 2021 in the UK when the proportion of cases associated with B.1.1.7 was rapidly increasing compared to cases seen in March to May 2020 (8).

- Another study evaluated viral load between children with the variant and those with the original SARS-CoV-2 variant and found no difference, which suggested that infection with the B.1.1.7 VOC does not result in a different clinical course compared to the original strain (10).

Table 1: Evidence of transmission of variants in children (n=6)

STUDY	METHOD	KEY OUTCOMES
Surveillance Data Analysis (n=2)		
Mensah 2021 (9) Surveillance data analysis UK Jul – Dec 2020	Analysis of SARS-CoV-2 infection rates based on Public Health England daily reports during the school year from July to December 2020, including the effect of a national month-long lockdown whilst keeping schools open in November 2020. Three educational settings: preschools (nursery, preschool<5 yr olds), primary schools (reception, age 5-11) and secondary schools (age 11-18) compared to adults (age 16-64) or young adults (age 18-29). Infection rate ratios were used to compare groups. Denominators for each group were taken from the census data.	• Infection rates in adults and children increased rapidly after the week of Nov 23, 2020. • Infection rates in children increased with the cases in the community August through November when the community locked down. In November 2020 schools remained open during lockdown, infection rates in children decreased more slowly than adult cases and the decrease showed a 1 week lag in children. After lockdown, cases in adults started to increase quickly which also coincided with the emergence of B.1.1.7. Cases in secondary school-aged children also increased at a similar rate to adults, whereas those in younger children increased more slowly. • Age specific infection rates were highest in young adults > secondary school children > primary school children > preschool-aged children. The relative rates compared to preschool-aged children were 1.91 (95% CI, 1.74–2.09) primary, 5.17 (95% CI 4.73–5.65) secondary and 10.73 (95% CI, 9.84–11.71) young adults during the week of 19 October 2020. These relative differences continued through the end of 2020 when B.1.1.7 rapidly spread through the UK despite schools being closed at the end of November. • A strong and statistically significant (P<0.001) correlation was observed between weekly SARS-CoV-2 infection rates in adults and the three educational cohorts, with the strongest correlation observed for secondary school-aged children which was seen through to the end of 2020.

Public Health England 2021 (3) Surveillance data analysis UK Sep 2020- Jan 2021	Surveillance data was analyzed from a total of 6,008 VOC cases and 68246 cases sequenced from 20 September 2020 until 4 January 2021. Contact tracing data 30 November 2020 to 20 December 2020 included 386 805 cases of which 90401/212943 were S-gene target failure (SGTF, a proxy for B.1.1.7) from those with TaqPath data and 3801/ 9321 were B.1.1.7 when sequenced.	• Epidemiologically the age-sex profile was similar between sequenced cases B.1.1.7 (Sept 2020-Jan 2021) and cases identified by SGTF (Dec 2020- Jan 2021) compared to non-B.1.1.7/ non-SGTF cases. • 0-9 year-olds represented 6.1% of B.1.1.7 isolates compared to non-B.1.1.7 at 4.0% among sequenced cases. • Contact tracing data report estimated attack rates are 10-70% higher across age groups. E.g., 0-9 year-olds had a 9.0% secondary attack rate for B.1.1.7 vs. 6.1% for non-B.1.1.7 cases. SGTF attack rates were similarly 30-50% higher, in 0-9 year-olds it was 8.9% for SGTF and 6.2% for non-SGTF. Similar to the originalSARS-CoV-2 variant, children under the age of ten are about half as likely as adults >20 years to transmit the variant to others.
Cohort Studies (n=3)		
Brookman 2021 (8) Retrospective cohort UK Feb 2021	Characteristics of children and young people (age <19 years) admitted with acute respiratory COVID-19 between March 1 and May 31, 2020 (n=20) were compared to those admitted Nov 1, 2020, and Jan 19, 2021 (n=60) to King's College Hospital for SARS-CoV-2 infection.	• No difference in demographics e.g., age, sex, ethnicity or deprivation score were identified between waves 1 and 2. • Severe disease necessitating oxygen therapy or ventilatory support was infrequent in both waves and was lower as a proportion of total admission in the second wave than in the first. • These November 2020 to January 2021 data show that many children and young people have been admitted to hospital due to the higher prevalence of SARS-CoV-2 in the hospital's community. The findings in this paper were in line with national data. • There was no evidence of more severe disease having occurred in children and young people since B.1.1.7 increased in circulation, suggesting that infection with the B.1.1.7 variant does not result in a different clinical course to the original strain.
Volz 2021 (4) *Preprint* Retrospective cohort UK	This study included an analysis of S-gene target failures (SGTF) a proxy for	• Analysis of trends during lockdown (November 2020) show that non-SGTF cases decreased, but SGTF cases increased across jurisdictions in the UK.

Jan 2021	B.1.1.7 and non-SGTF cases across England areas between November 8 to December 12, 2020. Age-distributions were assessed.	• After standardizing the cases to the population composition, there are significantly more SGTF cases among individuals aged 0-19 as compared to non-SGTF cases. • The authors suggest differences between the age-distributions of VOC and non-VOC community cases may result from the overall increase in transmissibility of the VOC (especially during a time where lockdown was in force, but schools were open).
Walker 2021 (10) *Preprint* Retrospective cohort UK Sep 2020- Jan 2021	This was a large community surveillance study in the UK. Data were analyzed from nose and throat swabs (n=1,553,687) collected and tested by RT-PCR. S-gene target failures (SGTF) was used as a proxy for B.1.1.7. Cycle threshold (Ct) values (a proxy for viral load), percentage of positives, population positivity and growth rates in SGTF vs non-SGTF positives was assessed by age.	• In the sample 0.98% were positive: 8545 non-SGTF and 3531 SGTF. From early November 2020 to December 31, 2020, the SGTF positives increased e.g., London samples 15% to 38% to 81%. • In November the non-SGTF cases remained stable and the SGTF cases increased adding to the SARS-CoV-2 cases rather than replacing the non-SGTF cases. The growth rate was similar in adults and children. • No association with Ct values (a proxy for viral load) and SGTF cases was identified. • In some regions SGTF cases in younger individuals emerged first, but this was not consistent across regions. No evidence of difference in SGTF growth rates between children up to high school (5% (1-8%)) and adults (6% (4-9%)). This supports B.1.1.7 not being particularly adapted to transmit more in children.
Predictive model (n=1)		
Davies 2021 (11) Predictive model UK Mar 2021	An age-and regionally-structured mathematical model of SARS-CoV-2 transmission was conducted using Google mobility data and social contact surveys. They used this model to test four different hypotheses to assess which had the best fit.	• The age-and regionally-structured mathematical model found the hypothesis that lower Ct values (an indicator for higher viral load) which supports that VOCs are more transmissible than pre-existing variants fits the model better than the hypothesis that children were more susceptible to infection with the VOC than pre-existing variants.

COVID-19 VOC TRANSMISSION PATTERNS IN SCHOOLS

Four studies were identified on COVID-19 transmission patterns in schools, three of which were predictive models (Table 2). Specifically, these studies explored the impact of school closures on transmission. The modelling studies assessed the reproduction number R(t), which indicates the ability of a disease to spread, for different scenarios of closures. R values greater than 1 indicate that cases will increase. These models showed that school closures did have some impact on reducing VOC community incidence, however transmission among school-aged children correlated most strongly with the level of community transmission. These models identified that transmission in schools contributes to but was not driving the spread of VOCs.

- One modelling study found that the reductions in cases and R(t) were largest with continual full national lockdown until April 19, 2021 compared to any of the scenarios with some schools reopened. Reopening primary schools and exam critical years only, or having primary schools open continuously with secondary schools on a two-weeks on-off rotation, will lead to a lower increase in cases and R than if all schools stayed open (6).
- Another modelling study found similar results that strict restrictions in community mobility along with closure of schools will reduce R(t) below 1 (11).
- A UK cohort study found that there was a large rise in school absences in secondary school settings in some regions in London due to the increased cases of the B.1.1.7 variant. This was not observed in primary school settings. There was also a positive correlation between cases in schools and cases in the community. Furthermore, there was no evidence identified that schools were playing a large role in driving the transmission in the community (5).
- A Canadian modelling study estimated that B.1.1.7 would result in a higher likelihood of an outbreak that is 3.6 times and 4.2 times that of an outbreak from original SARS-CoV-2 variant, even with strict control measures in place for adults and children respectively. This increase is predicted irrespective of whether schools are closed or open in scenarios where the community is open due to poor public health interventions and high community transmission risk. The modelling identified that schools do not have a large impact on the trajectory of the epidemic (7).

Table 2: Evidence of VOC transmission in schools (n=4)

STUDY	METHOD	KEY OUTCOMES
Predictive modelling studies (n=3)		
Davies 2021 (11) Predictive model UK Mar 2021	A transmission model fitted to seven NHS regions in England was used to project epidemic changes under different control measures from mid-December 2020 to the end of June 2021. The study is modelled on the assumption of increased transmissibility of the variants. Four scenarios were compared: (i) a moderate-stringency scenario; (ii) a high-stringency scenario with schools open; (iii) the same high-stringency scenario, but with schools closed until 15 February 2021; and (iv) a very high-stringency scenario with schools closed.	• The transmission model found that regardless of control measures, all regions were projected to experience a new wave of COVID-19 cases and deaths in early 2021, peaking in February if no substantial control measures were introduced or mid-January if strong control measures were in place. • The model also predicted that more stringent measures (iii and iv) would lead to larger rebound cases when simulated restrictions were lifted in March 2021. • The authors suggest that closing schools along with restrictions in the community can succeed in reducing R below 1.
Panovska-Griffiths 2021 (6) *Preprint* Predictive model UK Feb 2021	The Covasim model, calibrated until January 25, 2021, was used to simulate the impact of a full national lockdown (FNL) with schools closed until April 19, 2021 versus four different partial national lockdown (PNL) scenarios with different elements of schooling open: 1) PNL staggered start 2) PNL full-return 3) PNL with primary and critical exam years (Y11 and Y13) only returning to school and 4) PNL with primary full-time and secondary schools rotating two-weeks in class and two weeks online learning. The study is modelled on the assumption that the new variant is more transmissible, and that the	• The modelling suggests that the reduction in cases and in R is largest with continual FNL until April 19, 2021 compared to any of the scenarios with some schools reopened. Reopening primary schools and exam critical years only, or having primary schools open continuously with secondary schools on a two-weeks on-off rotation, will lead to a lower increase in cases and R than if all schools open. • National lockdown will reduce the number of cases by early March to a similar level as in October with R also falling and remaining below 1. • Across each scenario, the number of new infections is expected to decrease over January and early February lockdowns.

	relative proportion of the new strain increased from September 1, 2020 to January 31, 2021 following a logistic growth function, such that 30% of infections in December and 90% of infections by the end of January 2021 were caused by the new variant.	• Impacts upon deaths are lagged, with plateauing of cumulative deaths seen from February in each scenario. This is due to the vaccine effect having been modelled with a delay of 21 days. Overall, when schools open, we predict a rise in the number of infections and increase in R, and a possible shift in R above 1 once society opens also.
Yuan 2021 (7) *Preprint* Predictive model Toronto Jul– Nov 2020	Using a deterministic age-household-location structured extended SEIR model fitted to demographic data from Toronto, the model is calibrated to epidemiological data between July 31 and November 23, 2020. The model was developed to mimic transmission in households, the community and schools. The new VOC is based on B.1.1.7, assumed to have a 50% increased transmission probability and assumes children will be 70% as susceptible as adults. They also assume it will be the dominant strain after 1 month. The study modelled the impact of the new variant of concern assuming higher susceptibility of children and youth to the new variant.	• Compared to the baseline with the variant strain and the community restricted/ schools closed, which resulted in near epidemic control, the variant strain was estimated to increase the number of cases 3.6x for adults and 4.2x in children and youth. • The scenarios run considering the new variant indicate that schools closing do not have a large impact on the trajectory of the epidemic January to May 2021 as with stage 2 opening (partial opening) of the community the prediction was 7x or 7.5x more cases with schools closed vs. open. • Exponential increases in cases were predicted regardless of whether schools were open or closed in scenarios where the community is fully opened (stage 3) due to weak public health interventions and high community transmission risk.
Cohort studies (n=1)		
Southhall 2021 (5) *Preprint* Retrospective cohort UK	Analysis of absenteeism of pupils and teachers was conducted to assess the impact of the new variant, B.1.1.7. Specific regions were evaluated to assess the differential impact of the new variant. London and Kent were chosen due to the high number of new variant compatible cases reported, while Devon and the West Midlands were chosen due to having	• A large rise in the number of absences per school in secondary school settings was observed in the South East and Greater London in December but not in other regions or primary school settings. • Authors suspect absences were related to increased transmissibility of the new B.1.1.7 variant which contributed to the rise of cases in secondary schools in these regions.

Sep-Dec 2020	had fewer reported cases compatible with the new variant. Additionally, on the 3rd December 2020, Devon was in tier 2 and the West Midlands was in tier 3.	• A positive correlation was found between cases in the community and cases in schools in most regions. • No significant evidence to suggest that schools are playing a significant role in driving transmission in the community. • Careful monitoring may be required as schools re-open to determine the effect associated with opening schools upon community incidence. • In London, Kent and the West Midlands, a weak correlation between cases in secondary school pupils and community cases that increases with lag time, indicating that an increase in community cases is most positively correlated with an increase in school cases in pupils at a later date. • The same result was observed for primary school pupils in Kent and the West Midlands. However, a negligible correlation between community cases and cases in primary school children in London across all time lags was observed.

Methods:

A daily scan of the literature (published and pre-published) is conducted by the Emerging Science Group, PHAC. The scan has compiled COVID-19 literature since the beginning of the outbreak and is updated daily. Searches to retrieve relevant COVID-19 literature are conducted in Pubmed, Scopus, BioRxiv, MedRxiv, ArXiv, SSRN, Research Square and cross-referenced with the COVID-19 information centers run by Lancet, BMJ, Elsevier, Nature and Wiley. The daily summary and full scan results are maintained in a refworks database and an excel list that can be searched. Targeted keyword searching was conducted within these databases to identify relevant citations on COVID-19 and SARS-COV-2. Search terms used included:
SCHOOL TRANSMISSION TERMS: (B.1.1.7 or 501Y.V1 or B.1351 or 501Y.V2 or P1 or P2 or B1.1.1.28 or B.1.1.33 or 501Y.V3 or B.1.426 or variant) AND school AND transmission
CHILDREN TERMS: B.1.1.7 or 501Y.V1 or 202012/01 or B.1351 or 501Y.V2 or P1 or P2 or B1.1.1.28 or B.1.1.33 or 501Y.v3 B.1.426 or variant) AND (children or adolescent)
This review contains research published up to March 26, 2021.
Each potentially relevant reference was examined to confirm it had relevant data and relevant data was extracted into the review.

Grey Literature

A grey literature search was conducted to compliment the database search. The grey literature focused on key websites that reports on B.1.1.7 variants, including Public Health England and SPOR Evidence Alliance. The original grey literature search was conducted on March 24-March 26, 2021.

Peer-review

This document underwent peer-review by a subject matter expert, and editorial and science to policy review by the Office of the Chief Science Officer.

Nouveaux éléments de preuve sur la COVID-19

Synthèse en bref des données probantes sur les variants préoccupants du SRAS-CoV-2 et leur transmission chez les enfants

Introduction

Quelles sont les données probantes à l'échelle internationale sur la question de savoir si les variants préoccupants du SRAS-CoV-2 (COV) ont modifié la transmission chez les enfants et les modes de transmission dans les écoles?

Plusieurs variants préoccupants du SRAS-CoV-2 ont été identifiées depuis décembre 2020. Ainsi, en date du 26 mars 2021, ceux-ci comprenaient les variants B.1.1.7, B.1.351, P.1 (1) et B.1.429 (2) qui ont une plus grande infectiosité et sont plus transmissibles. Les nouveaux variants se sont rapidement répandus dans de nombreux pays et font l'objet d'études intensives pour comprendre leurs impacts cliniques et épidémiologiques. Cette synthèse en bref sur les données probantes indique et résume les données probantes disponibles jusqu'au 26 mars 2021 sur la transmission des variants préoccupants chez les enfants et l'impact sur la transmission dans les écoles.

Points clés

- Les données des médias recueillies sur le Web à propos des éclosions de COVID-19 dans les écoles partout au Canada indiquent qu'un nombre croissant d'éclosions de variants préoccupants ont été signalées dans les écoles de janvier à mars 2021.
- Au total, neuf études ont porté sur la transmission des variants préoccupants associés à la COVID-19 chez les enfants. De ce nombre, cinq portaient uniquement sur la transmission des variants préoccupants chez les enfants, trois ont évalué les modes de transmission dans les écoles et une étude a évalué les deux (tableaux 1 et 2). À l'heure actuelle, toutes les études ont porté sur les modèles de transmission du variant B.1.1.7 chez les enfants au Royaume-Uni entre novembre 2020 et janvier 2021, car la proportion de cas associés au B.1.1.7 a augmenté régulièrement à compter de la fin de novembre (3).
- Cinq études ont révélé que le variant B.1.1.7 ne touche pas de façon disproportionnée les enfants (< 11 ans) et les jeunes (âgés de 11 à 19 ans). L'augmentation de la transmissibilité de ce variant a été observée chez les adultes et les enfants, ce qui donne à penser que le variant n'est pas particulièrement adapté à quelque groupe d'âge que ce soit. Une étude de

modélisation ainsi que des données épidémiologiques sur la transmission du B.1.1.7 au Royaume-Uni ont révélé que les enfants n'étaient pas un vecteur dans la transmission des variants préoccupants.

  - Une seule étude a révélé une augmentation des cas associés au variant B.1.1.7 chez les enfants et les jeunes de moins de 20 ans comparativement aux adultes plus âgés (âgés de plus de 70 ans). Les écoles sont toutefois restées ouvertes pendant le confinement de la collectivité, ce qui fait que les enfants d'âge scolaire présentaient des taux de contact plus élevés et un risque d'exposition plus élevé que les adultes de plus de 70 ans (4).

- Chez les enfants et les jeunes hospitalisés, il n'y avait aucun signe de maladie plus grave (p. ex., nécessitant une ventilation assistée) en raison d'une infection par le B.1.1.7. Cela suggère que l'évolution clinique du virus n'est pas très différente.
- Les données probantes ont cependant démontré que la transmission chez les enfants d'âge scolaire était fortement corrélée avec le niveau de transmission dans la collectivité.
  - Aucune des études n'a estimé la probabilité d'éclosions dans les écoles associées aux variants préoccupants comparativement à la souche originale du SRAS-CoV-2.
  - Rien n'indique non plus que les écoles jouent un rôle important dans la transmission du B.1.1.7 dans la collectivité (5).
  - Il y a même une réduction du nombre de cas chez les enfants et les jeunes à la suite des fermetures d'école, ce qui peut être attribuable tant à une réduction du nombre de cas qu'à une réduction du nombre de tests pour ce groupe d'âge. La réouverture des écoles devrait accroître la proportion de cas associés aux variants préoccupants chez les enfants par rapport au niveau de transmission de variants préoccupants dans la communauté (6, 7).
  - Il n'y avait cependant pas suffisamment d'éléments de preuve pour quantifier l'effet de la transmission des variants préoccupants dans les écoles comparativement à la transmission dans l'ensemble de la collectivité.
- Selon un seul rapport publié au Royaume-Uni, les enfants de moins de dix ans sont deux fois moins susceptibles que les adultes de transmettre le variant B.1.1.7. Ainsi, alors que les taux d'attaque secondaires du B.1.1.7 chez les enfants ont augmenté de 30 à 50 %, les taux d'attaque secondaires chez les enfants étaient toujours deux fois moins élevés que ceux observés chez les adultes ayant eu une infection associée aux variants préoccupants (3). Ce résultat est semblable aux taux d'attaque du variant du SRAS-CoV-2.

- Les modèles prédictifs indiquent que la rigueur des mesures de santé publique autres que la fermeture des écoles, en particulier avec des variants préoccupants plus transmissibles, est le déterminant le plus important de la trajectoire de l'épidémie et que l'ouverture ou la fermeture des écoles a un impact minime sur le cours global de l'épidémie.

Vue d'ensemble des éléments de preuve

Huit études portant sur la transmission du variant B.1.1.7 chez les enfants et les modes de transmission dans les écoles ont été incluses dans la présente revue. Les études faisant état de la transmission chez les enfants étaient principalement observationnelles, la majorité étant des études de cohorte rétrospectives explorant la transmission du variant B.1.1.7 au Royaume-Uni de l'automne 2020 jusqu'au début de l'hiver 2021. On a également trouvé une analyse des données de surveillance, une étude de prévalence et deux modèles prédictifs. Les modèles prédictifs étaient axés sur la transmission des variants et les fermetures d'écoles.

Aucune évaluation officielle du risque de biais n'a été effectuée. Ces études d'observation présentent un risque de biais modéré à élevé en raison de la nature rétrospective du plan d'étude et de la question de savoir si l'échantillon est représentatif de la population et suffisamment grand pour obtenir des résultats généralisables. Les études rétrospectives ont permis d'obtenir des données de surveillance sur les enfants à partir de grandes bases de données nationales, tandis que d'autres portaient sur un petit nombre de cas dans un contexte particulier. De plus, en raison de la nature des plans d'étude, ces études peuvent présenter un risque plus élevé de biais en raison des informations manquantes, ainsi que des biais de sélection et de confusion.

Des modèles prédictifs quantitatifs ont été inclus. Même si ces modèles n'ont pas permis de déterminer les résultats réels des stratégies mises à l'essai, ils offrent un éventail de résultats plausibles en ce qui concerne les scénarios théoriques à l'étude. Bien que leurs résultats soient utiles pour comparer différentes options dans le cadre d'un processus décisionnel, il faut cependant faire preuve de prudence au moment de les interpréter, puisque ces modèles ont utilisé différentes hypothèses de base ainsi que des valeurs variables, notamment la période et les paramètres propres à la région.

L'absence d'études de grande qualité sur la transmission des variants préoccupants chez les enfants et sur les modes de transmission dans les écoles représente une lacune clé de cette recherche. Bien que les données actuelles associées à un petit nombre d'études sur le variant B.1.1.7 comportent des constatations semblables, il est possible que les conclusions changent avec d'autres recherches. Il existe peu de données probantes permettant d'évaluer la gravité et le déroulement clinique du

traitement, et d'autres études qui suivent de près ces résultats chez les enfants sont donc nécessaires. En outre, des études sur les effets des autres variants préoccupants seront nécessaires pour mieux comprendre le rôle que jouent ces variants dans la transmission du SRAS-CoV-2 chez les enfants et en milieu scolaire. Il faudra aussi des données supplémentaires sur l'épidémiologie clinique des variants préoccupants chez les enfants. D'autres recherches seront également nécessaires pour déterminer si la transmission des variants préoccupants dans les écoles a une épidémiologie différente de la souche originale du SRAS-CoV-2 et pourrait nécessiter une réévaluation des mesures de santé publique dans ce contexte.

TABLE DES MATIÈRES

ÉCLOSIONS DE COVID-19 EN MILIEU SCOLAIRE AU CANADA

Un résumé des données sur le nombre d'éclosions en milieu scolaire au Canada qui ont touché deux personnes ou plus est présenté à la figure 1. La proportion des éclosions associées aux variants préoccupants a augmenté entre janvier et mars 2021. Bien que ces données soient imparfaites, elles donnent un aperçu de la proportion d'éclosions en milieu scolaire attribuées aux variants préoccupants jusqu'à la fin de mars 2021.

Les données de la figure 1 sont fondées sur des reportages diffusés sur le Web et réalisés par l'Unité d'intervention en cas d'éclosion du Centre de l'immunisation et des maladies respiratoires infectieuses (CIMRI) et comportent les mises en garde suivantes :

- En raison du volume d'éclosions en milieu scolaire et de l'information limitée fournie à leur sujet par certaines administrations, la base de données ne comprend que les éclosions dans les écoles mentionnées dans les médias, et non celles déclarées par la santé publique dans ces provinces, tant en ce qui concerne la souche originale que les variants préoccupants.

- Lorsqu'aucun nom n'était indiqué pour l'école, les données associées n'ont pas été saisies dans la base de données Web.
- Par conséquent, le nombre total d'éclosions en milieu scolaire indiqué dans la base de données de recherche en ligne est probablement une sous-estimation, tant pour les éclosions associées à la souche originale que pour celles liées aux variants préoccupants.
- La date déclarée représente la date à laquelle l'éclosion a été déclarée si elle est disponible, sinon elle représente la date la plus hâtive à laquelle l'éclosion a été mentionnée dans les médias.

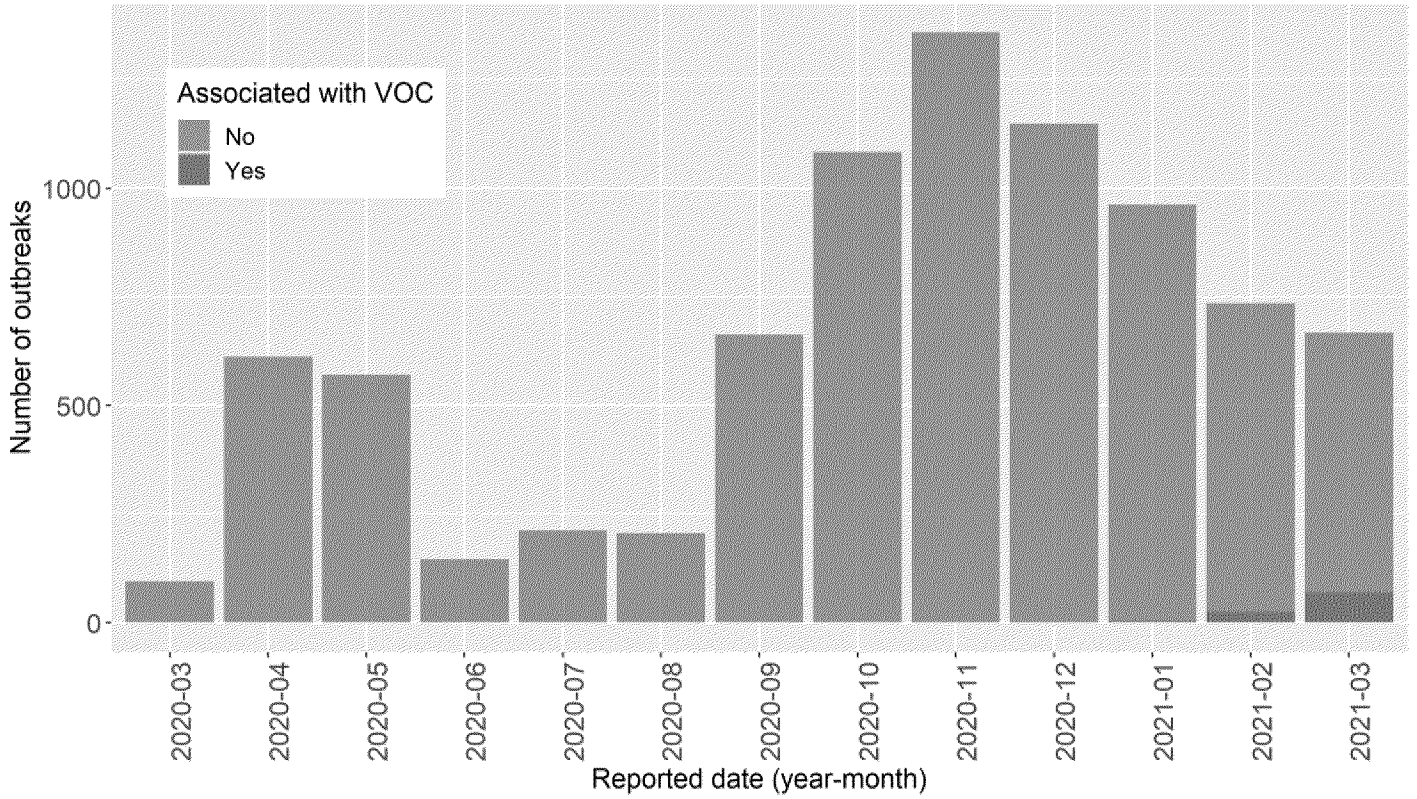

Figure 1 : Éclosions dans les écoles canadiennes mentionnées par les médias entre mars 2020 et mars 2021

TRANSMISSION DES VARIANTS PRÉOCCUPANTS ASSOCIÉS À LA COVID-19 CHEZ LES ENFANTS

Seules six études ont évalué l'impact du variant B.1.1.7 sur la transmission et la gravité de la maladie chez les enfants (tableau 1). Toutes les études présentent en détail les résultats de la transmission du variant B.1.1.7 chez les enfants du Royaume-Uni entre novembre 2020 et janvier 2021.

- Cinq études ont révélé que le variant B.1.1.7 ne se transmettait pas de façon disproportionnée chez les enfants que chez les adultes (3, 8 à 11). La transmissibilité accrue du variant a été observée chez les adultes et les enfants.
    - La transmission du variant B.1.1.7 chez les enfants était fortement corrélée avec la transmission dans la collectivité (5, 9, 10).
    - La défaillance cible du gène S (SGTF), qui sert de substitut pour les cas associés au variant B.1.1.7, a été étudiée chez les adultes et les enfants et aucune différence n'a été signalée dans les taux de croissance moyens de la SGTF chez les adultes (6 % (IC à 95 %, 4 à 9 %)) et chez les enfants (jusqu'au niveau de l'école secondaire) (5 % (IC à 95 %, 1 à 8 %) (10). Cela donne à penser qu'il y a une augmentation du nombre d'infections associées aux variants préoccupants par rapport aux infections associées à la souche originale du SRAS-CoV-2. La croissance est cependant semblable chez les enfants et les adultes. En outre, cette étude n'a trouvé aucune preuve que les enfants pouvaient être un vecteur dans la transmission des variants préoccupants (10).
    - Un seul rapport publié au Royaume-Uni a révélé que les enfants de moins de dix ans étaient environ deux fois moins susceptibles de transmettre le variant B.1.1.7 que les adultes de plus de 20 ans. Bien que les taux d'attaque secondaires du B.1.1.7 chez les enfants aient augmenté de 30 à 50 %, ces taux étaient toujours deux fois moins élevés que ceux observés chez les adultes ayant eu une infection associée aux variants préoccupants, comme l'indiquent les données obtenues pour les taux d'attaque de la souche originale du SRAS-CoV-2 (3).
    - Une étude de modélisation a révélé que les données n'appuyaient pas l'hypothèse selon laquelle les enfants étaient plus susceptibles d'être infectés par les variants préoccupants que par la souche originale du SRAS-CoV-2 (11).
- Une seule étude a révélé une augmentation des cas associés au variant B.1.1.7 chez les enfants et les jeunes de moins de 20 ans comparativement aux adultes plus âgés (âgés de plus de 70 ans). Les auteurs ont déterminé qu'étant donné que la collectivité était en confinement, mais que les écoles étaient ouvertes, les enfants présentaient un taux de contact et un risque d'exposition plus élevés que les adultes plus âgés (4).
- Deux études ont évalué la gravité de la maladie chez les enfants :
    - Une étude n'a révélé aucune preuve d'une maladie plus grave chez les enfants et les jeunes entre novembre 2020 et janvier 2021 au Royaume-Uni, alors que la proportion

de cas associés au variant B.1.1.7 augmentait rapidement par rapport au nombre de cas observés entre mars et mai 2020 (8).

- Une autre étude a évalué la charge virale chez les enfants atteints d'une infection causée par le variant et ceux atteints par la souche originale du SRAS-CoV-2 et n'a révélé aucune différence, ce qui signifie que l'infection par le variant B.1.1.7 n'entraîne pas une évolution clinique différente de celle de la souche originale (10).

Tableau 1 : Preuve de transmission des variants chez les enfants (n = 6)

ÉTUDE	MÉTHODE	RÉSULTATS PERTINENTS
Analyse des données de surveillance (n = 2)		
Mensah 2021 (9) Analyse des données de surveillance Royaume-Uni Juillet à décembre 2020	Analyse des taux d'infection par le SRAS-CoV-2 établie à l'aide des rapports quotidiens de la santé publique de l'Angleterre publiés pendant l'année scolaire, de juillet à décembre 2020, ce qui inclut l'effet qu'a eu un confinement national d'une durée d'un mois pendant lequel les écoles sont restées ouvertes (en novembre 2020). Les données concernant trois établissements d'enseignement ont été examinées : des établissements préscolaires (maternelle et prématernelle pour les enfants de moins de 5 ans), des écoles primaires (enfants âgés de 5 à 11 ans) et des	• Les taux d'infection chez les adultes et les enfants ont augmenté rapidement après la semaine du 23 novembre 2020. • Les taux d'infection chez les enfants ont augmenté au même rythme que dans la collectivité entre août et novembre, pendant le confinement. En novembre 2020, alors que les écoles restaient ouvertes pendant le confinement, les taux d'infection chez les enfants ont diminué plus lentement que les cas chez les adultes, et cette diminution était en retard d'une semaine chez les enfants. Après le confinement, les cas chez les adultes ont commencé à augmenter rapidement, ce qui a également coïncidé avec l'émergence du variant B.1.1.7. Le nombre de cas chez les enfants en âge d'aller à l'école secondaire a également augmenté à un taux semblable à celui des adultes, tandis que le nombre de cas chez les enfants plus jeunes a augmenté plus lentement. • Les taux d'infection selon l'âge étaient les plus élevés chez les jeunes adultes, puis chez les enfants qui allaient à l'école secondaire, ainsi que des enfants qui allaient à l'école primaire et des enfants d'âge préscolaire. Les taux relatifs par rapport aux enfants d'âge préscolaire étaient de 1,91 (IC à 95 %, 1,74 à 2,09) pour le primaire, de 5,17 (IC à 95 %, 4,73 à 5,65) pour le secondaire et de 10,73 (IC à 95 %, 9,84–11,71) pour les

	écoles secondaires (âgés de 11 à 18 ans) comparativement aux adultes (âgés de 16 à 64 ans) ou aux jeunes adultes (âgés de 18 à 29 ans). Les ratios des taux d'infection ont été utilisés pour comparer les données des différents groupes. Les dénominateurs pour chacun des groupes proviennent des données du recensement.	jeunes adultes pendant la semaine du 19 octobre 2020. Cet écart relatif s'est poursuivi jusqu'à la fin de 2020, lorsque le variant B.1.1.7 s'est rapidement répandu au Royaume-Uni, malgré la fermeture des écoles à la fin du mois de novembre. • Une corrélation forte et statistiquement significative ($P < 0,001$) a été observée entre les taux hebdomadaires d'infection par le SRAS-CoV-2 chez les adultes et les trois cohortes en milieu scolaire, la plus forte ayant été observée chez les enfants qui allaient à l'école secondaire et qui a perduré jusqu'à la fin de 2020.
Public Health England 2021 (3) Analyse des données de surveillance Royaume-Uni Septembre 2020 à janvier 2021	Des données de surveillance provenant d'un total de 6 008 cas de variants préoccupants et de 68 246 cas séquencés entre le 20 septembre 2020 et le 4 janvier 2021 ont été analysées. Les données sur la recherche des contacts établies entre le 30 novembre 2020 et le 20 décembre 2020 portaient sur 386 805 cas, dont 90 401 sur 212 943 provenait de TaqPath et étaient associées à la négativation de la détection du gène S (SGTF, un substitut pour le variant B.1.1.7) alors	• Sur le plan épidémiologique, le profil âge-sexe était semblable entre les cas séquencés pour le variant B.1.1.7 (entre septembre 2020 et janvier 2021) et les cas à SGTF (décembre 2020 et janvier 2021) comparativement aux cas non liés au variant B.1.1.7 ou sans SGTF. • Les enfants de 0 à 9 ans représentaient 6,1 % des isolats du variant B.1.1.7, comparativement à 4,0 % parmi les cas qui ont été séquencés • Les données sur la recherche des contacts indiquent que les taux d'attaque sont de 10 à 70 % plus élevés dans tous les groupes d'âge. P. ex., les enfants de 0 à 9 ans avaient un taux d'attaque secondaire de 9,0 % pour le variant B.1.1.7 comparativement à 6,1 % pour les autres cas. Les taux d'attaques pour les cas à SGTF étaient également de 30 à 50 % plus élevés, soit de 8,9 % pour les 0 à 9 ans et de 6,2 % pour les cas sans SGTF. Comme pour la souche originale du SRAS-CoV-2, cela indique que les enfants de moins de dix ans sont environ deux fois moins susceptibles que les adultes de plus de 20 ans de transmettre le variant aux autres.

	que les données de 3 801 sur 9 321 cas, une fois séquencées, ont plutôt été associées au variant B.1.1.7.	
Études de cohorte (n = 3)		
Brookman 2021 (8) Cohorte rétrospective. Royaume-Uni Février 2021	Les caractéristiques des enfants et des jeunes (âgés de moins de 19 ans) admis avec la forme respiratoire aiguë de la COVID-19 entre le 1er mars et le 31 mai 2020 (n = 20) ont été comparées à celles des personnes admises entre le 1er novembre 2020 et le 19 janvier 2021 (n = 60) à l'Hôpital King's College pour une infection au SRAS-CoV-2.	• Aucune différence démographique (p. ex., âge, sexe, origine ethnique ou cote de privation) n'a été relevée entre les première et deuxième vagues. • Les maladies graves nécessitant une oxygénothérapie ou un soutien respiratoire étaient peu fréquentes dans les deux vagues et représentaient une proportion plus faible du nombre total de personnes admisses lors de la deuxième vague que pendant la première. • Les données de novembre 2020 à janvier 2021 montrent que de nombreux enfants et jeunes ont été hospitalisés en raison de la prévalence plus élevée du SRAS-CoV-2 à l'hôpital. Les constatations présentées dans cette étude étaient conformes aux données nationales. • Rien n'indiquait de maladies plus graves chez les enfants et les jeunes depuis que le variant B.1.1.7 circule plus, ce qui donne à penser que l'infection par ce variant n'entraîne pas une évolution clinique différente de celle de la souche originale.
Volz 2021 (4) *Préimpression* Cohorte rétrospective. Royaume-Uni Janvier 2021	Cette étude comprenait une analyse des cas associés à la négativation de la détection du gène S (SGTF), un substitut pour le variant B.1.1.7 et non SGTF dans les différentes régions d'Angleterre entre le 8 novembre et le 12 décembre 2020. Les répartitions selon l'âge ont été évaluées.	• L'analyse des tendances pendant le confinement (novembre 2020) montre que les cas sans SGTF ont diminué, mais que les cas à SGTF ont augmenté dans l'ensemble des juridictions du Royaume-Uni. • Après avoir normalisé les cas en fonction de la composition de la population, on peut voir beaucoup plus de cas à SGTF chez les personnes de 0 à 19 ans que chez les personnes sans SGTF. • Les auteurs suggèrent que les différences entre les répartitions selon l'âge des cas dans la communauté associés ou non aux variants préoccupants peuvent découler de l'augmentation globale de la

		transmissibilité des variants préoccupants (surtout pendant une période où un confinement était en vigueur, mais où les écoles étaient ouvertes).
Walker 2021 (10) *Préimpression* Cohorte rétrospective. Royaume-Uni Septembre 2020 à janvier 2021	Il s'agissait d'une vaste étude de surveillance communautaire effectuée au Royaume-Uni. Les données ont été analysées à partir d'écouvillons provenant de la gorge et du nez (n = 1 553 687) recueillis et testés par RT-PCR. La négativation de la détection du gène S (SGTF) a été utilisée comme substitut pour le variant B.1.1.7. Les valeurs du seuil de cycle (Ct) (indicateur de la charge virale), le pourcentage de cas positifs, la positivité de la population et les taux de croissance chez les cas à SGTF par rapport aux cas positifs sans SGTF ont été évalués selon l'âge.	• Dans l'échantillon, 0,98 % ont obtenu un résultat positif, soit 8 545 sans SGTF et 3 531 à SGTF. Entre le début de novembre 2020 et le 31 décembre 2020, les résultats positifs pour les cas à SGTF ont augmenté (par exemple, dans le cas de Londres, les pourcentages d'échantillons sont passés de 15 % à 38 % à 81 %). • En novembre, les cas sans SGTF sont demeurés stables et les cas à SGTF ont augmenté, ce qui a fait augmenter le nombre de cas de SRAS-CoV-2 plutôt que de remplacer les cas sans SGTF. Le taux de croissance était semblable chez les adultes et les enfants. • Aucun lien n'a été déterminé entre les valeurs Ct (indicateur de la charge virale) et les cas à SGTF. • Dans certaines régions, les cas à SGTF chez les jeunes sont apparus en premier, mais ce n'était pas uniforme d'une région à l'autre. Il n'y a eu aucune preuve de différence dans les taux de croissance de la SGTF entre les enfants jusqu'à l'école secondaire (5 % (1 à 8 %)) et les adultes (6 % (4 à 9 %)). Cela vient appuyer le fait que le variant B.1.1.7 n'est pas particulièrement adapté pour être plus transmissible chez les enfants.
Modèle prédictif (n = 1)		
Davies 2021 (11) Modèle prédictif Royaume-Uni Mars 2021	Un modèle mathématique de la transmission du SRAS-CoV-2 structuré selon l'âge et les régions a été réalisé à l'aide des données de mobilité Google et des sondages sur les contacts sociaux. Ce modèle a été utilisé	• Le modèle mathématique structuré en fonction de l'âge et de la région a permis de dégager l'hypothèse selon laquelle des valeurs Ct plus faibles (un indicateur d'une charge virale plus élevée) qui appuient le fait que les variants préoccupants sont plus transmissibles que les souches préexistantes, correspond mieux au modèle que l'hypothèse selon laquelle les enfants étaient plus susceptibles d'être infectés par les variants préoccupants que les souches préexistantes.

	pour mettre à l'essai quatre hypothèses différentes afin d'évaluer laquelle était la plus appropriée.	

MODES DE TRANSMISSION DU VARIANT PRÉOCCUPANT DE LA COVID-19 EN MILIEU SCOLAIRE

Quatre études ont été recensées sur les modèles de transmission de la COVID-19 en milieu scolaire, dont trois étaient des modèles prédictifs (tableau 2). Plus précisément, ces études ont exploré l'impact des fermetures d'écoles sur la transmission. Les études de modélisation ont évalué le nombre de reproductions R(t), qui indique la capacité d'une maladie à se propager, associé à différents scénarios de fermeture. Les valeurs R supérieures à 1 indiquent que le nombre de cas augmentera. Ces modèles ont montré que les fermetures d'écoles ont eu une certaine incidence sur la réduction de l'incidence des variants préoccupants dans la collectivité, mais que la transmission chez les enfants d'âge scolaire était plus fortement corrélée au niveau de la transmission dans la collectivité. Ces modèles ont permis de déterminer que la transmission en milieu scolaire contribue à la propagation des variants préoccupants, mais qu'elle n'en est pas le vecteur principal.

- Une étude de modélisation a révélé que les réductions du nombre de cas et de R(t) ont été les plus importantes lors d'un confinement national complet continu jusqu'au 19 avril 2021, comparativement à n'importe lequel des scénarios associés à la réouverture de certaines écoles. La réouverture des écoles primaires et des niveaux comportant des examens obligatoires, ou l'ouverture continue des écoles primaires et l'ouverture des écoles secondaires en alternance avec deux semaines en classe et deux semaines d'apprentissage en ligne, entraînera une augmentation plus faible du nombre de cas et du R(t) que si toutes les écoles restaient ouvertes (6).
- Une autre étude de modélisation a permis d'obtenir des résultats semblables indiquant que des restrictions strictes à la mobilité communautaire et la fermeture des écoles réduiront le R(t) à moins de 1 (11).
- Une étude de cohorte effectuée au Royaume-Uni a révélé qu'il y avait une forte augmentation des absences dans les établissements d'enseignement secondaire dans certaines régions de Londres en raison de l'augmentation des cas associés au variant B.1.1.7. Cela n'a pas été observé dans les écoles primaires. On a également vu une corrélation positive entre les cas dans les écoles et les cas dans la collectivité. En outre, rien n'indique non

plus que les écoles jouent un rôle important dans la transmission de l'infection dans la collectivité (5).

- Une étude de modélisation canadienne a estimé que le variant B.1.1.7 entraînerait une probabilité d'éclosion plus élevée de 3,6 fois et de 4,2 fois qu'avec la souche originale du SRAS-CoV-2, même si des mesures de contrôle strictes étaient mises en place pour les adultes et les enfants respectivement. Cette augmentation devrait se produire, peu importe si les écoles sont fermées ou ouvertes dans des scénarios où la collectivité reste ouverte en raison de mauvaises interventions en matière de santé publique et d'un risque élevé de transmission dans la collectivité. La modélisation a permis de déterminer que les écoles n'ont pas d'impact important sur la trajectoire de l'épidémie (7).

Tableau 2 : Preuve de la transmission des variants préoccupants en milieu scolaire (n = 4)

ÉTUDE	MÉTHODE	RÉSULTATS PERTINENTS
Études de modélisation prédictive (n = 3)		
Davies 2021 (11) Modèle prédictif Royaume-Uni Mars 2021	Un modèle de transmission adapté à sept régions NHS en Angleterre a été utilisé pour effectuer des projections quant aux effets que différentes mesures de contrôle auraient sur l'épidémie entre la mi-décembre 2020 et la fin de juin 2021. L'étude est modélisée sur l'hypothèse d'une transmissibilité accrue des variants. Quatre scénarios ont été comparés : (i) un scénario moyennement restrictif; (ii) un scénario très strict dans lequel les écoles sont ouvertes; (iii) le même scénario très strict, mais en gardant les écoles fermées jusqu'au 15 février 2021; et (iv) un scénario très strict dans lequel les écoles sont fermées.	• Le modèle de transmission a révélé que, peu importe les mesures de contrôle mises en œuvre, toutes les régions devraient connaître une nouvelle vague de cas de COVID-19 et de décès au début de 2021, vague qui atteindra un sommet en février si aucune mesure de contrôle importante n'est mise en œuvre ou à la mi-janvier si des mesures de contrôle rigoureuses sont en place. • Le modèle prévoyait également que des mesures plus strictes (iii et iv) créeraient à un plus grand nombre de cas de rebonds lorsque les restrictions simulées seraient levées en mars 2021. • Les auteurs suggèrent que la fermeture des écoles et les restrictions dans la communauté pourraient réussir à réduire le R(t) en dessous de 1.
Panovska-Griffiths 2021 (6) *Préimpression* Modèle prédictif Royaume-Uni Février 2021	Le modèle Covasim, calibré jusqu'au 25 janvier 2021, a été utilisé pour simuler l'impact d'un confinement national complet (CNC) avec fermeture des écoles jusqu'au 19 avril 2021 par rapport à quatre scénarios différents de confinement national partiel (CNP) avec différents établissements scolaires ouverts : 1) CNP avec un début décalé; 2) CNP avec retour de tous les élèves; 3) CNP avec ouverture des écoles primaires et seuls les élèves dont les niveaux comportent des examens obligatoires	• La modélisation suggère que la réduction du nombre de cas et du R(t) est plus importante avec un CNC continu jusqu'au 19 avril 2021 comparativement à n'importe lequel des scénarios avec réouverture de certaines écoles. La réouverture des écoles primaires et des niveaux comportant des examens obligatoires, ou l'ouverture continue des écoles primaires et l'ouverture des écoles secondaires en alternance avec deux semaines en classe et deux semaines d'apprentissage en ligne, entraînera une augmentation plus faible du nombre de cas

	(11e et 13e années) seront de retour à l'école; et 4) CNP avec ouverture des écoles primaires à plein temps et des écoles secondaires en alternance avec deux semaines en classe et deux semaines d'apprentissage en ligne. L'étude est fondée sur l'hypothèse selon laquelle le nouveau variant est plus transmissible et la proportion relative de la nouvelle souche a augmenté entre le 1er septembre 2020 et le 31 janvier 2021 en raison d'une fonction de croissance logistique, 30 % des infections détectées en décembre et 90 % des infections détectées à la fin de janvier 2021 auraient été causés par le nouveau variant.	et du R(t) que si toutes les écoles restaient ouvertes. • Le confinement national complet ramènera le nombre de cas d'ici le début de mars à un niveau semblable à celui d'octobre puisque le R(t) sera également en baisse et restera inférieur à 1. • Dans chaque scénario, le nombre de nouvelles infections devrait diminuer en janvier et au début de février. • Les répercussions sur les décès seront cependant décalées, avec un plafonnement des décès cumulatifs à compter de février dans chacun des scénarios. Cela est dû au fait que l'effet du vaccin a été modélisé avec un délai de 21 jours. Dans l'ensemble, si les écoles ouvrent, nous prédisons une augmentation du nombre d'infections et une augmentation du R(t), et un changement possible du R(t) supérieur à 1 une fois que le confinement prendra fin.
Yuan 2021 (7) *Préimpression* Modèle prédictif Toronto Juillet à novembre 2020	À l'aide d'un modèle déterministe de type SEIR élargi fondé sur l'âge, la ville où vit le ménage et adapté aux données démographiques de Toronto, le modèle a été étalonné en fonction des données épidémiologiques obtenues entre le 31 juillet et le 23 novembre 2020. Le modèle a été élaboré pour imiter la transmission dans les ménages, la collectivité et les écoles. Le nouveau variant préoccupant est basé sur le B.1.1.7 et on suppose que la probabilité de transmission augmentera de 50 % et que les enfants seront 70 % plus sensibles que les adultes. Le modèle suppose	• Si on compare la souche de référence et le variant et qu'on tient compte des restrictions imposées à la collectivité et des fermetures d'écoles, qui ont permis un contrôle quasi complet de l'épidémie, on estime que le variant entraînerait une augmentation de 3,6 fois le nombre de cas chez les adultes et de 4,2 fois le nombre de cas chez les enfants et les jeunes. • Les scénarios qui tiennent compte du nouveau variant indiquent que la fermeture des écoles n'a que peu d'impact sur la trajectoire de l'épidémie de janvier à mai 2021, puisqu'avec une réouverture de la communauté (étape 2) (ouverture partielle), on prévoyait un nombre de cas 7 fois ou

	également que ce variant sera la souche dominante après un mois. L'étude a modélisé l'impact du nouveau variant préoccupant en supposant une plus grande susceptibilité des enfants et des jeunes à ce nouveau variant.	7,5 fois plus élevé si les écoles étaient fermées plutôt qu'ouvertes. • Des augmentations exponentielles du nombre de cas ont été prédites, peu importe si les écoles étaient ouvertes ou fermées dans les scénarios dans lesquels la collectivité est entièrement ouverte (étape 3) en raison de la faiblesse des interventions en santé publique et du risque élevé de transmission dans la collectivité.
Études de cohorte (n = 1)		
Southhall 2021 (5) *Préimpression* Cohorte rétrospective. Royaume-Uni Septembre à décembre 2020	Une analyse de l'absentéisme des élèves et des enseignants a été effectuée pour évaluer l'impact du nouveau variant B.1.1.7. Des évaluations ont été effectuées dans des régions précises afin d'évaluer l'incidence différentielle du nouveau variant Londres et Kent ont été choisis en raison du nombre élevé de nouveaux cas associés au variant, tandis que Devon et les West Midlands ont été choisis parce qu'il y avait moins de cas déclarés associés à ce variant. En outre, le 3 décembre 2020, Devon était au niveau 2 alors que les West Midlands étaient au niveau 3.	• Une forte augmentation du nombre d'absences dans les établissements d'enseignement secondaire a été observée dans le Sud-Est et le Grand Londres en décembre, mais pas dans d'autres régions ou établissements d'enseignement primaire. • Les auteurs soupçonnent que les absences étaient liées à la transmissibilité accrue du nouveau variant B.1.1.7, qui a contribué à l'augmentation des cas dans les écoles secondaires de ces régions. • On a constaté une corrélation positive entre les cas dans la collectivité et les cas dans les écoles dans la plupart des régions. • Il n'y a cependant pas de preuve importante indiquant que les écoles jouent un rôle important dans la transmission dans la collectivité. • Il pourra être nécessaire de surveiller attentivement la réouverture des écoles pour déterminer l'effet associé à leur ouverture sur l'incidence dans la collectivité. • À Londres, dans le Kent et dans les West Midlands, une faible corrélation entre les cas parmi les élèves du secondaire et les cas dans la collectivité a augmenté avec le

		temps, ce qui indique qu'une augmentation des cas dans la collectivité est corrélée de façon plus positive avec une augmentation des cas dans les écoles à une date ultérieure. • Le même résultat a été observé chez les élèves des écoles primaires de Kent et des West Midlands. Cependant, la corrélation était négligeable entre les cas dans les communautés et les cas chez les enfants d'âge primaire à Londres, quel que soit le type de décalage choisi pour la réouverture.

Méthodologies :

Une analyse documentaire quotidienne (ouvrages publiés et en prépublication) est effectuée par le Groupe des sciences émergentes de l'ASPC. L'analyse a compilé les ouvrages sur la COVID-19 depuis le début de l'éclosion et est mise à jour quotidiennement. Les recherches visant à extraire les ouvrages pertinents sur la COVID-19 sont menées dans Pubmed, Scopus, BioRxiv, MedRxiv, ArXiv, SSRN et Research Square, et les résultats sont recoupés avec les ouvrages figurant sur la liste de la documentation sur la COVID de l'Organisation mondiale de la Santé et des centres d'information sur la COVID-19 gérés par Lancet, BMJ, Elsevier, Nature et Wiley. Le résumé quotidien et les résultats complets de l'analyse sont conservés dans une base de données RefWorks et dans une liste Excel consultable. Une recherche ciblée par mot-clé était effectuée dans ces bases de données pour identifier les citations pertinentes sur la COVID-19 et le SRAS-COV-2. Les termes de recherche utilisés comprenaient :
TERMES ASSOCIÉS À LA TRANSMISSION DANS LES ÉCOLES : (B.1.1.7 ou 501Y.V1 ou B.1351 ou 501Y.V2 ou P1 ou P2 ou B1.1.1.28 ou B.1.1.33 ou 501Y.V3 ou B.1.426 ou variant) ET school ET transmission
TERMES ENFANTS : B.1.1.7 ou 501Y.V1 ou 202012/01 ou B.1351 ou 501Y.V2 ou P1 ou P2 ou B1.1.1.28 ou B.1.1.33 ou 501Y.v3 B.1.426 ou variant) ET (children ou adolescent)
La présente revue contient des recherches publiées jusqu'au 26 mars 2021.
Chaque référence potentiellement pertinente a été examinée pour confirmer qu'elle comportait des données pertinentes, qui ont été extraites dans la revue.

Littérature grise

Une recherche dans la littérature grise a été effectuée afin de compléter la recherche dans la base de données. La littérature grise portait sur les principaux sites Web qui font état des variants B.1.1.7, incluant Public Health England et SPOR Evidence Alliance. La recherche dans la littérature grise a été effectuée du 24 au 26 mars 2020.

Examen par les pairs

Ce document a fait l'objet d'un examen par les pairs dirigé par un expert en la matière et d'un examen en ce qui concerne la rédaction et la science par le Bureau de la Conseillère scientifique en chef.

Préparée par : Kusala Pussegoda, Lisa Waddell Groupe des sciences émergentes, ASPC.

Emerging Evidence on COVID-19

Rapid Review on the Impact of School Closures and Re-openings on COVID-19 Transmission

Introduction

What is the impact of school closures/re-openings on community transmission of COVID-19 and on the incidence of COVID-19 in primary and secondary schools?

Jurisdictions continue to implement a variety of non-pharmaceutical interventions (NPIs) to limit the spread of SARS-CoV-2 and the impact of COVID-19. Globally, closing schools was one of the earliest public health measures implemented, however this has not only disrupted the education and daily routines of students, but also the lives of teachers and parents.

While school closures have been implemented to combat the spread of SARS-CoV-2, they were also associated with negative effects on student's mental health, academic progress, and increased stress in parents and teachers (1). With a lack of school-based peer interactions and daily routines, students experience increased distress, loneliness, anxiety and depressive symptoms (1,2). School routines are crucial for maintaining the well-being of students with mental health or special education needs (3). In addition, school closures have been associated with reduced academic achievement due to delayed educational progress (1,4,5). It is uncertain whether virtual learning is equally effective and many students from low-income households lack access to, and accommodations with, online materials (5).

Given the negative impacts of school closures, it is important to consider whether they are significantly effective in reducing the impact of COVID-19. Initially, it was assumed that school closures would be effective in mitigating the spread of SARS-CoV-2 based on the evidence from the influenza epidemic (6,7). In contrast, modelling studies conducted in Ontario and Canada during the first and second waves found that school closures had limited impact on reducing the transmission of COVID-19 compared with other NPIs (8–10). Other modelling studies reported modest effects of school closures in delaying peak case numbers early in the pandemic (11,12) while some studies showed a smaller magnitude of effect when compared with other public health measures (13,14). Early modelling studies relied on the underlying assumption that there is a low transmission risk in children. Although modelling studies are excellent for making informed predictions, their accuracy is dependent on the assumptions and the quality of data used. Overall, there was a need to assess the potential benefits of school closures in reducing the spread of COVID-19.

This review summarizes empirical studies on the effectiveness of school closures and the impact of re-opening schools in reducing community transmission of COVID-19 and decreasing the incidence of COVID-19 in primary and secondary schools. The principal focus was the impact of primary and secondary school

closures, although if studies also included data from other types of schools this was included as well. Predictive modelling studies were excluded. This review summarizes literature until January 25th, 2021.

Key Points

- Twenty-four studies were identified on the topic of school closures or re-openings to limit the spread of COVID-19. There were 5 observational studies providing individual level data (two cohort studies, one cross-sectional study, and two cluster and outbreak investigations), and 19 ecological studies providing population level data.
- Most observational studies assessing the impact of school closures/re-openings on the spread of COVID-19 in schools reported no significant effects. Four studies found no difference in incidence of cases both before and after closing schools for the holidays, following children who stayed at home vs went to school with strict surveillance, or following school re-opening (15–18).
- Overall, the evidence from the ecological studies assessing community transmission was mixed. Five studies reported that school closures and re-openings were not significantly associated with reduction in the transmission and incidence of COVID-19, and were much less effective in reducing transmission when compared with other NPIs (19–23). Four studies reported a reduction in the incidence of COVID-19 in the community ranging from 8% to 62% following school closures (24–27) and other studies reported a significant reduction in the effective reproduction number (Rt) (28–30). Three studies attributed significant reductions in mortality to school closures (27,31,32) and one study reported increased mortality with delayed school closures (33).
- Many of the studies included post-secondary schools and half of the ecological studies did not describe what schools were included in their analyses.
- All of the ecological studies included in this review analyzed data on school closures/re-openings early in the pandemic, between January-August 2020, when multiple NPIs were implemented simultaneously so it was not possible to isolate the impact of school closures/re-openings on the number of cases of COVID-19 in the community.
- Only one of the ecological studies described if there was adherence to infection prevention and control (IPAC) measures in the schools assessed (23).
- Ecological studies are considered a low level of evidence due to the research design, the multiple confounding factors and the high degree of variability in the results, therefore there is a high degree of uncertainty with the evidence from the ecologic studies.

Overview of the Evidence

Twenty-four articles published prior to January 25, 2021 were identified on the impact of school closures/re-openings on the spread of COVID-19. This includes a cross-sectional study (n=1), cohort studies (n=2), cluster and outbreak investigations (n=2), and ecological studies (n=19). Eleven of these are studies are preprints or studies that have not been peer-reviewed.

The five observational studies use individual-level data to assess the effectiveness of school closures or the impact of school re-openings on COVID-19 transmission in schools and the community. Observational studies have moderate to high risk of bias if the study sample is not representative of the population. Cohort studies are one of the strongest observational study designs, especially if prospective, and can be used to determine a temporal relationship between school closures/re-openings and COVID-19 outcomes. These studies are at risk of selection bias if losses to follow-up occur or if confounding factors vary between groups. Cross-sectional studies provide a good picture of the impact of school closures at a particular point in time but with the use of self-reported data, there is a risk for recall bias so these studies cannot establish causation. Cluster and outbreak investigations are also at high risk of bias. Although these studies are useful, they are very situation specific and may not provide data that is generalizable to other populations.

The 19 ecological studies use population-level data mostly from publicly available data on COVID-19 outcomes. Ecological studies can be useful as an initial approach for determining public health trends and if there are strong associations observed, this can provide the opportunity for more carefully designed studies. However, these studies are at high risk of bias. It is important to note that ecological studies are prone to the ecological fallacy because what occurs at population-level may not occur at an individual level. There are many confounding factors involved in ecological studies so these studies are lower quality. Additionally, these studies were conducted very early in the pandemic simultaneously with other public health measures, therefore the findings are likely to change as new data becomes available.

An important limitation to be considered with this review is the inconsistency of the levels of schooling that were included in the measures of efficacy across studies. Most studies did not provide information on what schools were included when determining the impact of school closures on the spread of COVID-19. Some studies measured primary and secondary school closures alone, or in combination with other types of schools, therefore the magnitude of effect varies across studies. Additionally, the relative impact of school closures and re-openings will vary according to the time of implementation, level of community transmission, and the structure of populations from different countries. Overall, the confidence in this evidence is low given that the studies vary by several factors and were conducted at different times in a number of countries.

An important knowledge gap to consider is how the new variants of concern and the rollout of COVID-19 vaccinations will impact the transmission of COVID-19 within schools and the community. The evidence in this review pre-dates the introduction of the variants of concern, therefore it is unknown how this will impact the effectiveness of school closures or the impact of school opening on the spread of COVID-19.

CONTENTS

OBSERVATIONAL STUDIES

There were 5 observational studies that assessed the impact of school closures/re-openings on transmission of COVID-19 in schools using individual-level data (Table 1). IPAC measures implemented by the schools were similar across most of the observational studies: masks, physical distancing, frequent cleaning, reduced class sizes and hand hygiene. One cohort study did not report whether or not IPAC measures were implemented in the school (14). The implementation of IPAC measures in schools can act as a mediating variable with the results from these studies because of its ability to reduce transmission and risk of infection.

- Four studies found little or no impact of school closures or re-opening on transmission of COVID-19 in schools and the community:
    - A prospective cohort study that analyzed the association between school re-opening dates and COVID-19 cases across twenty-one regions in Italy found SARS-CoV-2 incidence among students was lower than the general population in 19/21 regions (16).
    - A retrospective cohort study found no evidence of transmission in schools prior to school closures despite several introductions and analysis of COVID-19. Infection attack rates (IAR) among family and relatives compared to teachers and staff of infected and not infected pupils provides evidence that most infections were likely acquired within the household (15).
    - A cross-sectional study comparing children in a school group with strict surveillance and a stay-at-home group found no significant differences in number of cases of SARS-CoV-2 in the children in each group (18).
    - A cluster investigation study reported a very low secondary attack rate overall after school re-opening, but that it was higher in secondary schools (6.6%) than in elementary schools (0.38%) (17).
    - A large outbreak was reported from a high school in Jerusalem, but this was confounded by the fact that the mask mandate was lifted as there was a heatwave shortly after re-opening (34).

Table 1: Observational studies assessing the impact of school closures or re-openings on the transmission of COVID-19 in schools and the community (n=5)

STUDY	METHOD	KEY OUTCOMES
Cohort studies (n=2)		
Gandini (2020) *preprint* (16) Prospective cohort study and cross-sectional study Italy	This study analyzed the association between school re-opening dates and COVID-19 cases across twenty-one Italian regions by using a database on positive cases in elementary, middle and high school. IPAC measures included: temperature control, hand hygiene, mask mandate for students/staff, physical distancing, ban on sports and music, and reduced duration of school.	• There was no evidence that the second SARS-CoV-2 wave was driven by schools re-opening across the regions. • SARS-CoV-2 incidence among students was lower than the general population of all but two Italian regions. • The increase in reproduction number R_t was not associated with the different school opening dates.

Sep-Nov 2020	Several COVID-19 outcomes were measured during school re-openings: growth of incidence, reproduction number (R_t), and secondary infections.	• School closures implemented in two regions did not affect the decline of R_t.
Fontanet (2020) *preprint* (15) Retrospective cohort study France Feb-Apr 2020	This retrospective cohort study included primary school pupils, teachers, non-teaching staff, parents, and relatives exposed to SARS-CoV-2 in February and March from 6 schools. IPAC measures were not described. A questionnaire covering sociodemographic information and history of recent symptoms was completed by participants. Blood samples were also tested for the presence of anti-SARS-CoV-2 antibodies using a flow-cytometry-based assay. Three introductions of SARS-CoV-2 occurred prior to school closures. Spread within schools vs families was investigated in this sero-epidmiological study. The infection attack rate (IAR) was compared between school contacts and family contacts to understand the potential impact of the school closure.	• The IAR was 45/510 (8.8%), 3/42 (7.1%), 1/28 (3.6%), 76/641 (11.9%) and 14/119 (11.8%) among primary school pupils, teachers, non-teaching staff, parents, and relatives, respectively (P = 0.29). • No secondary infections from COVID-19 introductions in schools was detected. • Among pupils who were infected, their parents were significantly more likely to be infected (61.0% versus 6.9%; P <0.0001), The same was identified among relatives of infected pupils compared to non-infected pupils (44.4% versus 9.1%; P = 0.002) • Transmission did not appear to be impacted by the closure of schools.
Cross-sectional studies (n=1)		
Kriger (2020) (18) Cross-sectional study Israel Mar-May 2020	During a national lockdown, an alternative school was used for healthcare workers' children to attend with strict symptom surveillance. Families with children who remained at home were compared to children at this alternative school. IPAC measures in the school included: daily disinfecting, face mask use by staff, and frequent hand washing. This cross-sectional study included 70 children who attended the alternative primary school and 36 who stayed home, along with their 78 parents. Data was collected through a short questionnaire; nasopharyngeal and oropharyngeal swabs were obtained and tested for SARS-CoV-2 by RT-PCR, and	• Symptoms were reported in approximately 16% of children in both groups: those who attended the school (11/70) and those who did not (6/36). • Positive serology tests showing previous exposure was detected in less than 2% of each group and they were not significantly different from each other. • There was no evidence of increased infection in those at school compared with those at home.

	blood was collected for SARS-CoV-2 IgA and IgG titres.	
Cluster and outbreak investigations (n=2)		
Larosa (2020) (17) Cluster investigation Italy Sep-Oct 2020	This cluster investigation analyzed the transmission of COVID-19 in 41 classes of 36 schools upon their re-opening in northern Italy. The secondary attack rate was measured in students and teachers in elementary and secondary schools (middle and high schools). IPAC measures included: mask mandate for high school students only, physical distancing, and ban of extracurricular activities.	• The secondary attack rate for COVID-19 was reported to be higher in secondary schools (6.6%) than in elementary schools (0.38%).
Stein-Zamir (2020) (34) Outbreak investigation Israel May-Jun 2020	This outbreak investigation study assessed the epidemiological characteristics of a high school outbreak in Jerusalem that displayed mass COVID-19 transmission upon school reopening on May 17th. The high school included grades 7 to 12. An extreme heatwave occurred upon the re-opening of the school. IPAC measures: face mask use was lifted for 3 days during the heatwave, physical distancing was below the standard in overcrowded classes, and extracurricular activities were not banned.	• It was reported that the proportion of the 10–19 years-olds was 19.8% (938/4,747) of the cases before May 24th, and then increased to 40.9% (316/772) after May 24th. • Testing of the whole school revealed that 153 students (attack rate: 13.2%) and 25 staff members (attack rate: 16.6%) were COVID-19 positive. • COVID-19 rates were higher in grades 7-9 than in grades 10-12.

CI = confidence interval, NPI = non-pharmaceutical intervention, Rt = effective reproduction number, SE = standard error, p = p-value, IPAC = infection prevention and control

ECOLOGICAL STUDIES

Nineteen ecological studies were identified that assessed the impact of school closures or re-openings on the spread of COVID-19 (Table 2). All ecological studies in Table 2 use population-level data to estimate the effectiveness of school closures or re-openings on preventing the spread COVID-19 in the community.

Overall, the evidence from the ecological studies assessing community transmission was mixed (n=19):

- Five studies reported that school closures and re-openings were not significantly associated with reduction in the transmission and incidence of COVID-19:
    - In a Japan study, the closure of primary and secondary schools was not found to be effective in decreasing the incidence of COVID-19 (21).

  - An ecological study in Germany found no significant effect on infections that could be attributed to school and day-care closures (22).
  - Child-to-child transmission in primary, secondary schools and childcare facilities in Germany was low and school reopening was not associated with a change in transmission (23).
  - A global study found that school closures were less effective than other NPIs (19).
  - A USA study found that closing schools was found to have the smallest reduction in Rt compared to 6 other NPIs that were assessed (20).
- Four studies reported a reduction in the incidence of COVID-19 ranging from 8% to 62% following school closures (24–27). Three studies reported a significant reduction in Rt:
  - A global study estimated an overall reduction in infection of 12% with closures of primary, secondary and tertiary educational institutions (28).
  - A USA study found that the closure of educational facilities was associated with a significant reduction in Rt compared to states without this policy (29).
  - A Hong Kong study reported a 44% reduction in transmission during the first 2 weeks of school closures including kindergartens up to tertiary and post-tertiary institutions, and tutorial centres (30).
- Three studies reported significant reductions in mortality with school closures (27,31,32) and one study reported increased mortality with delayed school closures (33).

Table 2: Ecological studies assessing the effectiveness of school closures or re-openings on reducing spread of COVID-19 in the community (n=19)

STUDY	METHOD	KEY OUTCOMES
Global (n=10)		
An (2021) *preprint* (19) Ecological study Global Jan-Jul 2020	This study aimed to identify associations between six NPIs and the number of COVID-19 infections. Using worldwide data on NPIs and COVID-19 infections between Jan-Jul 2020, analysis was conducted on the short-term and long-term effects of NPIs on new infection rates 5, 9, 12, and 21 days after their adoption. IPAC measures and level of schooling included in the study were not described. NPIs examined included mask mandates, international travel restrictions, domestic lockdowns, mass gathering bans, restaurant closures, and school closures.	• School closures took more time than other NPIs to show efficacy. After a time lag, the impact of school closures on new case rates was -0.492 (SE=0.16) at 12 days ($p<0.01$), -0.722 (SE=0.148) at 21 days ($p<0.001$), and -0.824 (SE=0.0967) at 30 days ($p<0.001$). • School closures were not found to have significant effects on population-adjusted infections in the long-term (90^{th} to 120^{th} day).

Banholzer (2020) *preprint* (25) Ecological study 20 countries Apr 2020	In this study, the impact of NPIs on the relative reduction of new COVID-19 cases using a Bayesian hierarchical model with a time-delayed effect for each NPI. IPAC measures were not described. NPIs examined included: (1) primary school closures, (2) border closures, (3) public event bans, (4) gathering bans, (5) venue closures, (6) lockdowns prohibiting public movements without valid reason, and (7) work bans on non-essential business activities.	• The mean reduction of new COVID-19 cases with primary school closures was 8% (95% CI: 0 to 23%). • Compared to other NPIs examined, school closures appeared to be one of the least effective NPIs.
Banholzer (2021) *preprint* (24) Ecological study 20 countries Feb-May 2020	Using a semi-mechanistic Bayesian hierarchical model, this study aimed to measure the effectiveness of seven NPIs in reducing the number of new infections. IPAC measures were not described. NPIs examined included: (1) primary school closures, (2) border closures, (3) public event bans, (4) gathering bans, (5) venue closures, (6) lockdowns prohibiting public movements without valid reason, and (7) work bans on non-essential business activities.	• The relative reduction of new COVID-19 cases with primary school closures was 17% (95% CI: 2% to 36%). • This reduction was lower than two other NPIs: event bans and venue closures.
Brauner (2021) (26) Ecological study 41 countries Jan-May 2020	This study estimated the effectiveness of NPIs in 41 countries using a Bayesian hierarchical model by linking intervention implementation dates to national case and death counts. Intervention effect sizes were categorized by the median reductions in the reproduction number R_t of <17.5% (small), between 17.5 and 35% (moderate), and >35% (large). NPIs examined included: limiting gatherings to <1000 or <100, or <10, closing some businesses, closing most businesses, closing schools and universities, and stay at home orders. IPAC measures were not described.	• The percentage reduction in Rt associated with closing both schools and universities in conjunction was 38% (95% CI: 16 to 54%) which was categorized as a large effect size. • The individual effects of school closures was not measured.

Klimek-Tulwin (2020) (35) Ecological study Global Mar 2020	This study aimed to assess the effect of school closures on COVID-19 cases globally by measuring correlation between the incidence rate on the day of school closure and the incidence rate in the following days. IPAC measures and level of schooling included in the study were not described.	• The results indicate that there was a strong correlation between the day of educational facilities closure and the incidence rate in the following days (16^{th} (p = 0.004), 30^{th} (p = 0.002), and 60^{th} (p = 0.031) days since the 100^{th} confirmed case in each country). • Early closure of schools is statistically significantly correlated with lower incidence rates further on during the different phases of the epidemic.
Papadopoulos (2020) *preprint* (36) Ecological study Global Jan-Apr 2020	The impact of lockdown measures was assessed globally using publicly available data. The timing and association of early NPIs with log10 national deaths (LogD) and log10 national cases (LogC) was compared between nations. IPAC measures and level of schooling included in the study were not described.	• Early generalised school closure (p=0.050, regression coefficient β=-0.012, 95% CI: 0 to -0.024) was associated with reduced LogC (log10 national cases).
Pasdar (2020) *preprint* (32) Ecological study 22 countries May 2020	The aim of this study was to determine the associations between NPIs and COVID-19 outcomes. Associations with NPIs were assessed with their respective stringency index (rs) on several outcomes that form the epidemic curve: mean mortality rate, time to peak, peak deaths per 100,000 population, cumulative deaths after peak per 100,000 population and ratio of the mean slope of the descending curve to the mean slope of the ascending curve. IPAC measures and level of schooling included in the study were not described.	• School closures were effective against all outcomes, except time to reaching the peak of the epidemic curve. • The strongest association was seen in cumulative deaths after peak, per 100,000 (rs = -0.744, p = 0.009). • In non-European countries, school closures were most effective against mean mortality rate (rs = -0.757, p = 0.049).
Esra (2020) *preprint* (28) Ecological study Global Jan-May 2020	This study used globally reported data on SARS-CoV-2 cases to fit a Bayesian model framework to estimate the association with NPIs and transmission. NPIs examined include stay home mandates, gathering limits, school closures (primary, secondary and tertiary educational	• There was an estimated mean reduction in Rt of 12% (95% CI: 5-19%) with school closures (primary, secondary and tertiary educational institutions).

	institutions), and mask policies. IPAC measures were not described.	
Jüni (2020) (37) Ecological study Global Mar 2020	This prospective study of geopolitical areas aimed to determine whether climate or public health interventions are associated with reducing transmission of COVID-19. A weighted random effects regression was used to determine the association between epidemic growth (ratios of rate ratios [RRR]) and climate measures and public health interventions such as school closures, restrictions of mass gatherings, and measures of social distancing during an exposure period 14 days previously. IPAC measures and level of schooling included in the study were not described.	• Strong negative associations with epidemic growth were found for school closures (RRR - 0.63, 95% CI: 0.52 to 0.78). • This association was more pronounced in areas that implemented 2 or 3 NPIs compared to 1 NPI.
Stokes (2020) *preprint* (31) Ecological study Global Jun 2020	This study examined the variation of NPIs in 130 countries in two periods: 1) prior to first COVID-19 death and 2) 14-days-post first COVID-19 death. This study examined associations with daily COVID-19 deaths per million and each 24 day period (time between virus transmission and mortality). IPAC measures and level of schooling included in the study were not described.	• Stricter/earlier school closures were associated with the largest reductions in COVID-19 deaths (-1.23 per million (95% CI: -2.20 to -0.27)) compared to other NPIs.
North America (n=5)		
Auger (2020) (27) Ecological study USA Mar-May 2020	This study aimed to determine if school closures were associated with a decrease in the cumulative incidence of COVID-19 and mortality. The impact of primary and secondary school closures was assessed using publicly available data from all 50 states. IPAC measures were not described.	• Results showed that school closures were associated with a significant decline in incidence of COVID-19 (−62% [95% CI: −71% to −49%]) and in mortality (−58% [95% CI: −68% to −46%]). • These associations were stronger in states with a low cumulative incidence of COVID-19 at the time of the school closure.
Dreher (2020) *preprint* (29) Ecological study	This study aimed to measure the impact of NPIs on the effective reproduction number (R_t) of COVID-19 in US states. The average R_t was measured during the weeks after each state reached 500 cases. R_t	• Educational facilities closure was associated with a significant reduction in R_t compared to states without this policy the week following 500 cases (ß = -0.17, 95% CI: -0.30 to -0.05, p = 0.009).

USA Apr 2020	was measured at the week immediately following 500th Case (days +1 to +7) and at a one-week delay from 500th case (days +8 to +14). NPIs examined included: stay at home order, educational facilities closure, and non-essential business closure. IPAC measures and level of schooling included in the study were not described.	• From days 8 to 14 after the 500th case date, educational facilities closure was associated with a significant reduction in R_t compared to controls (ß = -0.12, 95% CI: -0.21 to -0.04, p = 0.006).
Krishnamachari (2020) *preprint* (38) Ecological study USA May 2020	This study aimed to examine the effects of NPIs on the cumulative incidence rates of COVID-19 in the USA on a state-level in the 25 most populated cities, while adjusting for socio-demographic risk factors. A negative binomial regression was used to calculate adjusted rate ratios by comparing two levels of a binary variable: "above median value," and "median value and below" for days to implementing an NPI. NPIs assessed in this study included: days to closing of non-essential business; days to stay home orders; days to restrictions on gathering, days to restaurant closings and days to school closing. IPAC measures and level of schooling included in the study were not described.	• Days to school closing was associated with cumulative incidence on days 35 and 42, with an adjusted rate ratio of 1.59 (95% CI: 1.03 to 2.44, p=0.04) at 35 days, and adjusted rate ratio of 1.64 (95% CI: 1.07 to 2.52, p=0.04) at 42 days. • Delays in closing schools was positively associated with cumulative incidence at the state level.
Liu (2020) *preprint* (20) Ecological study USA Feb-Apr 2020	This study estimated the impact of nine different NPIs on reduction of the effective reproduction number (Rt) by using the daily number of reported new cases and inferred infections in 50 states. IPAC measures and level of schooling included in the study were not described.	• Closing schools was found to moderately reduce Rt by about 10% (95% CI: 7%-14%). • This reduction was smaller than 6 other NPIs assessed (stay-at-home order, face masks, gathering ban, non-essential business closure, declaration of state of emergency and interstate travel restriction).

Yehya (2020) (33) Ecological study USA Jan-Apr 2020	In this study, a state-level analysis was conducted to determine association between later implemented NPIs with higher mortality rates. Using a multivariable negative binomial regression, the association was tested between timing of emergency declarations and school closures with 28-day mortality. Day 1 for each state was set to when they recorded ≥ 10 deaths. IPAC measures and level of schooling included in the study were not described.	• Later school closure was associated with more deaths (adjusted mortality rate ratio aMRR 1.05; 95% CI: 1.01 to 1.09; p = 0.008).
Asia (n=2)		
Cowling (2020) (30) Ecological study Hong Kong Jan-Feb 2020	This study examined the effect of public health interventions on the incidence of COVID-19 and on the daily effective reproduction number (R_t). Laboratory-confirmed COVID-19 cases and on the daily effective reproduction number (R_t) were estimated to estimate changes in transmissibility over time. School closures included kindergartens up to tertiary and post-tertiary institutions, and tutorial centres. IPAC measures were not described.	• The estimated R_t was 1.28 (95% CI: 1.26–1.30) during the 2-week period before the start of the school closures and 0.72 (95% CI: 0.70–0.74) during the first 2 weeks of school closures, corresponding to a 44% (95% CI: 34–53%) reduction in transmissibility • R_t calculated from hospitalisation data was 1.10 (1.06–1.12) before the start of the school closures and reduced to 0.73 (0.68–0.77) after school closures, corresponding to a 33% (95% CI: 24–43%) reduction in transmissibility.
Kentaro (2020) (21) Ecological study Japan Mar 2020	This study aimed to assess the effectiveness of primary and secondary school closure on COVID-19 incidence nine days after implementation. IPAC measures were not described. Using a Bayesian method, time-series analyses were conducted and local linear trend models were developed for the number of newly reported cases of COVID-19.	• The school closure intervention was not effective in decreasing the incidence of COVID-19. • The newly reported COVID-19 cases continued to rise (α - 0.08, 95% CI: −0.36 to 0.65).
Europe (n=2)		

Wieland (2020) (22) Ecological study Germany Mar-Apr 2020	The aim of this study was to assess the effectiveness of different NPIs against the spread of COVID-19 over time. School closures included day-care closures as well. IPAC measures were not described. Using publicly available data on daily reported German cases, exponential growth models for infections and reproduction numbers were estimated and investigated with respect to change points in the time series.	• There was no significant effect found on COVID-19 infections that could be attributed to school and day-care closures.
Ehrhardt (2020) (23) Ecological study Germany Feb-Aug 2020	This study aimed to assess the transmission of SARS-CoV-2 among children in primary schools, secondary schools and childcare facilities in Baden-Württemberg, Germany after school reopening in May. IPAC measures included: reduced class size, disinfecting, hand hygiene, and banning of sports and music in primary and secondary schools. An epidemic curve was used to show the daily new cases after the schools reopened.	• Child-to-child transmission in schools was low. • The study estimated that one secondary case originates per 25 infectious school days (days that cases spent at school during infectious period). • School re-openings were not associated with a change in transmission of SARS-CoV-2.

CI = confidence interval, NPI = non-pharmaceutical intervention, Rt = effective reproduction number, SE = standard error, p = p-value, IPAC = infection prevention and control

Methods:

A daily scan of the literature (published and pre-published) is conducted by the Emerging Science Group, PHAC. The scan has compiled COVID-19 literature since the beginning of the outbreak and is updated daily. Searches to retrieve relevant COVID-19 literature are conducted in Pubmed, Scopus, BioRxiv, MedRxiv, ArXiv, SSRN, Research Square and cross-referenced with the COVID-19 information centers run by Lancet, BMJ, Elsevier, Nature and Wiley. The daily summary and full scan results are maintained in a refworks database and an excel list that can be searched. Targeted keyword searching was conducted within these databases to identify relevant citations on COVID-19 and SARS-COV-2. Search terms included: school AND closure OR re-opening. References were also used to search for additional relevant studies. The literature search was confined to English and French language. This review contains research published up to January 25th, 2021. Each potentially relevant reference was examined to confirm it had relevant data and relevant data was extracted into the review.

Peer-review

This document underwent peer-review by a subject matter expert, and editorial and science to policy review by the Office of the Chief Science Officer.

Nouvelles données sur la COVID-19

Examen rapide de l'impact des fermetures et réouvertures d'écoles sur la transmission de la COVID-19

Introduction

Quel est l'impact des fermetures/réouvertures des écoles sur la transmission communautaire de la COVID-19 et sur l'incidence de celle-ci dans les écoles primaires et secondaires ?

Les juridictions continuent de mettre en œuvre une variété d'interventions non pharmaceutiques (INP) pour limiter la propagation du SRAS-CoV-2 et l'impact de la COVID-19. À l'échelle mondiale, la fermeture des écoles a été l'une des premières mesures de santé publique mises en œuvre, mais cette mesure a non seulement perturbé l'éducation et la routine quotidienne des élèves, mais aussi la vie des enseignants et des parents.

Si les fermetures des écoles ont été mises en œuvre contrer la propagation du SRAS-CoV-2, elles ont également été associées à des effets négatifs sur la santé mentale des élèves, les progrès scolaires et l'augmentation du stress chez les parents et les enseignants (1). En l'absence d'interactions avec leurs pairs à l'école et de routine quotidienne, les élèves ressentent davantage de détresse, de solitude, d'anxiété et de symptômes dépressifs (1,2). Les routines scolaires sont essentielles au maintien du bien-être des élèves ayant des besoins en matière de santé mentale ou d'éducation spécialisée (3). En outre, les fermetures des écoles ont été associées à une baisse des résultats scolaires en raison d'un retard dans la progression de l'enseignement (1, 4, 5). Il n'est pas certain que l'apprentissage virtuel soit aussi efficace et de nombreux étudiants issus de foyers à faibles revenus n'ont pas accès aux matériels en ligne et ne peuvent pas s'y adapter (5).

Compte tenu des impacts négatifs de la fermeture des écoles, il est important de se demander si elles sont significativement efficaces pour réduire l'impact de la COVID-19. Au départ, on a supposé que les fermetures d'écoles seraient efficaces pour atténuer la propagation du SRAS-CoV-2, en se basant sur les données de l'épidémie de la grippe (6,7). En revanche, des études de modélisation menées en Ontario et au Canada au cours de la première et de la deuxième vague ont montré que la fermeture des écoles avait un impact limité sur la réduction de la transmission de la COVID-19 par rapport aux autres INP (8–10). D'autres études de modélisation ont fait état d'effets modestes de la fermeture des écoles pour retarder le pic de cas au début de la pandémie (11,12) tandis que certaines études ont montré un effet de moindre ampleur par rapport à d'autres mesures de santé publique (13,14). Les premières études de modélisation reposaient sur l'hypothèse sous-jacente selon laquelle le risque de transmission est faible chez les enfants. Bien que les études de modélisation soient excellentes pour faire des prévisions éclairées, leur précision dépend des hypothèses et de la qualité des données utilisées. Dans l'ensemble, il était nécessaire d'évaluer les avantages potentiels de la fermeture des écoles pour réduire la propagation de la COVID-19.

Cette revue résume les études empiriques sur l'efficacité de la fermeture des écoles et l'impact de la réouverture des écoles sur la réduction de la transmission communautaire de la COVID-19 et la diminution de l'incidence de celle-ci dans les écoles primaires et secondaires. L'accent a été mis principalement sur l'impact de la fermeture des écoles primaires et secondaires, mais si les études comprenaient également des données sur d'autres types d'écoles, celles-ci étaient également incluses. Les études de modélisation prédictive ont été exclues. Cette revue résume la littérature jusqu'au 25 janvier 2021.

Points clés

- Vingt-quatre études ont été identifiées sur le thème de la fermeture ou de la réouverture des écoles pour limiter la propagation de la COVID-19. Il y avait 5 études observationnelles fournissant des données au niveau individuel (deux études de cohorte, une étude transversale et deux enquêtes sur des grappes et des épidémies), et 19 études écologiques fournissant des données au niveau de la population.
- La plupart des études observationnelles évaluant l'impact des fermetures/réouvertures des écoles sur la propagation de la COVID-19 dans les écoles n'ont signalé aucun effet significatif. Quatre études n'ont trouvé aucune différence dans l'incidence des cas avant et après la fermeture des écoles pour les vacances, en suivant les enfants qui sont restés à la maison par rapport à ceux qui sont allés à l'école avec une surveillance stricte, ou après la réouverture des écoles (15–18).
- Dans l'ensemble, les résultats des études écologiques évaluant la transmission communautaire sont mitigés. Cinq études ont rapporté que les fermetures et réouvertures des écoles n'étaient pas significativement associées à une réduction de la transmission et de l'incidence de la COVID-19, et qu'elles étaient beaucoup moins efficaces pour réduire la transmission par rapport à d'autres INP (19–23). Quatre études ont rapporté une réduction de l'incidence de la COVID-19 dans la communauté allant de 8 % à 62 % suite à la fermeture des écoles (24–27) et d'autres études ont rapporté une réduction significative du nombre effectif de reproductions (Rt) (28–30). Trois études ont attribué des réductions significatives de la mortalité à la fermeture des écoles (27, 31, 32) et une étude a signalé une augmentation de la mortalité en cas de fermeture tardive des écoles (33).
- Un grand nombre d'études incluaient des écoles postsecondaires et la moitié des études écologiques ne décrivaient pas quelles écoles étaient incluses dans leurs analyses.
- Toutes les études écologiques incluses dans cette revue ont analysé des données sur les fermetures/réouvertures des écoles au début de la pandémie, entre janvier et août 2020, lorsque plusieurs IPN ont été mises en œuvre simultanément ; il n'a donc pas été possible d'isoler l'impact des fermetures/réouvertures d'écoles sur le nombre de cas de COVID-19 dans la communauté.
- Une seule des études écologiques a décrit si les mesures de prévention et de contrôle des infections (PCI) étaient respectées dans les écoles évaluées (23).
- Les études écologiques sont considérées comme un faible niveau de preuve en raison de la conception de la recherche, des multiples facteurs de confusion et du haut degré de variabilité des résultats, il y a donc un haut degré d'incertitude avec les preuves provenant des études écologiques.

Aperçu des données probantes

Vingt-quatre articles publiés avant le 25 janvier 2021 ont été identifiés sur l'impact des fermetures/réouvertures des écoles sur la propagation de la COVID-19. Il s'agit d'une étude transversale (n=1), d'études de cohorte (n=2), d'enquêtes sur les grappes et les épidémies (n=2) et d'études écologiques (n=19). Onze de ces études sont des prépublications ou des études qui n'ont pas été examinées par des pairs.

Les cinq études observationnelles utilisent des données au niveau individuel pour évaluer l'efficacité de la fermeture des écoles ou l'impact de la réouverture de celles-ci sur la transmission de la COVID-19 dans les écoles et la communauté. Les études observationnelles présentent un risque de biais modéré à élevé si l'échantillon de l'étude n'est pas représentatif de la population. Les études de cohorte sont l'un des modèles d'étude observationnelle les plus solides, surtout si elles sont prospectives, et peuvent être utilisées pour déterminer une relation temporelle entre les fermetures/réouvertures d'écoles et les résultats de la COVID-19. Ces études sont exposées à un risque de biais de sélection en cas de perte de suivi ou si les facteurs de confusion varient d'un groupe à l'autre. Les études transversales donnent une bonne image de l'impact de la fermeture des écoles à un moment donné, mais avec l'utilisation de données autodéclarées, il existe un risque de la partialité de rappel, de sorte que ces études ne peuvent pas établir de lien de causalité. Les enquêtes sur les grappes et les épidémies présentent également un risque élevé de partialité. Bien que ces études soient utiles, elles sont très spécifiques à une situation et peuvent ne pas fournir de données généralisables à d'autres populations.

Les 19 études écologiques utilisent des données au niveau de la population, provenant pour la plupart de données accessibles au public sur les résultats de la COVID-19. Les études écologiques peuvent être utiles en tant qu'approche initiale pour déterminer les tendances en matière de santé publique et si de fortes associations sont observées, elles peuvent offrir l'occasion de mener des études conçues plus soigneusement. Toutefois, ces études présentent un risque élevé de partialité. Il est important de noter que les études écologiques sont sujettes au sophisme écologique, car ce qui se produit au niveau de la population ne se produit pas forcément au niveau individuel. Les études écologiques comportent de nombreux facteurs de confusion et sont donc de moindre qualité. En outre, ces études ont été menées très tôt dans la pandémie, en même temps que d'autres mesures de santé publique, de sorte que les conclusions sont susceptibles de changer à mesure que de nouvelles données sont disponibles.

Une limite importante à prendre en compte dans cette analyse est l'incohérence des niveaux de scolarité inclus dans les mesures d'efficacité entre les études. La plupart des études n'ont pas fourni d'informations sur les écoles prises en compte pour déterminer l'impact de la fermeture des écoles sur la propagation de la COVID-19. Certaines études ont mesuré les fermetures d'écoles primaires et secondaires seules, ou en combinaison avec d'autres types d'écoles, par conséquent l'ampleur de l'effet varie selon les études. En outre, l'impact relatif des fermetures et réouvertures des écoles variera en fonction du moment de leur mise en œuvre, du niveau de transmission communautaire et de la structure des populations des différents pays. Dans

l'ensemble, la confiance dans ces preuves est faible étant donné que les études varient en fonction de plusieurs facteurs et ont été menées à des moments différents dans un certain nombre de pays.

Une importante lacune dans les connaissances à prendre en compte est la manière dont les nouvelles variantes préoccupantes et le déploiement de la vaccination contre la COVID-19 auront un impact sur la transmission de la COVID-19 dans les écoles et la communauté. Les données de cette étude datent d'avant l'introduction des variantes préoccupantes, on ne sait donc pas comment cela influencera l'efficacité des fermetures des écoles ou l'impact de l'ouverture des écoles sur la propagation de la COVID-19.

CONTENU

ÉTUDES OBSERVATIONNELLES

Cinq études observationnelles ont évalué l'impact des fermetures/réouvertures des écoles sur la transmission de la COVID-19 dans les écoles en utilisant des données au niveau individuel (tableau 1). Les mesures PCI mises en œuvre par les écoles étaient similaires dans la plupart des études observationnelles : masques, distance physique, nettoyage fréquent, classes de taille réduite et hygiène des mains. Une étude de cohorte n'a pas indiqué si des mesures PCI avaient été mises en œuvre ou non en milieu scolaire (14). La mise en œuvre de mesures PCI dans les écoles peut agir comme une variable médiatrice avec les résultats de ces études en raison de sa capacité à réduire la transmission et le risque d'infection.

- Quatre études n'ont trouvé que peu ou pas d'impact de la fermeture ou de la réouverture des écoles sur la transmission de la COVID-19 dans les écoles et la communauté :
    - Une étude de cohorte prospective qui a analysé l'association entre les dates de réouverture des écoles et les cas de COVID-19 dans vingt et une régions d'Italie a révélé que l'incidence du SRAS-CoV-2 chez les étudiants était inférieure à celle de la population générale dans 19 des 21 régions (16).
    - Une étude de cohorte rétrospective n'a trouvé aucune de preuve de transmission dans les écoles avant la fermeture des écoles, malgré plusieurs introductions et analyses de COVID-19. Les taux d'attaque de l'infection (TAI) chez les membres de la famille et les proches par rapport aux enseignants et au personnel des élèves infectés et non infectés montrent que la plupart des infections ont probablement été contractées au sein du foyer (15).
    - Une étude transversale comparant les enfants d'un groupe scolaire soumis à une surveillance stricte et d'un groupe restant à la maison n'a révélé aucune différence significative dans le nombre de cas de SRAS-CoV-2 chez les enfants de chaque groupe (18).

- Une étude d'enquête par grappes a rapporté un très faible taux d'attaque global après la réouverture des écoles, mais qu'il était plus élevé dans les écoles secondaires (6,6 %) que dans les écoles primaires (0,38 %) (17).
- Une épidémie importante a été signalée dans un lycée de Jérusalem, mais elle a été compliquée par le fait que le port du masque a été levé en raison d'une vague de chaleur peu après la réouverture (34).

Tableau 1 : Études observationnelles évaluant l'impact de la fermeture ou de la réouverture des écoles sur la transmission de la COVID-19 dans les écoles et la communauté (n=5)

ÉTUDE	MÉTHODE	PRINCIPAUX RÉSULTATS
Études de cohorte (n=2)		
Gandini (2020) *préimpression* (16) Étude de cohorte prospective et étude transversale Italie Sep-Nov 2020	Cette étude a analysé l'association entre les dates de réouverture des écoles et les cas de COVID-19 dans vingt et une régions italiennes en utilisant une base de données sur les cas positifs dans les écoles primaires, les collèges et les lycées. Les mesures PCI comprenaient : contrôle de la température, hygiène des mains, obligation de porter un masque pour les élèves et le personnel, éloignement physique, interdiction de faire du sport et de la musique et réduction de la durée de l'école. Plusieurs résultats sur la COVID-19 ont été mesurés pendant la réouverture des écoles : croissance de l'incidence, nombre de reproduction (R_t) et infections secondaires.	• Rien n'indique que la deuxième vague de SRAS-CoV-2 ait été provoquée par la réouverture des écoles dans les régions. • L'incidence du SRAS-CoV-2 chez les étudiants était inférieure à celle de la population générale dans toutes les régions italiennes sauf deux. • L'augmentation du nombre de reproductions R_t n'était pas associée aux différentes dates d'ouverture des écoles. • Les fermetures des écoles mises en œuvre dans deux régions n'ont pas affecté le déclin de la R_t.
Fontanet (2020) *préimpression* (15) Étude de cohorte rétrospective France Fév-Avril 2020	Cette étude de cohorte rétrospective a inclus des élèves des écoles primaires, des enseignants, du personnel non enseignant, des parents et des proches exposés au SRAS-CoV-2 en février et mars dans 6 écoles. Les mesures PCI n'ont pas été décrites. Un questionnaire couvrant les informations sociodémographiques et l'historique des symptômes récents a été rempli par les participants. Les échantillons de sang ont également été testés pour la présence d'anticorps anti-SARS-CoV-2 en utilisant un	• Le TAI était de 45/510 (8,8 %), 3/42 (7,1 %), 1/28 (3,6 %), 76/641 (11,9 %) et 14/119 (11,8 %) chez les élèves de l'école primaire, les enseignants, le personnel non enseignant, les parents et les proches, respectivement (P = 0,29). • Aucune infection secondaire due à l'introduction de la COVID-19 dans les écoles n'a été détectée. • Parmi les élèves infectés, leurs parents étaient significativement plus susceptibles d'être infectés (61,0 % contre 6,9 % ; P <0,0001), La même chose a été identifiée parmi les parents

	biotest basé sur la cytométrie en flux. Trois introductions du SRAS-CoV-2 ont eu lieu avant la fermeture des écoles. La propagation au sein des écoles et des familles a été étudiée dans cette étude séroépidémiologique. Le taux d'attaque de l'infection (TAI) a été comparé entre les contacts scolaires et les contacts familiaux afin de comprendre l'impact potentiel de la fermeture de l'école.	des élèves infectés par rapport aux élèves non infectés (44,4 % contre 9,1 % ; P = 0,002) • La transmission ne semble pas avoir été affectée par la fermeture des écoles.
Études transversales (n=1)		
Kriger (2020) (18) Étude transversale Israël Mars-Mai 2020	Lors d'un confinement national, une autre école a été utilisée pour les enfants des travailleurs de la santé, avec une surveillance stricte des symptômes. Les familles dont les enfants sont restés à la maison ont été comparées aux enfants de cette école alternative. Les mesures PCI dans l'école comprenaient : une désinfection quotidienne, le port d'un masque facial par le personnel et le lavage fréquent des mains. Cette étude transversale a inclus 70 enfants qui ont fréquenté l'autre école primaire et 36 qui sont restés à la maison, ainsi que leurs 78 parents. Les données ont été recueillies au moyen d'un court questionnaire ; des écouvillons nasopharyngés et oropharyngés ont été obtenus et testés pour le SARS-CoV-2 par RT-PCR, et du sang a été prélevé pour les titres IgA et IgG du SARS-CoV-2.	• Des symptômes ont été signalés chez environ 16 % des enfants des deux groupes : ceux qui fréquentaient l'école (11/70) et ceux qui ne la fréquentaient pas (6/36). • Des tests sérologiques positifs montrant une exposition antérieure ont été détectés dans moins de 2 % de chaque groupe et ils n'étaient pas significativement différents les uns des autres. • Il n'y avait aucune preuve d'une augmentation de l'infection chez les enfants scolarisés par rapport aux enfants à domicile.
Enquêtes sur les grappes et les épidémies (n=2)		
Larosa (2020) (17) Enquête sur les grappes Italie Sep-Oct 2020	Cette enquête sur les grappes a analysé la transmission de la COVID-19 dans 41 classes de 36 écoles lors de leur réouverture dans le nord de l'Italie. Le taux d'attaque secondaire a été mesuré chez les élèves et les enseignants des écoles primaires et secondaires (collèges et lycées). Les mesures du PCI comprenaient : le port d'un masque réservé aux élèves du secondaire, l'éloignement physique et l'interdiction des activités extrascolaires.	• Le taux d'attaque de la COVID-19 serait plus élevé dans les écoles secondaires (6,6 %) que dans les écoles primaires (0,38 %).

Stein-Zamir (2020) (34) Enquête sur les épidémies Israël Mai-Juin 2020	Cette étude d'enquête sur les épidémies a évalué les caractéristiques épidémiologiques d'une épidémie survenue dans un lycée de Jérusalem qui a présenté une transmission massive de la COVID-19 à la réouverture de l'école le 17 mai. Le lycée comprenait les classes de la 7 à la 12 années. Une vague de chaleur extrême s'est produite lors de la réouverture de l'école. Mesures PCI : le port du masque facial a été levé pendant 3 jours durant la canicule, l'éloignement physique était inférieur à la norme dans les classes surchargées et les activités périscolaires n'ont pas été interdites.	• Il a été rapporté que la proportion des 10-19 ans était de 19,8 % (938/4 747) des cas avant le 24 mai, puis a augmenté à 40,9 % (316/772) après cette même date. • Les tests effectués sur l'ensemble de l'école ont révélé que 153 élèves (taux d'attaque : 13.2 %) et 25 membres du personnel (taux d'attaque : 16.6 %) étaient des cas positifs de la COVID-19. • Les taux de COVID-19 étaient plus élevés dans les classes de 7e à la 9e année que dans les classes de la 10e à la 12e année.

IC = intervalle de confiance, INP = intervention non pharmaceutique, Rt = nombre effectif de reproductions, ES = erreur standard, p = valeur p, PCI = prévention et contrôle des infections

ÉTUDES ÉCOLOGIQUES

Dix-neuf études écologiques ont été identifiées pour évaluer l'impact de la fermeture ou de la réouverture des écoles sur la propagation de la COVID-19 (tableau 2). Toutes les études écologiques du tableau 2 utilisent des données au niveau de la population pour estimer l'efficacité de la fermeture ou de la réouverture des écoles sur la prévention de la propagation de la COVID-19 dans la communauté.

Dans l'ensemble, les résultats des études écologiques évaluant la transmission communautaire sont mitigés (n=19) :

- Cinq études ont rapporté que les fermetures et réouvertures des écoles n'étaient pas significativement associées à une réduction de la transmission et de l'incidence de la COVID-19 :
    - Dans une étude japonaise, la fermeture des écoles primaires et secondaires ne s'est pas avérée efficace pour réduire l'incidence de la COVID-19 (21).
    - Une étude écologique menée en Allemagne n'a révélé aucun effet significatif sur les infections qui pourrait être attribué à la fermeture des écoles et garderies (22).
    - La transmission d'enfant à enfant dans les écoles primaires, secondaires et les structures d'accueil en Allemagne était faible et la réouverture des écoles n'était pas associée à une modification de la transmission (23).
    - Une étude mondiale a révélé que les fermetures d'écoles étaient moins efficaces que les autres INP(19).

  - Une étude américaine a montré que la fermeture des écoles avait la plus faible réduction sur l'incidence de la pauvreté par rapport à 6 autres INP qui ont été évaluées (20).
- Quatre études ont rapporté une réduction de l'incidence de la COVID-19 allant de 8 % à 62 % suite à la fermeture des écoles (24-27). Trois études ont rapporté une réduction significative de la Rt :
  - Une étude mondiale a estimé une réduction globale de l'infection de 12 % avec la fermeture des établissements d'enseignement primaire, secondaire et tertiaire (28).
  - Une étude américaine a montré que la fermeture d'établissements d'enseignement était associée à une réduction significative de la Rt par rapport aux États n'ayant pas adopté cette politique (29).
  - Une étude réalisée à Hong Kong a fait état d'une réduction de 44 % de la transmission pendant les deux premières semaines de fermeture des écoles, y compris les écoles maternelles, les établissements d'enseignement supérieur et postsecondaire et les centres de tutorat (30).
- Trois études ont fait état de réductions significatives de la mortalité en cas de fermeture des écoles (27, 31, 32) et une étude a signalé une augmentation de la mortalité en cas de fermeture tardive des écoles (33).

Tableau 2 : Études écologiques évaluant l'efficacité de la fermeture ou de la réouverture des écoles sur la réduction de la propagation de la COVID-19 dans la communauté (n=19)

ÉTUDE	MÉTHODE	PRINCIPAUX RÉSULTATS
Global (n=10)		
An (2021) *préimpression* (19) Étude écologique Global Jan-Jul 2020	Cette étude visait à identifier les associations entre six INP et le nombre d'infections par la COVID-19. À l'aide de données mondiales sur les INP et les infections de COVID-19 entre janvier et juillet 2020, une analyse a été menée sur les effets à court et à long terme des INP sur les taux de nouvelles infections 5, 9, 12 et 21 jours après leur adoption. Les mesures PCI et le niveau de scolarité inclus dans l'étude n'ont pas été décrits. Les INP examinées comprenaient les mandats de port de masque, les restrictions aux voyages internationaux, les confinements nationaux, les interdictions de rassemblement de masse, les fermetures de restaurants et les fermetures d'écoles.	• Les fermetures des écoles ont mis plus de temps que les autres INP à montrer leur efficacité. Après un décalage temporel, l'impact de la fermeture des écoles sur les taux de nouveaux cas était de -0,492 (ES=0,16) à 12 jours (p<0,01), -0,722 (ES=0,148) à 21 jours (p<0,001) et -0,824 (ES=0,0967) à 30 jours (p<0,001). • Les fermetures des écoles n'ont pas eu d'effets significatifs sur les infections ajustées à la population à long terme (90^{e} à 120^{e} jour).

Banholzer (2020) *préimpression* (25) Étude écologique 20 pays Avril 2020	Dans cette étude, l'impact des INP sur la réduction relative des nouveaux cas de COVID-19 en utilisant un modèle hiérarchique bayésien avec un effet différé dans le temps pour chaque INP. Les mesures PCI n'ont pas été décrites. Les INP examinés sont les suivants : (1) fermetures des écoles primaires, (2) fermetures de frontières, (3) interdictions d'événements publics, (4) interdictions de rassemblements, (5) fermetures de lieux, (6) confinements interdisant les mouvements publics sans raison valable, et (7) interdictions de travail pour les activités commerciales non essentielles.	• La réduction moyenne des nouveaux cas de COVID-19 avec la fermeture des écoles primaires était de 8 % (IC 95 % : 0 à 23 %). • Par rapport aux autres INP examinées, la fermeture des écoles semble être l'une des INP les moins efficaces.
Banholzer (2021) *préimpression* (24) Étude écologique 20 pays Fév-Mai 2020	En utilisant un modèle hiérarchique bayésien semi-mécanique, cette étude visait à mesurer l'efficacité de sept INP dans la réduction du nombre de nouvelles infections. Les mesures PCI n'ont pas été décrites. Les INP examinés sont les suivants : (1) fermetures des écoles primaires, (2) fermetures de frontières, (3) interdictions d'événements publics, (4) interdictions de rassemblements, (5) fermetures de lieux, (6) confinements interdisant les mouvements publics sans raison valable, et (7) interdictions de travail pour les activités commerciales non essentielles.	• La réduction relative des nouveaux cas de COVID-19 avec la fermeture des écoles primaires était de 17 % (IC 95 % : 2 % à 36 %). • Cette réduction était inférieure à celle de deux autres INP : les interdictions d'événements et les fermetures de lieux.
Brauner (2021) (26) Étude écologique 41 pays Janvier-Mai 2020	Cette étude a estimé l'efficacité des INP dans 41 pays à l'aide d'un modèle hiérarchique bayésien en reliant les dates de mise en œuvre de l'intervention aux comptages nationaux des cas et des décès. Les tailles d'effet des interventions ont été catégorisées par les réductions médianes du nombre de reproductions R_t de <17.5 % (petit), entre 17,5 et 35 % (modéré), et >35 % (important).</17,5 %> Les INP examinées comprenaient : la limitation des rassemblements à <1000 ou <100, ou <10, la fermeture de certaines entreprises, la	• Le pourcentage de réduction de la R_t associé à la fermeture conjointe des écoles et des universités était de 38 % (IC 95 % : 16 à 54 %), ce qui a été classé comme une taille d'effet importante. • Les effets individuels des fermetures d'écoles n'ont pas été mesurés.

	fermeture de la plupart des entreprises, la fermeture des écoles et des universités, et l'ordre de rester à la maison. Les mesures PCI n'ont pas été décrites.	
Klimek-Tulwin (2020) (35) Étude écologique Global Mars 2020	Cette étude visait à évaluer l'effet de la fermeture des écoles sur les cas de COVID-19 au niveau mondial en mesurant la corrélation entre le taux d'incidence le jour de la fermeture de l'école et le taux d'incidence les jours suivants. Les mesures PCI et le niveau de scolarité inclus dans l'étude n'ont pas été décrits.	• Les résultats indiquent qu'il existe une forte corrélation entre le jour de la fermeture des établissements d'enseignement et le taux d'incidence dans les jours suivants (26^{e} [p = 0,004], 30^{e} [p = 0,002] et 60^{e} [p = 0,031] jours depuis le 100^{e} cas confirmé dans chaque pays). • La fermeture précoce des écoles est corrélée de manière statistiquement significative avec des taux d'incidence plus faibles au cours des différentes phases de l'épidémie.
Papadopoulos (2020) *préimpression* (36) Étude écologique Global Janvier-Avril 2020	L'impact des mesures de confinement a été évalué au niveau mondial à l'aide de données accessibles au public. Le moment et l'association des INP précoces avec les décès nationaux log10 (LogD) et les cas nationaux log10 (LogC) ont été comparés entre les nations. Les mesures PCI et le niveau de scolarité inclus dans l'étude n'ont pas été décrits.	• Fermeture généralisée précoce des écoles (p=0,050, coefficient de régression β=-0,012, IC 95 % : 0 à -0,024) était associée à une réduction du LogC (log10 des cas nationaux).
Pasdar (2020) *préimpression* (32) Étude écologique 22 pays Mai 2020	L'objectif de cette étude était de déterminer les associations entre les INP et les résultats de la COVID-19. Les associations avec les INP ont été évaluées à l'aide de leur indice de rigueur (irr) respectif sur plusieurs résultats qui forment la courbe épidémique : taux de mortalité moyen, temps jusqu'au pic, décès au pic pour 100 000 habitants, décès cumulés après le pic pour 100 000 habitants et rapport entre la pente	• Les fermetures d'écoles ont été efficaces pour tous les résultats, à l'exception du temps nécessaire pour atteindre le pic de la courbe épidémique. • L'association la plus forte a été observée dans les décès cumulés après le pic, pour 100 000 (irr = -0,744, p = 0,009). • Dans les pays non européens, la fermeture des écoles a été la plus

	moyenne de la courbe descendante et la pente moyenne de la courbe ascendante. Les mesures PCI et le niveau de scolarité inclus dans l'étude n'ont pas été décrits.	efficace contre le taux de mortalité moyen (irr = -0,757, p = 0,049).
Esra (2020) *préimpression* (28) Étude écologique Global Janvier-Mai 2020	Cette étude a utilisé les données rapportées au niveau mondial sur les cas de SRAS-CoV-2 pour adapter un cadre de modèle bayésien afin d'estimer l'association avec les INP et la transmission. Les INP examinées comprennent les mandats de rester à la maison, les limites de rassemblement, les fermetures d'écoles (établissements d'enseignement primaire, secondaire et tertiaire) et les politiques de port des masques. Les mesures PCI n'ont pas été décrites.	• Il y a eu une réduction moyenne estimée de la Rt de 12 % (IC 95 % : 5-19 %) avec des fermetures d'écoles (établissements d'enseignement primaire, secondaire et tertiaire).
Jüni (2020) (37) Étude écologique Global Mars 2020	Cette étude prospective de zones géopolitiques visait à déterminer si les interventions climatiques ou de santé publique sont associées à la réduction de la transmission du COVID-19. Une régression pondérée des effets aléatoires a été utilisée pour déterminer l'association entre la croissance de l'épidémie (ratios de taux [RT]) et les mesures climatiques et les interventions de santé publique telles que les fermetures des écoles, les restrictions des rassemblements de masse et les mesures de distanciation sociale au cours d'une période d'exposition 14 jours auparavant. Les mesures PCI et le niveau de scolarité inclus dans l'étude n'ont pas été décrits.	• Des associations négatives fortes avec la croissance épidémique ont été trouvées pour les fermetures des écoles (RT - 0,63, IC 95 % : 0.52 à 0,78). • Cette association était plus prononcée dans les zones qui ont mis en œuvre 2 ou 3 INP par rapport à 1 INP.

Stokes (2020) *préimpression* (31) Étude écologique Global Juin 2020	Cette étude a examiné la variation des INP dans 130 pays sur deux périodes : 1) avant le premier décès par COVID-19 et 2) 14 jours après le premier décès par COVID-19. Cette étude a examiné les associations avec les décès quotidiens par million de COVID-19 et chaque période de 24 jours (temps entre la transmission du virus et la mortalité). Les mesures PCI et le niveau de scolarité inclus dans l'étude n'ont pas été décrits.	• Les fermetures d'écoles plus strictes/précoces ont été associées aux réductions les plus importantes du nombre de décès par COVID-19 (-1,23 par million [IC 95 % : -2,20 à -0,27]) par rapport aux autres INP.
Amérique du Nord (n=5)		
Auger (2020) (27) Étude écologique É-U Mars-Mai 2020	Cette étude visait à déterminer si la fermeture des écoles était associée à une diminution de l'incidence cumulée du COVID-19 et de la mortalité. L'impact des fermetures d'écoles primaires et secondaires a été évalué à l'aide de données publiques disponibles dans les 50 États. Les mesures PCI n'ont pas été décrites.	• Les résultats ont montré que la fermeture des écoles était associée à une baisse significative de l'incidence de la COVID-19 (-62 % [IC 95 % : -71 % à -49 %]) et de la mortalité (-58 % [IC 95 % : -68 % à -46 %]). • Ces associations étaient plus fortes dans les états ayant une faible incidence cumulée de COVID-19 au moment de la fermeture de l'école.
Dreher (2020) *préimpression* (29) Étude écologique É-U Avril 2020	Cette étude visait à mesurer l'impact des INP sur le nombre effectif de reproductions (R_t) de COVID-19 dans les états américains. Le R_t moyen a été mesuré pendant les semaines suivant l'atteinte de 500 cas par chaque état. R_t a été mesuré à la semaine suivant immédiatement le 500^e cas (jours +1 à +7) et à une semaine de retard par rapport au 500^e cas (jours +8 à +14). Les INP examinées sont les suivantes : ordre de rester à la maison, fermeture d'établissements d'enseignement et fermeture d'entreprises non essentielles. Les mesures PCI et le niveau de scolarité inclus dans l'étude n'ont pas été décrits.	• La fermeture des établissements d'enseignement était associée à une réduction significative de la R_t par rapport aux États sans cette politique la semaine suivant 500 cas (ß = -0,17, IC 95 % : -0,30 à -0,05, p = 0,009). • Du 8^e au 14^e jour après la 500^e date de cas, la fermeture des établissements d'enseignement était associée à une réduction significative de R_t par rapport aux témoins (ß = -0,12, IC 95 % : -0,21 à -0,04, p = 0,006).

Krishnamachari (2020) *préimpression* (38) Étude écologique É-U Mai 2020	Cette étude visait à examiner les effets des INP sur les taux d'incidence cumulée du COVID-19 aux États-Unis au niveau des 25 villes les plus peuplées, tout en ajustant les facteurs de risque sociodémographiques. Une régression binomiale négative a été utilisée pour calculer les ratios de taux ajustés en comparant deux niveaux d'une variable binaire : « valeur supérieure à la médiane », et « valeur médiane et inférieure » pour les jours de mise en œuvre d'un INP. Les INP évalués dans cette étude comprennent : les jours de fermeture des commerces non essentiels, les jours d'ordre de rester à la maison, les jours de restriction des rassemblements, les jours de fermeture des restaurants et les jours de fermeture des écoles. Les mesures PCI et le niveau de scolarité inclus dans l'étude n'ont pas été décrits.	• Le nombre de jours avant la fermeture de l'école était associé à l'incidence cumulée aux jours 35 et 42, avec un rapport de taux ajusté de 1,59 (IC 95 % : 1.03 à 2,44, p=0,04) à 35 jours, et ratio de taux ajusté de 1,64 (IC 95 % : 1.07 à 2,52, p=0,04) à 42 jours. • Le retard dans la fermeture des écoles était positivement associé à l'incidence cumulée au niveau de l'État.
Liu (2020) *préimpression* (20) Étude écologique É-U Févr-Avril 2020	Cette étude a estimé l'impact de neuf INP différents sur la réduction du nombre effectif de reproductions (Rt) en utilisant le nombre quotidien de nouveaux cas signalés et d'infections déduites dans 50 États. Les mesures PCI et le niveau de scolarité inclus dans l'étude n'ont pas été décrits.	• On a constaté que la fermeture des écoles réduisait modérément d'environ 10 % (IC 95 % : 7 %-14 %). • Cette réduction était inférieure à celle de six autres INP évalués (ordre de rester à la maison, masques faciaux, interdiction de rassemblement, fermeture d'entreprise non essentielle, déclaration de l'état d'urgence et restriction des déplacements entre États).
Yehya (2020) (33) Étude écologique É-U Janvier-Avril 2020	Dans cette étude, une analyse au niveau de l'État a été réalisée pour déterminer l'association entre les INP mis en œuvre plus tard et les taux de mortalité plus élevés. À l'aide d'une régression binomiale négative multivariable, l'association entre le moment de la déclaration de l'état d'urgence et de la fermeture des écoles et la mortalité à 28 jours a été testée. Le jour 1 pour chaque État a été fixé au moment où ils ont enregistré ≥ 10 décès. Les mesures PCI et le niveau de	• La fermeture plus tardive des écoles a été associée à un plus grand nombre de décès (ratio de taux de mortalité ajusté aMRR 1,05 ; IC 95 % : 1.01 à 1,09 ; p = 0,008).

	scolarité inclus dans l'étude n'ont pas été décrits.	
Asie (n=2)		
Cowling (2020) (30) Étude écologique Hong Kong Janv.-Févr. 2020	Cette étude a examiné l'effet des interventions de santé publique sur l'incidence de la COVID-19 et sur le nombre de reproductions effectif quotidien (R_t). Les cas de COVID-19 confirmés en laboratoire et le nombre de reproductions effectif quotidien (R_t) ont été estimés pour estimer les changements de transmissibilité dans le temps. Les fermetures d'écoles ont concerné les garderies jusqu'aux établissements d'enseignement supérieur et postuniversitaire, ainsi que les centres de tutorat. Les mesures PCI n'ont pas été décrites.	• Le R_t estimé était de 1,28 (IC 95 % : 1.26-1,30) au cours de la période de deux semaines précédant le début de la fermeture des écoles et 0,72 (IC 95 % : 0,70-0,74) pendant les 2 premières semaines de fermeture des écoles, ce qui correspond à une baisse de 44 % (IC 95 % : 34-53 %) de réduction de la transmissibilité • Le R_t calculé à partir des données d'hospitalisation était de 1,10 (1,06-1,12) avant le début des fermetures d'écoles et a diminué à 0,73 (0,68-0,77) après les fermetures des écoles, ce qui correspond à une réduction de 33 % (IC 95 % : 24-43 %) de réduction de la transmissibilité.
Kentaro (2020) (21) Étude écologique Japon Mars 2020	Cette étude visait à évaluer l'efficacité de la fermeture des écoles primaires et secondaires sur l'incidence du COVID-19 neuf jours après sa mise en œuvre. Les mesures PCI n'ont pas été décrites. En utilisant une méthode bayésienne, des analyses de séries chronologiques ont été effectuées et des modèles de tendances linéaires locales ont été développés pour le nombre de nouveaux cas de COVID-19 ont été développés pour le nombre de nouveaux cas de COVID-19.	• L'intervention de fermeture de l'école n'a pas été efficace pour diminuer l'incidence de la COVID-19. • Les cas de COVID-19 nouvellement signalés ont continué à augmenter (α - 0,08, IC 95 % : -0.36 à 0,65).
Europe (n=2)		

Wieland (2020) (22) Étude écologique Allemagne Mars-Avril 2020	L'objectif de cette étude était d'évaluer l'efficacité de différentes INP contre la propagation de la COVID-19 sur un certain temps. Les fermetures des écoles incluent également les fermetures de garderies. Les mesures PCI n'ont pas été décrites. À l'aide de données accessibles au public sur les cas quotidiens signalés en Allemagne, des modèles de croissance exponentielle pour les infections et les nombres de reproductions ont été estimés et étudiés par rapport aux points de changement dans la série chronologique.	• On n'a pas trouvé d'effet significatif sur les infections à COVID-19 qui pourrait être attribué à la fermeture des écoles et des garderies.
Ehrhardt (2020) (23) Étude écologique Allemagne Févr. — août 2020	Cette étude visait à évaluer la transmission du SRAS-CoV-2 chez les enfants des écoles primaires, des écoles secondaires et des structures d'accueil du Baden-Württemberg, en Allemagne, après la réouverture des écoles en mai. Les mesures du PCI comprenaient : la réduction de la taille des classes, la désinfection, l'hygiène des mains et l'interdiction du sport et de la musique dans les écoles primaires et secondaires. Une courbe épidémique a été utilisée pour montrer les nouveaux cas quotidiens après la réouverture des écoles.	• La transmission d'enfant à enfant dans les écoles était faible. • L'étude a estimé qu'un cas secondaire est généré pour 25 jours d'école infectieuse (jours que les cas ont passé à l'école pendant la période infectieuse). • La réouverture des écoles n'a pas été associée à une modification de la transmission du SRAS-CoV-2.

IC = intervalle de confiance, INP = intervention non pharmaceutique, Rt = nombre effectif de reproductions, ES = erreur standard, p = valeur p, PCI = prévention et contrôle des infections

Méthodes :

Une analyse quotidienne de la littérature (publiée et prépubliée) est effectuée par le Groupe des sciences émergentes de l'ASPC. L'analyse a compilé la littérature sur la COVID-19 depuis le début de l'épidémie et est mis à jour quotidiennement. Les recherches pour retrouver la littérature pertinente sur la COVID-19 sont effectuées dans Pubmed, Scopus, BioRxiv, MedRxiv, ArXiv, SSRN, Research Square et croisées avec les centres d'information sur la COVID-19 gérés par Lancet, BMJ, Elsevier, Nature et Wiley. Le résumé quotidien et les résultats de l'analyse complète sont conservés dans une base de données Refworks et dans une liste Excel qui peut être consultée. Une recherche ciblée par mots-clés a été menée dans ces bases de données afin d'identifier les citations pertinentes sur la COVID-19 et SARS-COV-2. Les termes de recherche comprenaient : école ET fermeture OU réouverture. Les références ont également été utilisées pour rechercher d'autres études pertinentes. La recherche documentaire s'est limitée aux langues anglaise et française. Cette revue contient les recherches publiées jusqu'au 25 janvier 2021. Chaque référence potentiellement pertinente a été

examinée pour confirmer qu'elle contenait des données pertinentes et les données pertinentes ont été extraites dans l'examen.

Révision par les pairs

Le présent document a fait l'objet d'une révision par les pairs, par un expert en la matière, ainsi que d'un examen rédactionnel et d'un examen des aspects scientifiques et politiques par le Bureau du directeur scientifique.

Préparé par : Maryem El Jaouhari. Bureau des programmes et de la planification de la biosécurité, DGISS, ASPC.

Emerging Evidence on COVID-19

Evidence Brief on the Risk of COVID-19 Transmission in Flight, Update 2

Introduction

What is the evidence on transmission of COVID-19 during air travel and on assessing the risk and mitigation strategies around air travel?

Many changes have been implemented by airlines during the pandemic to reduce the risk of SARS-CoV-2 transmission during air travel. This evidence brief summarizes the literature on in-flight transmission of SARS-CoV-2, the characteristics of these events and the strategies used or studied to mitigate transmission in an airplane or during boarding and disembarkation. The first update of this review contained literature published up to October 28, 2020. This is the second update and includes studies up until April 26, 2021.

What's New

- Twenty-nine additional studies were added in this update (published between Oct 28, 2020 and Apr 26, 2021; nine new flight investigations (Table 1), nine reviews and risk assessments on in-flight transmission (Table 2) and eleven new simulation studies on reduction of respiratory virus spread and the relative impact of mitigation strategies during air travel (Table 3). These new studies bring the total number of studies included in this review to 64.

- Several studies estimated attack rates that varied depending on the proximity to the infected case when seated on the airplane. Estimates varied, but the attack rates were consistently low, particularly with mandatory face masks.

- Four risk assessments were added to this update and provide estimated overall probabilities of acquiring COVID-19 during a flight at different points in the pandemic. These estimates varied widely depending on the data used, assumptions of the model and whether or not the model accounted for under-reporting of in-flight transmission.

Key Points

- Twenty-six flight investigations (contact tracing or cohorts) were identified, of these nine reported no secondary cases (five on repatriation and four on commercial flights) and seventeen reported likely transmission from in-flight exposure. Whole genome sequencing results were available for five investigations and aided in linking cases to an on-flight single exposure. Implications of emerging Variants of Concern were not addressed in any of the captured studies.

- The overall attack rate of SARS-CoV-2 among passengers on short to medium-haul flights (1.5-2.5 hours long) was low.
- No transmissions from passengers to crew or between crew members were documented on repatriation flights.
- Most in-flight transmission events occurred on flights without mandatory face masks. Transmission was primarily passenger to passenger, although four studies reported transmission event(s) from passenger to crew. On flights with mandatory mask use, some transmission events occurred that were thought to be due to either incorrect mask use (e.g., not covering the nose) or to the removal of a mask to eat or drink.
- Symptom and temperature checks were conducted on some flights. Lack of adherence by passengers to self-report symptoms led to transmission on at least one flight.
- Proximity to an index case (two-row radius) was a risk factor in investigations where seating charts were available.
- The most common enhanced public health measures were in-flight physical distancing, enhanced cleaning, mandatory face masks, hand hygiene, physical distancing during boarding and disembarking, designated crew only areas, and quarantine areas for unwell passengers. One survey of passengers and crew indicated that both the passengers and crew felt safer after implementation of enhanced safety measures to curb transmission and felt that most measures were feasible to implement, apart from physical distancing of 1.5-2m while in-flight.

- Mitigating the risk of SARS-CoV-2 transmission during air travel was discussed directly in 14 reviews and risk assessments (Table 2) and indirectly in 24 reviews, predictive models, simulation experiments, environmental monitoring studies and *in silico* studies (Table 3).
  - The key findings of the SARS-CoV-2 literature on transmission during flights is that multiple interventions are needed to maximally reduce the risk of transmission (Table 2); this is summarized well in the Appendix figure from the Aviation Public Health Initiative report lead by Harvard (1).
    - A meta-analysis found that from January–June 2020, the risk of being infected with SARS-CoV-2 in an airplane cabin was estimated to be 1 case for every 1.7 million travelers.
    - The longer the duration of the flight, the higher the infection risk. Removing masks for meal service led to increased risk.
    - Public health measures to maintain physical distancing during boarding, disembarkation and in-flight, enhanced cleaning, hand hygiene and universal mask use for duration of flight implemented in a layered approach significantly reduce the risk of transmission.

- Airplane ventilation systems are designed to quickly refresh cabin air and this level of ventilation substantially reduces the time particles remain in the cabin compared to other indoor environments and thus reduces the opportunity for transmission, particularly when coupled with other public health measures (Table 2 & 3).
- Adherence to public health measures by passengers and crew are a critical factor to the impact of these measures to reduce the risk of transmission, such as symptom screening guidelines and on-board procedures.

- The indirect literature investigates the aerodynamics of droplets and aerosols to characterize high risk situations, or simulates boarding and in-flight movements to suggest strategies for minimizing interaction of people and maximizing the distance between people in flight (Table 3).
  - In-flight particle concentrations in the air in airplanes are lower than that of retail/grocery stores, restaurants, office spaces, homes, and other forms of transport.
  - Passengers who sneeze or cough while standing or moving about the cabin spread their respiratory droplets considerably further than those seated.
  - Wearing a face mask significantly decreased the spread of droplets (>90%).
  - Boarding an airplane by groups of related individuals, those seated in back of plane and window seats first as well as other more complicated algorithms were shown to reduce the interaction with other people. Decreasing the amount of carry-on luggage was also found to reduce interactions on-board. Although some strategies such as increasing the number of boarding groups or social distancing may sacrifice efficiency (i.e., longer total boarding/disembarkation time), they can significantly reduce the risk of infection.
  - Grouping families and strategically spacing passengers on flights that are not at capacity improves physical distance between passengers. Algorithms developed by researchers were presented to maximize this concept and demonstrated the potential performance of these algorithms compared to middle seat empty or aisle seat empty strategies. Across all of these strategies, their effectiveness decreased on fuller airplanes.

Overview of the Evidence

The in-flight transmission events recorded across studies were investigated through contact tracing investigations and cohorts. The cluster/outbreak investigations are at risk of bias due to their retrospective and descriptive nature. Cohorts were available for repatriation flights and are at lower risk of bias because the passengers and crew were followed-up in a uniform manner for a specific time period.

Other types of evidence include review literature ranging from good quality systematic reviews to commentaries. There was good agreement in the information and recommendations across the different review literature.

Quantitative risk assessments, predictive models, simulation experiments and other *in silico* studies were highly variable in their objectives and approaches. No attempt to assess the validity of these studies was conducted. These studies aim to mimic a real world scenario usually to explore options for different interventions. Their results should be interpreted with caution as they may not reflect what would happen in a field setting.

There were only a small number of flights for which epidemiological investigations of possible transmission events had been undertaken. These events are likely under-reported and/or under-investigated due to the logistics and available resources for contact tracing. It is also difficult to classify instances of in-flight transmission as acquisition of SARS-CoV-2 may occur prior to departure, at various points during travel, or during quarantine/upon arrival. Whole genome sequencing may help in linking cases to an on-flight single exposure. Future investigations, risk assessments, and predictive models should also address the implications that emerging SARS-CoV-2 variants and their attributes (e.g., increased transmissibility) may have on in-flight transmission risk, as well as vaccination status of both travellers and airline staff in mitigating risk.

CONTENTS

TRANSMISSION EVENTS ON AIRPLANES

The full extent of COVID-19 exposure associated with airplanes is not known. The table below lists 26 studies (9 are new since the last review update) where the possibility of in-flight SARS-CoV-2 transmission was investigated. Seventeen report transmission occurred and 9 report no transmission occurred during the flights. Several studies of repatriation flights where many precautions were taken report no transmission to the crew (2-7).

Symptom and temperature screening at the airport were mentioned in a few investigations. The failure of individuals to self-report and adhere to the screening guidelines demonstrate that screening was not an effective control measure on its own; it needs to be used in conjunction with other precautions. This was

demonstrated well in the business class outbreak reported by Khanh et al. (2020) where one index case caused 15 secondary cases on a flight where masks were not mandatory (8).

Many of the larger transmission events occurred before the mandatory use of face masks on flights (8-11) or other risk reduction strategies had been implemented. There are also a few instances where transmission events occurred even though face masks were mandatory (12-15). Investigations that examined adherence and proper use of face masks during these transmission events, reported both incorrect use of the mask (e.g., not covering the nose) and eating and drinking on the plane for a period of time when the mask was removed. One epidemiological investigation suggested in-flight SARS-CoV-2 transmission from a passenger to a flight attendant and then secondary transmission a few days later to another flight attendant who shared the crew resting area and ground transportation with the infected flight attendant (use of face masks on the flights was not mentioned) (16).

An investigation of 18 England-bound flights report the overall SARS-CoV-2 transmission on short to medium-haul flights (1.5-2.5 hours) to be low, with an attack rate of only 0.2% (95%CI 0.1-0.5) among flight-only contacts (17). The attack rate was higher for contacts who sat within a two-seat radius of the infectious cases (3.8% 95%CI 1.3-10.6%); however, the highest risk was among co-travellers with multiple non-flight exposures to the infected case (AR 13% 95%CI 7.6-21.4). Other outbreaks with seating charts, where available, were able to show the proximity of secondary cases to the index cases, which showed those seated within two rows of the index case were at higher risk of acquiring COVID-19 (8, 17, 18). However there were several cases across the outbreaks that were seated much further away and the mode or circumstance of transmission was not obvious (could have been from movement in cabin, shared restrooms, or fomite transmission) and cannot be confirmed (8, 9, 19, 20).

Across outbreak reports it was frequently mentioned that the window seat should be a safer seat as there are fewer contacts with other people compared to the aisle seats, however one investigation found that being in a window seat was a higher risk than the aisle seat (9). This was an unexpected finding that the authors could not explain. Table 3 describes studies that look at the potential differences in risk of sitting in different areas and seats on an airplane.

Whole genome sequencing (WGS) was undertaken in five investigations. In all cases it helped to identify cases linked to the same source and, particularly in the Australian and New Zealand investigations, WGS added a layer of information that the epidemiological investigation would have missed (9, 12, 21).

Several limitations are observed across these investigations mainly related to limitations in the data obtained. For example, pre/post flight contacts between index case and secondary contacts could not be excluded (8, 9, 15, 16, 18, 20, 22), and for some investigations, seating location was not known (8, 13).

Table 1: A list of transmission events that have occurred during flights (n=26)

STUDY	METHOD	KEY OUTCOMES
Flights with secondary cases identified		

Blomquist (2021) (17) *new* Cohort UK Dec 2020	Identified infections among passengers 18 England-bound flights with infectious cases using national case management datasets. Passengers were considered to be infectious during the flight if lab results were positive 7 days before or 2 days after the flight. Note: whole genome sequencing could not be applied as this data was not available for index and secondary cases from the same flight.	- The investigation determined 5 cases to be linked to potential aircraft transmission, 55 infectious passengers and 2313 co-passengers, with 2221 flight-only contacts. The overall SARS-CoV-2 transmission on short to medium-haul flights was estimated to be low. - The following attack rates were estimated: - 0.2% (95%CI 0.1-0.5) among all flight-only contacts. - 3.8% (95%CI 1.3-10.6) among contact-traced flight-only contacts who sat within a two-seat radius. - 13.0% (95%CI 7.6%-21.4%) among co-travellers with multiple non-flight exposures to infectious cases.
Swadi (2021) (21) *new* Outbreak Investigation New Zealand Sep 2020	A comprehensive investigation into the potential source of COVID-19 infections among 7 travelers that were on a flight from Dubai, UAB on Sept 29th 2020, with a stop in Kuala Lumpur, Malaysia, and landed in Auckland, New Zealand (18 hour duration). These 7 passengers had been seated within 4 rows of each other. The lineage of the genomes obtained from the 7 passengers was determined. Mask use was not mandatory. Post aircraft transportation to quarantine facilities was physically distanced where possible, and mask use was mandated.	- During the required 14-day managed isolation and quarantine period, 7 passengers who had traveled on the flight received positive SARS-CoV-2 test results. - The 7 passengers had begun their journeys from 5 different countries before a layover in Dubai; pre-departure SARS-CoV-2 test results prior to boarding were negative for 5. None of the passengers reported close contact at the Dubai airport. - Among the 7 passengers, 2 were probably index case-patients infected before the flight, 4 were probably infected during the flight, and the remaining passenger was probably infected while in isolation. - 5/7 cases wore masks and gloves while on the flight, including the two index cases, while the other two cases did not. - Genomic analysis found that the sequences obtained from all 7 cases were assigned to lineage B.1 and were genetically identical.
Eichler (2021) (12)	Investigated the origin of multiple COVID-19 cases	- Genomic sequence and epidemiological analysis identified a multi-branched chain of transmission

new Outbreak investigation New Zealand Aug 2020	identified after 14 days in post travel quarantine.	that included international and domestic air travel and probable aerosol transmission in the quarantine hotel (not summarized below). - The index case was identified to be a repatriated citizen returning to New Zealand from India. - Three secondary cases from the index case's 18 hour (35% occupancy) international flight on a Boeing 747 were identified by whole genome analysis. All three cases sat within 2 rows from each other, and were required to wear facemasks. - In-flight infection transmission also occurred from one of the secondary cases, who was unknowingly exposed during quarantine and released from quarantine before they were positive, to three passengers during an 85 minute domestic flight (50% capacity) on a Boeing 737. The three cases sat near one another (in front of each other) while the infectious case sat at a distance. - Note: All flight passengers wore masks during the flights.
Mun (2021) (16) *new* Case series South Korea Feb-Mar 2020	This case series describes two flight attendants diagnosed with COVID-19 who shared the crew's resting area and ground transportation, and discusses the risks experienced by flight attendants.	- The first case became ill on Feb 21, 2020 and was diagnosed on Feb 25, 2020. Thorough epidemiologic investigations suggested in-flight disease transmission as the source of infection as the flight attendant had worked during a flight on February 15th, 2020 which had on-board 39 Korean Catholic pilgrims coming from Tel Aviv, Israel. Soon after their return to South Korea, 30 pilgrims were diagnosed with COVID-19. There were no other identified sources for this case. After the flight, she continued to work between February 19 and February 22, 2020. - After the first flight attendant was diagnosed with COVID-19, a 2-week self-quarantine period was imposed on all crew members (n=30). Only one crew member was diagnosed with COVID-19 during this quarantine on Mar 6, 2020. While the two flight attendants worked on different decks of the plane, they had shared the crew's resting area and ground transportation after the first flight attendant had developed symptoms.

Wang (2021) (20) *new* Cluster Investigation China Feb 2020	Contact tracing activities of a family cluster of COVID-19. The reported cluster involved 3 confirmed cases, 2 asymptomatic infections, and a total of 34 close contacts within the family, of which 8 were visiting relatives from other provinces, and 1 was on the same flight as a confirmed case.	- The source of infection in this cluster was a family member's girlfriend who travelled via plane from Guizhou province. This case had close contact with a confirmed case on the plane while waiting in line for the bathroom as well as getting on and off the plane.
Murphy (2020) (19) Outbreak Investigation Ireland Jun-Aug 2020	An outbreak investigation into COVID-19 cases linked to an international flight into Ireland in the summer, 2020. Masks were worn by 9 cases, not worn by 1 child case and was unknown for 3.	- 13 cases were linked to a single international flight (duration 7.5h). The cases had come from three different continents. - Only 49 passengers and 12 crew were on the flight. No data on the crew or 11 passengers. - Whole genome sequencing showed 5 strains from passengers matched suggesting a single point source of infection. The index case(s) was not identified through the epidemiological investigation, but plausible theories suggest a proportion of cases acquired COVID-19 in-flight. - 4 of the flight cases were not seated near a positive case, had no contact in transit, wore face masks in-flight and would not have been considered a close contact. - A social network is shown to demonstrate how the flight cases spread SARS-CoV-2 to 46 secondary contacts in the community.
Speake (2020) (9) Cluster Investigation Australia Mar 2020	The flight, an Airbus A330-200, on Mar 19, 2020 from New South Wales to Perth (duration 5h) had 28 business class and 213 economy passengers. An epidemiologic and whole-genome sequencing investigation were undertaken.	- 29 passengers on the flight had SARS-CoV-2, and an additional 35 had compatible symptoms by tested negative. 18 from cruise ships and 10 domestic/international travellers. - Based on WGS 18 cases were considered primary: 13 Ruby Princess, 4 Ovation of the Seas and 1 traveller from the US. - 11 secondary cases, 3 did not have WGS and were classified as possible, 8 are considered to have occurred in-flight. The 8 did not know each other, 4 from USA and 4 Australians

	Mask use was rare on this flight and inconsistent.	- Among the 11 secondary cases, 8 were within 2 rows of an infected case and 3 were more distant. All secondary cases were from the mid section despite 5 infectious cases in the aft cabin. - 64% in were in a window seat, risk ratio 5.2 (95%CI 1.6-15.4). - WGS allowed proper attribution of cases to in-flight transmission.
Khanh (2020) (8) Cluster Investigation Vietnam Mar 2020	Flight from London, UK to Hanoi, Vietnam on March 2, 2020 (duration 10h). All successfully traced passengers and crew were interviewed, tested and quarantined. At arrival, there were temperature checks and symptom screening and some countries (not UK) had to undergo SARS-CoV-2 testing. Facemasks were not mandatory on airplanes.	- There were 16 crew and 201 passengers. The index case started to experience symptoms the day before the flight, she was seated in business class. - 14 passengers and 1 crew were identified as positive during the contact tracing investigation. - 12 were in business class and 92% were seated within 2 meters of the index case and 1 was more than 2 meters, risk ratio 7.3 (95%CI 1.2-46.2). - Three other contacts (2 passengers and 1 flight attendant) did not have a close encounter with the index case as they were in economy class.
Choi (2020) (10) Cluster Investigation Hong Kong Mar 2020	A study examining confirmed COVID-19 cases in Hong Kong and travel history identified 4 people that shared a flight from Boston, USA to Hong Kong, China March 9, 2020. The airplane was a Boeing 700-300ER (duration >15h), with 294 passengers. Not all passengers were tested. No mandatory quarantine or airport screening was in place. Use of facemasks was not mentioned.	- The cluster included 2 passengers (a married couple) in business class and 2 crew. - The couple both had symptom onset on March 10, so they were already infected during travel. - The flight attendants developed symptoms March 16 and 18. One of 2 flight attendants spent 5 days in Boston, the other could not be confirmed. - Their viral sequences all matched 100% and were not sequences that had been seen in Hong Kong. However, close matches were identified from Toronto, New York and Boston. - Based on this analysis the authors conclude it is likely that the couple transmitted SARS-CoV-2 to the flight attendants during the flight.
Hoehl (2020) (18)	102 passengers of a flight from Tel Aviv, Israel to Frankfurt, Germany March 9,	- The tourist group was tested for SARS-CoV-2 on arrival, 7 of 24 were positive. On the flight the 7 positive from the tourist group were symptomatic

Outbreak Investigation Germany Mar 2020	2020. 24 members were from a tourist group that unknowingly at the time had had contact with an infected hotel manager 7 days prior. No preventative measures were taken on the flight. Crew were not followed-up. Antibody tests were offered, however many passengers did not get tested, so additional transmission events may not have been detected.	(n=4), presymptomatic (n=2) and asymptomatic (n=1). - 1 of 71 other passengers with follow-up data reported having a positive RT-PCR test 4 days after the flight. 7 of 71 reported symptoms of COVID-19 within 14 days of the flight; one was confirmed with IgG serology and PRNT test. - Both confirmed cases are considered likely on-board transmission events, they were sitting within 2 rows of an index case.
Bae (2020) (13) Cohort South Korea Mar 2020	299 passengers were on an evacuation flight from Milan, Italy to South Korea (duration 11 h) March 31, 2020. Medical checks were conducted before the flight, everyone wore N95 respirators except when eating and social distancing was observed on embarkation and disembarkation. All evacuees were under medical observation during a 14 day quarantine with RT-PCR testing on day 1 and day 14.	- Based on RT-PCR testing and no development of symptoms, 6 evacuees had asymptomatic COVID-19. - One evacuee, who self quarantined for 3 weeks before the flight and then 2 weeks after the flight, had an RT-PCR positive test on day 14 of quarantine in South Korea. The authors suggest her exposure must have been on the flight where she was 3 rows from an asymptomatic case and they shared the same washroom.
Zhang (2020) (14) *preprint* Cohort China Mar 2020	During the month of March all passengers and crew suspected of being infected with SARS-CoV-2 on 830 international flights bound for Beijing were enrolled (n=4492/ 130000 total passengers). Suspects were quarantined, tested and epidemiological	- Of the 4492 suspect cases, 161 became confirmed upon testing (mean age 28·6 years). 94/830 flights (>10%) had a case on it. - On one flight Madrid to Beijing (duration 10h 18m), a cluster of eleven COVID-19 cases with a history of close contact were identified. No secondary cases from the passengers within two rows were identified. - Two cases may have been exposed on their flight as they did not have a plausible non-flight

	investigations were conducted. Universal facemask use was implemented. It was noted that many passengers were also wearing other protective clothing, gloves and goggles.	exposure to COVID-19. Assuming these 2 cases were infected on the aircraft, the attack rate (AR) was 0.14% (0.0-0.34%) across 94 flights with 14505 passengers - Universal facemask use and airplane ventilation systems were considered protective against transmission.
Pavli (2020) (23) Cluster Investigations Greece Feb-Mar 2020	Contact tracing activities of international passengers arriving or departing from Greece Feb 26- Mar 9, 2020. No public health measures were noted.	- 18 flights with 21 index cases and 891 passengers and 90 crew were traced. - Of the 21 index cases, 6 were symptomatic, 12 were pre-symptomatic and 2 developed symptoms 5-7 days after the flight. - 5 secondary cases were identified that many have been in-flight transmission from one flight (Israel to Greece, duration 2h) with two COVID-19 cases. The secondary cases were seated within 2 seats of an index case.
Eldin (2020) (22) Case report France Feb 2020	A case investigation of a French national who developed COVID-19 shortly after returning to France. He had left France February 13 for Bangui, Central African Republic and returned to Marseille, France with his partner on February 24th via Yaoundé, Cameroon.	- This investigation suggests that transmission occurred on the flight from Bangui to Yaoundé where French nationals were on the same plane as the first case of COVID-19 diagnosed in Cameroon after the February 24th flight. - The case developed symptoms shortly after returning to Marseille France. The flight is the most plausible point of exposure.
Yang (2020) (11) Cluster Investigation China Jan-Feb 2020	A flight from Singapore to Hangzhou (duration 5h) carrying 325 people on January 23, 2020. Seat assignments were not obtained, so physical proximity of the index and other cases is not known. Masks were worn by flight attendants, but not by most passengers.	- The index case developed a fever on the flight and did not wear a mask, he was identified during disembarkation and tested positive. All passengers were quarantined for 14 days. 11 other passengers developed symptoms and tested positive for an AR=3.4%

Chen (2020) (15) Cluster Investigation China Jan-Feb 2020	A flight from Singapore to Hangzhou (duration 5h) carrying 335 people on January 24, 2020. The flight was strictly managed because 100 people on the flight were from Wuhan. All passengers were quarantined for 14 days. Facemasks were worn on the flight except when eating and drinking.	- 16/335 COVID-19 cases were diagnosed among passengers, attack rate 4.8%. None of the crew were infected. - Only one passenger did not have a plausible epidemiological history of exposure prior to the flight. On the flight, he was seated near 4 infected passengers from Wuhan for approximately 1 hour and did not wear his facemask properly (not tight and nose not covered).
Kong (2020) (24) Retrospective cohort China Jan 2020	This paper details the travel and potential transmission of SARS-CoV-2 from an index case in tour group A to 3 other tour groups that were in Europe Jan 16-28. Shared flights and lodging were considered in the epidemiological investigation. Face mask use or other precautions were not mentioned.	- Transmission within the tour group (group A) resulted in 13 confirmed or suspected infections and could have occurred on flights, bus or during tours. The first case was hospitalized Jan 22, and others in the group fell ill starting Jan 26. - It seems unlikely that transmission from Group A to Group B tour group occurred on a January 16 flight as the 3 cases in Group B were not identified until January 29. - It is plausible that transmission from Group A to two others and a tour guide from group C and- an independent traveller,-occurred on a Jan 28 flight. - It is also plausible that transmission from Group A to 3 people in Group D occurred at lodging shared by both groups Jan 22.
Flights with no secondary cases identified		
Karim (2020) (5) *new* Descriptive Study Malaysia Feb-Apr 2020	This article summarizes the repatriation of Malaysian citizens using chartered commercial aircraft. The mission objectives were to repatriate as many citizens based on aircraft capacity and prevent onboard transmission of the disease to flight personnel. All flight team personnel underwent	- There were 82 positive cases detected among the repatriated citizens. Secondary transmission among repatriated citizens during the flight was not investigated. - There was a single positive case of a healthcare worker involved in the mission, based on the sample taken on arrival of the flight. This worker was asymptomatic and did not test positive again upon repeat testing (potential false positive or sampling error). No investigation into how the worker may have acquired infection was

	briefing on in-flight safety procedures and use of personal protective equipment (PPE). All repatriates were required to wear face masks and sanitise their hands upon boarding the flight.	described. There were no infections involving flight team members who worked with the case.
Ruonan (2021) (25) *new* Surveillance analysis China Jan-Apr 2020	Analyzed Guangzhou imported case data from The National Information Management System for Infectious Diseases Reports of the China Disease Control and Prevention Information System.	- Out of 34 flights, 10 (29.4%) had more than 3 cases on-board. There is no clear evidence of the spread of COVID-19 on any of the flights.
Kim (2020) (6) *new* Cohort South Korea Mar 2020	Describes a repatriation flight of 80 Koreans from Iran to Korea, with a direct transfer of passengers between airplanes in Dubai. Strict infection prevention precautions were implemented (i.e., vinyl curtains to separate clean and contaminated zones, PPE, face masks, and social distancing). Passengers with symptoms in the last two weeks were designated as 'patients under investigation' (PUI). Everyone aboard the flight was screened for SARS-CoV-2 upon arrival into Korea and completed a mandatory 14-day medical quarantine.	- One passenger was identified as a PUI during the first leg of the flight but tested negative upon arrival and one additional passenger was categorized as a PUI during the second leg of the flight upon developing a fever tested positive upon arrival. No additional passengers, aircrew, medical staff, or others involved in the evacuation, developed signs of infection during the 14-day observation period.
Suzuki (2021) (7) *new* Cohort Japan	Measured serum antibody titers for SARS-CoV-2 in 10 healthcare workers who were engaged in the operation of charter flights for the evacuation of	- Median compliance with PPE was 90% (range 70-100%, n=8). - The number of positive cases on each of the five flights was 3, 2, 2, 1, and 0, respectively.

Feb-Mar 2020	Japanese residents from Hubei Province. All participants wore PPE. Blood samples were collected at enrollment (after February 14th) and at every 2 weeks after enrollment until 4 weeks after the final participation in the evacuation operation.	- All samples from all healthcare workers were seronegative, indicating that PPE was effective in protecting staff during repatriation flights.
Draper (2020) (26) Contact tracing investigation Australia Mar-Apr 2020	Two flights with an infected crew member were identified in Northern Territory, Australia. All 555 passengers were considered close contacts necessitating contact tracing and quarantining activities. There were 28 cases and 527 close contacts over the two months. 94% follow-up rate was achieved. No public health measures or mask wearing noted.	- Due to a delay in getting manifests, it was almost a week before the flight passengers were notified (n=195 people to quarantine). - 326 air passengers from other flights were also monitored with 131 quarantined for being in the same row or within 2 rows of an infected case. - No secondary cases (0%, 95%CI 0-1.1%) from flights were identified.
Cornelius (2020) (2) Descriptive Study USA Jan-Mar 2020	This article summarizes the repatriation of USA citizens by US Department of health and human services air medical evacuation crews.	- The study included 39 flights with > 2000 individuals. - The article describes in depth the precautions taken to transport many potentially infected individuals. Best practices for IPC during air transport are described in the paper. No cases were identified of emergency workers acquiring COVID-19 during evacuation flights.
Nir-Paz (2020) (3) Cohort Israel Feb 2020	This article describes the repatriation of 11 citizens from the Diamond Princess cruise ship. Before boarding a 13.5 hour flight Feb 20, 2020 all 11 citizens had a negative SARS-CoV-2 RT-PCR test result.	- Two of the repatriated citizens (a couple), were SARS-CoV-2 positive upon arrival. Thus, it is assumed that they were infectious on the airplane. - No secondary cases were identified among the other repatriated citizens or 4 crew members. - Everyone on the flight were observed to wear their facemask except for eating and drinking.

	Precautions were taken, everyone wore surgical or FFP2 masks and crew had minimal interaction with passengers.	
Schwartz (2020) (27) Case reports Canada Jan 2020	Reports on the index case who arrived in Toronto on Jan 22, after taking a 15hr flight from China with 350 people onboard. No public health measures or mask wearing noted.	- No secondary COVID-19 cases were identified despite public health follow-up.
Qian (2020) (28) Contact-tracing investigation China Jan 2020	12 cases had taken a flight Ningbo to Zhejiang, China following a super spreading event at a temple in Ningbo. No public health measures or mask wearing noted.	- Eleven of these cases were linked to the temple; the exposure of one case was unknown, but not considered to have occurred on the flight. No secondary cases are known to have occurred from the flight. - The results of contact-tracing investigations identified 88 cases of COVID-19 admitted to five hospitals in Zhejiang province, China.

AR = attack rate

TRANSMISSION POTENTIAL OF SARS-COV-2 ON AIRPLANES

Fourteen citations are included in Table 2. These are a mixed group of review literature, commentaries, reports, a passenger survey and quantitative risk assessments that examine the risk of SARS-CoV-2 transmission while flying.

The report released by the Aviation Public Health Initiative (APHI) October 27, 2020 is the most comprehensive assessment of the risk of SARS-CoV-2 transmission from gate-to-gate (1). This report evaluates the available evidence and considers expert opinion and simulation results in its evaluation of reducing risk transmission of SARS-CoV-2 on flights. They outline why a layered risk mitigation strategy is necessary and the importance of compliance from passengers and the airlines. Similar conclusions and recommendations are described in the other reviews and commentaries in Table 2.

A single passenger and crew survey examined the impact and perception of enhanced safety measures to reduce the risk of SARS-CoV-2 transmission gate-to-gate (4). There was positive feedback about implemented changes such as crew only restrooms, frequent cleaning of restrooms, designated quarantine areas on the plane, masking everyone, use of face shields, frequent hand hygiene (alcohol gel provided to all passengers), and symptom and temperature checks. Passengers reported physical distancing of 1.5-2m could be maintained at check-in, pre-boarding and boarding, but not in-flight. Crew found that handing passengers

surgical masks, face shields and alcohol gel prior to the flight was impractical as passengers often had their hands full already with multiple pieces of carry-on luggage.

A meta-analysis found that from January–June 2020, the risk of being infected with SARS-CoV-2 in an airplane cabin was estimated to be 1 case for every 1.7 million travelers (95%CI 712000 to 8 million) (29). This analysis also showed the risk was substantially decreased with implemented mitigation measures where the risk in March 2020 was 1:425,062 and from April-September 2020, the risk was 1:7.1 million. Other quantitative risk assessments outlined in Table 2 also provide risk estimates of SARS-CoV-2 on airplanes and in many cases they estimate the risk of transmission is higher than the meta-analysis. While we know in-flight transmission has been under-reported and the risk of in-flight transmission varies depending on many factors and the parameters in the models, the variability across estimates from different studies cannot be reconciled due to the variation in approaches across analyses.

The combination of masks, social distancing among passengers, improved ventilation and vacant middle seats at 66% capacity, can reduce the number of infections by more than 50%, and N95 or surgical masks (ASTM 3) reduced infection risk to 0 (30). Infection probabilities for a 2 hour flight without face masks was comparable to a 12 hour flight where all passengers wore high efficiency facemasks (31). This study also found that removing mask for meal service increased risk. Further, removing roughly one-third of the passengers by keeping the middle seats empty and increasing social distancing while boarding can significantly reduce the infection risk (by 35-50%) compared to the full airplane (32, 33). One risk assessment estimated that a flight in the USA on June 30, 2020 had a risk of contracting SARS-CoV-2 of 1/4300 on a full flight and 1/7700 if the middle seat empty policy was in place (these numbers depend on the disease activity in the population) (34). The longer the duration of the flight, the higher the SARS-CoV-2 infection risk (31, 35).

Table 2: Reviews, reports, passengers survey and risk assessments related to SARS-CoV-2 transmission on airplanes (N=14)

STUDY	METHOD	KEY OUTCOMES
Pang (2021) (29) *Preprint* *new* Systematic review USA[1] Apr 2021[1]	Systematic review of COVID-19 cases related to air travel up to Sept 2020. The review was limited to flights with passenger index cases and did not include transmissions amongst air crew, ground crews, or airport staff. A quantitative approach was used to estimate the risk of air travel transmission. Correction factors were used in risk estimates for	- As of August 2020, there were at least 2866 index cases that were documented air passengers. - Fewer than 50 documented potential secondary cases associated with air travel during the pandemic were reported. - Mask use on reviewed flights ranged from use unknown to mandatory N95 use. - From January–June 2020, the risk of being infected with SARS-CoV-2 in an airplane cabin is estimated to be 5.927×10^{-7} or 1:1.7 million. Uncertainty in the correction factors and a 95% credible interval indicate risk ranges from 1 case for every 712,000 travelers to 1 case for every 8 million travelers.

	asymptomatic transmission and underreporting. Transmission risk was calculated for three time periods of interest: (1) January–June 2020 the period covered by the literature, (2) the month of March 2020 when the global spread of COVID-19 was occurring, and (3) April–September 2020 to account for the sharp drop in worldwide air travel and increased use of COVID-19 testing.	- For the month of March 2020, the risk is estimated to be 2.353×10^{-6} or 1:425,062. - From April-September 2020, the risk is estimated to be 1.413×10^{-7} or 1:7.1 million.
Sun (2021) (36) *new* Literature Review China[1] Apr 2021[1]	Narrative review of publications related to the COVID-19 pandemic and air transportation published in 2020.	- A summary of literature on airport screening operations and boarding strategies. - Summarizes the existing (2020) literature regarding in-flight operations in the presence of COVID-19 and in-flight transmission events. - Conclude that widely available, robust data for whether there are transmission occurs despite proper mask use on airplanes would yield more valuable insights.
Bielecki (2021) (37) *new* Literature Review Switzerland[1] Feb 2021[1]	Narrative review of topics related to air-travel in the pandemic period. Topics included traveller numbers, peri-flight prevention, and testing recommendations and in-flight SARS-CoV-2 transmission, photo-epidemiology of mask use, the pausing of air travel to mass gathering events, and quarantine measures and their effectiveness.	- Air travel numbers have significantly declined (51.6% decrease compared to 2019). - Flying will be safer by optimizing screening procedures, minimizing the risk of allowing pre- or asymptomatic cases to board (i.e., testing), and implementation of/adherence to simple hygiene measures and physical distancing that prevent the spread of diseases. Passenger screening is inadequate to detect all infectious cases. - High airflow and use of HEPA filters onboard planes make it unlikely to catch the virus from someone who is not seated close by. - Infection risk during flights is low: 1 infection per 54 h of flight and zero infections during a 12-h flight.

Khatib (2020) (38) *new* Literature Review Canada[1] Dec 2020[1]	Narrative review of literature on SARS-CoV-2 transmission risks and infection prevention strategies used by commercial air travel. Authors provide recommendations and propose strategies to mitigate the spread of COVID-19.	- Air quality aboard modern aircraft is very safe (HEPA filters are 99.97% effective in removing particles between 0.1 and 0.3 µm in diameter and 100% of larger particles). - Further study is needed to examine the interaction between airflow and resulting particle dispersion, but authors recommend turning on the personal airflow (gasper) above each passenger to improve travel comfort, air quality and reduce person-to-person transmission of exhaled contaminants. - Risk is highest during boarding and disembarkation. - A window seat is thought to be the safest option- though recent real-world outbreak studies are questioning this. - Recommendations included: masks should be used, frequent hand sanitization promoted and physical distancing ensured when feasible from boarding to disembarkation. High-frequency touchpoints should be disinfected between flights and in-flight. Pre-screening and pre-testing measures should be used in addition to the preventive measures enforced onboard. The implementation of a standardized digital health pass for COVID-19 and more robust contact tracing may be key factors to allow for a gradual safe return to air travel.
Marcus (2020) (1) Aviation Public Health Initiative Report from the Harvard TH Chan School of Public Health USA[1] Sep 2020[1]	This excellent quality APHI Report includes data up to September 28, 2020 This research-led guidance report reflects a mixture of literature review, *in silico* models and expert engagement to assess the following question: *In the midst of this complex, novel coronavirus crisis, how can aviation leaders advance an independent evidence-based*	- Layered non-pharmaceutical interventions (NPIs) significantly reduce the risk of disease transmission and includes: optimal ventilation, disinfection of surfaces, wearing face masks, procedures to encourage social distancing particularly during embarkation and disembarkation, but also during flight (e.g. no queuing for the restrooms or walking about the plane and minimizing interaction with crew.) - Airplane ventilation is highly sophisticated and delivers high amounts of clean air to the cabin which rapidly disperses exhaled air. - Crew and Passenger Behavior: Public safety on board and airplane depends a lot on individual behaviours: first health attestations and screening

	program to reduce the risks of SARS-CoV-2 disease transmission and with that, enhance the safety and confidence of its workforce and passengers?	pre-boarding, mandatory facemasks, social distancing and orderly conduct to avoid congestion combined with hand washing and cleaning. This is encouraged via the penalty of being on a "no-fly" list for non-compliance. - Overall, there is limited data on in-flight transmission, however it appears that a very low number of infections could be attributed to in-flight transmission and there is evidence that NPIs, particularly mask use, resulted in no transmission despite infectious passengers onboard. They describe 13 manuscripts (also included in Table 1) of studying in-flight transmission. Of note, no crew from repatriation flights acquired SARS-Cov-2, a demonstration that adherence to NPIs is effective. - Layered risk mitigation strategies can significantly reduce the risk of transmission, but require compliance from passengers and the airlines.
Freedman (2020) (39) Literature Review NA[1] Sep 2020[1]	Narrative review of all publications of possible in-flight SARS-CoV-2 up to Sep 21, 2020. This review summarized transmission events by attributes such as mask wearing on the flight in an attempt to describe and quantify the risk under different scenarios and considerations such as differing incidence rates of SARS-Co-V-2 at origin and destination, intensity of viral load in index cases, flight duration, masking practices onboard, pre-flight screening and passenger spacing. There were not enough data points to quantify the risk.	- Describe 4 well documented flights, three included in Table 1 (8-10) and the forth is an online inventory of flights to Hong Kong that reported transmission to 2 passengers, 1 seated with 5 index cases, masks were used on-board (duration 8 h). - 3 single transmission events have been reported, 2 were published (15, 18). - 6 high risk flights with no transmission are listed, 1 is published (27). The inventory of flights from Hong Kong lists many flights with positive passengers and no secondary transmission attributable to the flight. - 5 evacuation flights of which 3 are published (3, 13) are listed with one possible transmission event. The review states >1.7 million passengers were repatriated by their government or a cruse ship company during the pandemic, few have been documented in the literature. - Flights lists with known COVID-19 cases were identified from Canada and Australia. These lists are for other passengers to self identify and isolate. US CDC is also collecting data, but has not published any findings.

		- What risk factors have been identified? Clear clustering of cases where seat plans were available, but some transmission occurred to people > 2 rows from the index case. The flights with large transmission clusters occurred before face masks were mandated on flights and several high-risk flights with no transmission had mandatory masks.
Shaimoldina (2020) (40) *new* Commentary NA[1] Dec 2020[1]	A public dataset of international flight infection information was used to analyze the trend in flight traffic and infections during the pandemic. Based on existing literature, the authors then describe challenges of prevention of SARS-CoV-2 infected individuals from boarding flights and solutions for flight resumption.	- Flight infections have decreased and air travel has been significantly reduced. - Preventing SARS-CoV-2 infected individuals from boarding flights is challenging due to testing accuracy, asymptomatic cases and many other factors including the inability to maintain physical distance and density of passengers on a plane. - Solutions may include hotel quarantine for arriving passengers, mandatory PPE, airport diagnosis, and rapid imaging/biomarker diagnosis by advanced high-technology.
Harries (2020) (41) Commentary NA[1] Aug 2020[1]	How safe is it to fly? This commentary looks at the publications available up to August 2020. Historical outbreaks have been reported for tuberculosis, influenza like illness, SARS-CoV-1.	- Ventilation in an aircraft is very good. However it can be disrupted by passengers moving around, coughing etc. - Aisle seats tend to have more contact with others compared to a window seat. - They suggest following available guidance: wear a well-fitting mask and a face shield or glasses, use alcohol wipes to wipe surfaces, do not congregate or que for the washroom, change seats if near a symptomatic person, avoid drinking and eating if possible. - Use same precautions in the airport and exercise physical distancing when possible.
Pongpirul (2020) (4) Passenger and crew survey Thailand	This study targeted passengers and crew of two repatriation flights operated by Thai Airways (TG476 from Sydney 9.25h and TG492 from Auckland to Bangkok	- Response rate for the online questionnaire was low: 22.5% - Several risk reduction measures were implemented and well received. These included crew only restrooms, frequent cleaning of restrooms, designated quarantine areas on the plane, masking everyone, use of face shields, frequent hand

Apr 2020	11.5h), total 335 passengers and 35 crew. An online questionnaire was administered to get individual feedback about social distancing, mask wearing, and other procedures put in place to reduce the risk of SARS-CoV-2 transmission. In depth interviews were conducted with crew.	hygiene (alcohol gel provided to all passengers), symptom and temp checks. - Physical distancing of 1.5-2m could be maintained at checking, pre-boarding and boarding, but not in-flight. - Crew found that handing passengers surgical masks, face shields and alcohol gel prior to the flight was impractical as passengers often had their hands full already with multiple pieces of carry-on luggage.
Horstman (2021) (30) *new* Risk assessment US[1] Mar 2021[1]	Applied computer fluid dynamic results of virus transport and concentration, past data on Influenza transmission in airplanes, and the Wells Riley quanta estimation, to estimate infections risk of an arbitrary airborne viral infection on Boeing 737-600 airplanes. The parameters and data in the analysis were then compared to field data on SARS-CoV-2 on an airplane. Note: Field data based on the transmission event described by Hoehl (2020) in Table 1. Investigators assumed the virus emission rate was 1.6 ± 1.2 x 10^5 genome copies/m^3h that corresponded to 1267 viruses/minute released, and an Influenza human 50% infectious dose (HID_{50}) of 2554 copies/quanta.	- In a 3-hour flight, infection risk of an airborne infection was approximately 50% for passengers sitting in the vicinity (i.e., a single row) of infected cases (positioned at the 12^{th} row aisle seats), estimated as 2-3 infections per 131 passengers. - When the analysis was compared to field data where 4 symptomatic infected cases led to 2 secondary infections, SARS-CoV-2 was found to be less infectious and lie mid-range of the applied Influenza infectious dose data. - Masks, social distancing among passengers by 2.9 feet, vacant middle seat at 66% capacity, reduced the risk of transmission by more than 48%. The use of N95 masks and surgical masks (ASTM 3) reduced the number of secondary infections to 0.

Wang (2021) (31) *new* Quantitative Risk Assessment UK[1] Feb 2021[1]	Estimate inflight SARS-CoV-2 infection probability for a range of scenarios using experimental aerosol dispersion data and a modified Wells-Riley equation. Scenarios were varied based on quanta generation rates and face mask efficiencies, and specified for a B777-200 aircraft.	- Infection probabilities for a 2 hour flight without face masks were comparable to a 12 hour flight where all passengers wore high efficiency facemasks. Overall, infection probabilities were higher in the economy class cabins (MID-AFT) compared to the business class (FWD) sections. - Individual infection probabilities during a 2 hour unmasked flight ranged from 4.5%-60.2%. The average infection probabilities based on the number of infected passengers on the flight ranged from 0.1%-2.5% in the same scenario. For a 12 hour unmasked flight individual infection probabilities ranged from 24.1%-99.6%, average infection probability 0.8%-10.8%. - The use of high/low efficiency masks by passengers during a 12 hour flight except during 1 hour meal service increased average infection probabilities by ~59% to ~8%, compared to when masks were worn for the entire flight.
McCarthy (2021) (32) *new* Quantitative risk assessment NA* Jan 2021*	This mechanistic transmission model assumes that the probability of SARS-CoV-2 infection is additive over sub-activities. Sub-activities that together make up the air travel activity include boarding the plane, moving to and entering one's seat, sitting on the plane for the duration of the flight, and finally leaving ones seat and disembarking the plane. The model also assumes a three-hour long flight and that there is no direct physical contact between participants and that all surfaces are disinfected. It also assumes that all passengers are compliant	The relative benefits of different mitigation strategies on the airplane can be explored: - Time spent seated was the most important factor in total risk score. - Mask-wearing, making masks mandatory, given what we currently know, could be a (cost-) effective strategy for risk reduction. - Keeping the middle seat vacant unless there is a party of three travelling together at least halves the risk, under a very wide range of decay assumptions. - Managing boarding is less costly than leaving seats empty, but the analysis found that the total impact will be lower.

	with the boarding and masking policies. This is a risk-cost-benefit decision analysis framework that can be applied to many settings, including airplanes. The analysis can produce relative risks.	
Hu (2020) (35) *new* Quantitative Risk Assessment China Dec 2019- Mar 2020	This risk assessment applies epidemiological data from airplane passengers (n= 9,265 passengers and 175 index cases, on 291 airplanes) and close contacts to estimated attack rates (AR) and reproduction number (R_0) prior to the lockdown in Wuhan. Relative risk among seats by proximity to the index case was also estimated. AR upper bound was estimated, based on the assumption 34 and 69 close contacts were infected on the flight departing Wuhan.	- The overall risk of SARS-CoV-2 transmission on planes with high efficiency air filtration devices was reported to be relatively low. The estimated AR upper bound was 0.60% (95% CI: 0.43%-0.84%), and R0 ranged from 0.12 to 0.19. - Transmission risk was variable by seat distance from infected case(s) and duration of the trip. - The seats immediately adjacent to the index cases were the highest risk, AR of 9.2% (95% CI: 5.7% - 14.4%), relative risk (RR) of these seats compared to others seats on the airplane was 27.8 (95% CI: 14.4 - 53.7). The middle seats had the highest AR (0.7%, 95%CI 0.4% - 1.2%), followed by the window seats (0.6%, 95%CI 0.3% - 1.0%) and the aisle seats (0.6%, 95%CI 0.3% - 1.0%). - Lower bounds of AR estimates linked to air travel increased from 0.0% (95%CI 0.0% - 0.6%) to 0.4% (95%CI 0.02% - 2.2%), and upper bounds from 0.7% (95%CI 0.5%-1.0%) to 1.2% (95% CI 0.4% 3.3%) when trip duration increased from 1.5 hours to 3.3 hours. However these results were not significant due to limited data on secondary cases based on flight times.
Arnold (2020) (34) *Preprint* Quantitative Risk Assessment USA Jun 2020	This risk assessment calculates the risk of SARS-CoV-2 infection resulting from exposure on an airplane. It did not account for loading/unloading, going to the bathroom, length of the flight, and made some assumptions about the	- Based on the assumptions, the risk of contracting COVID-19 from a nearby passenger on a flight in the USA on June 30, 2020 was about 1 in 4,300 on a full flight. - Under the "middle seat empty" policy, that risk falls to in 7,700. - These numbers are based on the estimate that 1 in 120 Americans have Covid-19 on a given day,

	"protection" afforded by the seat backs as a barrier between rows. It is based on economy class in airplanes with 6 seats in a row.	40,000 confirmed cases per day x 10 x 7 days is about 1/120 of the US population of 330,000,000. - They suggest wearing a mask could reduce the risk by 82% (not part of the risk assessment and no reference.)

INDIRECT ANALYSES OF RESPIRATORY INFECTION TRANSMISSION RISK ON AIRPLANES AND POSSIBLE MITIGATION STRATEGIES

Several simulation and *in silico* models have been developed to explore ways to minimize the risk of transmitting an infectious disease on an airplane or during embarkation and disembarkation. There were nine studies on boarding/disembarking an airplane, six on optimal seating patterns to minimize in-flight transmission and seven on the aerodynamics of respiratory droplets in an airplane when coughing and sneezing that have been published during the pandemic (Table 3). A single review of these aerodynamic studies up to June 2020 and a systematic review on evidence for influenza transmission are also listed in Table 3. These studies look at strategies for boarding to minimize passenger interactions and seating plans to maximize distance and interaction with other people. The studies that look at ventilation on the airplane and how coughing or sneezing impacts airflow describe the distance and range of droplets and aerosols from various seats (e.g., window, middle, aisle) and when standing or walking about the cabin (Table 3).

Several predictive, simulation and *in silico* models have been developed to explore ways to assess and minimize the risk of transmitting an infectious disease during boarding and disembarkation. A variety of boarding/disembarkation methods were investigated across nine studies. Overall, increasing the number of boarding groups, decreasing carry-on luggage, and avoiding interaction with other passengers (i.e., boarding back of plane and window seats first) was found to decrease risk of infection significantly, albeit with a sacrifice in overall efficiency (i.e., lengthier boarding/disembarkation time) in some scenarios (42-49).

Environmental monitoring studies, *in silico* models, and simulation experiments provide risk estimates and mitigation strategies for transmission while in-flight. In-flight particle concentrations in the air in airplanes are lower than that of retail/grocery stores, restaurants, office spaces, homes, and other forms of transport (50, 51). Further, simulation experiments of in-flight aerosol transmission and surface contamination find that air in the cabin is rapidly renewed (52). When surgical masks were used in simulations, there was a >90% reduction in droplets released during the cough simulation compared to no mask (51).

The seats immediately adjacent to the index cases have the highest infection risk, followed by the row directly behind and in front (35, 51-53). The travel distance of cough particles is heavily influenced by the direction and type of cough (54, 55). There is conflicting evidence on what seats (aisle, middle, or window) have a higher infection risk. Standing or walking about the cabin can lead to much further spread of respiratory

droplets and aerosols (56). Differences in risk between different airplanes as well as business and economy seats are also discussed (57, 58).

An ECDC systematic review on evidence for influenza transmission (59) reports on transmission during flights reported in the literature was largely consistent with findings from the COVID-19 literature; low number of secondary cases and seating of a secondary case was usually within two rows of an infected person. Interestingly the length of the flight was not associated with risk of transmission in the studies captured in this review.

Table 3: Studies and reviews that examined the aerodynamics of respiratory droplets on airplanes and mitigation strategies for respiratory infections on planes (n=24)

STUDY	METHOD	KEY OUTCOMES
Simulation and *in silico* models		
Boarding/Disembarkation		
Cotfas (2021) (48) *new* Predictive model Romania[1] Mar 2021[1]	Use an agent-based model and stochastic simulation approach to investigate the impacts of the Reverse Pyramid method on average boarding time and health risk to aisle and window seat passengers. Assessments were based on social distancing by maintaining distances of 1-2 meters between passengers when walking down the aisle, keeping the middle seat empty, and different carry on luggage policies.	- When minimizing the health risk to passengers was the primary objective the optimal solution was to assign an equal number of window seat passengers to 1 and 2 boarding groups, and an equal number of aisle seat passengers to boarding groups 2 and 3. This option was robust to changes in luggage volume and aisle social distance. The option reduced health risk among aisle seat passengers by 22.76%-35.31%, when compared to other simulations which minimized boarding time. - Scenarios that reduce boarding time, and health risks to a lesser degree, are also discussed.
Milne (2021) (43) *new* Predictive Model NA[1] Feb 2021[1]	In these stochastic simulation experiments and agent-based models, the authors assess six boarding methods and compare their performance with that of the two best boarding methods used to date with social distancing according to four performance metrics. Three of the metrics are	- Increased luggage = increased boarding time. - In a scenario where there is 1 m aisle distancing, the back-to-front by row – WilMA method has shorter boarding times, fewer seat interferences, and less aisle seat risk than the baseline back-to-front method for each luggage scenario. The baseline back-to-front by row method has less window seat risk

	related to the risk of the virus spreading to passengers during boarding. The fourth metric is the time to complete boarding. The two "best" baseline boarding methods are back-to-front by row and modified reverse pyramid half zone (see figures for description). The back-to-front by row – WilMA method boards the passengers one row at a time starting from the rear of the airplane. The five other boarding methods are created by adjusting the back-to-front by row – WilMA method so that some of the window seat passengers board earlier. In particular, k rows of window seat passengers will board the airplane before any aisle seat passengers. In the five new methods, the value of k ranges between 2 and 6.	for the higher volumes of luggage scenarios. - In a scenario where there is 2 m aisle distancing, the back-to-front by row – WilMA – offset 3 method is superior to the baseline modified reverse pyramid half zone method because its boarding time is about the same and it has less significantly less aisle seat risk and window seat risk. The back-to-front by row – WilMA method has the lowest window seat risk.
Xie (2021) (44) *new* Predictive Model NA[1] Jan 2021[1]	Quantitatively compare the disembarkation process of a Boeing 737-300 before and after adopting disembarkation management strategies. Two strategies are investigated: Strategy I: Where there is one infected passenger, ground crews first disinfect cabin aisles before the disembarkation process begins, then passengers in front of the infected patient disembark from the front door while passengers in the rear of the case disembark from the rear door. The patient and his or her "close contacts" disembark	- The number of high-risk passengers decreased by 72% after adopting Strategy I. - After adopting Strategy II, the number of high-risk passengers again decreased by 27%. - Although both strategies sacrifice efficiency (i.e., longer total disembarkation time), they also significantly reduce the risk of infection.

	only after all passengers have left the cabin. Strategy II: Where there are multiple infected passengers, passengers are evacuated from the front door or rear door from traversed columns that do not contain patients or close contacts. After the passengers have left the cabin, the cases and "close-contacts" leave from the front or back door without picking up their luggage. After the cases have left, the ground crews perform a second disinfection of the cabin. After disinfection, the remaining passengers leave through the front or rear door.	
Milne (2020) (42) *new* Predictive Model NA[1] Nov 2020[1]	In these stochastic simulation experiments and agent-based models, the authors adapt the Reverse Pyramid method for social distancing when an airplane is boarded using a jet bridge that connects the terminal the airplane's front door. They assess the impact of number of boarding groups (2 vs. 6) to show the resulting impact on four performance evaluation metrics. The first performance metric is the average boarding time. The second performance metric is the number of type-3 seat interferences during the boarding (i.e., switching seats, moving out into aisle to allow window passenger access to seat). The third and the fourth performance metrics	- As the number of boarding groups increases from two to four, average boarding times decrease. - When the number of boarding groups increases from 3 to 6, the aisle seat risk decreases significantly from 44% to 21%. - As the volume of luggage carried aboard the airplane decreases, the risk duration decreases significantly. - Doubling the aisle social distance from 1 m to 2 m increases the average boarding time and decreases both aisle and window seat risks.

	pertain to seated passengers' health while later boarding passengers pass them	
Schwarzbach (2020) (60) *new* Simulation experiment NA[1] Oct 2020[1]	Evaluate the applicability of technology-based social distancing methods while boarding in an aircraft cabin environment using a radio propagation simulation based on a three-dimensional aircraft model. They perform a ray tracing propagation simulation in a section of a modeled Airbus A321 aircraft cabin.	- The authors demonstrate that commonly utilized Receiver Signal Strength Indicator (RSSI) measurements can lead to false-positive and false-negative encounter classification, depending on the path-loss model tuning, lowering the reliability and user acceptance of technology-aided social distancing options. - From an application point of view, a possible implementation of the proposed technological approaches could look at the following: Real-time proximity warning, Post-processing contact tracing, Boarding/deboarding scheduling.
Delcea (2021) (49) *new* Predictive Model Romania [1] May 2020[1]	Estimate the number of passengers for each boarding group assuming reverse pyramid boarding with the middle seats unoccupied. Apply agent-based modeling and a stochastic simulation to evaluate impacts on boarding time and health risk to passengers in each scenario.	- If the objective is to minimize health risk among passengers, then reverse pyramid boarding first group should be those with window seats in the rear half of the airplane, the third group should be passengers with aisle seats in the front half of the airplane, with the second boarding group being the remaining passengers. This arrangement was found to be the most ideal as it reduced health risk to aisle seat passengers by 25% and by 22% for window seat passengers, while increasing boarding time by 2%.
Milne (2020) (45) Predictive Model NA[1]	In these stochastic simulation experiments, the authors assess nine adaptations of boarding methods according to four	- Average boarding time is the comparable measurement between several scenarios.

Aug 2020[1]	performance metrics. Three of the metrics are related to the risk of the virus spreading to passengers during boarding. The fourth metric is the time to complete boarding of the two-door airplane when apron buses transport passengers to the airplane.	- Increased social distance (1m to 2m) = increased boarding time. - Increased proportion of people with luggage = increased boarding time. - Seating the window seat passengers before aisle seat passengers decreases the risk of seat interference (where the aisle seat has to get up to let the window seat in). - Aisle seat risk is higher when social distance is lower (1m), luggage is carried, when boarding is random. - The author indicates that window seat risk is less than aisle seat risk during boarding, but does not estimate what the difference may be.
Schultz (2020) (46) Predictive model UK[1] Jul, 2020[1]	A cellular automata model that models the movement of passengers during the boarding process. They do not consider facemasks. They model distance to index case and contact time to estimate transmission risk.	- The model shows that compared to random boarding of people, boarding groups (e.g., families) together individually will result in the shortest boarding time 41% of the random scenario and least transmission risk 0.09 compared to 0.57-0.62 for any of the random scenarios when the plane is half-full. These boarding times were relatively stable at 75% and 100% capacity; however, transmission risk increased to 0.31 and 0.66 for the boarding in groups, individually scenario.
Cotfas (2020) (47) Predictive Model NA[1] May 2020[1]	An agent-based model is used to simulate the passenger boarding process, mainly interactions with agents and other people. (used NetLogo platform) They model the length of time to board the plane under a number of scenarios and considering hand luggage storage times.	- Back to Front boarding of the plane took the longest time, but had the lowest health risk in the simulation. - The risk is similarly low if a 2-meter social distance is maintained when boarding. - Boarding is more efficient and less risky when passengers do not have luggage to store.

	The outcome is about length of time already seated passengers come into contact with other people either as they pass by down the aisle or due to having to get up to let a person into the window or middle seat.	
In-flight transmission and seating		
Dietrich (2021) (33) *new* Environmental monitoring and predictive model study USA[1] Apr 2021[1]	Used bacteriophage MS2 virus dispersion data as a surrogate for SARS-CoV-2 and modeled the relationship between SARS-CoV-2 exposure and aircraft seating proximity. Both full occupancy and vacant middle seat occupancy scenarios were considered.	- Compared with exposures in full occupancy scenarios, relative exposure risk to an individual passenger in vacant middle seat scenarios was reduced by 23% to 57%. - The 23% exposure reduction was observed for a single passenger who was in the same row and two seats away from the SARS-CoV-2 source, empty middle seat between. - A 57% in a scenario involving a three-row section that contained a mix of SARS-CoV-2 sources and other passengers - Overall exposure risk reduction in a full 120-passenger cabin with vacant middle seats ranged from 35.0% to 39.4%.
Desai (2021) (57) *new* *In silico* study USA[1] Feb 2021[1]	Modeled the airflow, transport of oral and nasal expired particles (e.g. CO_2 and coronavirus) at different seat positions inside Airbus Airbus 380 and Boeing B747 aircraft. Simulations considered First, Business and Economy class sections in each aircraft. Seat positions were ranked based on CO_2 mass fraction, temperature, and velocity corresponding to passenger nose positions at each seat location.	- Seat ranking across aircrafts were highly variable. - In the first class section: The Airbus best ranked seat was warmer than the Boeing best ranked seat, but has worse circulation. - In business class: Airbus best ranked seat was colder, but offered better circulation than the Boeing best ranked seat. The Airbus seat was located in the side bank of the seats on the aisle side and the Boeing seat was is located next to the window.

		- In economy class: The best ranked seat for the Airbus was located next to the window while the best ranked seat for the Boeing was the middle seat in the side bank of the seats. The Airbus seat had a higher temperature, lower CO2 concentration, and lower air velocity, the trade-off for a warmer seat was worse circulation. - Overall, airbus economy best ranked seat was both warm and with good circulation; the Boeing seat performed worse in all these areas.
Ghorbani (2020) (61) preprint *In silico* study NA[1] Oct 2020[1]	The model, Monte Carlo Simulations, optimizes the number of passengers and their arrangements under a social distancing measure for the airline industry for single aisle and double aisle scenarios.	- The figures in the paper depict optimal arrangement of passengers in an airplane. Key to safely increasing the number of passengers is to group families closely together.
Salari (2020) (62) *In silico* study NA[1] Jun 2020[1]	A mixed integer programming (MIP) model to properly assign passengers to seats on an airplane while effectively preserving two types of social distancing: keeping the passengers seated far enough away from each other and providing a safe distance between seat assignments and the aisle. They use an airbus A320 with 20 row, single aisle and three seats on each side. The MIP model ran a number of scenarios: - Middle seat empty - Social distance of 3.3 ft when seated - Aisle seat empty	- If social distance is completely adhered to, no aisle seat use and no one within 3.3ft, the max load is 20 passengers in a 120-seat plane. - If passengers can sit in the aisle seat, this increases to 30 passengers socially distanced 3.3ft+. Sitting in the aisle should include strategies to limit movement / possible exposure of people moving around the plane. - Middle seat blocking policy lead to less multiple people within 3.3.ft compared to the leave the aisle seat open policy. - The more people on the plane, the more people were seated close to each other and thus considered to be in increasingly higher risk situations with 1, 2 or 3+ people within 3.3.ft. See figures for illustration.

	- Hybrid	
Wagner (2009) (58) Quantitative Risk assessment USA[1] Dec 2009[1]	This quantitative risk assessment estimates the possibility of within-flight transmission of H1N1. The simulation uses a Boeing 747.	- Even during long flights, a low to moderate within-flight transmission risk if the source case travels First Class. - Index sits in first class: • 0-1 infections could occur during a 5-hour flight, • 1-3 during an 11-hour flight • 2-5 during a 17-hour flight. - However, within-flight transmission could be significant, particularly during long flights, if the source case travels in Economy Class. - Index sits in economy class: • 2-5 infections could occur during a 5-hour flight, • 5-10 during an 11-hour flight • 7-17 during a 17-hour flight
Hertzberg (2018) (63) Environmental monitoring study and an *in silico* study USA[1] Mar 2018[1]	During flu season on 10 transcontinental US flights, they chronicled behaviors and movements of individuals in the economy cabin on single-aisle aircraft and did some environmental sampling. They simulated transmission during flight based on these data. This data-driven, dynamic network transmission model of droplet-mediated respiratory disease is unique.	- None of the 229 environmental samples were positive. - The results indicate there is low probability of direct transmission to passengers not seated in close proximity to an infectious passenger.
Aerosol Simulations on an Airplane		
Talaat (2021) (52) *new*	Studies in-flight aerosol transmission and surface contamination using a	- Particles take 2–3 min to deposit or leave the system as air in the cabin is rapidly renewed.

Simulation experiment USA[1] Feb 2021[1]	computational model of a cabin zone of a Boeing 737. The investigation aims to understand the effect of reducing passenger capacity (from 60 to 40) and to compare to alternative intervention measures such as using sneeze shields (sneeze guards) between passengers on a full capacity flight. The investigation considers a wide range of particle sizes (1–50 µm). This study does not take into account more than one infection on board, human behaviour e.g. talking, eating, drinking, adherence to mask wearing, or moving down the aisles.	- Aerosol in the 1 µm–20 µm size range is concentrated within one row of the index patient, and virtually, no particles make it past two rows from the index patient. Larger particles such as 50 µm particles are only present in the row of the index patient. - A relatively small fraction (21–26%) of exhaled particles are directly removed by the ventilation system. The majority of the particles deposit on surfaces in the cabin, with more 1 µm particles depositing on the walls than on the ground (10–14% vs 3%–6%). - The most contaminated surfaces in the full capacity model (60 passengers) with no sneeze guards are the passengers (including the index patient) at 31% deposition fraction followed by the seats at 27%. In the reduced capacity model with no sneeze guards and the full capacity model with sneeze guards, total deposition on passengers is reduced to 21% and 15%, respectively. - The total inhalable fraction is the lowest in the full capacity model with sneeze guards (0.5%) followed by the reduced passenger capacity model without sneeze guards (0.7%) and then the full capacity model without sneeze guards (1.7%). However, reduction in passenger capacity and use of sneeze guards eliminates the direct transmission of 50 µm particles. Although these particles deliver a much smaller inhalable fraction compared to 1 µm particles, they contain substantially more virions than 1 µm particles due to their volume.
Kinahan (2021) (53) *new*	Aerosol dispersion and deposition in two wide-body aircraft (Boeing 767-300 and Boeing 777-200 at	- The maximum exposure, 0.0947-0.4614%, occurs in a seat next to a source, with the next highest risk of

Simulation experiment USA[1] Jan 2021[1]	30,000 ft) was measured using fluorescent and DNA-tagged microspheres. Experimental data included over 300 releases from a simulated SARS-CoV-2-infected passenger in seats while in-flight. The tests were designed to measure the aerosol concentration within passenger breathing zones in neighboring seats and rows from the simulated infected passenger. The breathing releases included a mix of tests with the mannequin not wearing a mask and tests with a mask. This study does not take into account more than one infection on board, or human behaviour (e.g., talking, eating, drinking, or adherence to mask wearing).	inhalation typically occurring in the seats in front and behind the simulated infected passenger. This maximum exposure risk equates to a minimum reduction of 99.54% of 1 µm aerosols from the index source to the breathing zone of a typical passenger seated directly next to the source. - Less than 0.03% of tracer particles settle out on solid surfaces during testing, with the highest concentration on the surfaces closest to each release location. Notably horizontal surfaces, such as arm rests were typically higher than vertical surfaces such as seatbacks and inflight entertainment (IFE) systems. - The average reduction with a mask in total particles counted was 15.6%.
Rivero-Rios (2021) (50) *new* Biological monitoring study USA July 2020	Particulate matter (PM) concentrations were measured in a variety of indoor spaces including 19 flights, retail/grocery stores, restaurants, office spaces, homes, and other transport (private cars, buses, trains). Flights were chosen to cover a range of flight durations/destinations and aircraft models and including the following stages of air travel: Terminal (departure), Boarding, Taxiing (out), Climbing, Cruising, Descending, Taxiing (in), Disembarkation, and Terminal (arrival).	- In-flight particle concentration in the air in aircraft was lower than that of retail/grocery stores, restaurants, office spaces, homes, and other transport tested. - Particles with diameters smaller than 1 µm dominate the total particle number concentrations (because they are the most difficult to remove by filtration). - PM concentrations exhibited a V-shape pattern, with high levels at boarding and a continued decrease and stable minimum concentration during cruising. Slight increases in particle mass concentration during food service were observed. When the plane began descending, particle concentrations started increasing and an abrupt increase was typically observed once

		the cabin door was opened and the disembarkation process began. - Air exchange rates in the cabin are rapid during flight, reducing the number of particles in the cabin significantly. Ambient air at altitude contains fewer particles than air at the surface, contributing to low cruising particle number and mass concentrations and also explains the decrease and increase observed during climbing and descending.
Kotb (2020) (56) *In silico* study Egypt[1] Sep 2020[1]	In this computational fluid dynamic (CFD) modeling simulation to examine what happens to respiratory droplets when expelled by a sneeze or cough by a person moving around an airplane cabin.	- The airflow of coughing and sneezing droplets produced from the moving passengers could reach seated passengers several rows from the source compared to when standing still. Cough distance 1.1m, sneeze went further when standing still. - Comparing the droplets spread range resulting from the moving passenger and stand-still one, the quicker the passenger moves, the further the droplets spread. - Figures illustrate coughing/sneezing during standing and in motion in an economy class airplane cabin.
Silcott (2020) (51) *Unpublished* Simulation experiments USA Aug 2020	The simulations used 767-300 and 777-200 aircrafts/models to study aerosol penetrations by an infected COVID-19 passenger into the area around them. 300 replications were conducted including terminal loading and unloading. Inflight simulations conducted in the hanger and at 35 000ft. This study does not take into account human behaviour e.g. talking, eating, drinking, adherence	- High air exchange rates 1.8 x 108 on aircraft. Cumulative particle exposure was 10x less on the airplane compared to a residential house. - Particles were in the cabin less than 6 minutes (vs. 1.5h in a house). Air particulate removal was 15x faster than in a house and 5x faster than in a modern hospital isolation room. - Surgical masks were used in simulations, there was a >90% reduction in droplets released during the cough simulation compared to no mask.

	to mask wearing or other modes of transmission e.g. fomite.	- Sharing a row with a COVID-19 case is the highest risk, the row behind and in front are the next highest risk. There was little practical difference in risk between seats. See figures in paper. - The individual air nozzle did not make a difference to the risk. - During embarking and disembarking, keeping the air circulating, loading in small groups may reduce risk. There was low risk of jet wave exposure from an infected person already sitting on the plane.
Yan (2020) (54) Simulation experiment Australia[1] Aug 2020[1]	This study developed a computational model to mimic a Boeing 737 economy section with three rows and 9 manikins. This cough flow rate	- The cough flow was found to have a long and effective impact on contaminants transport, up to 4 s (or 8x longer than the cough). - A wide range of sizes of droplets was dispersed in the direction of the cough due to the strong jet-effects of coughing compared to what occurs with ventilated flow. (see figures in paper)
Yang (2018) (55) *In silico* study Australia[1] Dec 2017[1]	Using computational fluid dynamics, this study investigated the effect of cough-jet on local airflow and containment transport in a typical airplane cabin. The particle dispersion from a cough in a three-seat airplane row was simulated.	- The travel distance of cough particles was heavily influenced by the direction and type of cough. The aisle seat person coughing resulted in longer particle travel distance than the middle and window seat. The middle seat was considered the most at risk of exposure seat.
Reviews		
Jayaweera (2020) (64) Review Sri Lanka[1] Jun 2020[1]	Literature Review on aerodynamics of SARS-CoV-2 in droplets and aerosols – in an Airplane Cabin (see appendix). The section of the review that focuses on airplane cabins.	- They describe the flow of air in the cabin and reports a complete air exchange within 2-3 minutes, which should be good for quickly dissipating virus-laden droplets. They also indicate the air is passed through a HEPA filter, which can remove particles >0.3 µm. Cough-jet trajectories with no mask,

		surgical mask and N95 mask are described in the paper.
Leitmeyer (2016) (59) Systematic Review ECDC[1] Aug 2016[1]	A systematic review was conducted on air travel association with the spread of influenza through infected passengers and potential for in-flight transmission. 14 publication, 11 from H1N1 pandemic were included. The systematic review is high quality and includes studies up to October 2015	- Across studies, 2165/4252 traceable passengers were followed-up and of these 163 secondary cases were identified (7.5% secondary attack rate). 42% were seated within two rows of the index case. - The length of the flight was not associated with risk of transmission in this review.

[1] Country of study based on author affiliations and date of study based on publication date.

Methods:

A daily scan of the literature (published and pre-published) is conducted by the Emerging Sciences Group, PHAC. The scan has compiled COVID-19 literature since the beginning of the outbreak and is updated daily. Searches to retrieve relevant COVID-19 literature are conducted in Pubmed, Scopus, BioRxiv, MedRxiv, ArXiv, SSRN, Research Square and cross-referenced with the COVID-19 information centers run by Lancet, BMJ, Elsevier, Nature and Wiley. The daily summary and full scan results are maintained in a refworks database and an excel list that can be searched. Targeted keyword searching is conducted within these databases to identify relevant citations on COVID-19 and SARS-COV-2. Search terms used included: flight or airplane or aircraft or plane. The search netted 649 citations (507 from initial search up to October 28, 2020 and 147 from updated search conducted April 26, 2021), which were screened for relevance to the review. Additional references to relevant synthesis research not related to SARS-CoV-2 or the current pandemic were identified through citations in articles on the current pandemic and an additional google search was executed May 4, 2021 to identify any new non-indexed reports using (COVID-19 or SARS-CoV-2) AND (flight OR plane). Potentially relevant citations were examined to confirm it had relevant data and relevant data is extracted into the review.
This review contains research published up to April 26, 2021.

Peer-review

Route of Transmission:

- Direct contact with infectious droplets
- Inhalation of infectious aerosols
- Indirect contact with infectious agents contaminating inanimate surfaces (fomites)

Nouveaux éléments de preuve sur la COVID-19

Synthèse en bref sur le risque de transmission du COVID-19 en vol, mise à jour 2

Introduction

Quelles sont les preuves de la transmission du COVID-19 lors des voyages aériens, et de l'évaluation du risque et des stratégies d'atténuation autour des voyages aériens?

De nombreux changements ont été mis en œuvre par les compagnies aériennes pendant la pandémie, afin de réduire le risque de transmission du SRAS-CoV-2 lors des voyages aériens. Le présent document résume la documentation sur la transmission du SRAS-CoV-2 en vol, les caractéristiques de ces événements et les stratégies utilisées ou étudiées pour atténuer la transmission dans un avion ou pendant l'embarquement et le débarquement. La première mise à jour de cette revue contenait la littérature publiée jusqu'au 28 octobre 2020. Il s'agit de la deuxième mise à jour et elle inclut les études jusqu'au 26 avril 2021.

Quoi de neuf?

- Vingt-neuf études supplémentaires ont été ajoutées dans cette mise à jour (publiées entre le 28 octobre 2020 et le 26 avril 2021; neuf nouvelles études en vol [tableau 1], neuf examens et évaluations des risques sur la transmission en vol [tableau 2] et onze nouvelles études de simulation sur la réduction de la propagation des virus respiratoires, et l'impact relatif des stratégies d'atténuation pendant les voyages aériens [tableau 3]. Ces nouvelles études portent à 64 le nombre total d'études incluses dans cette revue.

- Plusieurs études ont estimé des taux d'attaque qui varient en fonction de la proximité du cas infecté lorsqu'on est assis dans l'avion. Les estimations varient, mais les taux d'attaque étaient toujours faibles, notamment lorsque le port du masque était obligatoire.

- Quatre évaluations des risques ont été ajoutées à cette mise à jour. Elles fournissent des estimations des probabilités globales de contracter le COVID-19 pendant un vol à différents moments de la pandémie. Ces estimations varient largement en fonction des données utilisées, des hypothèses du modèle et de la prise en compte ou non par le modèle de la sous-déclaration des transmissions en vol.

Points clés

- Vingt-six études sur les vols (recherche des contacts ou cohortes) ont été identifiées, dont neuf n'ont pas rapporté de cas secondaires (cinq sur des rapatriements et quatre sur des vols commerciaux) et dix-sept ont rapporté une transmission probable par exposition en vol. Les résultats du séquençage

du génome entier étaient disponibles pour cinq études et ont permis de relier les cas à une exposition unique en vol. Les implications des nouveaux variants préoccupants n'ont été abordées dans aucune des études capturées.

- Le taux d'attaque global du SRAS-CoV-2 parmi les passagers de vols courts et moyen-courriers (d'une durée de 1,5 à 2,5 heures) était faible.
- Aucune transmission de passagers à l'équipage ou entre membres d'équipage n'a été documentée sur les vols de rapatriement.
- La plupart des cas de transmission en vol se sont produits sur des vols où le port du masque n'était pas obligatoire. La transmission se faisait principalement de passager à passager, bien que quatre études aient rapporté un ou plusieurs événements de transmission de passager à équipage. Sur les vols où le port du masque était obligatoire, certains événements de transmission sont survenus et on pense qu'ils sont dus à une mauvaise utilisation du masque (p. ex., le fait de ne pas couvrir le nez) ou au retrait du masque pour manger ou boire.
- Des contrôles de symptômes et de température ont été effectués sur certains vols. Le manque d'adhésion des passagers à l'autodéclaration des symptômes a entraîné une transmission sur au moins un vol.
- La proximité d'un cas de référence (rayon de deux rangées) était un facteur de risque dans les études où des plans de cabine étaient disponibles.
- Les mesures de santé publique renforcées les plus courantes étaient la distanciation physique en vol, le nettoyage renforcé, les masques obligatoires, l'hygiène des mains, la distanciation physique lors de l'embarquement et du débarquement, les zones réservées à l'équipage et les zones de quarantaine pour les passagers malades. Un sondage mené auprès des passagers et des membres d'équipage a révélé que ces derniers se sentaient plus en sécurité après la mise en œuvre de mesures de sécurité renforcées pour enrayer la transmission et qu'ils estimaient que la plupart des mesures étaient réalisables, à l'exception de la distance physique de 1,5 à 2 m en vol.

- L'atténuation du risque de transmission du SRAS-CoV-2 pendant les voyages aériens a été abordée directement dans 14 examens et évaluations des risques (tableau 2) et indirectement dans 24 examens, modèles prédictifs, expériences de simulation, études de surveillance environnementale et études *in silico* (tableau 3).
  - Les principales conclusions de la littérature sur la transmission du SRAS-CoV-2 pendant les vols sont que de multiples interventions sont nécessaires pour réduire au maximum le risque de transmission (tableau 2); ceci est bien résumé dans la figure de l'annexe du rapport de l'Aviation Public Health Initiative dirigée par l'Université Harvard (1).
    - Une méta-analyse a révélé qu'entre janvier et juin 2020, le risque d'être infecté par le SRAS-CoV-2 dans une cabine d'avion était estimé à 1 cas pour 1,7 million de voyageurs.

- Plus la durée du vol est longue, plus le risque d'infection est élevé. Le retrait des masques pour le service des repas a entraîné une augmentation du risque.
- Les mesures de santé publique visant à maintenir une distance physique pendant l'embarquement, le débarquement et le vol, le renforcement du nettoyage, l'hygiène des mains et le port universel du masque pendant la durée du vol, mises en œuvre dans le cadre d'une approche à plusieurs niveaux, réduisent considérablement le risque de transmission.
- Les systèmes de ventilation des avions sont conçus pour rafraîchir rapidement l'air de la cabine et ce niveau de ventilation réduit considérablement le temps pendant lequel les particules restent dans la cabine par rapport à d'autres environnements intérieurs et réduit ainsi les possibilités de transmission, en particulier lorsqu'il est associé à d'autres mesures de santé publique (tableaux 2 et 3).
- L'adhésion des passagers et de l'équipage aux mesures de santé publique est un facteur essentiel de l'impact de ces mesures visant à réduire le risque de transmission, tout comme les directives de dépistage des symptômes et les procédures à bord.

- La littérature indirecte étudie l'aérodynamique des gouttelettes et des aérosols pour caractériser les situations à haut risque, ou simule les mouvements d'embarquement et en vol pour suggérer des stratégies visant à minimiser l'interaction des personnes et à maximiser la distance entre les personnes en vol (tableau 3).
  - Les concentrations en nombre et en masse de particules en vol dans les avions sont inférieures à celles des magasins de détail/épiceries, des restaurants, des bureaux, des habitations et d'autres moyens de transport.
  - Les passagers qui éternuent ou toussent en étant debout ou en se déplaçant dans la cabine propagent leurs gouttelettes respiratoires beaucoup plus loin que ceux qui sont assis.
  - Le port d'un masque facial a considérablement réduit la propagation des gouttelettes (>90 %).
  - Il a été démontré que l'embarquement dans un avion par groupes d'individus apparentés, les personnes assises en premier à l'arrière de l'avion et aux hublots, ainsi que d'autres algorithmes plus complexes, réduisent l'interaction avec les autres personnes. On également constaté que la diminution du nombre de bagages à main réduisait les interactions à bord. Bien que certaines stratégies telles que l'augmentation du nombre de groupes d'embarquement ou la distanciation sociale puissent sacrifier l'efficacité (c'est-à-dire une durée totale d'embarquement/débarquement plus longue), elles peuvent réduire considérablement le risque d'infection.

- Le regroupement des familles et l'espacement stratégique entre les passagers sur les vols qui ne sont pas au maximum de leur capacité améliorent la distance physique entre les passagers. Les algorithmes développés par les chercheurs ont été présentés pour maximiser ce concept et ont démontré les performances potentielles de ces algorithmes par rapport aux stratégies de siège central vide ou de siège côté couloir vide. Toutes ces stratégies ont vu leur efficacité diminuer sur des avions plus pleins.

Vue d'ensemble des éléments de preuve

Les événements de transmission en vol enregistrés dans les différentes études ont été étudiés par le biais d'études de recherche de contacts et de cohortes. Les études sur les groupes et les épidémies présentent un risque de distorsion en raison de leur nature rétrospective et descriptive. Des cohortes étaient disponibles pour les vols de rapatriement et le risque de distorsion est jugé moindre, car les passagers et l'équipage ont été suivis de manière uniforme pendant une période spécifique.

Parmi les autres types de preuves, citons la littérature d'analyse, allant des examens systématiques de bonne qualité aux commentaires. Il y avait une bonne concordance dans les renseignements et les recommandations entre les divers documents passés en revue.

Les évaluations quantitatives des risques, les modèles prédictifs, les expériences de simulation et autres études *in silico* étaient très variables dans leurs objectifs et leurs approches. Aucune tentative d'évaluation de la validité de ces études n'a été effectuée. Ces études visent à imiter un scénario du monde réel, généralement pour explorer divers choix d'interventions. Leurs résultats doivent être interprétés avec prudence, car ils peuvent ne pas refléter ce qui se passerait sur le terrain.

Il n'y avait qu'un petit nombre de vols pour lesquels des études épidémiologiques sur d'éventuels événements de transmission avaient été entreprises. Ces événements sont probablement sous-déclarés ou sous-enquêtés en raison de la logistique et des ressources disponibles pour la recherche des contacts. Il est également difficile de classer les cas de transmission en vol, car l'infection au SRAS-CoV-2 peut se produire avant le départ, à divers moments du voyage, ou pendant la quarantaine/à l'arrivée. Le séquençage du génome entier peut aider à établir un lien entre les cas et une exposition unique en vol. Les étudess, évaluations des risques et modèles prédictifs à venir devraient également porter sur les implications des variants émergents du SRAS-CoV-2 et leurs attributs (p. ex., transmissibilité accrue) sur le risque de transmission en vol, ainsi que sur le statut vaccinal des voyageurs et du personnel des compagnies aériennes pour atténuer le risque.

CONTENU

ÉVÉNEMENTS DE TRANSMISSION DANS LES AVIONS

L'étendue complète de l'exposition au COVID-19 associée aux avions n'est pas connue. Le tableau ci-dessous énumère 26 études (9 sont nouvelles depuis la dernière mise à jour de l'examen) dans lesquelles la possibilité de transmission du SRAS-CoV-2 en vol a été étudiée. Dix-sept rapportent qu'une transmission a eu lieu et 9 rapportent qu'aucune transmission n'a eu lieu pendant les vols. Plusieurs études portant sur des vols de rapatriement où de nombreuses précautions ont été prises ne rapportent aucune transmission à l'équipage (2-7).

Le dépistage des symptômes et de la température à l'aéroport a été mentionné dans quelques études. L'incapacité des personnes à se déclarer et à respecter les directives de dépistage démontre que le dépistage n'est pas une mesure de contrôle efficace en soi; il doit être utilisé en conjonction avec d'autres précautions. Cela a été bien démontré dans l'épidémie de la classe affaires rapportée par Khanh et coll. (2020) où un cas de référence a provoqué 15 cas secondaires sur un vol où les masques n'étaient pas obligatoires (8).

Bon nombre des événements de transmission les plus importants se sont produits avant le port obligatoire de masques sur les vols (8-11) ou la mise en œuvre d'autres stratégies de réduction des risques. Il existe également quelques cas où des événements de transmission se sont produits alors que les masques faciaux étaient obligatoires (12-15). Les études qui ont examiné l'adhésion et l'utilisation correcte des masques faciaux lors de ces événements de transmission ont rapporté à la fois une utilisation incorrecte du masque (p. ex., il ne couvrait pas le nez), et le fait de manger et de boire dans l'avion pendant le retrait du masque. Une étude épidémiologique a suggéré une transmission en vol du SRAS-CoV-2 d'un passager à un agent de bord, puis une transmission secondaire quelques jours plus tard à un autre agent de bord qui a partagé la zone de repos de l'équipage et les transports terrestres avec l'agent de bord infecté (l'utilisation de masques faciaux sur les vols n'a pas été mentionnée) (16).

Une étude portant sur 18 vols à destination de l'Angleterre rapporte que la transmission globale du SRAS-CoV-2 sur les vols courts et moyen-courriers (1,5-2,5 heures) est faible, avec un taux d'attaque de seulement 0,2 % (IC 95 %, 0,1-0,5) parmi les contacts en vol seulement (17). Le taux d'attaque était plus élevé chez les contacts qui étaient assis dans un rayon de deux sièges des cas infectieux (3,8 %; IC95 % : 1,3-10,6 %); cependant, le risque le plus élevé se trouvait chez les covoyageurs ayant eu de multiples expositions hors vol au cas infecté (AR 13 %; IC95 % : 7,6-21,4). D'autres épidémies pour lesquelles on disposait d'un plan des sièges, lorsqu'il était disponible, ont pu montrer la proximité des cas secondaires par rapport aux cas de référence, ce qui a montré que les personnes assises dans les deux rangs du cas de référence avaient un risque plus élevé de contracter le COVID-19 (8, 17, 18). Cependant, dans l'ensemble des épidémies, plusieurs cas ont été observés dans des endroits beaucoup plus éloignés et le mode ou les circonstances de

transmission n'étaient pas évidents (ils auraient pu provenir d'un déplacement dans la cabine, de toilettes partagées ou d'une transmission par vecteur) et ne peuvent être confirmés (8, 9, 19, 20).

Dans les rapports d'épidémies, il est souvent mentionné que le siège côté hublot devrait être plus sûr, car il y a moins de contacts avec d'autres personnes que sur les sièges côté couloir. Cependant, une étude a montré que le fait d'être sur un siège côté hublot présentait un risque plus élevé que le siège côté couloir (9). Il s'agit d'un résultat inattendu que les auteurs n'ont pas pu expliquer. Le tableau 3 décrit les études qui examinent les différences potentielles de risque liées au fait d'être assis dans différentes zones et sur différents sièges d'un avion.

Le séquençage du génome entier (SGE) a été entrepris dans cinq études. Dans tous les cas, il a permis d'identifier les cas liés à la même source et, dans les études australienne et néo-zélandaise, il a permis d'obtenir des renseignements que l'étude épidémiologique n'aurait pu fournir (9, 12, 21).

Plusieurs limites sont observées dans ces études; elles sont principalement liées aux limitations des données obtenues. Par exemple, les contacts avant/après le vol entre le cas de référence et les contacts secondaires n'ont pas pu être exclus (8, 9, 15, 16, 18, 20, 22), et pour certaines études, le lieu de séjour n'était pas connu (8, 13).

Tableau 1 : Liste des événements de transmission qui se sont produits pendant les vols (n = 26)

ÉTUDE	MÉTHODE	PRINCIPAUX RÉSULTATS
Vols avec cas secondaires identifiés		
Blomquist (2021) (17) *nouveau* Cohorte ROYAUME-UNI Déc. 2020	Infections identifiées parmi 18 passagers sur des vols limités à l'Angleterre, avec des cas infectieux, en utilisant des ensembles de données de gestion de cas nationaux. Les passagers ont été considérés comme infectieux pendant le vol si les résultats de laboratoire étaient positifs sept jours avant ou deux jours après le vol. Note : le séquençage du génome entier n'a pas pu être appliqué, car ces données n'étaient pas disponibles pour les cas de	- L'étude a permis de déterminer que cinq cas étaient liés à une transmission potentielle par avion, 55 passagers infectieux et 2 313 copassagers, avec 2 221 ayant eu des contacts uniquement en vol. La transmission globale du SRAS-CoV-2 à court et à moyen terme a été estimée faible. - Les taux d'attaque suivants ont été estimés : - 0,2 % (IC 95 %, 0,1- -0,5) parmi tous les contacts en vol seulement. - 3,8 % (IC 95 %, 1,3- -10,6) parmi les personnes ayant eu des contacts seulement en vol, qui se sont assises dans un dans un rayon de deux sièges. - 13,0 % (IC 95 %, 7,6 %- -21,4 %) parmi les covoyageurs ayant eu de multiples expositions non aériennes à des cas infectieux.

	référence et secondaires du même vol.	
Swadi (2021) (21) *nouveau* Étude sur les épidémies Nouvelle-Zélande Sept. 2020	Une étude approfondie sur la source potentielle des infections au COVID-19 chez sept voyageurs qui étaient sur un vol de Dubaï, UAB, le 29 septembre 2020, avec une escale à Kuala Lumpur, Malaisie, et un atterrissage à Auckland, Nouvelle-Zélande (durée : 18 heures). Ces sept passagers avaient été assis à quatre rangées les uns des autres. Il a été possible de déterminer la lignée des génomes obtenus à partir des sept passagers. L'utilisation du masque n'était pas obligatoire. Le transport après le vol vers les installations de quarantaine a été éloigné physiquement dans la mesure du possible, et le port du masque a été rendu obligatoire.	- Au cours de la période requise de 14 jours d'isolement et de quarantaine gérée, sept passagers qui avaient voyagé sur le vol ont reçu des résultats positifs aux tests de dépistage du SRAS-CoV-2. - Les sept passagers avaient commencé leur voyage depuis cinq pays différents avant une escale à Dubaï. Les résultats des tests de dépistage du SRAS-CoV-2 effectués avant l'embarquement étaient négatifs pour cinq d'entre eux. Aucun des passagers n'a signalé de contact rapproché à l'aéroport de Dubaï. - Parmi les sept passagers, deux étaient probablement des cas de référence infectés avant le vol, quatre ont été probablement infectés pendant le vol, et le dernier passager a été probablement infecté pendant son isolement. - Cinq des sept cas ont porté des masques et des gants pendant le vol, y compris les deux cas de référence, tandis que les deux autres cas ne l'ont pas fait. - L'analyse génomique a montré que les séquences obtenues à partir des sept cas étaient attribuées à la lignée B.1 et génétiquement identiques.
Eichler (2021) (12) *nouveau* Étude sur les épidémies Nouvelle-Zélande Août 2020	Étude sur l'origine des multiples cas de COVID-19 identifiés après 14 jours de quarantaine post-voyage.	- La séquence génomique et l'analyse épidémiologique ont permis d'identifier une chaîne de transmission à ramifications multiples comprenant des voyages aériens internationaux et nationaux et une probable transmission par aérosol dans l'hôtel de quarantaine (non résumée ci-dessous). - Le cas de référence a été identifié comme étant un citoyen rapatrié d'Inde qui revenait en Nouvelle-Zélande. - Trois cas secondaires provenant du cas de référence du vol international de 18 heures (35 % d'occupation) sur un Boeing 747 ont été identifiés par analyse du génome entier. Les trois

		cas étaient assis à deux rangées l'un de l'autre et devaient porter des masques faciaux. - La transmission de l'infection en vol s'est également produite à partir d'un des cas secondaires qui a été exposé sans le savoir pendant la quarantaine et libéré de la quarantaine avant d'être positif; trois passagers ont été infectés pendant un vol intérieur de 85 minutes (capacité de 50 %) sur un Boeing 737. Les trois cas étaient assis les uns à côté des autres (en face les uns des autres), tandis que le cas infectieux est assis à l'écart. - Note : Tous les passagers portaient des masques pendant les vols.
Mun (2021) (16) *nouveau* Série de cas Corée du Sud Février-Mars 2020	Cette série de cas décrit deux agents de bord ayant reçu un diagnostic de COVID-19, qui ont partagé l'aire de repos de l'équipage et les transports terrestres. Elle traite des risques encourus par les agents de bord.	- Le premier agent est tombé malade le 21 février 2020 et a été diagnostiqué le 25 février 2020. Des étudess épidémiologiques approfondies ont suggéré que la transmission de la maladie en vol était la source de l'infection, car l'agent de bord avait travaillé pendant un vol le 15 février 2020, qui avait à son bord 39 pèlerins catholiques coréens venant de Tel-Aviv, Israël. Peu après leur retour en Corée du Sud, 30 pèlerins ont reçu un diagnostic de COVID-19. Il n'y avait pas d'autres sources identifiées dans ce cas. Après le vol, l'agent a continué à travailler entre le 19 et le 22 février 2020. - Après que le premier agent de bord eut reçu un diagnostic de COVID-19, une période d'autoquarantaine de deux semaines a été imposée à tous les membres de l'équipage (n=30). Un seul membre d'équipage a reçu un diagnostic de COVID-19 pendant cette quarantaine, le 6 mars 2020. Bien que les deux agents de bord travaillaient sur des ponts différents de l'avion, ils avaient partagé la salle de repos de l'équipage et les transports terrestres après que le premier agent de bord eut développé des symptômes.
Wang (2021) (20) *nouveau*	Activités de recherche au sein d'un groupe familial en contact avec le COVID-19. Le groupe signalé comprenait	- La source d'infection dans ce groupe était la petite amie d'un membre de la famille qui avait voyagé par avion depuis la province de Guizhou. Ce cas a été en contact étroit avec un cas

Étude sur les groupes Chine Février 2020	trois cas confirmés, deux infections asymptomatiques et un total de 34 contacts étroits au sein de la famille, dont huit rendaient visite à des parents d'autres provinces, et 1 était sur le même vol qu'un cas confirmé.	confirmé dans l'avion, alors qu'elle faisait la queue pour les toilettes, et qu'elle montait et descendait de l'avion.
Murphy (2020) (19) Enquête sur l'éclosion Irlande De juin à août 2020	Une enquête sur l'éclosion de cas de COVID-19 lors d'un vol international à destination de l'Irlande pendant l'été 2020. Dans cette étude, 9 personnes portaient un masque, 1 enfant n'en portait pas et aucun détail n'est indiqué pour les 3 autres personnes.	Ce vol international (d'une durée de 7,5 h) a donné lieu à 13 cas. Les cas provenaient de trois continents différents. L'avion ne comptait que 49 passagers et 12 membres d'équipage. Aucune autre donnée n'est disponible pour les membres d'équipage ou les 11 autres passagers. Le séquençage du génome entier (SGE) a montré que les 5 souches provenant des passagers étaient appariés, ce qui suggère une source unique d'infection. L'enquête épidémiologique n'a pas permis de déterminer le ou les cas index, mais des théories plausibles suggèrent qu'une proportion des cas aurait attrapé la COVID-19 pendant le vol. Parmi les personnes qui auraient attrapé le virus en vol, 4 n'étaient pas assises près d'un cas positif, n'avaient aucun contact pendant le voyage, portaient des masques pendant le vol et n'auraient pas eu ce qui est jugé comme des contacts étroits avec d'autres. - L'exemple d'un réseau social est utilisé pour montrer comment un cas en vol peut entraîner la propagation du SRAS-CoV-2 à 46 contacts secondaires dans la collectivité.
Speake (2020) (9) Enquête sur les grappes Australie Mars 2020	Le 19 mars 2020, un Airbus A330-200 reliant la Nouvelle-Galles du Sud à Perth (vol d'une durée de 5 h) transportait 28 passagers en classe affaires et 213 en classe économique.	29 passagers de ce vol ont été atteints de SRAS-CoV-2 alors que 35 autres ont présenté des symptômes compatibles, mais avec des résultats négatifs. 18 personnes provenaient de navires de croisière alors que 10 autres étaient des voyageurs nationaux et internationaux. Le SGE a permis d'établir que 18 cas étaient des cas considérés comme primaires : 13 provenant du

	Une étude épidémiologique et de séquençage du génome complet a été effectuée. Lors de ce vol, peu de personnes portaient le masque et lorsqu'il était porté, il l'était de façon inconsistante.	Ruby Princess, 4 provenant du Ovation of the Seas et 1 voyageur venu des États-Unis. Parmi les 11 cas secondaires, 3 n'avaient pas de SGE et ont été classés comme possibles, alors que 8 contagions ont été considérées comme ayant eu lieu en vol. Les 8 cas ne se connaissaient pas, et 4 venaient des États-Unis alors que les 4 autres venaient d'Australie. Des 11 cas secondaires, 8 se trouvaient à moins de 2 rangées d'un cas infecté alors que 3 étaient plus loin. Tous les cas secondaires provenaient de la section centrale de l'avion, malgré 5 cas d'infection qui se trouvaient dans la partie arrière de la cabine. 64 % des répondants occupaient un siège près du hublot avec un rapport de risque de 5,2 (IC à 95 %, de 1,6 à 15,4). - Le SGE a permis d'attribuer correctement les cas à la transmission en vol.
Khanh (2020) (8) Enquête sur les grappes Vietnam Mars 2020	Vol de Londres (Royaume-Uni) à Hanoï (Vietnam) le 2 mars 2020 (durée : 10 h). Tous les passagers et membres d'équipage qui ont été retracés avec succès ont été interrogés, testés et mis en quarantaine. Lors de l'arrivée, des contrôles de température et un dépistage des symptômes ont été effectués et les passagers de certains pays (pas le Royaume-Uni) ont dû subir des tests de dépistage pour le SRAS-CoV-2. Le port du masque n'étaient pas obligatoire à bord des avions.	Cet avion comptait 16 membres d'équipage et 201 passagers. Le cas index, assis en classe affaires, a commencé à avoir des symptômes la veille du vol. Pendant l'enquête de recherche de contacts, 14 passagers et 1 membre d'équipage ont été jugés positifs. 12 personnes étaient en classe affaires et 92 % d'entre elles étaient assis à moins de 2 mètres du cas index et 1 autre se trouvait à plus de 2 mètres, rapport de risque de 7,3 (IC à 95 %, de 1,2 à 46,2). Trois autres contacts (2 passagers et 1 agent de bord) n'ont pas eu de contact étroit avec le cas index, car ils étaient en classe économique.
Choi (2020) (10) Enquête sur les grappes Hong Kong	Une étude portant sur les cas confirmés de COVID-19 à Hong Kong et sur l'historique de voyage des personnes a permis d'identifier quatre	La grappe comprenait 2 passagers (un couple marié) en classe affaires et 2 membres d'équipage.

Mars 2020	personnes qui ont pris un vol en partance de Boston, aux États-Unis, à destination de Hong Kong, en Chine, le 9 mars 2020. L'avion était un Boeing 700-300ER (vol d'une durée de plus de 15 h), avec 294 passagers. Les passagers n'ont pas tous été soumis à des tests. Il n'y avait ni quarantaine obligatoire ni contrôle à l'aéroport. L'utilisation des masques n'a pas été mentionnée.	Le couple a eu des symptômes le 10 mars, ce qui veut dire qu'il était déjà infecté au moment du voyage. Les agents de bord ont développé des symptômes le16 et 18 mars. L'un des 2 agents de bord a passé 5 jours à Boston, mais les déplacements de l'autre n'ont pu être confirmés. Leurs séquences virales étaient 100% identiques et n'étaient pas les séquences vues à Hong Kong. Cependant, des correspondances étroites ont été effectuées avec des cas à Toronto, à New York et à Boston. - D'après cette analyse, les auteurs concluent qu'il est probable que le couple a transmis le SRAS-CoV-2 aux agents de bord pendant le vol.
Hoehl (2020) (18) Enquête sur l'éclosion Allemagne Mars 2020	102 passagers d'un vol en partance de Tel-Aviv (Israël) à destination de Francfort (Allemagne), le 9 mars 2020. 24 personnes faisaient partie d'un groupe de touristes qui, sans le savoir, avaient été en contact avec un gérant d'hôtel infecté 7 jours auparavant. Aucune mesure préventive n'a été prise pendant le vol. L'équipage n'a pas fait l'objet d'un suivi. Des tests d'anticorps ont été offerts, mais de nombreux passagers n'ont pas été testés, ce qui veut dire d'autres événements de transmission n'ont peut-être pas été détectés.	A leur arrivée, le groupe de touristes a été testé pour le SRAS-CoV-2 et 7 personnes sur 24 ont obtenu un résultat positif. Sur ce vol, les 7 membres du groupe ayant obtenu des résultats positifs étaient symptomatiques (n = 4), présymptomatiques (n = 2) et asymptomatiques (n = 1). 1 seul des 71 autres passagers pour lequel des données de suivi ont été obtenues a déclaré avoir subi un test RT-PCR positif 4 jours après le vol. 7 des 71 personnes ont indiqué avoir eu des symptômes de la COVID-19 dans les 14 jours suivant le vol. L'une d'elles a obtenu un résultat positif à la suite d'un test sérologique de l'IgG et d'un test PRNT. - Les deux cas confirmés sont considérés comme des événements probables de transmission à bord; ils se trouvaient à moins de deux rangées d'un cas index.
Bae (2020) (13) Étude de cohorte Corée du Sud Mars 2020	299 passagers ont pris un vol d'évacuation en provenance de Milan, en Italie, à destination de la Corée du Sud (vol d'une durée de 11 h) le 31 mars 2020. Des	Selon les résultats du test RT-PCR et l'absence de symptômes, 6 personnes évacuées étaient asymptomatiques. - L'une des personnes évacuées, qui s'est mise en quarantaine pendant trois semaines avant le vol,

	examens médicaux ont été effectués avant le vol, tout le monde portait des masques N95, sauf quand une distanciation sociale était respectée au moment de l'embarquement et du débarquement et pendant les repas. Toutes les personnes évacuées ont été en observation médicale pendant une quarantaine qui a duré 14 jours et ont subi des tests RT-PCR les jours 1 et 14.	puis deux semaines après le vol, a subi un test RT-PCR positif le 14e jour de sa quarantaine en Corée du Sud. Les auteurs suggèrent que l'exposition s'est probablement produite pendant le vol puisqu'elle se trouvait à 3 rangées d'un cas asymptomatique et qu'ils ont partagé la même toilette.
Zhang (2020) (14) *préimpression* Étude de cohorte Chine Mars 2020	Au cours du mois de mars, tous les passagers et membres d'équipage soupçonnés d'avoir été infectés par le SRAS-CoV-2 sur 830 vols internationaux à destination de Pékin ont été inscrits (n = 4 492/130 000 passagers au total). Les suspects ont été mis en quarantaine, testés et des enquêtes épidémiologiques ont été effectuées Le port universel du masque avait été mis en place. On a également remarqué que de nombreux passagers portaient d'autres vêtements de protection, des gants et des lunettes de protection.	Des 4 492 cas suspects, 161 ont été confirmés après des tests (âge moyen de 28,6 ans). On trouvait un cas dans 94 vols sur 830 (> 10 %). Lors d'un vol entre Madrid et Pékin (durée du vol de 10 h 18), une grappe de 11 cas de COVID-19 ayant des antécédents de contact étroit a été identifiée. Aucun cas secondaire de passagers assis dans les deux rangées autour n'a été identifié. Il se pourrait que deux cas aient été exposés pendant le vol, car ils n'avaient pas d'expositions plausibles à la COVID-19, autre que le vol. En supposant que ces 2 cas ont été infectés pendant le vol, le taux d'attaque était de 0,14 % (entre 0,0 et 0,34 %) sur 94 vols avec 14 505 passagers. Le port universel du masque et les systèmes de ventilation des avions étaient considérés comme une protection contre la transmission.
Pavli (2020) (23) Enquête sur les grappes Grèce	Activités de recherche des contacts pour des passagers internationaux en provenance de la Grèce ou à destination de ce pays entre	On a retracé 18 vols comprenant 21 cas index, 891 passagers et 90 membres d'équipage. Des 21 cas index, 6 étaient symptomatiques, 12 étaient pré-symptomatiques et 2 ont présenté des symptômes 5 à 7 jours après le vol.

Entre février et mars 2020	le 26 février et le 9 mars 2020. Aucune mesure de santé publique n'a été notée.	En outre, 5 cas secondaires ont également été identifiés. Il est fort possible que cette transmission ait eu lieu pendant un même vol (d'Israël en Grèce, durée de 2 h) où se trouvaient 2 cas de COVID-19. Les cas secondaires se trouvaient à moins de deux sièges d'un cas index.
Eldin (2020) (22) Fiche d'observation France Février 2020	Enquête sur un ressortissant français qui a développé la COVID-19 peu après son retour en France. Il avait quitté la France le 13 février pour Bangui, en République centrafricaine, et il était retourné à Marseille, en France, avec son partenaire le 24 février en passant par Yaoundé, au Cameroun.	Cette enquête suggère que la transmission s'est produite lors du vol entre Bangui et Yaoundé, où des ressortissants français se trouvaient dans le même avion que le premier cas de COVID-19 diagnostiqué au Cameroun après le vol du 24 février. Le ressortissant français a développé des symptômes peu après son retour à Marseille, en France. Le vol est le point d'exposition le plus plausible.
Yang (2020) (11) Enquête sur les grappes Chine Entre janvier et février 2020	Un vol de Singapour à Hangzhou (vol d'une durée de 5 h) transportant 325 personnes le 23 janvier 2020. Le plan de cabine n'a pas été obtenu, ce qui veut dire que la proximité physique entre le cas index et d'autres cas n'est pas connue. Les agents de bord portaient des masques, mais pas la plupart des passagers.	- Le cas index a développé une fièvre pendant le vol et ne portait pas de masque. Il a été identifié au moment du débarquement et a subi des tests qui se sont révélés positifs. Tous les passagers ont été mis en quarantaine pendant 14 jours. 11 autres passagers ont développé des symptômes et ont reçu un résultat positif, ce qui donne un taux d'attaque de 3,4 %.
Chen (2020) (15) Enquête sur les grappes Chine Entre janvier et février 2020	Un vol de Singapour à Hangzhou (vol d'une durée de 5 h) transportant 335 personnes le 24 janvier 2020. Le vol a été géré de façon stricte parce que 100 personnes qui s'y trouvaient venaient de Wuhan.	L'on a diagnostiqué 16 cas de COVID-19 sur 335 passagers, soit un taux d'attaque de 4,8 %. Aucun des membres de l'équipage n'a été infecté. - Seul un passager n'avait pas d'antécédents épidémiologiques plausibles d'exposition avant le vol. Pendant le vol, il a été assis pendant 1 heure près de 4 passagers infectés en provenance de Wuhan et il n'a pas porté son masque de façon appropriée (non serré et nez non couvert).

	Tous les passagers ont été mis en quarantaine pendant 14 jours. Les gens ont porté un masque pendant tout le vol, sauf au moment de manger et de boire.	
Kong (2020) (24) Cohorte rétrospective. Chine Janvier 2020	Ce document décrit en détail le voyage et la transmission potentielle du SRAS-CoV-2 d'un cas index du groupe A à trois autres groupes de voyageurs qui ont été en Europe du 16 au 28 janvier. Les vols et l'hébergement partagés ont été pris en compte dans l'enquête épidémiologique. L'utilisation d'un masque ou d'autres précautions n'ont pas été mentionnées.	La transmission dans le groupe de touristes (groupe A) a entraîné 13 infections confirmées ou présumées qui auraient pu se produire à bord d'un avion, d'un autobus ou pendant des visites guidées. Le premier cas a été hospitalisé le 22 janvier, et d'autres membres du groupe sont tombés malades à compter du 26 janvier. Il semble peu probable que la transmission du groupe A au groupe B se soit produite lors du vol du 16 janvier, puisque les 3 cas du groupe B n'ont été identifiés que le 29 janvier. Il est plausible que la transmission du groupe A à deux autres, à un guide touristique du groupe C et à un voyageur indépendant se soit produite sur un vol le 28 janvier. - Il est également plausible que la transmission du groupe A à trois personnes du groupe D se soit produite dans le lieu l'hébergement partagés par les deux groupes le 22 janvier.
Vols sans cas secondaires identifiés		
Karim (2020) (5) *nouveau* Étude descriptive Malaisie Février-Avril 2020	Cet article résume le rapatriement des citoyens malaisiens à l'aide d'un avion commercial affrété. La mission avait pour but de rapatrier autant de citoyens que possible en fonction de la capacité de l'avion et d'empêcher la transmission de la maladie au personnel de bord. Tout le personnel de bord a suivi une séance d'information sur les procédures de sécurité en vol et sur l'utilisation des	- On a détecté 82 cas positifs parmi les citoyens rapatriés. La transmission secondaire parmi les citoyens rapatriés pendant le vol n'a pas été étudiée. - Un seul cas positif a été relevé chez un travailleur de la santé impliqué dans la mission, sur la base de l'échantillon prélevé à l'arrivée du vol. Ce travailleur était asymptomatique; lorsqu'il a refait le test, le résultat était négatif (possiblement faux positif ou erreur d'échantillonnage). Aucune étude sur la façon dont le travailleur a pu contracter l'infection n'a été décrite. Il n'y a pas eu d'infection chez les membres d'équipage qui ont travaillé sur le cas.

	équipements de protection individuelle (EPI). Tous les rapatriés devaient porter des masques et se désinfecter les mains à l'embarquement.	
Ruonan (2021) (25) *nouveau* Analyse de la surveillance Chine Janvier-Avril 2020	Nous avons analysé les données sur les cas importés de Guangzhou à partir du Système national de gestion de l'information pour les rapports sur les maladies infectieuses du Système d'information sur le contrôle et la prévention des maladies en Chine.	- Sur 34 vols, 10 (29,4 %) avaient plus de trois cas à bord. Il n'y a aucune preuve évidente de la propagation du COVID-19 sur chacun des vols.
Kim (2020) (6) *nouveau* Cohorte Corée du Sud Mars 2020	Décrit un vol de rapatriement de 80 Coréens de l'Iran vers la Corée, avec un transfert direct des passagers entre avions à Dubaï. Des précautions strictes de prévention des infections ont été mises en place (c'est-à-dire des rideaux en vinyle pour séparer les zones propres et contaminées, des EPI, des masques faciaux et une distanciation sociale). Les passagers présentant des symptômes au cours des deux dernières semaines ont été désignés comme « patients faisant l'objet d'examens » (PUI). Toutes les personnes à bord du vol ont subi un dépistage du SRAS-CoV-2 à leur arrivée en Corée et ont été soumises à une quarantaine médicale obligatoire de 14 jours.	- Un passager a été identifié comme étant un PUI pendant la première partie du vol, mais le test s'est avéré négatif à l'arrivée et un autre passager a été catégorisé comme étant un PUI pendant la deuxième partie du vol après avoir développé une fièvre et le test s'est avéré positif à l'arrivée. Aucun autre passager, équipage, personnel médical ou autre personne ayant participé à l'évacuation n'a développé de signes d'infection pendant la période d'observation de 14 jours.
Suzuki (2021) (7) *nouveau*	Mesure des titres d'anticorps sériques pour le SRAS-CoV-2 chez 10 travailleurs de la santé qui ont participé à	- Le taux médian de conformité à l'EPI était de 90 % (intervalle 70-100 %, n=8).

Cohorte Japon Février-Mars 2020	l'exploitation des vols affrétés pour l'évacuation des résidents japonais de la province du Hubei. Tous les participants portaient un EPI. Des échantillons de sang ont été prélevés lors de l'inscription (après le 14 février) et toutes les deux semaines après l'inscription jusqu'à quatre semaines après la participation finale à l'opération d'évacuation.	- Le nombre de cas positifs sur chacun des cinq vols était respectivement de 3, 2, 2, 1 et 0. - Tous les échantillons de l'ensemble du personnel de santé étaient séronégatifs, ce qui indique que l'EPI a permis de protéger efficacement le personnel lors des vols de rapatriement.
Draper (2020) (26) Enquête sur la recherche des contacts Australie Entre mars et avril 2020	Deux vols avec un membre d'équipage infecté ont été signalés dans le Territoire du Nord, en Australie. Les 555 passagers ont tous été considérés comme des contacts étroits qui exigeaient des activités de recherche de contacts et de mise en quarantaine. Il y a eu 28 cas et 527 contacts étroits au cours de ces deux mois. Un taux de suivi de 94 % a été atteint. Aucune mesure de santé publique ni aucune mention du port de masque n'a été notée.	En raison d'un retard dans l'obtention des manifestes, il a fallu presque une semaine avant que les passagers du vol ne soient avisés (n = 195 personnes qui ont dû se mettre en quarantaine). On a également surveillé 326 passagers aériens qui ont pris d'autres vols, dont 131 ont été mis en quarantaine parce qu'ils se trouvaient dans la même rangée ou à moins de 2 rangées d'un cas infecté. - Aucun cas secondaire (0 %, IC à 95 % : entre 0 et 1,1 %) associé à ces vols n'a été identifié.
Cornelius (2020) (2) Étude descriptive États-Unis Entre janvier et mars 2020	Cet article résume le rapatriement de citoyens américains par les équipes d'évacuation médicale aérienne du ministère de la Santé et des Services sociaux des États-Unis.	L'étude a porté sur 39 vols comptant plus de 2 000 personnes. - L'article décrit en détail les précautions prises pour transporter de nombreuses personnes potentiellement infectées. Les pratiques exemplaires en matière de protocoles de contrôle et de prévention des infections pendant le transport aérien sont décrites dans le document. Aucun cas de COVID-19 acquis pendant ces vols d'évacuation n'a été identifié chez les travailleurs des interventions d'urgence.

Nir-Paz (2020) (3) Étude de cohorte Israël Février 2020	Cet article décrit le rapatriement de 11 citoyens qui se trouvaient sur le navire de croisière Diamond Princess. Avant d'embarquer dans un vol de 13,5 heures le 20 février 2020, les 11 citoyens ont d'abord obtenu un résultat négatif au test RT-PCR pour le SRAS-CoV-2. Des précautions ont été prises, tout le monde portait des masques chirurgicaux ou des masques FFP2 et l'équipage n'a eu qu'un minimum d'interactions avec les passagers.	Deux des citoyens rapatriés (un couple) étaient séropositifs au SRAS-CoV-2 à leur arrivée. On suppose donc qu'ils étaient infectieux lorsqu'ils ont pris l'avion. Aucun cas secondaire n'a été identifié parmi les autres citoyens rapatriés ou parmi les 4 membres d'équipage. - Tous les passagers du vol ont porté leur masque, sauf pour manger et boire.
Schwartz (2020) (27) Études de cas Canada Janvier 2020	Rapports sur le cas index qui est arrivé à Toronto le 22 janvier, après un vol de 15 heures en provenance de la Chine avec 350 personnes à bord. Aucune mesure de santé publique ni aucune mention du port de masque n'a été notée.	- Aucun cas secondaire de COVID-19 n'a été relevé malgré le suivi de la santé publique.
Qian (2020) (28) Enquête sur la recherche des contacts Chine Janvier 2020	12 cas ont pris un vol de Ningbo à Zhejiang, en Chine, après un événement de super-propagation du virus dans un temple de Ningbo. Aucune mesure de santé publique ni aucune mention du port de masque n'a été notée.	Onze de ces cas étaient liés au temple; l'exposition pour un cas était inconnue, mais on ne pensait pas qu'elle avait eu lieu pendant le vol. Aucun cas secondaire n'est connu pour s'être produit à la suite du vol. Les résultats des enquêtes de recherche des contacts ont permis d'identifier 88 cas de COVID-19 admis dans cinq hôpitaux de la province du Zhejiang, en Chine.

TA = taux d'attaque

POTENTIEL DE TRANSMISSION DU SRAS-COV-2 EN AVION

Quatorze citations sont incluses dans le tableau 2. Il s'agit d'un groupe mixte de documents de synthèse, de commentaires, de rapports, d'un sondage auprès des passagers et d'évaluations quantitatives des risques qui examinent le risque de transmission du SRAS-CoV-2 en vol.

Le rapport publié par l'Aviation Public Health Initiative (APHI) le 27 octobre 2020 constitue l'évaluation la plus complète du risque de transmission du SRAS-CoV-2 de porte à porte (1). Le présent rapport évalue les preuves disponibles et tient compte de l'avis d'experts et des résultats de simulations dans son évaluation de la réduction du risque de transmission du SRAS-CoV-2 sur les vols. Ils expliquent pourquoi une stratégie d'atténuation des risques à plusieurs niveaux est nécessaire et l'importance de la conformité des passagers et des compagnies aériennes. Des conclusions et recommandations similaires sont décrites dans les autres examens et commentaires du tableau 2.

Un seul sondage auprès des passagers et des équipages a permis d'examiner l'impact et la perception des mesures de sécurité renforcées visant à réduire le risque de transmission du SRAS-CoV-2 de porte à porte (4). Les changements mis en œuvre, tels que les toilettes réservées à l'équipage, le nettoyage fréquent des toilettes, les zones de quarantaine désignées dans l'avion, le port du masque pour tous, l'utilisation d'écrans faciaux, l'hygiène fréquente des mains (gel alcoolisé fourni à tous les passagers) et les contrôles des symptômes et de la température, ont suscité des réactions positives. Les passagers ont indiqué qu'une distance physique de 1,5 à 2 m pouvait être maintenue lors de l'enregistrement, du pré-embarquement et de l'embarquement, mais pas en vol. L'équipage a constaté que remettre aux passagers des masques chirurgicaux, des écrans faciaux et du gel alcoolisé avant le vol n'était pas pratique, car les passagers avaient souvent déjà les mains pleines avec plusieurs bagages à main.

Une méta-analyse a révélé que, de janvier à juin 2020, le risque d'être infecté par le SRAS-CoV-2 dans une cabine d'avion était estimé à 1 cas pour 1,7 million de voyageurs (IC 95 %, 712 000 à 8 millions) (29). Cette analyse a également montré que le risque a été considérablement réduit grâce aux mesures d'atténuation mises en œuvre. En mars 2020, le risque était de 1:425 062 et d'avril à septembre 2020, il était de 1:7,1 millions. D'autres évaluations quantitatives du risque présentées dans le tableau 2 fournissent également des estimations du risque de transmission du SRAS-CoV-2 en avion et, dans de nombreux cas, elles estiment que le risque de transmission est plus élevé que la méta-analyse. Bien que nous sachions que la transmission en vol a été sous-déclarée et que le risque de transmission en vol varie en fonction de nombreux facteurs et des paramètres des modèles, la variabilité des estimations provenant de différentes études ne peut être réconciliée en raison de la variation des approches entre les analyses.

L'effet combiné du port de masques, d'une distanciation sociale entre les passagers, d'une ventilation améliorée et de sièges intermédiaires vacants à 66 % de leur capacité, peut réduire le nombre d'infections de plus de 50 %, et les masques N95 ou chirurgicaux (ASTM 3) réduisent le risque d'infection à 0 (30). Les probabilités d'infection pour un vol de 2 heures sans masque facial étaient comparables à celles d'un vol de 12 heures où tous les passagers portaient des masques à haute efficacité (31). Cette étude a également révélé que le retrait du masque pour le service des repas augmentait le risque. De plus, le fait de retirer environ un tiers des passagers en gardant les sièges du milieu vides et d'augmenter la distance sociale pendant l'embarquement peut réduire considérablement le risque d'infection (de 35 à 50 %) par rapport à un avion

complet (32, 33). Une évaluation des risques a estimé qu'un vol aux États-Unis le 30 juin 2020 présentait un risque de contracter le SRAS-CoV-2 de 1/4300 sur un vol complet et de 1/7700 si la politique du siège central vide était en place (ces chiffres dépendent de l'activité de la maladie dans la population) (34). Plus la durée du vol est longue, plus le risque d'infection par le SRAS-CoV-2 est élevé (31, 35).

Tableau 2 : Examens, rapports, sondage auprès des passagers et évaluations des risques liés à la transmission du SRAS-CoV-2 dans les avions (N=14)

ÉTUDE	MÉTHODE	PRINCIPAUX RÉSULTATS
Pang (2021) (29) *Préimprimé* *nouveau* Examen systématique USA1 Avril 20211	Examen systématique des cas de COVID-19 liés à des voyages aériens jusqu'en septembre 2020. L'examen s'est limité aux vols avec des cas de référence de passagers et n'a pas inclus les transmissions entre l'équipage aérien, le personnel au sol ou le personnel de l'aéroport. Une approche quantitative a été utilisée pour estimer le risque de transmission par les voyages aériens. Des facteurs de correction ont été utilisés dans les estimations de risque pour la transmission asymptomatique et la sous-déclaration. Le risque de transmission a été calculé pour trois périodes d'intérêt : (1) de janvier à juin 2020, période couverte par la littérature; (2) le mois de mars 2020 lorsque la propagation mondiale du COVID-19 se produisait; et (3) d'avril à septembre 2020 pour tenir compte de la forte baisse des voyages aériens dans le monde et de l'utilisation accrue des tests de dépistage du COVID-19.	- En août 2020, il y avait au moins 2 866 cas de référence documentés qui étaient des passagers aériens. - Moins de 50 cas secondaires potentiels documentés associés aux voyages aériens pendant la pandémie ont été signalés. - L'utilisation des masques sur les vols examinés allait de l'utilisation inconnue à l'utilisation obligatoire du N95. - De janvier à juin 2020, le risque d'être infecté par le SRAS-CoV-2 dans une cabine d'avion est estimé à 5,927 x 10-7 ou 1:1,7 million. L'incertitude des facteurs de correction et un intervalle crédible à 95 % indiquent que le risque varie de 1 cas pour 712 000 voyageurs à 1 cas pour 8 millions de voyageurs. - Pour le mois de mars 2020, le risque est estimé à 2,353 x 10-6 ou 1:425 062. - D'avril à septembre 2020, le risque est estimé à 1,413 x10-7 ou 1:7,1 millions.

Soleil (2021) (36) *nouveau* Revue de la littérature Chine[1] Avril 2021[1]	Revue narrative des publications relatives à la pandémie de COVID-19 et au transport aérien publiées en 2020.	- Un résumé de la documentation sur les opérations de contrôle des aéroports et les stratégies d'embarquement. - Résume la littérature existante (2020) concernant les opérations en vol en présence du COVID-19 et les événements de transmission en vol. - La conclusion est que des données robustes et largement disponibles sur les cas de transmission, malgré l'utilisation correcte du masque dans les avions, permettraient d'obtenir des renseignements plus utiles.
Bielecki (2021) (37) *nouveau* Revue de la littérature Suisse[1] Février 2021[1]	Examen narratif des sujets liés au transport aérien en période de pandémie. Parmi les sujets abordés, citons le nombre de voyageurs, la prévention et les recommandations de dépistage en vol, la transmission du SRAS-CoV-2 en vol, la photo-épidémiologie du port du masque, l'interruption des voyages aériens vers les rassemblements de masse, ainsi que les mesures de quarantaine et leur efficacité.	- Le nombre de voyages aériens a considérablement diminué (baisse de 51,6 % par rapport à 2019). - Les vols seront plus sûrs si l'on optimise les procédures de dépistage, si l'on minimise le risque de laisser monter à bord des cas pré ou asymptomatiques (c'est-à-dire si l'on procède à des tests), et si l'on met en œuvre/respecte des mesures d'hygiène simples et de distanciation physique qui empêchent la propagation des maladies. Le contrôle des passagers est insuffisant pour détecter tous les cas infectieux. - Grâce à la circulation d'air élevée et à l'utilisation de filtres HEPA à bord des avions, il est peu probable d'attraper le virus d'une personne qui n'est pas assise à proximité. - Le risque d'infection pendant les vols est faible : Une seule infection par 54 heures de vol et aucune infection pendant un vol de 12 heures.
Khatib (2020) (38) *nouveau* Revue de la littérature Canada[1] Déc. 2020[1]	Examen narratif de la littérature sur les risques de transmission du SRAS-CoV-2 et les stratégies de prévention de l'infection dans le cadre du transport aérien commercial. Les auteurs fournissent des recommandations et proposent des stratégies	- La qualité de l'air à bord des avions modernes est très sûre (les filtres HEPA sont efficaces à 99,97 % pour éliminer les particules comprises entre 0,1 et 0,3 µm de diamètre et 100 % des particules plus grosses). - Des études supplémentaires sont nécessaires pour examiner l'interaction entre le débit d'air et la dispersion des particules qui en résulte, mais les auteurs recommandent d'allumer le débit d'air personnel (*ventilation*) au-dessus de chaque passager pour améliorer le confort durant le voyage, la qualité de l'air, et pour réduire la

	pour atténuer la propagation du COVID-19.	transmission de personne à personne des contaminants exhalés. - Le risque est le plus élevé lors de l'embarquement et du débarquement. - On pense qu'un siège côté hublot est l'option la plus sûre, bien que des études récentes sur des épidémies réelles remettent en question cette hypothèse. - Parmi les recommandations, citons l'utilisation de masques, la promotion d'une désinfection fréquente des mains et l'instauration d'une distance physique, lorsque cela est possible, entre l'embarquement et le débarquement. Les points de contact les plus fréquents doivent être désinfectés entre les vols et pendant le vol. Des mesures de présélection et de prétestage doivent être utilisées en plus des mesures préventives appliquées à bord. La mise en place d'un laissez-passer numérique standardisé pour le COVID-19 et une recherche plus solide des contacts pourraient être des facteurs clés pour permettre un retour progressif et sûr aux voyages aériens.
Marcus (2020) (1) Aviation Public Health Initiative Report from the Harvard TH Chan School of Public Health É.-U.[1] Septembre 2020[1]	Ce rapport de l'APHI comprend les données disponibles jusqu'au 28 septembre 2020 Le présent rapport d'orientation axé sur la recherche évalue la question indiquée ci-dessous à l'aide d'un mélange de revues de la littérature, de modèles *in silico* et d'opinons d'experts : *Au milieu de cette crise complexe et nouvelle de coronavirus, comment les chefs de file du secteur de l'aviation peuvent-ils faire progresser un programme indépendant fondé sur des*	Les interventions non pharmaceutiques à plusieurs niveaux réduisent considérablement le risque de transmission de la maladie. Elles incluent notamment une ventilation optimale, la désinfection des surfaces, le port de masques, des procédures visant à encourager la distanciation sociale, tout particulièrement au moment de l'embarquement et du débarquement, mais aussi pendant le vol (p. ex., pas de file d'attente pour les toilettes ou éviter de se déplacer dans l'avion et réduire au minimum les interactions avec l'équipage). La ventilation des avions est très sophistiquée et fournit une grande quantité d'air pur à la cabine, qui disperse rapidement l'air expiré. Comportement des membres de l'équipage et des passagers : La sécurité du public à bord des avions dépend beaucoup des comportements individuels, y compris les certificats de santé et les vérifications

	données probantes afin de réduire les risques de transmission du SRAS-CoV-2 et, par le fait même, améliorer la sécurité et la confiance des employés et des passagers?	avant l'embarquement, le port obligatoire du masque, le respect de la distanciation sociale et l'adoption de comportements ordonnés pour éviter la congestion, sans oublier le lavage des mains et le nettoyage. Ces bons comportements sont fortement encouragés elle sera inscrite sur une liste d'interdiction de vol pour cause de non-respect. Dans l'ensemble, il n'existe que peu de données sur la transmission pendant le vol, mais il semble qu'un très faible nombre d'infections pourrait être attribué à ce type de transmission. Il existe également des preuves que les interventions non pharmaceutiques, tout particulièrement le port du masque, n'ont pas entraîné de transmission malgré le fait que certains passagers infectieux se trouvaient dans les avions. Ils décrivent 13 manuscrits (également inclus dans le tableau 1) portant sur l'étude de la transmission en vol. Il faut également noter qu'aucun des équipages des vols de rapatriement n'a contracté le SRAS-CoV-2, ce qui démontre que l'utilisation et le respect des interventions non pharmaceutiques sont efficaces. - Des stratégies d'atténuation des risques à plusieurs niveaux peuvent réduire grandement le risque de transmission, mais exigent la conformité tant des passagers que des compagnies aériennes.
Freedman (2020) (39) Analyse bibliographique N.d.[1] Septembre 2020[1]	Examen narratif de toutes les publications sur la transmission du SRAS-CoV-2 en vol, disponibles jusqu'au 21 septembre 2020. Cet examen résume les événements de transmission à l'aide d'attributs comme le port du masque pendant le vol pour tenter de décrire et de quantifier le risque selon différents scénarios et considérations, comme les	Décrit 4 vols bien documentés, dont trois sont indiqués dans le tableau 1 (5 à 7), alors que le quatrième est un inventaire en ligne des vols à destination de Hong Kong qui ont signalé une transmission à 2 passagers, 1 assis avec 5 cas index, alors que les personnes portaient des masques dans l'avion (vol d'une durée de 8 h). 3 événements de transmission uniques ont été signalés et 2 ont été publiés (9, 11). 6 vols à haut risque sans transmission sont répertoriés, 1 a été publié (17). L'inventaire des vols en provenance de Hong Kong comprend de nombreux vols avec des

	taux d'incidence différents du SRAS-CoV-2 au point d'origine et à destination, l'intensité de la charge virale dans les cas index, la durée du vol, les pratiques associées au port de masque dans l'avion, les vérifications effectuées avant le vol et la distanciation entre les passagers. Il n'y avait pas suffisamment de points de données pour quantifier le risque.	passagers ayant eu un résultat positif et aucune transmission secondaire attribuable au vol. 5 vols d'évacuation dont 3 ont été publiés (3, 13) sont répertoriés avec un événement de transmission possible. Selon cet examen, plus de 1,7 million de passagers ont été rapatriés par leur gouvernement ou une compagnie de navires de croisière pendant la pandémie, mais peu de ces rapatriements ont été documentés. Des listes de vols contenant des cas connus de COVID-19 ont été signalées au Canada et en Australie. Ces listes permettent aux autres passagers de s'auto-identifier et de s'isoler. Le CDC des États-Unis recueille également des données, mais n'a publié aucune conclusion. Quels facteurs de risque ont été signalés? Grappe évidente avec cas lorsque des plans de cabine étaient disponibles, mais une certaine transmission a tout de même touché les personnes se trouvant à plus de 2 rangées du cas index. Les vols avec d'importantes grappes de transmission ont été effectués avant que les masques ne soient obligatoires pendant les vols et plusieurs vols à haut risque sans transmission ont exigé que les passagers portent des masques.
Shaimoldina (2020) (40) *nouveau* Commentaire NA[1] Déc. 20201	Un ensemble de données publiques sur les infections liées aux vols internationaux a été utilisé pour analyser la tendance du trafic aérien et des infections pendant la pandémie. En se basant sur la littérature existante, les auteurs décrivent ensuite les défis à relever pour empêcher les personnes infectées par le SRAS-CoV-2 de monter à bord des avions et les	- Les infections en vol ont diminué et les voyages en avion ont été considérablement réduits. - Il est difficile d'empêcher les personnes infectées par le SRAS-CoV-2 de monter à bord des avions en raison de la précision des tests, des cas asymptomatiques et de nombreux autres facteurs, notamment l'impossibilité de maintenir une distance physique et la densité des passagers dans un avion. - Les solutions peuvent inclure la mise en quarantaine des passagers dans les hôtels, l'obligation de porter un EPI, le diagnostic dans les aéroports et le diagnostic rapide par imagerie/biomarqueurs grâce à une technologie de pointe.

	solutions pour la reprise des vols.	
Harries (2020) (41) Commentaires N.d.[1] Août 2020[1]	Est-il sécuritaire de prendre l'avion? Ce commentaire examine les publications disponibles jusqu'en août 2020. Des éclosions historiques ont été signalées pour la tuberculose, les maladies semblables à la grippe et le SRAS-CoV-1.	La ventilation dans un avion est très bonne. Elle peut toutefois être perturbée par les déplacements des passagers, la toux, etc. Les sièges près de l'allée ont tendance à entraîner plus de contacts avec les autres personnes que les sièges près des hublots. Ils recommandent de suivre les documents d'orientation disponibles : porter un masque bien ajusté et un écran facial ou des lunettes, d'utiliser des lingettes imbibées d'alcool pour essuyer les surfaces, de ne pas se rassembler ou de faire la file pour aller à la toilette, de changer de siège si l'on se trouve près d'une personne symptomatique, ainsi que d'éviter de boire et de manger si possible. Prenez les mêmes précautions à l'aéroport et assurez-vous de respecter, dans la mesure du possible, la distanciation physique.
Pongpirul (2020) (4) Sondage réalisé auprès des passagers et des membres d'équipage Thaïlande Avril 2020	Cette étude a porté sur les passagers et les membres d'équipage de deux vols de rapatriement effectués par Thai Airways (TG476 en provenance de Sydney, soit un vol d'une durée de 9,25 h et TG492 entre Auckland et Bangkok, soit un vol de 11,5 h), pour un total de 335 passagers et de 35 membres d'équipage. Un questionnaire en ligne a été utilisé pour obtenir des commentaires individuels sur la distanciation sociale, le port du masque et d'autres procédures mises en place	Le taux de réponse au questionnaire en ligne était faible puisqu'il n'était que de 22,5 %. Plusieurs mesures de réduction des risques ont été mises en œuvre et bien accueillies. Cela incluait notamment les toilettes réservées à l'équipage, le nettoyage fréquent des toilettes, les zones de quarantaine désignées dans l'avion, le port du masque pour tout le monde, l'utilisation d'écrans faciaux, l'hygiène des mains fréquente (gel d'alcool fourni à tous les passagers), la vérification des symptômes et la prise de température. Parmi les conclusions obtenues, notons le fait que les passagers ont déclaré qu'il était possible de maintenir une distance physique de 1,5 à 2 m lors de la vérification, du pré-embarquement et de l'embarquement, mais pas en vol. En raison des bagages à main, les membres de l'équipage ont déclaré qu'il n'était pas pratique de

	pour réduire le risque de transmission du SRAS-CoV-2. Des entrevues approfondies ont été menées auprès des membres de l'équipage.	remettre des masques chirurgicaux, des écrans faciaux et du gel alcoolisé aux passagers avant le vol.
Horstman (2021) (30) *nouveau* Évaluation des risques US[1] Mar. 2021[1]	Application des résultats de la dynamique des fluides informatiques du transport et de la concentration des virus, des données antérieures sur la transmission de la grippe dans les avions et de l'estimation des quanta de Wells Riley, pour estimer le risque d'infection d'une infection virale aérienne arbitraire dans les avions de type Boeing 737-600. Les paramètres et les données de l'analyse ont ensuite été comparés aux données de terrain sur le SRAS-CoV-2 dans un avion. Note : Données de terrain basées sur l'événement de transmission décrit par Hoehl (2020) dans le tableau 1. Les enquêteurs ont supposé que le taux d'émission du virus était de 1,6 ± 1,2 x10^5 copies du génome/m^3h, ce qui correspondait à 1 267 virus libérés par minute, et à une dose infectieuse humaine de 50 % (HID_{50}) de 2 554 copies/quanta.	- Au cours d'un vol de trois heures, le risque d'infection par voie aérienne était d'environ 50 % pour les passagers assis à proximité (c'est-à-dire dans une seule rangée) des cas infectés (positionnés aux sièges de la 12e rangée de l'allée); on estime alors à deux ou trois le nombre d'infections pour 131 passagers. - Lorsque l'analyse a été comparée aux données de terrain où quatre cas d'infection symptomatique ont entraîné deux infections secondaires, le SRAS-CoV-2 s'est avéré moins infectieux et se situe au milieu de la fourchette des données appliquées aux doses infectieuses de grippe. - Les masques, la distance sociale entre les passagers de 2,9 pieds, le siège central vacant à 66 % de sa capacité ont réduit le risque de transmission de plus de 48 %. L'utilisation de masques N95 et de masques chirurgicaux (ASTM 3) a permis de réduire à zéro le nombre d'infections secondaires.

Wang (2021) (31) *nouveau* Évaluation quantitative des risques UK[1] Fév. 2021[1]	Estimer la probabilité d'infection par le SRAS-CoV-2 en vol pour une série de scénarios en utilisant les données expérimentales de dispersion des aérosols et une équation de Wells-Riley modifiée. Les scénarios ont été variés en fonction des taux de génération de quanta et de l'efficacité des masques faciaux, et spécifiés pour un avion B777-200.	- Les probabilités d'infection pour un vol de deux heures sans masque facial étaient comparables à celles d'un vol de 12 heures où tous les passagers portaient des masques à haute efficacité. Dans l'ensemble, les probabilités d'infection étaient plus élevées dans les cabines de la classe économique (MID-AFT) que dans celles de la classe affaires (FWD). - Les probabilités d'infection individuelle au cours d'un vol non masqué de deux heures variaient de 4,5 % à 60,2 %. Les probabilités moyennes d'infection basées sur le nombre de passagers infectés sur le vol variaient de 0,1 % à 2,5 % dans le même scénario. Pour un vol de 12 heures sans port du masque, les probabilités d'infection individuelles variaient de 24,1 % à 99,6 %, la probabilité d'infection moyenne étant de 0,8 % à 10,8 %. - L'utilisation de masques à haute/faible efficacité par les passagers pendant un vol de 12 heures, à l'exception de l'heure de repas, a fait passer les probabilités moyennes d'infection de ~59 % à ~8 %, par rapport au cas où les masques étaient portés pendant tout le vol.
McCarthy (2021) (32) *nouveau* Évaluation quantitative des risques NA* Jan 2021*	Ce modèle de transmission mécaniste suppose que la probabilité d'infection par le SRAS-CoV-2 est cumulative et liée aux sous-activités. Les sous-activités qui, ensemble, constituent l'activité de voyage aérien comprennent l'embarquement dans l'avion, le déplacement vers et dans le siège, le fait de s'asseoir dans l'avion pendant la durée du vol, et enfin le fait de quitter son siège et de débarquer de l'avion. Le modèle suppose également que le vol dure	Les avantages relatifs de différentes stratégies d'atténuation sur l'avion peuvent être explorés : - Le temps passé en position assise était le facteur le plus important du score de risque total. - Le port du masque, rendu obligatoire, compte tenu de ce que nous savons actuellement, pourrait être une stratégie (rentable) de réduction des risques. - Le fait de laisser le siège du milieu vacant, à moins qu'un groupe de trois personnes ne voyage ensemble, réduit au moins de moitié le risque, dans un très large éventail d'hypothèses de dégradation. - Gérer l'embarquement est moins coûteux que de laisser des sièges vides, mais l'analyse a montré que l'impact total est moindre.

	trois heures, qu'il n'y a pas de contact physique direct entre les participants et que toutes les surfaces sont désinfectées. Il suppose également que tous les passagers respectent les politiques d'embarquement et de port du masque. Il s'agit d'un cadre d'analyse décisionnelle risque-coût-bénéfice qui peut être appliqué à de nombreux contextes, y compris celui des avions. L'analyse peut produire des risques relatifs.	
Hu (2020) (35) *nouveau* Évaluation quantitative des risques Chine Déc 2019- Mar 2020	Cette évaluation du risque applique les données épidémiologiques des passagers d'avions (n= 9 265 passagers et 175 cas de référence, sur 291 avions) et des contacts proches pour estimer les taux d'attaque (TA) et le nombre de reproductions (R_0) avant le verrouillage de Wuhan. Le risque relatif entre les sièges selon la proximité du cas de référence a également été estimé. La limite supérieure du TA a été estimée sur la base de l'hypothèse que 34 et 69 contacts proches ont été infectés sur le vol au départ de Wuhan.	- Le risque global de transmission du SRAS-CoV-2 dans les avions équipés de dispositifs de filtration de l'air à haute efficacité serait relativement faible. La limite supérieure estimée du TA était de 0,60 % (IC 95 % : 0,43 %-0,84 %), et R_0 variait de 0,12 à 0,19. - Le risque de transmission était variable selon la distance du siège par rapport au(x) cas infecté(s) et à la durée du voyage. - Les sièges immédiatement adjacents aux cas de référence étaient les plus à risque, avec un TA de 9,2 % (IC 95 % : 5,7 % — 14,4 %), le risque relatif (RR) de ces sièges par rapport aux autres sièges de l'avion était de 27,8 (IC 95 % : 14,4 - 53,7). Les sièges du milieu présentaient le TA le plus élevé (0,7 %, IC 95 % : 0,4 % — 1,2 %), suivis des sièges côté hublot (0,6 %, IC 95 % : 0,3 % - 1,0 %) et des sièges côté couloir (0,6 %, IC 95 % : 0,3 % — 1,0 %). - Les limites inférieures des estimations de TA liées aux voyages en avion sont passées de 0,0 % (IC 95 % : 0,0 % — 0,6 %) à 0,4 % (IC 95 % : 0,02 % - 2,2 %), et les limites supérieures de 0,7 % (IC 95 % : 0,5 % — 1,0 %) à 1,2 % (IC 95 % : 0,4 % - 3,3 %) lorsque la durée du voyage est passée de 1,5 heure

		à 3,3 heures. Cependant, ces résultats n'étaient pas significatifs en raison des données limitées sur les cas secondaires par rapport au temps de vol.
Arnold (2020) (34) *Prépublication* Évaluation quantitative des risques États-Unis Juin 2020	Cette évaluation des risques permet de calculer le risque d'infection par le SRAS-CoV-2 à la suite d'une exposition dans un avion. Cette évaluation ne tenait pas compte de l'embarquement et du débarquement, de l'accès à la toilette et de la durée du vol et a fait certaines suppositions en ce qui concerne la « protection » offerte par les dossiers de siège comme barrière entre les rangées. Elle utilise les données provenant des passagers qui se trouvaient en classe économique dans des avions comportant 6 sièges par rangée.	Selon ces hypothèses, le risque d'attraper la COVID-19 d'un passager à proximité sur un vol aux États-Unis le 30 juin 2020 était d'environ 1 sur 4 300 si l'avion était rempli. Lorsque la politique du « siège central vide », ce risque descend à 7 700. Ces chiffres sont fondés sur l'estimation selon laquelle 1 Américain sur 120 a la COVID-19 à n'importe quel jour, ce qui donne 40 000 cas confirmés par jour x 10 x 7 jours, donc environ 1/120 de la population américaine de 330 000 000. Cette évaluation suggère que le port du masque pourrait réduire le risque de 82 % (n'est pas inclus dans le taux d'attaque et ne contient aucune référence).

ANALYSES INDIRECTES DU RISQUE DE TRANSMISSION DES INFECTIONS RESPIRATOIRES À BORD DES AVIONS ET STRATÉGIES D'ATTÉNUATION POSSIBLES

Plusieurs modèles de simulation et *in silico* ont été développés pour explorer les moyens de minimiser le risque de transmission d'une maladie infectieuse dans un avion ou lors de l'embarquement et du débarquement. Neuf études sur l'embarquement et le débarquement d'un avion, six sur la configuration optimale des sièges pour minimiser la transmission en vol et sept sur l'aérodynamique des gouttelettes respiratoires dans un avion lors de la toux et des éternuements ont été publiées pendant la pandémie (tableau 3). Un examen unique de ces études aérodynamiques jusqu'en juin 2020 et un examen systématique des preuves de la transmission de la grippe sont également répertoriés dans le tableau 3. Ces études portent sur les stratégies d'embarquement permettant de minimiser les interactions entre les passagers et sur les plans des sièges pour maximiser la distance et l'interaction avec les autres personnes. Les études portant sur la ventilation à bord d'un avion et sur l'impact de la toux ou des éternuements sur la circulation de l'air

décrivent la distance et la portée des gouttelettes et des aérosols à partir de différents sièges (par exemple, hublot, milieu, couloir) et lorsque l'on est debout ou que l'on marche dans la cabine (tableau 3).

Plusieurs modèles prédictifs, de simulation et *in silico* ont été développés pour explorer les moyens d'évaluer et de minimiser le risque de transmission d'une maladie infectieuse lors de l'embarquement et du débarquement. Diverses méthodes d'embarquement et de débarquement ont été examinées dans neuf études. Dans l'ensemble, on a constaté qu'en augmentant le nombre de groupes d'embarquement, en réduisant le nombre de bagages à main et en évitant l'interaction avec les autres passagers (c'est-à-dire en embarquant à l'arrière de l'avion et en commençant par les sièges côté hublot), le risque d'infection diminuait de manière significative, bien qu'il faille sacrifier l'efficacité globale (c'est-à-dire le temps d'embarquement et de débarquement) dans certains scénarios (42-49).

Les études de surveillance de l'environnement, les modèles *in silico* et les expériences de simulation fournissent des estimations du risque et des stratégies d'atténuation pour la transmission en vol. Le nombre de particules en vol et les concentrations massiques dans les avions sont inférieurs à ceux des magasins de détail/épiceries, des restaurants, des bureaux, des maisons et d'autres formes de transport (50, 51). En outre, des expériences de simulation de la transmission d'aérosols en vol et de la contamination de surface montrent que l'air de la cabine est rapidement renouvelé (52). Lorsque des masques chirurgicaux ont été utilisés dans des simulations, on a constaté une réduction de plus de 90 % des gouttelettes libérées pendant la simulation de la toux par rapport à l'absence de masque (51).

Les sièges immédiatement adjacents aux cas de référence présentent le risque d'infection le plus élevé, suivis par la rangée directement derrière et devant (35, 51-53). La distance de déplacement des particules de toux est fortement influencée par la direction et le type de toux (54, 55). Il existe des données contradictoires sur les sièges (couloir, milieu ou hublot) qui présentent un risque d'infection plus élevé. Le fait de rester debout ou de marcher dans la cabine peut entraîner une propagation beaucoup plus importante des gouttelettes respiratoires et des aérosols (56). Les différences de risque entre les différents avions, ainsi que les sièges en classe affaires et économiques, sont également discutées (57, 58).

Une revue systématique de l'ECDC sur les preuves de la transmission de la grippe (59) rapporte que la transmission pendant les vols que rapporte la littérature était largement cohérente avec les résultats de la littérature sur le COVID-19; le nombre de cas secondaires est faible et le siège d'un cas secondaire se trouve généralement à moins de deux rangées d'une personne infectée. Il est intéressant de noter que la durée du vol n'était pas associée au risque de transmission dans les études prises en compte dans cette revue.

Tableau 3 : Études et analyses portant sur l'aérodynamique des gouttelettes respiratoires dans les avions et sur les stratégies d'atténuation des infections respiratoires dans les avions (n=24)

ÉTUDE	MÉTHODE	PRINCIPAUX RÉSULTATS
Simulation et modèles *in silico*		

Embarquement/Débarquement		
Cotfas (2021) (48) *nouveau* Modèle prédictif Roumanie[1] Mar. 2021[1]	Utiliser un modèle à base d'agents et une approche de simulation stochastique pour étudier les impacts de la méthode de la pyramide inversée sur le temps moyen d'embarquement et le risque sanitaire pour les passagers assis dans les allées et les hublots. Les évaluations étaient basées sur la distanciation sociale en maintenant une distance de 1 à 2 mètres entre les passagers lorsqu'ils marchent dans l'allée, en gardant le siège du milieu vide et en appliquant différentes politiques en matière de bagages à main.	- Lorsque la minimisation du risque sanitaire pour les passagers était l'objectif principal, la solution optimale consistait à affecter un nombre égal de passagers en siège côté hublot aux groupes d'embarquement 1 et 2, et un nombre égal de passagers en siège côté couloir aux groupes d'embarquement 2 et 3. Cette option était imposante quant aux changements du volume de bagages et de la distance sociale de l'allée. Elle a permis de réduire de 22,76 % à 35,31 % le risque pour la santé des passagers du siège côté couloir, par rapport à d'autres simulations qui minimisaient le temps d'embarquement. - Les scénarios permettant de réduire le temps d'embarquement et, dans une moindre mesure, les risques sanitaires sont également examinés.
Milne (2021) (43) *nouveau* Modèle prédictif NA[1] Fév. 2021[1]	Dans ces expériences de simulation stochastique et ces modèles basés sur des agents, les auteurs évaluent six méthodes d'embarquement et comparent leurs performances à celles des deux meilleures méthodes d'embarquement utilisées à ce jour avec la distanciation sociale selon quatre paramètres de performance. Trois de ces paramètres sont liés au risque de propagation du virus aux passagers durant l'embarquement. La quatrième mesure est le temps nécessaire pour achever l'embarquement. Les deux « meilleures » méthodes d'embarquement de base sont	- Plus il y a de bagages = plus le temps d'embarquement est long - Dans un scénario où la distance entre les allées est de 1 m, la méthode d'arrière à l'avant par rangée — WilMA présente des temps d'embarquement plus courts, moins d'interférences entre les sièges et moins de risques pour les sièges côté allée que la méthode de base à l'envers pour chaque scénario de bagages. La méthode de base d'arrière à l'avant par rangée présente moins de risques pour les sièges côté hublot dans les scénarios où le volume de bagages est plus élevé. - Dans un scénario où la distance entre les allées est de 2 m, la méthode d'arrière à l'avant par rangée — WilMA — décalée de trois est supérieure à la méthode de base de la demi-zone en pyramide inversée modifiée parce que

	l'embarquement à l'envers par rangée et la demi-zone pyramidale inversée modifiée (voir les figures pour la description). La méthode d'arrière à l'avant par rangée — WilMA fait monter les passagers une rangée à la fois en commençant par l'arrière de l'avion. Les cinq autres méthodes d'embarquement sont créées en ajustant la méthode d'embarquement d'arrière à l'avant par rangée — WilMA de façon à ce que certains des passagers assis aux hublots embarquent plus tôt. En particulier, les passagers en siège côté hublot des rangées K embarqueront dans l'avion avant les passagers en siège côté couloir. Dans les cinq nouvelles méthodes, la valeur du K se situe entre 2 et 6.	le temps d'embarquement est à peu près le même et qu'elle comporte moins de risques liés aux sièges côté allée et aux sièges côté hublot. La méthode d'arrière à l'avant par rangée — WilMA présente le plus faible risque pour les sièges côté hublot.
Xie (2021) (44) *nouveau* Modèle prédictif NA[1] Jan. 2021[1]	Comparer quantitativement le processus de débarquement d'un Boeing 737-300 avant et après l'adoption de stratégies de gestion du débarquement. Deux stratégies sont étudiées : Stratégie I : Lorsqu'il y a un seul passager infecté, les équipes au sol commencent par désinfecter les allées de la cabine avant de commencer le processus de débarquement, puis les passagers situés devant le patient infecté débarquent par la porte avant, tandis que les passagers situés à l'arrière du cas débarquent par la porte arrière. Le patient et ses	- Le nombre de passagers à haut risque a diminué de 72 % après l'adoption de la stratégie I. - Après l'adoption de la stratégie II, le nombre de passagers à haut risque a de nouveau diminué de 27 %. - Bien que ces deux stratégies sacrifient l'efficacité (c'est-à-dire une durée totale de débarquement plus longue), elles réduisent également de manière significative le risque d'infection.

	« contacts proches » ne débarquent que lorsque tous les passagers ont quitté la cabine. Stratégie II : Lorsqu'il y a plusieurs passagers infectés, les passagers sont évacués par la porte avant ou la porte arrière à partir des colonnes traversées qui ne contiennent pas de patients ou de contacts proches. Après que les passagers ont quitté la cabine, les valises et les « contacts proches » sortent par la porte avant ou arrière sans récupérer leurs bagages. Après le départ des bagages, les équipes au sol procèdent à une seconde désinfection de la cabine. Après la désinfection, les autres passagers sortent par la porte avant ou arrière.	
Milne (2020) (42) *nouveau* Modèle prédictif NA[1] Nov. 2020[1]	Dans ces expériences de simulation stochastique et ces modèles à base d'agents, les auteurs adaptent la méthode de la pyramide inversée pour la distanciation sociale lors de l'embarquement dans un avion à l'aide d'une passerelle d'avion à réaction qui relie le terminal à la porte avant de l'avion. Ils évaluent l'impact du nombre de groupes d'embarquement (2 contre 6) pour montrer l'impact résultant sur quatre mesures d'évaluation des performances. La première mesure de performance est le temps moyen d'embarquement. La deuxième mesure de performance est le nombre de mouvements de	- Lorsque le nombre de groupes d'embarquement passe de deux à quatre, le temps moyen d'embarquement diminue. - Lorsque le nombre de groupes d'embarquement passe de 3 à 6, le risque lié au siège côté couloir diminue sensiblement, passant de 44 % à 21 %. - Plus le volume des bagages transportés à bord de l'avion diminue, plus la durée du risque diminue de manière significative. - Le fait de doubler la distance sociale de l'allée, de 1 m à 2 m, augmente la durée moyenne de l'embarquement et diminue les risques liés aux sièges de l'allée et des hublots.

	siège de type 3 pendant l'embarquement (c'est-à-dire changement de siège, déplacement dans l'allée pour permettre au passager du hublot d'accéder à son siège). Les troisième et quatrième paramètres de performance concernent la santé des passagers assis pendant que les passagers embarquant plus tard les dépassent.	
Schwarzbach (2020) (60) *nouveau* Expérience de simulation NA[1] Oct. 2020[1]	Évaluer l'applicabilité des méthodes de distanciation sociale basées sur la technologie lors de l'embarquement dans la cabine d'un avion en utilisant une simulation de propagation radio basée sur un modèle d'avion tridimensionnel. Ils effectuent une simulation de propagation par traçage de rayons dans une section de la cabine modélisée d'un avion Airbus A321.	- Les auteurs démontrent que les mesures de l'indicateur de force du signal de réception (RSSI) couramment utilisées peuvent conduire à une classification de faux positifs et de faux négatifs en fonction du réglage du modèle de prévision d'affaiblissement, ce qui réduit la fiabilité et l'acceptation par les utilisateurs des options de distanciation sociale assistées par la technologie. - Du point de vue de l'application, une mise en œuvre possible des approches technologiques proposées pourrait ressembler à ce qui suit : Avertissement de proximité en temps réel, recherche des contacts après traitement, programmation de l'embarquement et du débarquement.
Delcea (2021) (49) *nouveau* Modèle prédictif Roumanie [1] Mai 2020[1]	Estime le nombre de passagers pour chaque groupe d'embarquement en supposant un embarquement en pyramide inversée avec les sièges du milieu inoccupés. Applique une modélisation basée sur les agents et une simulation stochastique	- Si l'objectif est de minimiser le risque sanitaire parmi les passagers, le premier groupe d'embarquement en pyramide inversée devrait être constitué de ceux qui ont des sièges côté hublot dans la moitié arrière de l'avion, le troisième groupe devrait être constitué de passagers ayant des sièges

	pour évaluer les impacts sur le temps d'embarquement et le risque sanitaire pour les passagers dans chaque scénario.	côté couloir dans la moitié avant de l'avion, le deuxième groupe d'embarquement étant constitué des autres passagers. Cette disposition s'est avérée être la meilleure, car elle réduit de 25 % le risque sanitaire pour les passagers assis du côté de l'allée et de 22 % pour les passagers assis à côté d'un hublot, tout en augmentant de 2 % le temps d'embarquement.
Milne (2020) (45) Modèle prédictif N.d.[1] Août 2020[1]	Dans ces expériences de simulation stochastique, les auteurs ont évalué neuf adaptations des méthodes d'embarquement en fonction de quatre mesures de rendement. Trois des mesures sont liées au risque que le virus se propage aux passagers au moment de l'embarquement. La quatrième mesure est le temps qu'il faut pour monter à bord d'un avion à deux portes lorsque les autobus d'aéroport transportent des passagers sur l'aire de circulation avant qu'ils n'embarquent dans l'avion.	Le temps d'embarquement moyen est la mesure comparable entre les différents scénarios. Augmentation de la distance sociale (de 1 m à 2 m) = augmentation du temps d'embarquement Augmentation de la proportion de personnes qui ont des bagages = augmentation du temps d'embarquement Le fait d'asseoir les passagers près des hublots avant ceux qui occuperont les sièges près de l'allée réduit le risque d'interférence avec le siège (lorsque la personne assise dans le siège près de l'allée doit se lever pour permettre à la personne qui s'assoit près du hublot de passer). Le risque lié au siège près de l'allée est plus élevé lorsque la distanciation physique est plus faible (1 m), que les personnes ont des bagages et que l'embarquement est aléatoire. L'auteur indique que le risque associé au siège près du hublot est inférieur au risque lié au siège près de l'allée pendant

		l'embarquement, mais sans cependant estimer la différence.
Schultz (2020) (46) Modèle prédictif R.-U.[1] Juillet 2020[1]	Modèle d'automate cellulaire qui modélise les déplacements des passagers pendant le processus d'embarquement. Ne tient pas compte des masques. Modélise la distance jusqu'au cas index ainsi que le temps de contact pour estimer le risque de transmission.	- Le modèle montre que, comparativement à l'embarquement aléatoire, le fait de faire embarquer ensemble les membres des groupes (p. ex., les familles) réduira le temps d'embarquement puisque celui-ci sera 41 % plus court que le scénario aléatoire. Ce type d'embarquement « groupé » entraîne également le risque de transmission le plus faible, soit de 0,09 comparativement à une valeur variant entre 0,57 et 0,62 pour n'importe lequel des scénarios aléatoires lorsque l'avion est à moitié plein. Ces temps d'embarquement étaient relativement stables à 75 % et à 100 % de la capacité de l'avion, toutefois, le risque de transmission a augmenté à une valeur variant entre 0,31 et 0,66 pour l'embarquement en groupe, par rapport à un scénario individuel.
Cotfas (2020) (47) Modèle prédictif N.d.[1] Mai 2020[1]	Un modèle basé sur des agents est utilisé pour simuler le processus d'embarquement des passagers, principalement en ce qui concerne les interactions avec les agents et d'autres personnes (la plateforme NetLogo a été utilisée pour ce faire). Ils ont modélisé le temps nécessaire pour embarquer dans l'avion en fonction d'un certain nombre de scénarios et ont tenu compte du temps pour ranger les bagages à main. Le résultat porte donc sur le temps pendant lequel les passagers déjà assis sont en contact avec d'autres	L'embarquement de l'arrière à l'avant de l'avion a pris le plus de temps, mais selon la simulation, c'était ce cas que le risque pour la santé était le plus faible. Le risque est tout aussi faible si une distanciation physique de 2 mètres est maintenue pendant l'embarquement. - L'embarquement est plus efficace et moins risqué lorsque les passagers n'ont aucun bagage à ranger.

	personnes, soit lorsque ces dernières circulent dans l'allée, soit parce qu'ils doivent se lever pour laisser entrer une personne qui doit aller s'asseoir au centre ou près du hublot.	
Transmission et répartition des sièges en vol		
Dietrich (2021) (33) *nouveau* Surveillance de l'environnement et étude des modèles prédictifs USA[1] Avril 2021[1]	Utilisation des données de dispersion du virus du bactériophage MS2 comme substitut du SRAS-CoV-2 et modélisation de la relation entre l'exposition au SRAS-CoV-2 et la proximité des sièges d'avion. Les deux scénarios d'occupation complète et d'occupation vacante du siège central ont été envisagés.	- Par rapport aux expositions dans les scénarios d'occupation complète, le risque d'exposition relatif pour un passager individuel dans les scénarios de siège central vacant a été réduit de 23 % à 57 %. - La réduction de 23 % de l'exposition a été observée pour un seul passager qui se trouvait dans la même rangée et à deux sièges de la source du SRAS-CoV-2, avec un siège central vide entre les deux. - On obtient 57 % dans un scénario impliquant une section à trois rangées contenant un mélange de sources de SRAS-CoV-2 et d'autres passagers. - La réduction globale du risque d'exposition dans une cabine complète de 120 passagers avec des sièges centraux vacants allait de 35,0 % à 39,4 %.
Desai (2021) (57) *nouveau* Étude*in silico* USA[1] Fév. 2021[1]	Modélisation de l'écoulement de l'air, du transport des particules expirées par voie orale et nasale (par exemple, CO_2 et coronavirus) à différentes positions du siège à l'intérieur des avions Airbus 380 et Boeing B747. Les simulations ont pris en compte les sections de première classe, de classe affaires et de classe économique dans chaque avion. Les positions des	- Le classement des sièges d'un avion à l'autre était très variable. - Dans la section de première classe : Le siège le mieux classé d'Airbus était plus chaud que le siège le mieux classé de Boeing, mais la circulation y était moins bonne. - En classe affaires : Le siège le mieux classé d'Airbus était plus froid, mais offrait une meilleure circulation que le siège le mieux classé de Boeing. Le siège de l'Airbus était situé dans la

	sièges ont été classées en fonction de la fraction de masse de CO_2, de la température et de la vitesse correspondant aux positions du nez des passagers pour chaque siège.	rangée latérale des sièges, côté couloir, et le siège du Boeing était situé près d'un hublot. - En classe économique : Le siège le mieux classé pour l'Airbus était situé côté hublot, tandis que le siège le mieux classé pour le Boeing était le siège du milieu dans la rangée latérale de sièges. Le siège de l'Airbus avait une température plus élevée, une concentration de CO_2 plus faible et une vitesse de l'air plus faible, la contrepartie pour un siège plus chaud étant une moins bonne circulation. - Dans l'ensemble, le siège d'Airbus le mieux classé en économie était à la fois chaud et doté d'une bonne circulation; le siège de Boeing était moins performant dans tous ces domaines.
Ghorbani (2020) (61) préimpression Étude *in silico* N.d.[1] Octobre 2020[1]	Le modèle appelé simulations de Monte-Carlo optimise, pour le secteur du transport aérien, le nombre de passagers et leur aménagement, dans le respect des mesures de distanciation sociale, pour des scénarios d'avions comportant une seule ou deux allées.	- Les figures présentées dans le document montrent l'aménagement optimal des sièges des passagers dans un avion. La clé pour augmenter le nombre de passagers en toute sécurité consiste à s'assurer de regrouper les familles.
Salari (2020) (62) Étude *in silico* N.d.[1] Juin 2020[1]	Un modèle de programmation linéaire mixte est utilisé pour répartir correctement les passagers dans les sièges tout en s'assurant de respecter deux types de distanciation physique, c'est-à-dire garder les passagers assis assez loin les uns des autres et assurer une distance sécuritaire entre l'allée et les sièges qui ont été attribués. Un Airbus A320 avec 20 rangées de sièges, une allée et trois sièges de	Si la distanciation physique est respectée entièrement, si aucun siège près de l'allée n'est utilisé et si personne ne se trouve à moins de 1 m d'une autre personne, la charge maximale sera de 20 passagers dans un avion de 120 places. Si les passagers peuvent s'asseoir dans le siège près de l'allée, le total passe à 30 passagers ayant une distanciation sociale de 1 m et plus. Le fait de s'asseoir près de l'allée doit inclure des stratégies visant à limiter les déplacements et

	chaque côté a été utilisé pour ce faire. Ce modèle a permis de réaliser un certain nombre de scénarios : - Siège central vide - Distanciation physique de 1 m une fois la personne assise - Siège près de l'allée vide - Hybride	l'exposition possible des personnes qui se déplacent dans l'avion. La politique qui vise à bloquer les sièges du centre permet de réduire le nombre de personnes dans un rayon de 1 m par rapport à la politique de n'asseoir personne dans les sièges près des allées. Plus il y a de passagers dans l'avion, plus les personnes se retrouvent assises à proximité les unes des autres, ce qui veut dire que le risque va en augmentant lorsque 1, 2 ou 3 personnes ou plus se retrouvaient dans un rayon de 1 m. Voir les illustrations dans les figures.
Wagner (2009) (58) Évaluation quantitative des risques É.-U.[1] Décembre 2009[1]	Cette évaluation quantitative des risques permet d'estimer la possibilité de transmission de la grippe H1N1 pendant un vol. La simulation utilise un Boeing 747.	Même lors de longs vols, le risque de transmission en vol est faible à modéré si le cas index voyage en première classe. Si le cas index se trouve en première classe, • De 0 à 1 infection pourrait survenir pendant un vol de 5 heures, • De 1 à 3 infections pourraient survenir pendant un vol de 11 heures, • De 2 à 5 infections pourraient survenir pendant un vol de 17 heures. Cependant, la transmission en vol pourrait être importante, particulièrement pendant les longs vols, si le cas index se déplace en classe économique. Si le cas index se trouve en classe économique, • De 2 à 5 infections pourraient survenir pendant un vol de 5 heures,

		• De 5 à 10 infections pourraient survenir pendant un vol de 11 heures, • De 7 à 17 infections pourraient survenir pendant un vol de 17 heures.
Hertzberg (2018) (63) Étude de surveillance de l'environnement et étude *in silico* É.-U.[1] Mars 2018[1]	Pendant la saison de la grippe sur 10 vols transcontinentaux aux É.-U., les auteurs ont établi la chronique des comportements et des déplacements des personnes dans la cabine économique d'un avion avec une seule allée et ont procédé à un échantillonnage environnemental. Ils ont simulé la transmission en vol à partir de ces données. Ce modèle axé sur les données et dynamique, de transmission en réseau de maladies respiratoires par gouttelettes, est unique en son genre.	Aucun des 229 échantillons prélevés dans l'environnement ne s'est révélé positif. - Les résultats indiquent qu'il y a une faible probabilité de transmission directe aux passagers qui ne sont pas assis à proximité d'un passager infectieux.
Simulations d'aérosols dans un avion		
Talaat (2021) (52) *nouveau* Expérience de simulation USA[1] Fév. 2021[1]	Étude de la transmission des aérosols en vol et de la contamination des surfaces à l'aide d'un modèle de calcul de la zone de la cabine d'un Boeing 737. L'étude vise à comprendre l'effet de la réduction de la capacité du nombre de passagers (de 60 à 40) et à la comparer à d'autres mesures d'intervention telles que l'utilisation d'écrans anti-éternuements (pare-haleine) entre les passagers d'un vol au maximum de sa capacité. L'étude prend en compte une large	- Les particules mettent 2 à 3 minutes pour se déposer ou quitter le système, car l'air de la cabine est rapidement renouvelé. - L'aérosol situé dans le spectre de dimension de 1 µm–20 µm est concentré à une rangée du patient de référence, et pratiquement aucune particule ne dépasse deux rangées du patient de référence. Les particules plus grandes, telles que celles de 50 µm, ne sont présentes que dans la rangée du patient de référence. - Une fraction relativement faible (21-26 %) des particules exhalées est

	gamme de tailles de particules (1-50 µm). Cette étude ne tient pas compte de la présence de plus d'une infection à bord, du comportement humain (parler, manger, boire, respecter le port du masque ou se déplacer dans les allées).	directement éliminée par le système de ventilation. La majorité des particules se déposent sur les surfaces dans la cabine et plus de particules de 1 µm se déposant sur les parois que sur le sol (10-14 % contre 3-6 %). - Les surfaces les plus contaminées dans le modèle au maximum de sa capacité (60 passagers) sans pare-haleine sont les passagers (y compris le patient de référence) avec une fraction de dépôt de 31 %, suivis des sièges avec 27 %. Dans le modèle à capacité réduite sans pare-haleine et dans le modèle au maximum de sa capacité avec pare-haleine, le dépôt total sur les passagers est réduit à 21 % et 15 %, respectivement. - La fraction respirable totale est la plus faible dans le modèle au maximum de sa capacité avec pare-haleine (0,5 %), suivi du modèle à capacité réduite pour passagers sans pare-haleine (0,7 %), puis du modèle au maximum de sa capacité sans pare-haleine (1,7 %). Cependant, la réduction du nombre de passagers et l'utilisation de pare-haleine éliminent la transmission directe de particules de 50 µm. Bien que ces particules laissent échapper une fraction respirable beaucoup plus faible que les particules de 1 µm, elles contiennent nettement plus de virions que les particules de 1 µm en raison de leur volume.
Kinahan (2021) (53) *nouveau* Expérience de simulation USA[1] Jan. 2021[1]	La dispersion et le dépôt d'aérosols dans deux avions gros porteurs (Boeing 767-300 et Boeing 777-200 à 30 000 pieds) ont été mesurés à l'aide de microsphères fluorescentes et marquées à l'ADN. Les données expérimentales	- Durant la simulation, l'exposition maximale, de 0,094 7 à 0,461 4 %, se produit dans un siège situé à côté d'une source, le risque d'inhalation le plus élevé suivant se produisant généralement dans les sièges situés devant et derrière le passager infecté. Ce risque d'exposition maximal équivaut à une réduction minimale de

	portaient sur une simulation de plus de 300 rejets d'un passager infecté par le SRAS-CoV-2 dans les sièges pendant le vol. Les tests ont été conçus pour mesurer la concentration d'aérosols dans les zones de respiration des passagers des sièges et des rangées voisines du passager infecté durant la simulation. Les rejets respiratoires comprenaient un mélange de tests avec le mannequin ne portant pas de masque et de tests avec un masque. Cette étude ne tient pas compte de la présence de plus d'une infection à bord ni du comportement humain (par exemple, parler, manger, boire ou respecter le port du masque).	99,54 % des aérosols à particules de 1 µm de la source de référence par rapport à la zone de respiration d'un passager type assis directement à côté de la source. - Moins de 0,03 % des particules décelables se déposent sur les surfaces solides pendant les essais, la concentration la plus élevée se trouvant sur les surfaces les plus proches de chaque point de rejet. On note que les surfaces horizontales comme les accoudoirs étaient généralement plus élevées que les surfaces verticales telles que les dossiers de sièges et les systèmes de divertissement à bord (IFE). - Avec le port du masque, la réduction moyenne du nombre total de particules comptées était de 15,6 %.
Rivero-Rios (2021) (50) *nouveau* Étude de suivi biologique États-Unis Juillet 2020	Les concentrations de particules (PM) ont été mesurées dans divers espaces intérieurs, notamment 19 vols, des magasins de détail/épiceries, des restaurants, des bureaux, des habitations et d'autres moyens de transport (voitures privées, bus, trains). Les vols ont été choisis de manière à couvrir un éventail de durées/destinations de vol et de modèles d'avions, et les étapes suivantes du voyage aérien : Terminal (départ), embarquement, taxi (sortie), montée, en vol, descente, taxi (entrée), débarquement et terminal (arrivée).	- Le nombre de particules durant le vol et les concentrations massiques dans les avions étaient inférieures à celles des magasins de détail/épiceries, des restaurants, des bureaux, des habitations et des autres moyens de transport testés. - Les particules dont le diamètre est inférieur à 1 µm dominent les concentrations totales en nombre de particules (car elles sont les plus difficiles à éliminer par filtration). - Les concentrations de particules présentaient une forme en V, avec des niveaux élevés à l'embarquement, une diminution continue et une concentration minimale stable pendant le vol. De légères augmentations de la concentration de masse des particules pendant le service des aliments ont été

		observées. Lorsque l'avion a commencé à descendre, les concentrations de particules ont commencé à augmenter et une augmentation brutale a été observée une fois que la porte de la cabine a été ouverte et que le processus de débarquement a commencé. - Le taux de renouvellement de l'air dans la cabine est rapide pendant le vol, ce qui réduit considérablement le nombre de particules dans la cabine. L'air ambiant en altitude contient moins de particules que l'air à la surface, ce qui contribue aux faibles concentrations en nombre et en masse de particules en altitude, et explique également la diminution et l'augmentation observées pendant la montée et la descente.
Kotb (2020) (56) Étude *in silico* Égypte[1] Septembre 2020[1]	Cette simulation avec modélisation informatique de la dynamique des fluides numériques est utilisée pour examiner ce qui arrive aux gouttelettes respiratoires lorsqu'elles sont expulsées par l'éternuement ou la toux d'une personne qui se déplace dans une cabine d'avion.	L'écoulement de l'air des gouttelettes produites par les toux et éternuements des passagers qui se déplacent pouvait atteindre les passagers se trouvant à plusieurs rangées de la source, comparativement à ceux qui restaient immobiles. Si la personne tousse et qu'elle se trouve à 1,1 m, l'éternuement aura une plus grande portée si la personne reste immobile. En comparant la plage de propagation des gouttelettes résultant d'un passager en mouvement et d'un passager immobile, plus le passager se déplace rapidement, plus les gouttelettes se propagent. - Les chiffres illustrent le fait de tousser ou d'éternuer debout et en mouvement dans une cabine d'avion de classe économique.

Silcott (2020) (51) *Non publiée* Expériences de simulation États-Unis Août 2020	Les simulations ont utilisé les modèles d'avion 767-300 et 777-200 pour étudier les pénétrations d'aérosol associées à un passager infecté par la COVID-19 dans la zone autour d'eux. Ces simulations ont été effectuées à 300 reprises, y compris avec l'embarquement et le débarquement. Les simulations en vol ont été effectuées dans le hangar et à une altitude de 35 000 pi. Cette étude ne tient pas compte du comportement humain, p. ex., parler, manger, boire, adhérence à porter le masque ou d'autres modes de transmission, p. ex., transmission par fomites.	Taux d'échange d'air élevé de 1,8 x 10^8 dans l'avion. L'exposition cumulative aux particules était de 10x moins élevée dans l'avion que dans une maison. Les particules se trouvaient dans la cabine moins de 6 minutes (contre 1,5 h dans une maison). L'élimination des particules dans l'air était 15x plus rapide que dans une maison et 5x plus rapide que dans une chambre d'isolement moderne d'un hôpital. Des masques chirurgicaux ont été utilisés dans les simulations. On a pu voir une réduction de plus de 90 % des gouttelettes libérées pendant la simulation de la toux comparativement au taux obtenu sans masque. Le fait de partager une rangée avec une personne atteinte de COVID-19 comporte le risque le plus élevé, alors que la rangée derrière et celle qui est devant offrent le deuxième niveau de risque le plus élevé. En fait, il y avait peu de différences pratiques du risque entre les sièges. Voir les données dans le document. La buse d'air individuelle ne fait aucune différence en ce qui concerne le risque. Pendant l'embarquement et le débarquement, si l'on s'assure de garder une circulation d'air, l'embarquement en petits groupes peut réduire le risque. Il y avait un faible risque d'exposition aux ondes du jet d'une personne infectée qui était déjà assise dans l'avion.
Yan (2020) (54) Expérience de simulation Australie[1]	Cette étude a mis au point un modèle informatique pour imiter une section économique de	On a constaté que le flux causé par la toux avait une portée longue et efficace en ce qui concerne le déplacement des

Août 2020[1]	Boeing 737 avec trois rangées et neuf mannequins.	contaminants, soit jusqu'à 4 s (ou 8x plus long qu'une simple toux). Un large éventail de gouttelettes de toutes tailles ont été dispersées dans la direction de la toux en raison du fort jet d'air associé à la toux, comparativement à ce qui se produit lorsque le flux d'air circule sous l'effet de la ventilation de l'avion (voir les figures sur papier).
Yang (2018) (55) Étude *in silico* Australie[1] Décembre 2017[1]	À l'aide de la mécanique des fluides numérique, cette étude a étudié l'effet du jet d'air associé à la toux sur le flux d'air local et le transport des particules dans un espace confiné comme une cabine d'avion type. La dispersion des particules émises par la toux a été simulée dans une rangée d'avions avec trois sièges.	- La distance de déplacement des particules associées à la toux était fortement influencée par la direction et le type de toux. La toux de la personne assise près de l'allée a créé une distance de déplacement des particules plus longue que celle qui se produisait lorsque la personne était assise sur le siège central ou près du hublot. Le siège du milieu a été considéré comme le siège le plus à risque d'exposition.
Bilans		
Jayaweera (2020) (64) Revue Sri Lanka [1] Juin 2020[1]	Revue de la littérature sur l'aérodynamique du virus SRAS-CoV-2 dans les gouttelettes et les aérosols dans une cabine d'avion (voir l'annexe). Nous nous sommes intéressés à la partie de la revue qui porte sur les cabines d'avion.	- Elle décrit la circulation de l'air dans la cabine et indique qu'un échange d'air complet est effectué en 2 à 3 minutes, ce qui devrait être bon pour dissiper rapidement les gouttelettes chargées de virus. Elle indique également que l'air passe à travers un filtre HEPA, qui peut éliminer les particules dont la taille est inférieure à 0,3 µm. Les trajectoires des jets de toux lorsque la personne ne porte pas de masque, lorsqu' elle porte un masque chirurgical et lorsqu'elle porte un masque N95 sont décrites dans le document.
Leitmeyer (2016) (59) Revue systématique ECDC[1] Août 2016[1]	Une revue systématique a été effectuée à propos du lien entre le transport aérien et la propagation de la grippe chez les passagers infectés et la possibilité de transmission en	Dans l'ensemble des études, 2 165/4 252 passagers pouvant être retracés ont été suivis et de ces passagers, 163 cas secondaires ont pu être identifiés (taux d'attaque secondaire de 7,5 %). 42 %

	vol. 14 publications, 11 sur la pandémie de grippe H1N1 ont été incluses. La revue systématique est de haute qualité et comprend des études jusqu'en octobre 2015.	des personnes étaient assises à moins de deux rangées du cas index. - La durée du vol n'a pas été associée à un risque de transmission dans cette étude.

Méthodes :

Une analyse quotidienne de la littérature (publiée et prépubliée) est effectuée par le Groupe des sciences émergentes de l'ASPC. La numérisation a compilé la littérature sur le COVID-19 depuis le début de l'épidémie et une mise à jour est effectuée quotidiennement. Les recherches pour retrouver de la documentation pertinente sur le COVID-19 sont effectuées dans Pubmed, Scopus, BioRxiv, MedRxiv, ArXiv, SSRN, Research Square, et font l'objet d'une vérification de concordance avec les centres d'information sur le COVID-19 gérés par Lancet, BMJ, Elsevier, Nature et Wiley. Le résumé quotidien et les résultats de l'analyse complète sont conservés dans une base de données Refworks et dans une liste Excel pouvant être consultée. Une recherche ciblée par mots-clés est effectuée dans ces bases de données, afin d'identifier les citations pertinentes sur le COVID-19 et SRAS-COV-2. Les termes de recherche utilisés comprenaient : vol ou avion, ou aéronef ou avion. La recherche a permis d'obtenir 649 citations (507 à partir de la recherche initiale jusqu'au 28 octobre 2020 et 147 à partir de la recherche actualisée menée le 26 avril 2021), qui ont été examinées pour leur pertinence à étudier. Des références supplémentaires à des recherches de synthèse pertinentes non liées au SRAS-CoV-2 ou à la pandémie actuelle ont été identifiées par le biais de citations dans des articles sur la pandémie actuelle et une recherche supplémentaire sur Google a été effectuée le 4 mai 2021 pour identifier tout nouveau rapport non indexé en utilisant (COVID-19 ou SRAS-CoV-2) ET (vol OU avion). Les citations potentiellement pertinentes ont été examinées pour confirmer qu'elles contenaient des données pertinentes, et les données pertinentes ont été extraites pour étude.
Ce bilan contient les recherches publiées jusqu'au 26 avril 2021.

Révision par les pairs

Le présent document a fait l'objet d'un examen par les pairs, par un expert en la matière, ainsi que d'un examen rédactionnel et d'un examen des aspects scientifiques de la politique par le Bureau de la Conseillère scientifique en chef.

Route of Transmission:

- Direct contact with infectious droplets
- Inhalation of infectious aerosols
- Indirect contact with infectious agents contaminating inanimate surfaces (fomites)

Emerging Evidence on COVID-19

Evidence Brief of Size of Gatherings and Characteristics of High Risk Transmission Events

Introduction

What evidence is available on the thresholds or allowable sizes of gatherings or events?

Are there characteristics of gathering events that would make them high risk of transmission of SARS-CoV-2?

This review will address the state of the evidence up to August 18, 2020 with respect to the size of community-based gatherings as well as the characteristics of gatherings that are associated with transmission of SARS-CoV-2. It does not include transmission at home, in congregate living settings (e.g., long-term care facilities, prisons, dormitories) or healthcare organizations, however, it does distinguish social gatherings where people generally do or do not know each other.

Key Points

- Fifty-five studies were identified, including modelling studies, risk assessments, ecological and epidemiologic studies and outbreak reports.
- The studies showed a clear relationship between increased gathering size and risk, but there was not a consistent assessment of different gathering size thresholds (Table 1).
    - An ecological study estimated a 36% reduction in Ro if the cut-off for gathering size was 10 people, compared to 21% if it was 100 people, and a 2% reduction in Ro if the cut-off for gathering size was 1000 people (Brauner et al., 2020). Another study estimated overall 10% reduction in infections associated with gathering size restrictions (Esra et al., 2020).
    - Two models explored thresholds for epidemic collapse, one identified a gathering cut off of 23 people (St-Onge , 2020) and another identified limiting contacts to seven people per 5-day period (Zhao, 2020).
- Several predictive models that employ a network structure were developed to explore the impact of different sizes, types of gatherings and whether they included people that knew each other or did not know each other (Table 1).
    - Small closed community networks (e.g., where groups of people only interact with a chosen group of other people and there is limited interaction outside of that network) were identified as having a low risk of virus introduction. The risk increased with increasing bridges to other networks (e.g., commuting to work in another place, attending a sporting event) (Scott et al., 2020; Sneppen et al., 2020).

  - Random mixing events such as public transit, restaurants/bars and sporting events were high-risk events because people from many small networks mixed and, if transmission occurred could then take the virus back to their network (Scott et al., 2020).
- There were a number of studies that evaluated the risk associated with certain activities:
  - One assessment estimated the relative risk of going to a nightclub was 200-fold higher than eating at a restaurant (Dalton et al., 2020). This was consistent with another study that found >50% attack rate in direct contacts at night clubs (Prakash et al., 2020), a qualitative risk assessment that identified nightclubs, karaoke, restaurant, gymnasiums, ski resorts and cruise ships as high risk gathering settings (Dalton et al., 2020) and a study in Hong Kong found that 30.4% of cases were linked to exposure to bars and bands (Adam et al., 2020).
  - Large gatherings are associated with the largest outbreaks. A carnival in Germany, for example, was associated with 1,700 cases (Walker et al., 2020). Sporting events were associated with approximately 50-100 cases (Leclerc et al., 2020). Small gatherings, such as interactions among household members, had the majority of documented transmission events but usually result in a small number of secondary cases (<5).
  - Other common gathering settings where transmission events were documented included family gatherings (birthday parties, meals etc.), religious gatherings, weddings, social settings, gyms, shopping facilities, shared accommodations and a variety of workplaces from office environments to factory type settings (such as food processing plants).
- Non-pharmaceutical interventions, such as individual hand hygiene practices and community mask wearing and limiting the number of individual contacts, can reduce the risk of a transmission event occurring during gatherings, particularly gatherings of random individuals (Scott et al., 2020).
- Super spreading events (SSEs) have been associated with large gatherings and the following characteristics (Table 3):
  - The index case is often asymptomatic or mildly symptomatic.
  - Several studies have estimated that 10-20% of COVID-19 cases cause ~80% of new infections (Adam et al., 2020; Pozderac et al., 2020, James et al., 2020, Laxminara et al., 2020).
  - The risk of transmission in closed environments is higher than in open-air environments (OR 18.7 (6.0-57.9) (Nishiura et al., 2020).
  - Most transmission events were attributed to the number of close and sustained contact; loud talking, shouting and singing have all been associated with high attack rates.
- These findings need to be considered in light of other individual factors that can affect transmission, such as viral load (Pfefferle et al., 2020) and that some people may have a higher Ro than others e.g., women had a higher Ro than men in Korean clusters (Kim & Jiang, 2020).

Overview of the Evidence

The risk of transmission during gatherings and the relationship of the size of that gathering to the risk of transmission has been directly and indirectly explored in a number of predictive models. Many of the models more directly exploring this question are preprints and still need to undergo the peer-review process. These models are based on scenarios and are parameterized using observational data from the outbreak. The extent to which the findings can be generalized to the local context is variable and should be used with caution.

Published ecological studies estimate the impact of gatherings on the epidemic based on studying the changes in the trajectory of the epidemic after policies to limit gathering sizes were implemented and/or lifted in a region or country. By nature, these studies are at high risk of bias and ecological fallacy.

Estimates of transmission rates and descriptions of SSEs or outbreaks are obtained from data collected during retrospective outbreak investigations, which have a high risk of bias. Thus, these studies are considered to be of low quality and there is a high probability that the conclusion will change as additional evidence becomes available.

CONTENTS

THRESHOLDS FOR GATHERING EVENTS

Eleven agent-based and other network models explore the impact of different restrictions on gatherings and how segmented groups that have minimal random contacts can be protective (Block et al., 2020; Deforche et al., 2020; Kain et al., 2020; Leng et al., 2020; Phillips et al., 2020; Scott et al., 2020; Sneppen et al., 2020; St-Onge et al., 2020; Szapudi, 2020; Weiner et al., 2020; Zhao, 2020). Some of the models explore and explain the concept of small-segmented community networks providing increased protection to an introduction of the virus and the activities that degrade the protection of a segmented network. Activities classified as random gathering events where unknown people mix, such as transportation, commuting to a workplace outside of the segmented network, social places such as bars and restaurants, or sporting events, were considered to degrade the protection afforded by having a segmented community. Other models look at super spreading activities and how the number of contacts in a gathering may lead to a higher number of transmission events. Few studies provided threshold values for gatherings or even explored the implications of different cut offs.

One ecological study reported the impact of gathering size restrictions generally to be a 10% reduction in infections (Esra et al., 2020). Another study estimated a 2% reduction of Ro if the cut-off for different gatherings was 1000 people, compared to 21% if it was 100 people and 36% if it was 10 people (Brauner et

al., 2020). Two other models explored thresholds for epidemic collapse, one suggested a gathering cut off of 23 people under one scenario (St-Onge et al., 2020) and another suggested limiting contacts to seven people per 5-day period (P. J. Zhao, 2020).

Two risk assessments evaluate the risk associated with certain activities and try to put individual risk into perspective. The first estimates the risk of transmission was approximately 1 infection per 3,836, (Range: 626 to 31,800) unprotected community-level contacts in the USA on May 31, 2020 (Bhatia & Klausner, 2020). A qualitative risk assessment from Australia describes several high-risk gathering settings and estimates a 200 fold difference in the relative risk of going to a restaurant for dinner versus a nightclub (Dalton et al., 2020). Other settings unpacked in this risk assessment include karaoke clubs, gymnasiums, ski resorts and cruise ships (Dalton et al., 2020).

Given the evidence is primarily predictive models, risk assessments and ecological studies, the extent that the estimates can be generalized beyond the populations and scenarios studied is unknown. It should also be noted that most epidemiological studies on the impact of non-pharmaceutical interventions (NPI's) are not included in this review, as they do not isolate the effect of gathering size restrictions from other NPIs that were implemented almost simultaneously.

Table 1: Thirteen predictive models and risk assessments that explore the impact of gatherings and risk of transmission.

Reference	Study Description	Relevant Outcomes
Predictive Models		
(Phillips et al., 2020) *preprint*	Agent-based model to explore outbreak potential in daycares/schools in Ontario. They explored different ratios of child-educator ratios. The simulations considered 2:8, 3:7, 2:15, 1:15 and 1:30 ratios of teacher to child.	Conclusion: A ratio of 3:7 was most protective and the 2:15 model performed far worse. - Doubling class size from 8 to 15 to 30 doubled the outbreak size. - Drivers of increased risk/impact of larger classes= • higher probability that someone is positive • more students affected when class is quarantined • outbreak size is larger due to a higher number of exposed individuals
(Weiner et al., 2020) *preprint*	Age-of-infection model developed to explore the impact of NPIs on the potential second wave in Illinois. Model starts August 1, 2020. For comparison, Arizona and Florida are also modelled. Data is borrowed from other states already experiencing their second wave e.g., Texas.	- In the two scenarios run, the strict scenario limits on gatherings, closing bars and indoor dining to bring super spreading under control (assuming 80% of cases come from 10-20% of infected people) prevents a second wave.

(Szapudi, 2020) *preprint*	SIR model with modification using a power-law model that allows for inclusion of social connection networks.	- This model shows that by stopping super-spreading events through NPIs, the pandemic is significantly slowed.
(Kain et al., 2020)	SEIR model parameterized for COVID-19 epidemic dynamics by estimating a time-varying transmission rate that incorporates the impact of NPIs that change over time, in five epidemiologically distinct settings:Los Angeles and Santa Clara Counties, California; Seattle (King County), Washington; Atlanta (Dekalb and Fulton Counties), Georgia; and Miami (Miami-Dade County), Florida.	- Effective reproduction number (Re) dropped below 1 rapidly following social distancing orders in mid-March, 2020 - Re started increasing in late May 2020 in LA, Miami, and Atlanta and in June 2020 in Santa Clara and Seattle. - The authors show decreasing the risk of super-spread events (crowded enclosed spaces) is effective.
(Deforche et al., 2020)	SEIR model: Incidence data and deaths in 35 countries (includes Canada) data until mid-May 2020. The authors explore which mobility changes during lockdown were significantly associated with the changes in disease transmission.	- Reductions in individuals using transit and going to work were highly correlated with a reduction in the incidence of COVID-19 in the multi-variable model. - Retail and recreation changes were most significant/ highly associated with Rt changes: Mean reduction of Rt of 0.50 (95% CI 0.18 – 0.81), or an average reduction of 22% (95% CI 8 – 35) in transmission. - Thus, across countries the parameter retail/recreation indicates that venues such as bars, restaurants, malls, mass gatherings provide optimal circumstance for the spread of SARS-CoV-2, as opposed to individual factors.
(Block et al., 2020)	Stochastic Model: Adopting a social network approach, the authors evaluate the effectiveness of three distancing strategies designed to keep the curve flat and aid compliance in a post-lockdown world. They demonstrate that a strategic social network-based reduction of contact strongly enhances the effectiveness of social distancing measures while keeping risks lower.	Three approaches to defining a closed contact network were evaluated to be protective, all of which can be protective if closely adhered to. - Individuals choose their contact partners based on similarity of a predetermined individual characteristic. This facilitates forming small groups e.g., neighbourhood/ small organization. - Individuals consider who their contact partners interact with and do not see people outside of a defined contact network. - Build bubbles through repeat contacts. Individuals decide who they want to interact with. This can be used with work

		units as well. It is difficult for the virus to penetrate these micro-communities.
(Leng et al., 2020) *preprint*	Individual-based model: Using the UK as a case study, a mathematical model was used to assess the effectiveness of various social bubble strategies as part of a gradual lockdown exit strategy.	- Using a base case where non-essential shops and schools are closed, the household attack rate is 20% and Ro=0.8, a number of social bubble strategies are simulated. Results demonstrate that in this base case scenario, social bubbles reduced cases and fatalities by 17% compared to an un-clustered increase of contacts. - Clustering contacts outside the household into exclusive social bubbles is an effective strategy of increasing contacts while limiting some of the associated increase in epidemic risk (e.g., 2 families interact).
(Scott et al., 2020)	Australian agent-based open source model "Covasim". This model allows for contact networks and random/clustered interactions, specifically: households; schools; workplaces; social networks; cafés and restaurants; pubs and bars; public transport; places of worship; professional sport; community sport; beaches; entertainment (cinemas, performing arts venues etc.); national parks; public parks; large events (concerts, festivals, sports games etc.); child care; and aged care.	- The model indicated that the largest risk was re-opening bars and restaurants, followed by workplaces and large events. - Social gatherings <10 were the least risky type of gathering. - The model also implies that it could take more than two months to identify an increase in cases. - The largest risk in a resurgence was allowing individuals to have large contact networks, particularly where there is mixing of individuals who do not know each other. - Random mixing of a large number of people at sporting events for example, is risky because it exposes the individual's smaller, clustered network (home/work/close contacts) to potential introduction of the virus.
(Sneppen & et al., 2020) *preprint*	This agent-based model explored the impact of super-spreading events. In the base model super-spreading events had little effect on the epidemic, however under various intervention strategies, limiting diffuse social contacts – random gathering events - in settings such as bars, transportation, restaurants, parties, concerts and lecture halls is far more effective than limiting the same	- Limiting random gathering events had a large impact on the risk of super spreading events in this model under scenarios where various intervention strategies are implemented.

	amount of contact events in the home and work setting.	
(Zhao, 2020) *preprint*	Social network model: The epidemic is dependant on network connectivity and time to spread. Thus, transmission of the virus is affected by public health interventions such as isolation, quarantine and physical distancing. This social network model explores the level of NPIs needed to contain the COVID-19 pandemic. Contact definition: a spouse, two children, a friend, a neighbor, a colleague, and a cashier during grocery shopping.	- Without social distancing, if a single individual is infected with COVID-19, the average probability that any given person will be infected is 1 in 1.03 million. - After shutting down all non-essential businesses in Italy on March 21, the average number of unique contacts per individual over each viral generation period is expected to be 6.6, leading to a predicted reproductive number of 0.97 - The epidemic in the U.S. can be controlled by limiting the average number of contacts per person to 7 unique individuals over each 5-day period.
(St-Onge et al., 2020) *preprint*	Canadian authors from Laval University provide SIS/SIR models using a network science framework to look at the impact of having structures aka gatherings (groups/ classrooms/ sports teams etc.)	- Demonstrate that localized epidemics can collapse if the group or gathering size remains below a threshold. - The threshold for the mesoscopic localization regime, with a transmission rate $\beta = 0.07$ was 23 people and below.
Risk Assessments		
(Dalton et al., 2020)	This is a qualitative risk assessment on re-opening where they examine the characteristics of retail and recreational situations for high risk of super spreading events. Assumption is that up to 80% of cases may be caused by 10-20% of infected people and some setting characteristics are higher risk than others. Case studies used nightclub and karaoke rooms, gymnasiums, ski resorts, cruise ships, churches and religious gatherings.	- High risk venues should only start to open after low risk venues have been open a sufficient time to know there is no spike in cases. - The relative risk of going to a nightclub is 200 fold higher than eating at a restaurant. - Case study setting characteristics: Nightclubs: 100s of people, close proximity, poor ventilation, social behaviours. Karaoke rooms: 10 people, enclosed room. Gymnasiums: high touch surfaces and increased risk of droplet/aerosol transmission >1.5 meters. Dance/aerobic classes are higher risk where higher respiration rate and movement may be associated with further transmission.

		Ski resorts: unclear Cruise ships: 19 cruise ships had cases prior to March 2020. The design and close contacts allow high attack rates. Screening of crew and passengers is unlikely to prevent COVID-19 cases even in low transmission areas. Churches: Activities include singing and sharing a meal. Several outbreaks have been related to these activities.
(Bhatia et al., 2020)	Risk Assessment: What is the average probability of acquiring COVID-19 infection, being hospitalized, or dying from an unprotected community-level contact in US? Estimates of individual level probability for COVID-19 infection may inform more accurate risk perceptions and facilitate re-engagement with social activity. Among the 100 most populous US Counties, for the week ending May 30, 2020, the median daily case incidence is 5.92 per 100,000, (Range, 0.65 - 35).	- The median probability of COVID-19 infection transmission is 1 infection per 3836, (Range: 626 to 31,800) unprotected (e.g., without social distancing, wearing of masks, hand hygiene, etc.) community-level contact. - For a 50 to 64 year old individual, the estimated median probability of hospitalization is 1 hospitalization per 852,000, (Range: 139,000 to 7,080,000) community level person-contacts and the median probability of a fatality is 1 fatality per 19.1 million, (Range,:3.13 million to 159,000,000 million) community-level person-contacts
Ecological Studies – impact of policies to restrict gatherings on the epidemic		
(Esra et al., 2020) *preprint*	Ecological study: Bayesian model framework to estimate transmission associated with NPIs in 26 countries and 34 US states.	- The estimated overall reduction in infection associated with different NPIs was: • 23% (95% CI: 18-27%) associated with household confinement • 10% (95% CI: 1-18%) with limits on gatherings • 12% (95% CI: 5-19%) with school closures • 17% (95% CI: 6-28%) with mask policies. - 12% (95% CI: 9-15%) overall
(Brauner et al., 2020) *preprint*	Ecological study: Bayesian hierarchical model, by linking non-pharmaceutical interventions (NPI) implementation dates to national case and death counts. Chronological data on NPIs in 41 countries between January and May 2020 was analysed.	Estimate the mean reduction in Ro across the countries for eight NPIs: - Mandating mask-wearing in (some) public spaces (2%; 95% CI: -14%–16%) – this NPI had been implemented after most other NPIs were fully implemented. - Limiting gatherings to:

	Each NPI's effect as a multiplicative (percentage) reduction in the reproduction number R. Many of these were implemented at the same time, however the authors claim their model was able to estimate individual intervention effect due to the large dataset. They present a lengthy sensitivity analysis. Results are averaged across countries, some countries may have had more success than others, this is not reflected in this analysis. (Canada and the USA are not studied)	• 1,000 people or less (2%; 20%–22%), • 100 people or less (21%; 1%–39%), • 10 people or less (36%; 16%–53%), - Closing some high-risk businesses (31%; - 13%–46%), - Closing most nonessential businesses (40%; 22%–55%), - Closing schools and universities (39%; 21%–55%), the model cannot distinguish between these and there may be additive effects such as parents staying home that increases the impact of these NPIs - Issuing stay-at-home orders (18%; 4%–31%).

SIR= susceptible – infected –recovered model, SEIR= susceptible-exposed-infected-recovered, NPI= non-pharmaceutical interventions. Ro= basic reproduction number, Rt= effective reproduction number.

CHARACTERISTICS OF COMMUNITY GATHERING TRANSMISSION EVENTS

Super spreading events (SSEs) or outbreaks include multiple people acquiring infection. Gatherings provide an opportunity for SSEs to occur. By limiting certain high-risk activities and implementing public health measures, including limiting the size of gatherings, the risk of SARS-CoV-2 transmission and the likelihood of super spreading events should be reduced.

Table 2 highlights the importance of controlling super spreaders or SSEs. Retrospective analyses estimate that a large proportion of cases (80%) are due to a small proportion of those infected (10-20%) (Adam et al., 2020; Pozderac et al., 2020; James et al., 2020b; Laxminarayan et al., 2020). One ecological study of North American professional sports reported an association with professional games played early in the epidemic and the number of cases and COVID-19 mortality in that city, which was attributed to large gatherings associated with the game (Wing, Simon, & Carlin, 2020).

Three studies quantify the impact of gathering size restrictions and individual contacts (Jarvis et al., 2020; Scire et al., 2020; Zhang et al., 2020). These studies provide an estimate of the change in behaviour and may help to parameterize or estimate incremental changes in contact patterns that are tolerable at different points in the epidemic.

Table 2: Estimates on the importance of controlling super spreading cases and events.

Reference	Study Description	Relevant Outcomes
Estimates of Impact		

(Wing et al., 2020) *preprint*	Ecological study to compare COVID-19 caseload and mortality between cities that hosted many vs. few NHL, NBA and NCAA games in the first quarter of 2020.	- Found an association with the number of games: • Each NHL or NBA game lead to an additional 783 cases and 52 deaths March - mid-May, 2020. - NCAA games were associated with 31 cases and 2.4 deaths.
(Pozderac & Skinner, 2020) *preprint*	Model to estimate the variation in infectiousness by examining the variation in early-time growth rates of new cases among different subpopulations in the USA.	- Estimates the dispersion of the epidemic and reports that 88% of the case likely were from 10% of the cases.
(A. James et al., 2020b) *preprint*	Analysis of New Zealand's epidemic. COVID-19 cases =1499 Children under 10 were under-represented. Children infected fewer people/ lower secondary attack rate. Asymptomatic cases transmitted to fewer people than clinical cases. Serial interval ~5 days	- Super spreading is a significant contributor to the epidemic dynamics, with 20% of cases among adults responsible for 65-85% of transmission.
(Laxminarayan et al., 2020) *preprint*	This study analyses the epidemiological data from two states in India. Case identification and contact tracing investigations.	- The analysis indicates that 5.4% of cases accounted for 80% of infected contacts.
(Adam et al., 2020) *preprint*	This study analyses the super spreading events in Hong Kong across 135 clusters	- The analysis inferred 20% of infections were responsible for 80% of the transmission events in Hong Kong. - One notable cluster of 106 cases traced to bars and bands accounted for 30.4% of the local transmission early in the epidemic.
Impact of Gathering Restrictions		
(Saidan et al., 2020)	This study calculates context specific Ro based on cluster investigations. This transmission model (SIR) was developed to only model clusters compared and not the entire population.	- Estimated Ro by gathering type • Weddings/ party Ro=5 • Religious gatherings Ro=2.5 • Processing plants (meat) Ro=2.0
(Scire et al., 2020)	Switzerland February 27 - April 22, 2020: Strict gathering rules of <5 people in public places was implemented and self-quarantine for 10 days for anyone with symptoms. Using surveillance data for the number of cases, Ro was calculated for different periods of the epidemic. Sensitivity analysis indicates this result is not an artifact of testing intensity.	- Prior to the gathering restrictions Ro was between 1.5-2. After gathering restrictions were put in place Ro dropped to between 0.6-0.8 in the first third of April 2020.

(Jarvis et al., 2020)	UK survey on contact patterns before and after lockdown. Survey was done the day after lockdown, so it can't really measure longer term adherence.	- 74% reduction in the number of daily contacts (10.8 contacts per day to 2.8). - This would be expected to reduce Ro from 2.6 to 0.62 (95%CI 0.37-0.53) for all types of contacts.
(J. Zhang et al., 2020)	Contact patterns in Wuhan and Shanghai were assessed before and after lockdown using a survey run February 1-10, 2020. 'Contact' was a conversation of three or more words in the presence of another person and/or direct contact.	- Age weighted mean contacts per day was 14.0-18.8 at baseline and reduced to 1.9-2.1 during the outbreak period ($p<0.001$). Overall, contacts during the outbreak mostly occurred at home with household members (94.1% in Wuhan and 78.5% in Shanghai). - The interventions (lockdown) were predicted to block transmission for a Ro before the interventions of 6-7.8.

Table 3 lists repositories of SSEs and outbreaks of COVID-19, studies that investigate the characteristics of these clusters, review literature that summarizes COVID-19 SSEs associated with gatherings and primary epidemiological investigations that implicate gatherings. This list is not exhaustive but describes a wide range of situations under which transmission events have been documented. There are limitations to the research and resources presented in this section including biases that may make some SSEs more likely to be identified and documented. For example, social events are more likely to be recalled than everyday activities and events are more easily traced. Further, some settings may be better represented because they have the infrastructure in place to monitor and identify outbreaks (e.g., prisons or long-term care facilities may have routine monitoring and testing).

Databases of SSEs compiled by researchers and journalists were identified; the most comprehensive one currently has more than 1,400 SSEs documented from the primary and grey literature (Table 3). All include descriptions of the size, setting and other attributes, such as the activity associated with the SSE.
